University of Nevada, Reno

Preface

It has been our great pleasure and honor to organize the Thirty-Third Annual Conference of the Psychology of Mathematics Education North American Chapter in Reno, Nevada. We have a great selection of speakers and papers included in these proceedings that include researchers from Canada, the United States, and Mexico. In addition, several researchers from countries in other parts of the world, such as Turkey, England, and Australia, will present their work at the conference.

This year's conference theme is "Transformative Mathematics Teaching and Learning." The plenary speakers were chosen to address this theme. Research should not only address issues in mathematics education; it should also help us transform mathematics teaching and learning. Plenary speakers include Megan Franke from the University of California-Los Angeles with Discussant James Middleton from Arizona State University, David Reid from Acadia University in Nova Scotia with Discussant Carolyn Maher from Rutgers University, and Marty Simon from New York University with Discussant Douglas Clements from the University of Buffalo.

We would like to thank all authors for contributing papers, as well as the reviewers for taking the time to carefully read the proposals and provide constructive feedback and professional opinions. We would also the University of Nevada, Reno faculty and graduate students, as well as Extended Studies at the University of Nevada, Reno (Shera Alberti-Annuzio, Sheehan Niethold, and Martin Morales), who assisted in conference preparations. Finally, we would like to thank the University of Nevada, Reno for hosting this year's conference.

TEACHER FOLLOW-UP: COMMUNICATING HIGH EXPECTATIONS TO WRESTLE WITH THE MATHEMATICS

Megan Franke

In-depth analyses of six elementary mathematics classrooms (with varying student achievement) captured student and teacher interactions and documented the critical role of teacher follow-up in shaping opportunities for low-income students of color to engage in algebraic reasoning. This paper details the efforts of teachers as they, contrary to existing school practices, found ways to support student engagement around explanations. Examining the variation in teacher follow-up that existed across classrooms illuminated how one high-achieving classroom teacher's use of follow-up communicated a set of high expectations around mathematical work for students and supported them to wrestle productively with the mathematics.

Across a number of studies, Cognitively Guided Instruction (CGI) research documents the relationship between teachers' knowledge of student thinking and student mathematical achievement. We have found that teachers draw upon their knowledge of students' mathematical thinking as they pose problems, encourage the use of a range of strategies, and support students to share their ideas. We also have evidence of variability in the ways teachers engage in these practices, and we are interested in how that variability relates to student outcomes. We believe that knowing more about the details of teachers' classroom practice within the context of student outcomes can help both to elaborate Hiebert and Grouws' (2007) argument for allowing students to "wrestle" with the mathematics and to address our concern of the kinds of opportunities provided for marginalized students.

Efforts to detail the aspects of teachers' mathematical classroom practice that support the development of mathematical proficiency are not new (see Franke, Kazemi & Battey, 2007; Lampert, 2001; Stein, Engle, Smith & Hughes, 2008; Wood, 1998). For example, researchers have studied how posing rich mathematical tasks, allowing students to solve problems in different ways, and encouraging students to share their strategies may foster learning (Franke, Kazemi & Battey, 2007; Hiebert & Grouws, 2007) or how teachers might orchestrate sharing of student explanations and use students' explanations to highlight a mathematical goal (Lampert, 2001; Forman & Ansell, 2002; Forman, Larreamendy-Joerns, Stein & Brown, 1998). And while evidence shows these practices are not likely in many classrooms, they are even less likely in classrooms of low-income students of color (Anyon, 1981, Ladson-Billings, 1997; Lubienski, 2002; Means & Knapp, 1991). Our project builds on these studies and focuses particularly on tying the classroom practices of teachers working to make use of students' mathematical thinking to student outcomes.

Teacher Practice and Student Learning

This study was a follow-up to a larger experimental study that found teachers who had participated in one year of CGI algebraic thinking professional development knew more about students' algebraic thinking and the students in their classroom performed better on algebraic reasoning assessment items than a comparison group (Jacobs, et al., 2007). Yet, even within the CGI professional development group, variability existed; thus we wanted to understand what teachers were doing in classrooms with higher student achievement to support student learning that may not have been occurring in the classrooms of teachers in the same professional development but with lower achievement outcomes. The teachers of this project were second or third grade teachers with student achievement on our algebraic thinking measure that was consistently high, low, or on average fell to the middle range. We then observed in these classrooms while the teachers were engaged in working on relational thinking, doing so in a way that captured the teacher's interactions with students in whole class settings, as well as all of the talk of twelve randomly selected target students (see Webb et al., 2008, 2009 for details).

The schools participating in this study served predominately low-income students of color and are considered some of the lowest performing in the state (99% Latino and African-American students combined in each school, over 98% students receiving free or reduced lunch, 49-64% English Language Learners, and scored 1-3 out of 10 on California's Academic Performance Index). The district was expected to: use curricula that focused on developing skills over conceptual understanding, "drill" rather than engage in mathematical conversation, and target the students "on the bubble" of proficiency to raise test scores. However, this characterization of the schools only reflects one aspect of the district. At the time of this work, the local district leadership was working with the schools to meet a new vision for developing mathematical understanding, showing what students were capable of, and creating school learning communities. The schools involved in the project had been working hard to meet the needs of students in a variety of ways. The elementary school principals all wanted to participate in our work, seeing algebraic thinking as critical to their students' success and believing that it was appropriate content to take on.

We engaged schools in site-based professional development focused on relational thinking[1], providing professional development first for one group of schools and the following year for a comparison group. Our experimental study showed that the students in both the algebraic thinking group and the comparison group thought relationally and were able to solve a range of algebraic thinking problems. While not all students in the schools understood mathematics in ways we would hope, this study showed that students across the district were capable of engaging in algebraic thinking and the schools were willing to support students in doing so.

Understanding that working on algebraic thinking in the ways we suggested through professional development was contrary to many existing practices, we conducted this follow-up study of six classrooms to understand in detail exactly how teachers were finding space to create opportunities for students to engage in algebraic reasoning.

Classroom Practice

Our observations of these six classrooms found that on the surface they looked much like what we would expect in a CGI classroom. The teachers posed problems that often encouraged more than one strategy, asked students (98% of the time) how they solved the problem, and asked for elaboration of student thinking (76% of the time). These practices are not what we would expect more typically in elementary classrooms, and we would argue that these practices are important for creating opportunities for students to engage in wrestling with the mathematics. These practices alone, however, did not lead to productive student outcomes for all students in these classrooms (See Table 1), suggesting that closer examination of the ways in which teachers engaged students and content was needed to understand opportunities for student learning.

Table 1. Mean student achievement[a] across classrooms

	Group 3 (low-achieving classrooms)		Group 2 (medium-achieving classroom)	Group 1 (high-achieving classrooms)		
	Guo	Collins	Gomez	Lane	Lee	Theissen
Mean	18	27	50	60	75	88
(SD)	(30)	(35)	(46)	(46)	(35)	(25)

[a]Percent of algebraic reasoning posttest problems correct.
Note: Differences across classrooms: $F(5,68) = 5.91$, $p<.001$.

Problems Posed

Looking more closely at the problems teachers posed – taking into account that they were all working on common CGI algebraic reasoning content of relational thinking – we did find that there were differences in the problems posed. If we focus on one teacher from each of the achievement groups—Ms. Guo, Ms. Gomez, and Ms. Lee—we can examine closely how the problems posed were the same and different. Ms. Guo posed the most mathematically powerful sequence of problems that built toward a relational understanding of the equal sign. The majority of Ms. Lee's problems were drawn from ones the students had written. She chose problems that provided opportunities to use relational thinking, but without a particular sequence except when she added a problem to build from student responses. Ms. Gomez's problems often did not lend themselves to using relational thinking, as they focused mainly on multi-digit computation. An examination of the problems teachers posed across classroom observations is one approach to understanding opportunities for student mathematical learning. Yet, the teacher with the "best" problem sequence had the lowest achieving students, suggesting that while the tasks differed in the mathematical opportunities provided for students, they alone did not determine student outcomes.

Student explanations. As we looked further at what was occurring for students in these classrooms, we focused on the explanations students provided to the problems posed. We tracked student answers and explanations, given both to other students and to the teacher, within the whole-class setting and in small-group or pair-share settings. Students were participating in giving explanations in each classroom and for a high percentage of problems. (see Table 2).

Table 2. Overall level of student participation

	Group 3		Group 2	Group 1		
	Collins	Guo	Gomez	Lee	Lane	Theissen
Percent of target students who ever gave an explanation or answer	85	100	100	100	87	83
Percent of problems in which students gave explanations	64	80	88	100	86	70

It was not just the giving of explanations that differentiated classrooms, but rather the kinds of explanations that were given. The degree to which the explanations were complete and accurate varied across classrooms (see Table 3).

Table 3. Work contributed by students during the whole class: Percent of classwork problems with student contributions of each type

	Group 3		Group 2	Group 1		
	Collins	Guo	Gomez	Lee	Lane	Theissen
Correct/complete explanations	55	40	88	100	86	70
Incorrect/incomplete explanations only	9	40	0	0	0	0
Correct answer but no explanation	36	20	13	0	14	30
Incorrect answer but no correct answer or explanation	0	0	0	0	0	0

Note: Numbers in a column do not always sum to 100, due to rounding.

We found that students who gave complete, correct explanations scored better on the student achievement measures designed to measure algebraic thinking (see Table 4). We have examined this finding in a number of ways and each time we find the same pattern: it is not the mere act of explaining that is related to positive student achievement, but rather the giving of correct and complete explanations.

Table 4. Correlations between Student Participation and Achievement Scores

Highest level of student participation on a problem[a]	Achievement Score[b]
Gives explanation	.52***
Correct and complete	.59***
Ambiguous, incomplete, or incorrect	-.01
Gives no explanation	-.41***

[a]Percent of problems in which a student displayed this behavior. Problems discussed during pair-share and whole-class interaction are included. [b]Percent of problems correct. (n=74)

There are two critical points to be made here. First, "correct and complete" is not simply about making an explanation that gets to an end. Correct and complete explanations are about students articulating the steps in their solution in a way that details the mathematical relationships. In explaining a solution to 24 + 19 = 25 + ___, rather than saying the answer has to be 18 "because of the 24 and 25", the student would say (or point to) "24 is one less than 25 so whatever you add to 25 has to be one less than 19". The latter articulation makes explicit the particular relationship between the 24 and 25 and thus the 19 and the unknown. In complete explanations students are articulating in a way that as one listens and watches they can tell exactly what the student did to solve the problem. Second, as this is correlational data one might argue that students in Ms. Lee's class simply knew the math better and that is why their explanations are complete and correct. While we have no data that supports that these students came in knowing more, it is a possibility. What makes it less likely as an argument is that as we examined what teachers did to support students to make correct and complete explanations we found clear differences within and across classrooms. As the data we share will show, when teachers followed up in particular ways, it was more likely that students would produce correct and complete explanations.

Engagement around Explanations

Teacher Follow-Up

As we continued our examination of classroom practice across classrooms with a range of student achievement, we looked closely at the interactions among students and teachers as students gave explanations. We wanted to know how teachers were supporting students to give complete and correct explanations. We focused specifically on teacher follow-up that resulted in the articulation of more student thinking, whether their initial explanations were complete, incomplete, or ambiguous. The teachers with the highest achieving students followed up in ways that led to more explanation being given by the student (see Table 5).

Table 5. Experiences of target students when engaging with the teacher around their contribution during the whole class: Percent of target students who experienced each type of student participation

	Group 3		Group 2	Group 1		
	Collins	Guo	Gomez	Min	Lane	Theissen
More student thinking was provided beyond the initial explanation[a], engagement ended with a correct/complete explanation	8	18	17	92	60	83
More student thinking was provided beyond the initial explanation[a], but the engagement never led to a correct/complete explanation	0	45	17	0	0	0
No more student thinking was provided beyond initially correct/complete explanation	31	55	25	8	33	8
No more student thinking was provided beyond initially incorrect/incomplete/ ambiguous explanation	15	64	0	8	0	0
No more student thinking was provided beyond the student's correct answer	69	27	9	23	60	17
No more student thinking was provided beyond the student's incorrect answer	46	36	0	8	7	0

[a]In most cases, the target students themselves provided the additional thinking; in a few cases, another student in the class provided the additional thinking.

Looking closely at the follow-up, we expected to see that the teachers supporting more complete and correct explanations would be using particular approaches to do so – more probing questions, revoicing, providing tools, and so on. We did not find this to be true. All of the teachers drew upon a repertoire of follow-up moves. It was how they used these moves in relation to the students and the mathematics that seems to support students to provide more explanation, take an incorrect explanation to correct, or an explanation from incomplete to complete.

Returning to our one focus teacher per group, Ms. Guo, Ms. Gomez and Ms. Lee, we found that not only did they draw upon a repertoire of follow-up moves, but that the substance of their follow up was quite different. We examined these interactions in detail to gain insight into the different experiences students had as they solved problems and gave explanations (Franke et al, 2009).

Ms. Guo, the teacher with the lowest achieving students, posed productive problems, asked students how they solved the problems, and while she followed up on student thinking less often than the other teachers, she did follow up. For 45 percent of her students, however, her follow up did not lead to more explanation. Often this was due to her not pressing the student idea and posing a new problem or to confusion about what she was asking.

Problem: a= a; True or False?

Marcus: It's true, true true.
Lindsay: It's a letter. It's an alphabet letter. It's true because A is the same as A.
Marcus: It's true for everything.
Ms. Guo: You guys think that this one is true?
Marcus: Yes.
Lindsay: Yes. Because A and A is the same letters.
Ms. Guo: So they are the same letters, so that makes it true?
Lindsay and Marcus: Yeah.
Ms. Guo: We'll check it out.
Marcus: Everything is true, huh?

Here Ms. Guo followed up on Marcus and Lindsay's thinking and even asked a question that was specific to what students had said. However, she did not press either of the students to articulate what they mean by "A is the same letter as A" and then what that means for the problem they were solving. We do not learn more about either Lindsay or Marcus' thinking as they engaged with Ms. Guo.

In addition, Ms. Guo often followed up but rather than press the student, she revoiced or posed a new problem for the students to consider. In the next example Ms. Guo posed 100 + ☐ = 100 + 50 as a follow-up to a previous unresolved discussion. The class had begun to refer to this idea as "partners", that is, 50 is "partnered" with the other 50. Here Fernando used his notion of needing the same numbers on both sides to argue that 50 goes in the box.

Problem: 100+ ___ = 100 + 50

Ms. Guo:	Ok. One hundred plus box over here is the same as…one hundred plus fifty. What would go inside that box now and why? Fernando?
Fernando:	One hundred…no, the fifty will go right there because it has to be the same number.
Ms. Guo:	What has to be the same number?
Fernando:	One hundred fifty and the other side has to be one hundred fifty too *(unclear whether Fernando is saying 150 or 100 and 50)*.
Ms. Guo:	Ok, so you are adding these together. You said this side has to be *(bell rings)* one hundred fifty?
Fernando:	No.
Ms. Guo:	Oh, what were you saying?
Fernando:	That they have to be those because… 'cause it has to have the same numbers.
Ms. Guo:	It has to have the same numbers. Ok.

Fernando: Fifty, fifty, and one hundred.
Ms. Guo: Ok, this side has a fifty and this side has a fifty. Ok. I see that relation going across. But what if I did this though? What if I did this? If I called…I did one hundred and I called box, B for box. And if I did one hundred plus (*writes: 100 + B = 100 + 75*)…what would B have to be?

It was never clear if Fernando was considering numbers on each side as equivalent quantities across the equal sign or matching to find the same number in the number sentence. Ms. Guo followed up by posing another problem, but not one that would necessarily clarify the mathematical issue of "partners". This issue came up a number of times as the lesson progressed, causing difficulty as students began to match numbers regardless of the position in the number sentence (such as a + a = b + b being always true because "the a's have partners"). The issue is never resolved.

Ms. Gomez, whose problems were often focused on a computational solution and not related to the algebraic thinking, followed up about half of the time and half of that follow-up led to more explanation. Ms. Gomez asked follow-up questions directed at the mathematics, but she did so to help the student through the solution that they could not complete. So the follow-up, while framed as a question, was structured to help the student see the next step rather than to elicit more student thinking. Here Ms. Gomez stopped in while Miguel and Maricela were working on the problem.

Problem: 14 ÷ 2 = 3 x __ + 1

Miguel: Three times…
Ms. Gomez: You are working on number one right?
Miguel: Three times one…
Ms. Gomez: Ok, but you are working on number one… So remember, we always ask ourselves, which of the two sides is complete. The left side or the right side?
Miguel: Left side. *(pointing on paper with pencil)*
Ms. Gomez: Ok, so can you solve the one that's complete? *(Miguel nods)* So, do you think that's a good idea if you solve that first? *(Miguel nods)* Ok. *(Miguel looks up at teacher)* So what does that tell you?
Miguel: That fourteen divided by two equals, is the same as seven?
Ms. Gomez: Ok, very well read. Now so, if this side equals seven, what does this side… Oh my, you've already solved it.

Ms. Gomez wanted to help Miguel with an approach that starts with solving one side of the equation and then using that to help you figure out the other side. This is an example of a problem Ms. Gomez posed that does not readily lend itself to relational thinking, so her approach of solving one side may be best. She did not, however, ask Miguel how he was thinking about the problem nor did she ask him to think about the whole problem, what it is asking and what he knows in relation to what it is asking. If Ms. Gomez's approach made sense to you as a student, it could be very helpful; if not you could be lost. Ms. Gomez did not leave incorrect strategies unaddressed, yet she often did not ask any additional questions when a correct and complete explanation was given.

Ms. Lee, who chose productive relational thinking problems from those her students had written, regularly followed up on students' explanations and regularly supported students to provide additional explanation. She followed up on the mathematical ideas embedded in the student explanations and could always find something productive in what the student had offered, using it to ask a follow up question. Her questions took into account both the mathematics and the student's thinking. Ms. Lee had posed the problem, 11 + 2 = 10 + __. During the whole-class share she followed up on Andrew's explanation by asking him a clarification question and then specific to his explanation as well as the mathematics.

Problem: 11 + 2 = 10 + __

Andrew: I put eleven here, put a two right here, then I plussed it, and it was thirteen. I put take away… take away (*holds fingers up*). I wrote thirteen right here. I put right here a caret and put thirteen. I put here a thirteen. Three, thirteen take away, take away ten and then I minus, I minus (*counting on fingers*)… ten. And then *(inaudible).*

Ms. Lee: Wow. Okay. This is really interesting. Okay, let's look at this. Does everybody understand how you got eleven plus two equals thirteen?

Students: Yeah.

Ms. Lee: Okay. Why did you minus ten? And where did you get that ten from?

Andrew: Cause on the three I added first… I went three, four, five, six, seven, eight, nine, ten, eleven, twelve, thirteen (*inaudible*).

Ms. Lee: Okay, is there anywhere else in the problem that has a ten?

Andrew: Yes here (*points to the 10 to the right of the equal sign*).

Ms. Lee: There. Okay, does anyone see that connection?

As she followed up with Andrew, she asked a question particular to his explanation and to the mathematics within the problem that has the potential of encouraging him to think relationally. She also worked to connect their interaction to the whole class.

Ms. Lee also, more than any other teacher, asked extension questions about the mathematical properties. In sharing his strategy D'ante stated that he knew when he took zero from 30 it would still be 30. Ms. Lee followed up on this particular idea.

D'ante: Because thirty take away zero is still thirty.

Ms. Lee: Okay, is that true? Is that true that thirty take away zero is still thirty?

Students: Yes. *(a small number of students)*

Ms. Lee: How do you know that's true?

Student: When you have thirty and you don't take away nothing, so it's still thirty.

Ms. Lee: Can you say it louder so everyone can hear you?

Student: Because you have thirty fingers and you don't take away nothing so it's still thirty.

Jennifer: *(loudly, to herself)* 'Cause you don't take away nothing. You have nothing to take away.

Ms. Lee: Is that always true?

This conversation continued for over five minutes and then Ms. Lee took it back to the problem at hand, connecting to why it would help you to use this idea. This type of follow-up was typical in her classroom. Following up on the students' ideas, while following up on a relevant math idea, and pushing beyond the solution given occurred in the highest achieving classes.

Another way to consider the follow up that occurred in Ms. Lee's class is to think about the way that her follow-up sets up expectations for students and the effect this has on opportunities for mathematics learning. In their studies of teachers of African American students, Clark and his colleagues (2009) found that teacher expectations stood out as a major factor in shaping the mathematics learning of students. Battey and Stark (2009) showed how deficit beliefs created impoverished mathematical practices for Latino and African American students. Ms. Lee's actions reflect her belief that students are capable of high-level mathematical work and thus expected to participate as such. Ms. Lee demonstrated follow-up (in ways similar to what Kazemi and Stipek (2001) term "press") to each students' ideas in a way that communicated these high expectations. Ms. Lee did not shy from addressing the mathematical properties or working with variables with her second and third graders. She had the students write the problems they solve together. She asked follow-up questions to everyone (each student shared an explanation at some point across two class sessions), questions that pushed them to articulate their mathematical ideas but in a way that was connected to their own ideas. Ms. Lee found something positive –mathematically—in what each student shared and used it to move the group's mathematical work forward. A growing literature suggests that this focus on what students can do, positioning students competently, matters and matters often for the lowest achieving students (Battey (under review); Boaler & Greeno, 2000; Boaler, 2003; Empson, 2003). In addition, she expected and supported students to do this with each other. This is not only about holding high expectations; it is a set of actions that communicate those expectations.

Student Follow-Up

We are finding that students do the same types of follow-up that their teachers do when they are in small groups or pairs together. In Ms. Guo's class the students in pair share frequently discussed ideas for solving the problem, but they did not complete the solutions nor did they work to make sense of each other's ideas. The goal seemed to be to get ideas out on the table, much like Ms. Guo did, with little to no follow-up to further detail these ideas or move them toward completion. Ms. Gomez's follow-up in both pair-share and whole-class discussions communicated an expectation of completing the problem, often with a particular procedure that the class had been working on. Rarely were there interchanges among students that moved beyond working through a procedure to involve probing of explanations. Students in Ms. Lee's class exhibited further probing of each others' ideas as they shared explanations and worked toward finding more than one way to approach the problem. The ways in which students engaged with each other in pair share reflected the kinds of opportunities created as Ms. Guo and Ms. Gomez engaged students.

As we further examined the interactions in Ms. Lee's class, however, we recognized that there were other potentially productive outcomes occurring through these interactions beyond the sharing of explanations. Students were learning a way of participating in mathematics that included: sharing their ideas to a greater degree of detail, listening and engaging with someone else's ideas, asking mathematical questions based on another's strategy, understanding someone else's ideas in relation to their own, and so on. The following interchange demonstrates both how students follow up like their teacher (Ms. Lee) and how they are learning a range of things beyond how to correctly solve a mathematics problem.

In this example Ana and Michael were working during pair share on a problem posed to their class: 8 + 8 = 15 + ☐. Michael thought the answer to the problem was 15 (likely due to a similar "partner" misunderstanding as in Ms. Guo's class). Ana, who knew the answer was one, worked to get Michael to see that he was not thinking about it correctly.

Problem: 8 + 8 = 15 + ☐

Ana:	It's not... it's not... it's not fifteen, because eight plus... I'll explain it back to you so you can understand that it's one. Because eight plus eight sixteen…
Michael:	I already tried two times.
Ana:	Huh?
Michael:	I already tried two times.
Ana:	It's not... it's not fifteen, because eight plus eight is sixteen. So this one has to... has to equal sixteen—"the same".
Michael:	*(pause)* The equal sign means "the same" and there's eight (*trails off*)...
Ana:	But it, the equal sign means that "the same answer"… It has to be the same answer. Like if... if I put... (*pause)* I could switch it: fifteen plus one is the same as eight plus eight.
Michael:	OH! I know what you're talking about.
Ana:	It's just gonna be sixteen.
Michael:	So it's worth sixteen right here (*gestures to one side of paper)* and sixteen right here *(gestures to the other side).* Ohhh!

Ana's first move to challenge Michael's incorrect idea was to explain that the expressions on both sides had to equal sixteen, but that explanation did not make sense to him. She emphasized the language "the same." Michael agreed with the idea of "the same", but this did not resolve his incorrect answer. Ana persisted. She added that it was not only "the same" but it was "the same answer." As that explanation did not convince Michael, she made yet another attempt to get her point across: she flipped the number sentence around to say "fifteen plus one is the same as eight plus eight." It was this specific move that helped Michael understand the quantity sixteen on both sides of the equal sign, moving him away from his incorrect answer of fifteen.

Ana helps Michael with a way to think about the solution that made sense to him. You can see him gesture in a way that shows you can move the 15 + 1 together and the 8 + 8 together and they are the same because they are both just 16. This interchange exemplifies the impressive caliber of mathematical discourse that occurred in Ms. Lee's classroom. Ana explains; Michael listens and works to make sense. Ana listens to Michael and tries a different approach she thinks might be more successful. Ana finally makes a mathematically powerful move that helps Michael make a connection about the quantities on both sides of the equal sign. There is a sense in watching this interchange that Ana is confident that she can communicate with Michael, and she has the skills and tools to do so. The types of interactions in this exchange occurred in other pairshare episodes in Ms. Lee's class. It is though an interchange that contrasts significantly those in Ms. Gomez's and Ms. Guo's classrooms.

Summary

Freund (2011) found in examining the aspects of mathematical proficiency developed within theses classrooms that developing the types of classroom norms seen in the higher achieving classrooms was not a matter of simply telling kids to work with each other or explain their thinking (all of the teachers did this). It was a combination of norms statements as well as communication of expectations through interaction that determined what constituted engagement around a mathematical explanation (Cobb et al, 2001). We can see through the work shared here and Freund's study that teachers and students together are developing a set of norms that shape participation in ways that allow students to make complete and correct explanations and create a culture of what it means to do mathematics together.

Ms. Guo, Ms. Gomez, and Ms. Lee serve as exemplars of what occurred across the six classrooms with differing student outcomes. Each of these teachers engaged their students in mathematics that countered the prevailing district culture. Each of these teachers was working to reach each of their students and engage them in developing an understanding of algebraic ideas often not addressed in second and third grade and certainly not addressed in the lowest performing schools at these grade levels. Each of these teachers carried out practices that research would contend are productive for developing mathematical understanding. What these three cases do is help us understand the nuance of Ms. Lee's interaction with her students and how that is related to student outcomes. Ms. Lee through her follow-up interactions connected with students' mathematical ideas and pressed students to detail their ideas for themselves and the class. She expected her students to participate in high-level mathematics and worked with them so they would know how.

Conclusions

In understanding the classroom practices that support student achievement in mathematics the data from this project suggest that posing productive mathematics problems while necessary, is not sufficient. Asking students the initial "how did you solve that" is necessary, but not sufficient. Following up on the students' explanation is necessary, but not sufficient. The way one follows up matters. It matters that the follow up presses students to provide more explanation and the explanation gets to something that is complete and correct. It matters that the follow-up is connected to what the student has articulated or shown as well as to the mathematical ideas being addressed in the lesson. It matters that, as the teachers are following up, they are supporting students to learn a way of engaging with the mathematics and creating a culture of doing mathematics that signals that wrestling with the mathematics means asking each other questions, considering others' ideas, and connecting mathematical ideas. It matters that teacher and student interactions create a set of expectations and a way of positioning students that make explicit that each child brings mathematical knowledge to the interactions and can engage in challenging mathematical work. It matters that the interactions highlight persistence, detailing thinking, listening, questioning, as well as the process of getting stuck and unstuck. We would argue that this type of work constitutes creating opportunities to "work and wrestle" with the mathematics in ways that set expectations through action for each of her students.

Endnote

1. Relational Thinking involves children's use of fundamental properties of operations and equality to analyze a problem in the context of a goal structure and then to simplify progress towards this goal. (Carpenter, Franke, & Levi, 2003; Empson, Levi, & Carpenter, 2011)

UNDERSTANDING PROOF AND TRANSFORMING TEACHING

David A Reid
Acadia University
david.reid@acadiau.ca

This article reviews some key ideas about the nature of proof, kinds of proofs, and the way of reasoning called proving. This provides background for a discussion of the teaching of proof, in which some important aspects of teaching that support students' proving are described, and the ideas of a tool-box of accepted premises and local organization of knowledge are explored as ways to structure teaching. Finally, lessons learned from approaches to teaching proof and problem solving in the past are connected with the earlier discussions of understanding and teaching proof to suggest a transformation of proof teaching into proof based teaching, in which proof is a process of coming to understanding rather than a topic to be taught and learned.

The Reasoning and Proof Standard (National Council of Teachers of Mathematics [NCTM], 2000) advocates that all students should recognize proof as fundamental to mathematics, should read and write mathematical proofs, and should reason in various ways, including the way called *proving*. In this article I will consider what these goals might mean, and how they might be achieved. I will begin by considering the nature of proof and four ways in which it is fundamental to mathematics: as a means to verify, explain, discover and belong. I will give some examples of proofs and compare their formats and functions. And I will examine the types of reasoning involved in conjecturing and proving. This will provide the background for a consideration of the teaching of proof. I will describe aspects of teaching that seem to create a good context for proving in school, and two ideas, a tool-box of accepted premises and local organization of knowledge, that have potential as ways to structure teaching. Finally, I will bring together my discussions of the nature of proof, proofs and proving and the teaching of proof to suggest a possible role for proof in mathematics teaching, as a way to teach rather than a topic to be taught.

Proof

What does it mean to recognize proof as a fundamental aspect of mathematics? How is proof fundamental? It is clear that proof is essential to the work of professional mathematicians. Papers without proofs do not get published. But why are proofs needed in mathematics?

Verification

Fischbein and Kedem (1982) say that proofs are needed because "a formal proof of a mathematical statement confers on it the attribute of a priori universal validity" (p. 128). In other words, proof tells us what is true and what is not. This idea, that mathematical proofs verify mathematical statements, has been recognized and admired for a long time. For example, Descartes commented:

> Of all those who have already searched for truth in the sciences, only the mathematicians were able to find demonstrations, that is, *certain* and evident reasons. (Descartes, 1637/1993, p. 11, italics added)

Mathematical proofs provide certainty. That is one answer why they are needed and why proof is a fundamental aspect of mathematics.

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

While many people believe that the essential role of proof in mathematics is verification of theorems, there are objections to this position. Some are fairly abstract, like the observation that Gödel's Incompleteness Theorem tells us that there are true statements in mathematics that have no proofs. Others are completely pragmatic, like Davis's (1972) comment that "most proofs in research papers are unchecked other than by the author ... They are loaded with errors." (p. 259). Obviously proofs with mistakes in them cannot tell us what is true and what is not in any absolute way. Davis concludes that "A derivation of a theorem or a verification of a proof has only probabilistic validity." And there are objections based on looking at how mathematicians actually behave, as opposed to what they say they do. Gila Hanna (1983, p. 70), for example, lists five factors other than a mathematical proof that contribute to the acceptance of theorems, including the reputation of the author and the plausibility of the result.

Explanation

There are other roles proof plays that make proof fundamental to mathematics. "Proof, in its best instances, increases understanding by revealing the heart of the matter." (Davis & Hersh, 1981, p. 151). Proof helps us understand and explain mathematics. Especially in the context of education, this explanatory role has increasingly come to be seen as vital. Gila Hanna was perhaps the first to point out to mathematics educators, at PME 13 in Paris (1989, p. 2-45), that proofs that explain, that show not only that the statement is true but also why it is true, should be favored in mathematics education.

To understand this distinction, consider these two proofs, both of which show that the sum of the first n integers $S(n)$ is $n(n+1)\div 2$:

Initial step
For n = 1 it is true since $1 = 1(1 + 1) \div 2$.

Induction step
Assume it is true for some arbitrary k, that is,
$S(k) = k(k + 1) \div 2$.

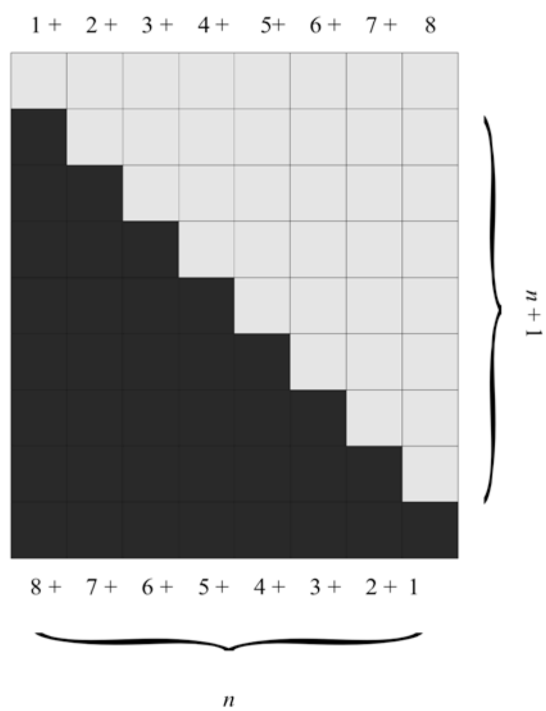
Then consider

$$\begin{aligned} S(k + 1) &= S(k) + (k + 1) \\ &= k(k + 1) \div 2 + (k + 1) \\ &= (k + 1)(k + 2) \div 2 \end{aligned}$$

Therefore, if the statement is true for k it is true for $k + 1$.

Hence, by mathematical induction, the statement is true for all n.
(adapted from Reid & Knipping, 2010, p. 99)

Proof 1



Proof 2

Both proofs require some unpacking, but of a very different kind. To understand Proof 1 the reader must be familiar with mathematical induction as a proof technique, and even then if the technique has been taught formally, without first establishing a link to informal ways of reasoning recursively, the whole process can seem entirely arbitrary. In that case a proof like Proof 1 can be not only non-explanatory, but also unconvincing. Proof 2 offers an example. It does not show that $S(n)$ is $n(n+1)\div 2$. All it shows is that $S(8)$ is $8(8+1)\div 2$. The reader must see that this specific example is in fact a generic example; that the same process would work for any n. But once this is grasped, the proof is explanatory. It gives answers to questions like "Why do you divide by 2?" and "Why do you multiply by $n+1$?"

Discovery

Proof is also fundamental to mathematics as a way of discovering new knowledge. In mathematics education de Villiers seems to have been the first to point this out. In 1990 he noted:

> Proof can frequently lead to new results. To the working mathematician proof is therefore not merely a means of a posteriori verification, but often also a means of exploration, analysis, discovery and invention. (p. 21)

The role of proof in the discovery of non-Euclidean geometries is an historically significant example of proof as a means of discovery. Here is a more simple example:

There are many ways to prove that the sum of any two consecutive odd numbers is even. The simplest is to note that the sum of any two odd numbers (consecutive or not) is even. This verifies the statement and explains it. It is also possible to verify the statement with a proof using mathematical induction, if you believe in it, producing a proof that verifies but does not explain. You could use a generic example: 7+9 = 7+7+2, which must be even because 7+7 must be even and 2 is even. This proof both verifies and explains. Or you could do some algebra: $2n - 1 + 2n + 1 = 2(2n)$ which is even. The final proof lets you discover something more that you were trying to prove. $2(2n)$ is $4n$, so the sum of any two consecutive odd numbers is not only even, it is a multiple of four.

Being a Mathematician

Papers without proofs do not get published. That signals another role of proof in mathematics. Publishing proofs is part of being a mathematician. As Thurston (1995) points out:

> We are driven by considerations of economics and status. Mathematicians, like other academics, do a lot of judging and being judged. Starting with grades, and continuing through letters of recommendation, hiring decisions, promotion decisions, referees reports, invitations to speak, prizes...we are involved in a fiercely competitive system. (p. 34, ellipses in original) In our credit driven system, [mathematicians] also want and need *theorem credits* (p. 36, emphasis in original).

By "theorem credits" Thurston means the social acknowledgement that comes from publishing theorems, and in mathematics results must be published with proofs to count.

This social role of proof is usually implicit. As long as everyone conforms to the norm, it does not become evident. However, when a mathematician publishes without proving theorems, the reaction can be very strong. For example, when Benoit Mandelbrot named and began publishing images of fractals Steven Krantz (1989) published a critique in the *Mathematical Intelligencer* that focused on the lack of definitions, proofs and theorems in Mandelbrot's work. Without these, could fractal geometry be part of mathematics? The exclusion of non-Europeans from the history of mathematics, on the same basis that they did not prove their work (Joseph, 1991), provides another example.

Proofs

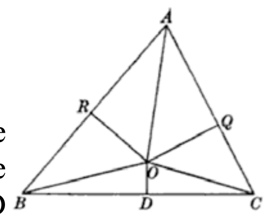
Let us turn now to proofs, as opposed to the concept of proof. What is a proof? The NCTM has a simple definition:

> By the end of secondary school, students should be able to understand and produce mathematical proofs—arguments consisting of logically rigorous deductions of conclusions from hypotheses—and should appreciate the value of such arguments. (2000, p. 56)

This definition is not far from the first ones published in the North American mathematics textbooks:

> Every statement in a proof must be based upon a postulate, an axiom, a definition, or some proposition previously considered of which the student is prepared to give the proof again when he refers to it. ... No statement is true simply because it appears to be true from a figure. ... [In a proof] are set forth, in concise steps, the statements to prove the conclusion ... asserted. (Beman and Smith, 1899, pp. 19–20, cited in Herbst, 2002)

A proof is something like this:



Given an arbitrary triangle ABC we will show that AB = AC.

Construction

Let O be the intersection of the angle bisector of ∠BAC and the perpendicular bisector of segment BC. (In the case where these lines are parallel it is easy to show AB = AC. This is left as an exercise.) Draw OD perpendicular to BC, OR perpendicular to AB, and OQ perpendicular to AC. Draw OB and OC.

Proof

1	OD = OD	reflexive property of equality
2	BD = CD	OD bisects BC, definition of perpendicular bisector
3	∠ODB ≅ ∠ODC	both are right angles, definition of perpendicular bisector
4	△ODB ≅ △ODC	Side Angle Side congruence property
5	OB = OC	Corresponding Parts of Congruent Triangles are Congruent
6	AO = AO	reflexive property of equality
7	∠OAQ ≅ ∠OAR	AO bisects ∠A, definition of angle bisector
8	∠ARO ≅ ∠AQO	both are right angles, definition of perpendicular bisector
9	△RAO ≅ △QAO	Angle Angle Side congruence property
10	AR = AQ & OR = OQ	Corresponding Parts of Congruent Triangles are Congruent
11	∠ORB ≅ ∠OQC	both are right angles, definition of perpendicular bisector
12	OB = OC	from 5
13	OR = OQ	from 10
14	△ROB ≅ △QOC	Hypotenuse Leg congruence property
15	RB = QC	Corresponding Parts of Congruent Triangles are Congruent
16	AB = AR + RB	segment addition postulate
17	AR + RB = AQ + QC	from 10 and 15, addition property of equality
18	AQ + QC = AC	segment addition postulate
19	AB = AC [Q.E.D.]	transitivity of equality

Proof 3 (adapted from Maxwell, 1959, Chapter II, § 1)

Every statement in the proof is based upon a postulate, an axiom, a definition, or some proposition previously proven. The conclusions follow from the hypotheses by logically rigorous deductions. To make it clear that this is happening, the proof is arranged in two columns, one giving the concise steps of the proof, and the other providing the supporting postulates and so on. This is the famous two column proof format that was invented by two American textbook authors, Arthur Schultze and Frank Sevenoak in the early years of the twentieth century (Herbst, 2002, p. 297). According to Herbst, the two column proof format was an innovation that allowed teachers to better handle some of the challenges they faced. At that time a greater proportion of the population was attending secondary school and taking high school geometry, and at the same time the focus of high school geometry courses had shifted from the content of geometry to the process of proving. Explicit descriptions of what a proof should be (like that of Beman and Smith quoted above) and the general use of the two column format to present all proofs seen in schools, meant that the object of learning, proofs, was explicit. This meant that the teacher and students were clear about the object of the class.

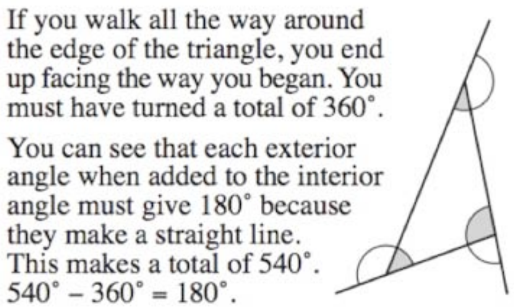
However, writing school mathematics proofs in the two column format means that they no longer resemble mathematicians' proofs. In mathematicians' proofs any step that the reader can be expected to supply is omitted, and explicit reference is made to supporting postulates, definitions and theorems only when they are unusual. If our goal is that "High school students should be able to present mathematical arguments in written forms that would be acceptable to professional mathematicians" (NCTM, 2000, p. 58) then we will have to start teaching written forms that are more like those of professional mathematicians.

Another disadvantage of the two column format is that it shifts the focus away from the statement being proven and towards the form and details of the proof. As a result, students are likely to believe that a proof like Proof 3 would be accepted, and even praised, by their teachers, in spite of the fact that its conclusion is false.

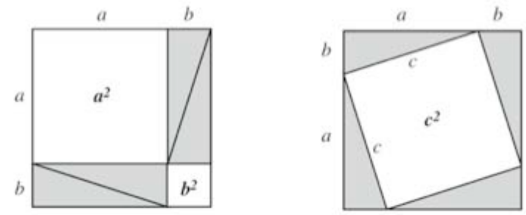
As well as illustrating the two column format, Proof 3 also allows us to revisit the question of the role of proof with a concrete example. Assuming you know that some triangles are not isosceles, you are unlikely to have been convinced by Proof 3. It does not verify anything. Nor is it particularly explanatory or useful for discovering new knowledge (unless you do find it convincing, and then it would lead you to the new knowledge that not only are all triangles isosceles, they are all equilateral, as the same reasoning can be applied to any two sides of the triangle.) What it might be useful for, from a student's point of view, is satisfying school norms for what a proof should look like. A student might expect, in the context of a tradition in which the two column format is highly valued, to be rewarded for producing such a proof. Proof 3 also illustrates a pitfall in Beman and Smith's description of a proof. They require that "No statement is true simply because it appears to be true from a figure." This reflects a general distrust of reasoning using pictures that was dominant in the twentieth century. But pictures can be extremely useful. The simplest way to see what is wrong with Proof 3 is not to go through it line by line looking for a missing or unjustified step. The simplest way to is draw a picture, as accurately as you can, following the steps of the initial construction.

As we have seen above, visual proofs can be both convincing and explanatory, especially in school contexts. Proof 4 (from Hoyles, 1997, p. 12) is another example, and one that works even better as an action proof if you trace a triangle on the floor and walk around it, paying attention to the way that your body turns.

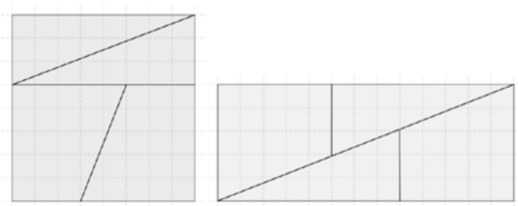
Another well known visual proof is Proof 5, of the Pythagorean Theorem. This kind of proof reflects a very old Chinese tradition of proving using dissections of shapes. Occasionally, such proofs are rejected because of the existence of false proofs like Proof 6, which shows that 64=65. But this makes no more sense than rejecting all two column proofs because Proof 3 exists.



Proof 4



Proof 5



Proof 6

Proving

I have discussed the concept of proof, the texts that are called proofs, and now I will turn to the activity of proving. As the NCTM notes "a mathematical proof is a formal way of expressing particular kinds of reasoning" (2000, p. 56). But what kinds of reasoning should be called *proving*?

We have seen that in the twentieth century there was an emphasis in schools on a form of proofs that made their deductive structure very clear. In addition to the ways in which two column proofs helped teachers, their emphasis on deduction may also have derived from the focus on foundational questions in the first part of the century, which provided axiomatic structures for all branches of mathematics. The work of Polya and Lakatos later in the twentieth century critiqued this focus on axiomatics and deductive logic, pointing out the historical importance of analogies and empirical approaches in mathematical discovery and conjecturing. Their critiques, along with the growing awareness that teaching proving in schools was not very successful, led some jurisdictions, notably England, to put a greater emphasis on pattern noticing and conjecturing. The NCTM's 1989 *Curriculum and Evaluation Standards* also placed conjecturing as an equal partner to verification by deductive reasoning. Hoyles (1997) points out that the emphasis on discovery and conjecturing in England meant that the majority of students saw nothing else. "The majority of students will engage in data generation, pattern recognition, and inductive methods while only a minority, at levels 7 or 8, are expected to prove their conjectures in any formal sense" (p. 9). Duval (1991) goes further, claiming that because arguments leading to conjectures and deductive proving "use very similar linguistic forms and propositional connectives," an emphasis on discovery and conjecturing "is one of the main reasons why most of the students do not understand the requirements of mathematical proofs." (p. 233). However, according to a group of Italian researchers, the relationship between conjecturing and proving is one of "cognitive unity" and their research has shown cases in which students built on what they had learned in making a conjecture to develop a deductive proof. Clearly, the relationship between conjecturing and proving deductively is unclear. However, it is clear that there is a useful distinction to be made between these two kinds of reasoning. The particular kind of reasoning that is called proving is *deductive*. So it is especially important to clarify what deductive reasoning looks like.

When reasoning about a familiar context, even quite young students can produce deductive arguments. For example, consider this argument in favor of the existence of the tooth fairy made by five year olds:

> Kim: My sister says there isn't even a tooth fairy. She says it's our mother.
>
> Teacher: What do you think?
>
> Kim: I think the fairy came in after my sister was asleep. Because my sister said I would get one dime and I got two dimes.
>
> Kenny: I got a dollar. My mom can't spend a dollar because we are saving money for a car. So it has to be the tooth fairy.
>
> (Paley, 1981, p. 40)

Kenny's deductions start with some prior knowledge: He knows he got a dollar for his lost tooth, and he knows that his mother is not spending any money because they are saving for a car. From this knowledge he deduces that his mother did not put the dollar under his pillow and so he rejects Kim's sister's conjecture in favor of Kim's, that the tooth fairy exists. Kenny does not include every step; he never says, "It can't be my mother". He also makes use of a hidden assumption that the only two possible sources of the tooth money are his mother and the tooth fairy. This is typical of children's deductions. Steps are skipped and hidden assumptions are made. But recall that mathematicians also skip steps and use shared assumptions without explicitly mentioning them. Kenny is far from producing a two column proof but he might not be so far from producing a proof acceptable to mathematicians.

Older children can link together simple deductions into chains in which conclusions of one step are used to justify subsequent steps. For example, consider Maya, age 11, who is explaining why the number of squares in a 10 by 10 grid is 10×10 + 9×9 + 8×8 + ... + 1 (Long dashes — represent pauses. Ellipses ... represent omissions).

> Maya: Can everyone see? So you count 1, 2, 3, 4, 5, 6, 7, 8, 9 right? … Since a square—this—any square—the square is 10 by 10 no matter how you turn it, it's always going to be…the same. So you don't have to measure it again. You can go 9 times 9. Do you understand why? Yeah? OK, So you go 9 times 9 like Gino said, 81. Then you can do 3 by 3, 1, 2, 3, 4, 5, 6, 7, 8—and then again you don't have to measure again you know. It's going to be the same. So 8 times 8—64. And you can keep on going.… You can do the 7 times 7—49. And 6 times 6—36. 5 times 5—25. 4 times 4—16. 3 times 3—9.
>
> (Reid & Knipping, 2010, p. 88)

First Maya counts how many 2 by 2 squares will fit along the top edge. Then she deduces that the number of 2 by 2 squares down either side will be the same, because the square is the same length on all sides. So the number of 2 by 2 squares is 9 times 9. For the 3 by 3 squares there are 8 along the top and the same reasoning gives 8 times 8. "And you can keep on going." The same reasoning gives the number of all the remaining sizes of squares.

Deductive reasoning is not something children need to be taught, although clearly contexts in which deductive reasoning is useful will encourage them to develop their reasoning further. However an important step toward proving is the formulation of that reasoning. It is necessary for students to become aware of their own reasoning and to explore ways to express that reasoning so that it can be understood by others. Maya is taking steps in that direction as she explains her reasoning to her classmates. In the next section I will discuss ways to support he development of students' proving in classrooms.

I have discussed the role of proof, some kinds of proofs, and the nature of proving. I would like now to turn to the theme of the conference, transformative mathematics teaching and learning, and consider the teaching of proof. How might the goals of the NCTM's Reasoning and Proof Standard be realized? In what contexts do students learn to prove? How might teaching be transformed by a renewed attention to proof?

Teaching proof

Efforts to teach proof in the twentieth century occurred either in the context of a high school geometry course, or, in the New Math era, in a unit on logic. The NCTM is clear about one thing we learned from this experience:

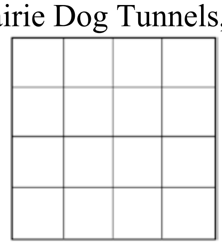
> Reasoning and proof cannot simply be taught in a single unit on logic, for example, or by "doing proofs" in geometry. (2000, p. 56)

But how *should* proof be taught? In this section I will consider first five aspects of teaching that Vicki Zack and I identified as contributing to students' proving in her classroom and in others'. I will then turn to two ideas that I believe help to clarify what it means to teach proof.

In Reid and Zack (2009) we describe how five key aspects of Vicki's teaching contributed to her grade 5 students' proving. They are: a focus on problem solving, allowing sufficient time, encouraging conjecturing, expectations concerning the nature of students' communications, and the teacher's expertise in listening closely and seizing opportunities to provoke discussion.

Problem Solving

Problem solving was at the core of the mathematics curriculum in Vicki's classroom. Non-routine problems were integrated into the everyday mathematics lessons, and a problem solving approach was also taken to other areas of the curriculum. The Problem of the Week tasks were especially rich as contexts for proving. These differ from the other non-routine problem-solving tasks used in the class in that the children were asked to write detailed explanations at two or more points in the problem solving process. For the most part Vicki used the same problems year after year. This allowed her to make small adjustments in phrasing or in follow up tasks that further supported the development of the children's reasoning (Brown, Reid & Zack, 1998). Four of the Problem of the Week tasks have received the most attention in our research. They are Prairie Dog Tunnels, Handshakes, Decagon Diagonals and Count the Squares (see Figure 1).



Find all the squares in the figure on the left. Can you prove that you have found them all?
What if ... ? [A five by five grid is given as a figure]. Can you prove you have them all?
Extension: What if it were a 10 by 10 square? What if it were a 60 by 60 square?

Figure 1: The Count the Squares problem

The prompts for Prairie Dog Tunnels, Handshakes, and Decagon Diagonals are:

- Nine prairie dogs need to connect all their burrows to one another in order to be sure they can evade their enemy, the ferret. How many tunnels do they need to build?
- If everyone in your class shakes hands with everyone else, how many handshakes would there be?
- How many diagonal lines can be drawn inside a figure with 10 sides? [Figures were provided of a triangle, square, pentagon and hexagon, labeled: 3 sides, 0 diagonals; 4 sides, 2 diagonals; 5 sides, 5 diagonals; 6 sides, 9 diagonals]
  How many diagonal lines would there be in a 25-sided polygon?
  How many diagonal lines ... in a 52 sided polygon?

In these tasks the students used common techniques such as making organized tables, using diagrams, and searching for patterns in sequences and using differences. The first three problems involve finding the sum for the whole numbers from 1 to n. In solving them the equivalence of $(1+2+3+4+\ldots+n-1)$ and $n(n-1)/2$ was discovered through a combination of empirical testing and deduction. Empirical strategies such as drawing all the possible diagonals were used to establish correct answers when n was small. These gave way (as n increased) to reasoning deductively either that each person shakes one less hand than the previous person (the first shakes $n-1$ hands, the next $n-2$, and so on) or that each of the n people shakes $n-1$ hands but that counts each handshake twice so the correct number is $n(n-1)/2$. The fact that these two methods of reasoning both correctly solve the problem established their equivalence.

Generally, the students did not spontaneously use symbols. Generalizations were most often expressed as procedures tied to the structure of the problem, for example, "Multiply the number of people by the number of handshakes each person does, which is one less, and divide by two because you counted all the handshakes twice." Vicki then nudged the students to go further, asking them if they could express this idea by using a letter to represent any number of people shaking hands. In some years expressions like *n*(*n*–1)¸2 were written using variables. For example, Micky recorded this proof of a formula for finding the number of diagonals in a polygon:

> If you can find all the diagonals possible from one [vertex] you can figure out the whole amount of inside diagonal lines.... I know that a [vertex] connects with all of the other [vertices] except for 3, itself the [vertex] to the left and right. You subtract 3 from the amount of total sides, ... here's the rule: (Z = no. of sides)...Z – 3 ´ Z ¸ 2 = no. of diagonal lines in figure.
>
> (from Micky's Math Log, May 16, 1994, described in Zack, 1995)

Micky's proof has several steps. He is explicit about one: that the number of diagonals from each vertex is Z – 3 (because each vertex is connected by diagonals to all the others, except itself and its neighbors). However, he leaves the justification for another step implicit: Every diagonal is counted twice, so the formula ends with dividing by two.

Time

In Vicki's class the children were given a great deal of time to experiment with, think through, discuss and refine their understandings. Each Problem of the Week was assigned on a Monday. The students worked independently on the problem during class time (an extended 90 minute class period) and wrote a detailed description in their Math Logs. On Tuesday, she allowed time for the students to review their Logs if they chose to do so and at times prompted some students to reflect upon their explanation (for example, to clarify their thinking, elaborate on a diagram or add a diagram). Wednesday was the day the discussions took place, again in a 90-minute session. They worked first in pairs (or in a group of three), and then came together in a group of four or five. In these small groups they compared solutions and discussed further, and then reported to the half-class, with more discussion following. On occasion, if the discussions in the small group or the class warranted, class time on Thursday and Friday was also used to allow the discussions to come to a fruitful conclusion. This means that the exploration of the problems occurred over a significant period of time, almost four hours per task. This allowed for conjectures to be made and explanations sought without being artificially cut short by time constraints.

Conjecturing

The problems used allowed the students to make hypotheses and discover solutions, which they then proved in order to verify and explain. The processes of conjecturing and proving were intertwined in two ways. Proving made use of insights gained through the explorations that led to conjectures (For example, cut-out squares of different sizes were used to support the counting of squares, but they were also used in proving. See Maya's proving above and Zack, 2002). Conjectures were also used as the basis for proving (For example, one child conjectured that the number of squares would always be a multiple of 5, unless the size of the grid was a multiple of 3. He later rejected answers conjectured by his peers if they contradicted his general rule; see Reid, 2002).

Expectations

The groundwork for proving laid during the year included an expectation that the children would be looking for patterns, and that they could be nudged to think about the mathematical structure underlying the pattern (Zack, 1997). In addition, there were expectations that everyone's answers should be considered and that answers should not be changed without discussing how they arose and what might be the source of an error.

This valuing of clarity, explanation, and attention to others supported the expression of the students' thinking, whether it involved proving or not, but also made that thinking available to others to question. At the close of each session, Vicki distributed a sheet entitled "Helpful explanations/Helpful ideas" and asked the children to note any ideas or explanations they found helpful, to tell why, and to credit the peer(s) who helped. She found that the children became increasingly aware of the contribution others had made to their understanding, and at times could indicate how they have reshaped others' ideas to make them their own (See Zack & Graves, 2001 for further elaboration).

Expertise

In terms of her mathematical background, Vicki could be considered a typical elementary school teacher in that she describes her background in formal mathematics as weak. She is not an expert on the nature and role of mathematical proof, and has not formally proven anything herself since high school. However, her research interest in how meaning is constructed in dialogue led to a close look at the children's ways of expressing their ideas, and then in turn at issues of convincing and proving.

Working with the children's ways of making meaning is central to Vicki's teaching. Her expertise lay in listening closely, recognizing potentially fruitful avenues and seizing opportunities to provoke discussion. There was a constant expectation for explanation (e.g., asking "Explain how it works and why it works."), and for generalization (Will it always work? Can you construct a general rule?). Vicki discovered the richness of the mathematical tasks in large measure due to the children's ways of solving the problem. The tasks lent themselves to algebraic thinking and generalizing and proving. The proving arose from the tasks, even though there had been no 'a priori' objective to teach proof and proving.

The five aspects of teaching described above, problem solving, sufficient time, conjecturing, expectations for communication, and teacher expertise, seem to be important in creating a context for proving, even where no explicit intent to teach proof existed. However, in higher grades where the teaching of proof might become more structured, more attention must be paid to two key ideas: the tool-box, and local organization.

The Tool-box

Mathematicians' and children's proofs make reference to, or assume without stating, other theorems or assumptions. Things are taken for granted. Even in the work of professional mathematicians there are theorems that are used without their proofs being read, and even without any source being known.

> Within any field, there are certain theorems and certain techniques that are generally known and generally accepted. When you write a paper, you refer to these without proof. You look at other papers in the field, and you see what facts they quote without proof, and what they cite in their bibliography. You learn from other people some idea of the proofs. Then you're free to quote the same theorem and cite the same citations. You don't necessarily have to read the full papers or books that are in your bibliography. Many of the things that are generally known are things for which there may be no known written source. As long as people in the field are comfortable that the idea works, it doesn't need to have a formal written source. (Thurston, 1995, p. 33)

Netz (1999) discusses the omission of references to theorems and assumptions in classical Greek proofs. He calls the set of theorems and assumptions that can be used without comment the "tool-box". For example, Archimedes can assert that two segments are of the same length because they are radii of the same circle. He does not have to make any reference to this justification. He simply states that they are the same length and leaves it to the reader to figure out why (Netz, 1999, p. 172). As his readers were all members of a cultural community for whom the same tool-box was taken for granted, this was acceptable.

Similarly, Proofs 1, 2, 4 and 5, above, make use of tools from my tool-box which includes rules governing algebraic symbolization and manipulations, the idea of mathematical induction, and even implicit rules about using generic examples that have probably never been stated anywhere, but which are followed by those who consider such proofs acceptable.

Netz argues that the results proven in Euclid's Elements constitute most of the classical Greek tool-box. One might imagine that the study of the Elements was undertaken as the beginning of a scholar's mathematical education and so thereafter mathematicians could assume that anything in Euclid could be used without comment or reference. However, Netz suggests that the contents of the tool-box could become known in another way.

> The very fact that an argument was made, without any intuitive or diagrammatic support for that argument, must have signalled for the audience that the argument was sanctioned by the Elements. Once this is the expectation, the need to refer explicitly to the Elements declines, which would in turn support the same tendency: the regular circle in which local conventions are struck without explicit codification. (p. 232)

In other words, the process might resemble that described by Thurston, above; the reader comes to know, by observing what things are taken for granted in proofs, what is in the tool-box, without even being told explicitly.

In a mathematics classroom, determining what is in the class tool-box can be done in various ways. One approach sometimes taken is to inform the students that they must forget everything they already know and start from the axioms and definitions given in the textbook. But experience tells us that the students do not forget everything they know, and the axioms and definitions given in the textbook are never complete themselves. What results is the class pretending to base its arguments on the given axioms and definitions, while being guided by their prior knowledge. The tool-box is supposed to be limited to what the textbook allows, but is actually larger.

Another approach is for a teacher to start presenting proofs without establishing what is in the tool-box, so that, as Netz says happened for the Greeks, the contents of the tool-box become known to the students through the making of arguments without stating their justifications. If a proof is based on an assumption that the measures of angles can be added, but this is never stated or justified, then it must be part of the tool-box.

The idea of the tool-box can be usefully connected with another idea, that of local organization.

Local Organization

Freudenthal (1971) discusses the introduction of proving and claims that proving must begin with what he calls “local organization” as opposed to the “global organization” of an axiomatic system. In a globally organized system the definition of parallelogram would be part of the tool-box and would either be explicitly taught or would become known through its use in proofs. Freudenthal describes another approach: A discussion, for example, of the properties of parallelograms can begin by simply listing all those that are apparent to the students. Similar lists might be made for rectangles and rhombuses. In examining such lists, Freudenthal claims, “There are a host of visual properties which ask for organization. Here starts deductivity; rather than being imposed it unfolds from local germs. The properties of the parallelogramme become deductively interrelated” (p. 424). Finally, one property emerges as a definition from which the others can be deduced. This is local organization. It can be extended as the properties of parallelograms are related to the properties of rectangles, rhombuses and squares.

So rather than a definition being given at the outset, the students’ proving determines which property is a definition and which ones are consequences of it. There is a local organization of mathematical knowledge, but no global system into which that knowledge fits. This is necessary, Freudenthal states, because, “a student who never exercized organizing a subject matter on local levels will not succeed on the global one” (p. 426). It is at the local level that proving and defining are learned, before being used (perhaps much later) to define and prove in an axiomatic system.

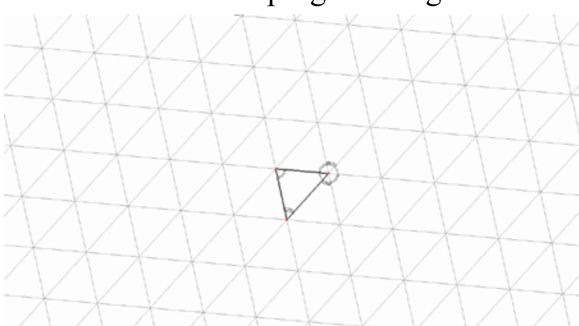
Freudenthal’s implications for teaching are clear:

> In general, what we do if we create and if we apply mathematics, is an activity of local organization. Beginners in mathematics cannot do even more than that. Every teacher knows that most students can produce and understand only short deduction chains. They cannot grasp long proofs as a whole, and still less can they view substantial part of mathematics as a deductive system. (p. 431)

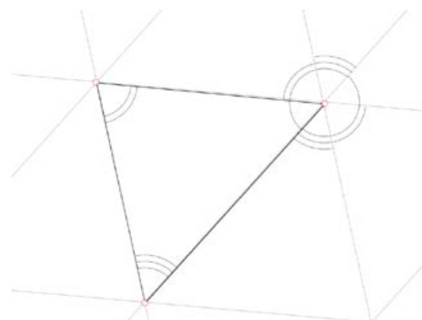
Local organization and use of an implicit tool-box raise the question for teaching of what must be made explicit, what requires proof, and what can be left implicit. Freudenthal’s examples (in *Mathematics as an Educational Task*, 1973) offer a resolution to this problem. The decision as to what to leave implicit, what to make explicit and what to prove must be made in order to develop students' understanding of mathematical concepts and ability to apply them. In cases where the proof brings a new understanding of the concepts involved, the proof is useful. Assumptions that have unexpected implications will need to be made explicit in exploring those implications. Assumptions that would seem obvious and trivial to the students if made explicit can safely be left implicit.

Proof 7 is another visual proof that the angle sum of a triangle is 180 degrees. It depends on an assumption that any triangle can be used to tile the plane. It is clear that the six angles around a vertex total 360 degrees (although this depends an another hidden assumption, that angle measures can be added, and a hidden definition, of degrees). The congruence of the marked angles depends on the fact that all the triangles are congruent. All of the hidden assumptions here are likely to be accepted without question by students, and making them explicit would be pointing out the obvious. In contrast, the typical two column proof depends on properties of transversals that are not so obvious as assumptions, and if proven depend on the even less obvious parallel postulate.

Proof 7 makes use of a minimal tool-box, and puts together its elements in a way that proves an important mathematical property of plane triangles, a property which in turn contributes to many other proofs of significant results. As it is based on assumptions that are more obvious than the conclusion it verifies and explains the result, in a way that the traditional two column proof does not. A similar comment could be made about Proof 4, although unless it is actually enacted the fact that one turns 360 degrees in tracing around a triangle may not be obvious to those who have not done LOGO programming.



Proof 7



Proof 7 detail

Teaching Proof versus Proof Based Teaching

The NCTM opened the twenty-first century with a call for increased attention on mathematical proof and reasoning, for all students. Reform movements at the beginning of the twentieth century also called for mathematics teaching, and especially high school geometry teaching, to focus much more on proof, at a time when parallel reforms were allowing many more students to go to high school. In North America this resulted in the invention of a new proof format, the two column proof, along with other pedagogical innovations designed to help teachers teach proof.

> To make student proving possible, a system of resources had to be developed and coordinated with a norm for accomplished proofs. The integration of all those elements produced a stable geometry course oriented toward students' learning the art of proving embodied in the two-column format. However, that stability came with a price – that of

> dissociating the doing of proofs from the construction of knowledge. (Herbst, 2002, p. 307)

Instead of school proofs being like mathematicians proofs in that they gave insight into mathematics, school proofs became another topic to be covered, disconnected from all others. Proofs became an object, rather than a process of learning.

To avoid following the same path now, we must tread carefully. We must ensure that we see proof as fundamental to mathematics as a way to develop understanding of mathematical concepts, and as a way to discover new and significant mathematical knowledge. Proof cannot be limited to the format of proofs, and to the role of verification of knowledge (for which there is probably good empirical or other evidence already).

We have recent experience with a comparable reform effort, the increased focus on mathematical problem solving after the 1970s. At first, problem solving was an object of teaching. Texts added new chapters on problem solving, including Polya's four stages, sets of heuristics and even larger sets of strategies to help teachers and students learn to be better problem solvers. Problem solving was a huge area for research in mathematics education. Unfortunately, a lot of the research indicated that making problem solving an object of mathematics teaching wasn't making anyone better problem solvers (Schoenfeld, 1987, p. 30). Perhaps the people with the best success in developing problem solving in students, the mathematics faculty who coached students for the Putnam exam or for various Olympiads, had it right. "Students don't learn to solve problems by reading Polya's books, they said. In their experience, students learned to solve problems by ... solving lots of problems." (p. 30). Some decades on now, problem solving is taking on a different role in mathematics teaching. Textbooks for new teachers and some curricula and school mathematics textbooks are advocating that problems not be an object of mathematics teaching, but instead be the means by which mathematics is taught.

I would like to conclude by suggesting that today proof teaching and research is in a similar state to problem solving in the 1980s. Much research is being done, but proof is still seen as a topic to be taught. In the case of problem solving we have moved towards seeing it as a way of teaching, and there are early hints that something like proof based teaching, akin to problem based teaching, might emerge in the next decades. It will be interesting to see.

STUDYING MATHEMATICS CONCEPTUAL LEARNING: STUDENT LEARNING THROUGH THEIR MATHEMATICAL ACTIVITY

Martin A. Simon
New York University
ms4573@nyu.edu

This paper describes a program of research aimed at better understanding mathematics conceptual learning. Rather than studying the products of learning (conceptual steps), it focuses on the process (mechanism) of students' learning – learning that occurs through their mathematical activity in the context of a sequence of mathematical tasks. Intensive design research investigates subtle shifts in thinking that lead to the development of new abstractions.

Introduction

In Simon (1995), I introduced the idea of a "hypothetical learning trajectory (HLT)" to characterize important aspects of pedagogical thinking. The HLT consists of (1) the educator's goal for the students' learning, (2) the mathematical tasks that will be used to promote the students' learning, and (3) hypotheses about the process by which the students will learn. The paper emphasized the interdependency of the learning tasks and the learning process. Much research is still needed to support all of the three components. However, my colleagues[1] and I have embarked on a research program to investigate particular aspects of the conceptual learning process, which also implies careful attention to tasks. Whereas considerable important work has been going on investigating social interactive aspects of learning that take place during class discussions, our research focuses on cognitive learning that can take place when students are engaged in a series of mathematical tasks in small groups and individually. In this paper, I describe this emerging research program.

What Do We Mean by "Studying Learning?"

> In spite of the animated theoretical debate that has taken place on the nature of abstraction, little experimental research is available. … We surmise that the lack of experimental evidence is due to the difficulty of observing the processes of abstraction (as opposed to the products, for which there is more evidence). (Hershkowitz et al., 2001, p. 197)

Because our research focuses on learning through interaction with a task, we use primarily cognitive (constructivist) constructs as the basis for this work.[2] The focus of this work is on the process by which abstractions are developed.[3] Much of the important research in mathematics education over the last 30 years has been referred to as "research on mathematics learning." Given that this language is already widespread, it is difficult to denote the differences between our research program and the research that has been labelled "research on mathematics learning." I will try to articulate two key distinctions. First, most of the work subsumed under this heading has characterized static mathematical student understandings (e.g., Steffe, 2003) or a hierarchy of student understandings (schemes, classroom practices) (e.g., Cobb, McClain, & Gravemeijer, 2003). Whereas this work has been foundational to our work, it is not what we mean by "studying learning." Our focus is in understanding the subtle shifts in thinking that account for the transition between two consecutive schemes (or understandings or classroom practices). Our goal is to explain how the scheme or understanding has come about as students interact with a sequence of mathematical tasks. Second, when learning is explained, it is often explained using broad concepts such as reflective abstraction, generalizing assimilation or negotiation of meaning. For us, these are not sufficiently nuanced to be useful for instructional design. Siegler (1996) argued,

> The standard labels for hypothesized transition processes: assimilation, accommodation, and equilibration; change in M-space; conceptual restructuring; differentiation and hierarchic integration; are more promissory notes, telling us that we really should work on this some time, than serious mechanistic accounts. (p. 223)

And diSessa & Cobb (2004, p. 81) pointed out, "Piaget's theory is powerful and continues to be an important source of insight. However, it was not developed with the intention of informing design and is inadequate, by itself, to do so deeply and effectively." Our research program is aimed at moving from Piagetian constructs as a source of insight and broad hypothesis toward an explication of students' mathematics learning through engagement with tasks that can support instructional design.

What is the Nature of a Mathematical Concept?

Understanding the nature of mathematical concepts and understanding how they are learned are necessarily intertwined. Each has implications for the other. Thus, investigating how mathematical concepts are learned requires a useful characterization of the nature of concepts, but as will become clear, the nature of a concept involves considering aspects of how it is learned. To make some key distinctions about mathematical concepts, I use the following example presented in Simon (2006, pp. 4-5):

> In a fourth-grade class [students 11-12 yrs old], I asked the students to use a blue rubber band on their geoboards to make a square of a designated size, and then to put a red rubber band around one half of the square. Most of the students divided the square into two congruent rectangles. However, Mary cut the square on the diagonal, making two congruent right triangles. The students were unanimous in asserting that both fit with my request that they show half of the square. Further, they were able to justify that assertion by explaining that each of the parts was 1 of 2 equal parts and that the two parts made up the whole. I then asked, "Is Joe's (rectangular) half larger; is Mary's half larger, or are they the same size?" Approximately a third of the class chose each option.[4]

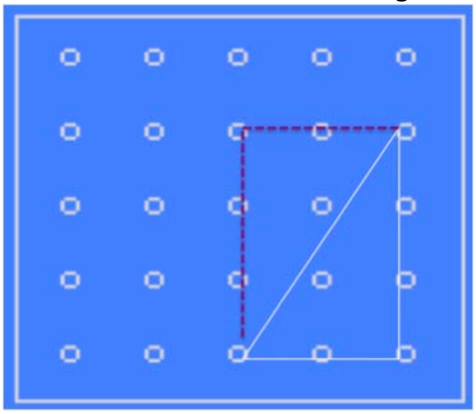
When I share this scenario and ask current and prospective mathematics educators about potential instructional interventions for the two thirds of the class who did not recognize the equality of the area of the two parts, the overwhelming majority suggest having students cut up the triangular half and superimpose it on the rectangular half (and additional activities of this type). Let us examine this response.

No matter how many such experiences are created for the student, these experiences will never teach the students the critical concept involved. Readers of this paper likely know that the areas of the two different shaped halves are equal. They know this, not because they have cut up and superimposed one half on the other half; they know that the two halves *must* be equal. They know the logical necessity of their equality. Having students cut and superimpose the halves may convince the students *that* the halves have equal area, but the activity does nothing to help them learn that the halves *must* have the same area.

The cutting up and superimposing activity could be done with different fractions and different shaped parts. Students could come to believe that the same fraction with a different shape has the same area. This is what I have called an "empirical learning process" (Simon, 2006). In an *empirical learning process*, the student introduces a number of inputs and sees a pattern in the outputs. However, an empirical learning process *never* produces a mathematical concept. A mathematical concept involves knowledge of the logical necessity of an idea. I have used Piaget's (2001) term *reflective abstraction* to identify learning processes that lead to mathematical concepts. The choice of this term will become clearer in the subsequent discussion.

Let's consider a second example (Heinz et al, 2000). Ivy is a sixth-grade teacher (students 11-12 yrs old) who is committed to her students learning mathematics with understanding. In this episode, she was beginning the teaching of the area of triangles. Following is an outline of her lesson as it unfolded:

1. Students worked in groups to find the area of a right triangle (legs 2 and 3 units) on a geoboard.
2. The class discussed their strategies. Completing the rectangle was a popular strategy.



3. Students worked in groups to find areas of other right triangles on their geoboards. Following Ivy's instructions, they recorded measures of the base, height, and area for each triangle in a chart.
4. Ivy convened the class and recorded in a large chart the base, height, and area of the different triangles contributed by the students.
5. Ivy then directed,

> Look at how these numbers are in this chart with our areas . . . and see if you can figure out a pattern that you can use every time using the numbers [measures of base and height] to come up with the area. . . . There is something that you can do to these [measures of] the bases and the heights to get the area. (Heinz et al., 2000, p. 94)

Ivy's encouragement of students to find a pattern in the "numbers" is a promotion of an empirical learning process. In her lesson, she treated the geoboard work as if it was a black box that turned inputs (measures of the legs of the triangles) into outputs (measures of the areas) for the purpose of finding a pattern in the numbers. Finding a pattern in this way does not result in knowing the logical necessity of the relationships expressed in the formula for the area of a triangle.

At this point, I anticipate the following objection, "Denoting patterns is a key aspect of doing mathematics." Mathematics has been called "the science of patterns" (Steen, 1988; Devlin, 1996). We do not want to eliminate attention to patterns in mathematics classrooms. However, the discussion here is about explaining the process of learning mathematical concepts, not of doing mathematics more broadly. Empirical identification of a pattern never, in itself, results in conceptual understanding. It may be the trigger for some other activity that results in such learning. I argue that identifying patterns empirically is neither necessary nor sufficient for conceptual learning. Further, in some situations it might not even be appropriate. In our example, looking for a pattern among the legs of a triangle and the area is neither optimal for learning nor does it provide a useful model of mathematics.

Consider now this modification of Ivy's lesson. I begin the lesson as Ivy did in order to highlight particular contrasts in students' opportunities to learn, even though more effective lessons might be designed for this subject matter. The sequence follows:

1. Students work in groups to find the area of a right triangle (legs 2 and 3 units) on a geoboard.
2. The class discusses their strategies. Completing the rectangle is a popular strategy.
3. Students work in groups to find areas of other right triangles on their geoboards. *No recording chart*.
4. Students are given a ruler and asked to find the area of right triangles drawn on plain paper (legs not parallel to sides of paper).
5. 6. Students are given the measurement of the legs of right triangles involving larger numbers for the dimensions. They are asked to find the area of each triangle (without drawing) by mentally running the process they did on paper.
7. Students are asked to write a generalization (algorithm) for how to calculate the area of a right triangle given the measures of the sides.

What do we see in this example? If we accept that the lesson sequence could promote reinvention of an algorithm for the area of a right triangle, we can see that it does so *without* employing an empirically generated pattern. The sequence is designed so that students can explain the appropriateness of each step in the algorithm based on the relationship between a right triangle and a particular related rectangle. I will engage in further analysis of this lesson in the next section.

Evolving Constructs for Studying Learning during Engagement with Mathematical Tasks

If we are convinced that empirical learning processes alone do not result in conceptual learning, then the important question is, *how might we think about learning that develops conceptual understanding?* The modified lesson discussed above is not an exemplary lesson and the intended learning is not particularly impressive. However, the simplicity of the lesson, allows it to be used for exemplification of particular ideas.

Students are able, without difficulty, to find the area of right triangles on the geoboard by completing the rectangle and taking half of it. For the purpose of this paper, we are not concerned with where the idea came from to complete the rectangle, only that carrying out the strategy with understanding is not beyond their current conceptual knowledge. The geoboard work developed an activity from which the learning could take place. It became a *process* in the APOS sense (Dubinsky & McDonald, 2001). That is, students reached a point where they were able to anticipate the whole process, not needing to stop and determine each next step. [5]

Note that for an elementary student, adding a rubber band to complete the rectangle, determining the number of little boxes contained in the rectangle (perhaps by counting) and taking half of that number is still pretty far from knowing how to compute the area of a right triangle given the measures of its legs. In the modified lesson, the diagrams of right triangles are given next. This changes the context, putting additional demands on the student. First, the student needs to draw the rectangle that produces two congruent triangles. When the geoboard was used, the choice of rectangle probably occurred without discrimination, because the geoboard is arranged as an orthogonal array and the triangles were arranged with the legs parallel to the sides of the geoboard. When working with the diagram, the students are able to produce appropriate rectangles based on their anticipation of a rectangle made up of two congruent triangles. Once again their strategy becomes a process as they reach a point where they do not need to think about how to draw the additional lines to complete the rectangle. The second difference in the paper context is the unit squares do not appear on the paper. Therefore, the students need to use their prior knowledge of measurement and computation of the area of a rectangle.

The mental run problems offer a third context, again changing the demands of the task. These problems are aimed at fostering abstraction of the relationships involved. On the geoboard or on paper, the student could determine the length of the rectangular sides using visual clues after having completed the rectangle. For the mental run problems, the students have no rectangle to visually examine. They need to anticipate the dimensions of the rectangle based on the dimensions of the triangle. They are able to do this based on an anticipation of how they constructed the rectangle (on paper) from the triangle. At this point they should have the abstractions that can be represented by $A = \frac{1}{2} l_1 l_2$, where l_1 and l_2 are the legs of the right triangle.

What can we take from this example?

1. This was not a problem solving activity. That is, at no point were the students facing a real problem. They moved smoothly through the tasks. Problem solving is an important part of mathematics. However, there are ways of teaching concepts that do not depend on students spontaneously solving the “next” problem.
2. Related to #1, this lesson sequence was not constructed to foster cognitive conflict. Rather, it was anticipated that the students would have the knowledge to operate at every point in the lesson when they reached those points.
3. The lesson sequence was designed to foster conceptual learning without hints or leading questions on the part of the teacher.
4. The learning was not the result of an empirical learning process. Students were not involved in finding a pattern in the numbers. Students came to understand the logical necessity of the relationships represented by the formula above.

If the learning is not the result of empirical learning, problem solving, or cognitive conflict, and if the teacher did not lead the student to the idea, how can we understand the learning process that was hypothesized in this lesson? (See Simon, et al, 2010 for the analysis of a teaching experiment involving division of fractions.) I will provide a brief, rudimentary explanation. We use three constructs adapted from Piaget's (2001) description of reflective abstraction: *goal-directed activity*, which can be mental and/or physical, *reflection*, which we understand as humans' innate ability (and tendency) to recognize (not necessarily consciously) commonality in their experience (von Glasersfeld's, 1995), and *abstraction*, which involves a learned anticipation. Using these constructs we view the students' hypothesized learning as the development of abstractions through reflection on their goal-directed activity (consistent with Piaget's reflective abstraction). If you return to the description above, at each point the students came to anticipate a process that coordinated particular aspects of their extant knowledge. In particular, the students came to anticipate:

1. the right triangle as half a rectangle divided diagonally,
2. the requisite rectangle formed by creating sides at right angles to the legs of the triangle,
3. the sides of the resultant rectangle having the dimensions of the legs of the right triangle,
4. the area of the triangle determined using a known formula for the area of a rectangle and halving the result.

But what does it mean that they "came to anticipate?" The student, faced with a task, engages in activity to meet their goal. Initially, the student engages step by step, determining the next action as they complete the preceding one. As they encounter similar situations, they at some point begin to notice a commonality (reflection) in their *activity* used to meet their goal. This results in anticipation of the needed actions. The sequence of actions no longer need to be assembled, the whole activity sequence is anticipated in response to recognizing the situation. Finally, the anticipation of the process reaches a point at which not all of the activity needs to be carried out in order to arrive at the intended result. The student no longer needs to create or imagine the rectangle to find the area of the right triangle.

Vision of a More Scientific use of Tasks for Engendering Conceptual Learning

I offered the example above to provide a concrete basis for discussing the particular vision for mathematics education that underlies our research program. Overall, my colleagues and I support the shared goals of the mathematics education community: equal opportunity, deep understanding, strong problem solving abilities, and competence in communicating mathematical ideas. However, our research program is focused on a specific goal that can advance the larger goal of deep understanding of mathematics. This particular goal is an improved ability to engineer task sequences that can foster particular understandings for a diverse set of students. We use the term "foster" to emphasize that teaching cannot *cause* learning. However, mathematics teaching has the potential to make conceptual learning likely.

To consider the vision, I invite engagement in the following thought experiment. A highly competent teacher gives her mathematics class a problem whose solution requires the mathematics to be learned. The students are asked to work in small groups, provided with a rich set of representations to work with, and asked after considerable work time to discuss their work with the class as a whole. A couple groups generate solutions to the problem, but the majority are not able to generate solutions (although there is considerable variability in their efforts). During the class discussion, different students talk about their work and one of the students who solved the problem presents her solution. After some questions and paraphrasing by the teacher, many of the students who did not solve the problem, seem to understand the solution presented.

I have probably described many classes with which you are familiar. Now I ask you to make a prediction. Who will more likely retain the new mathematics, apply it appropriately, and build on it – a student who independently generated the solution or a student who came to understand it in the context of the class discussion?[6] I think most mathematics educators would predict that the student who generated the solution to be more successful with the concept in the future. There is a difference in the cognitive demands of generating a solution versus understanding a solution (analogous to active versus passive knowledge of a language). This difference is not generally discussed.[7] Further, one can see this distinction as an equity issue. Who are the students who usually solve the mathematical tasks during small group time? It is the students who are more advanced in their mathematical knowledge. In the common scenario I described, the more-advanced students continue to work novel problems, while the less-advanced students struggle to follow the explanations of solutions given by the more-advanced students. This phenomenon can work against narrowing the gap between less-advanced and more-advanced students and even contribute to increasing the gap.

The hypothetical class described is not an unusual one. Particularly when a difficult new idea is the focus, generally few students generate the mathematics on their own. Sometimes no one in the class is able to generate a solution prior to the class discussion. This is where our research program comes in. What if we had the research-based knowledge so that typically 80% or more of the students could generate the new mathematical ideas through their engagement with the mathematical tasks? Would this improve the quality of student learning? Would this improve the quality and impact of the class discussion? Would this increase access to high-quality learning for more students? – an issue of equity.

The vision behind our research program is just that: understand how students learn through their mathematical activity, so that pedagogical design principles can be created that guide task sequence design. As a result, task sequences would be designed to engage students in the particular activity that allows them to abstract the intended new ideas. Currently, mathematical tasks often discriminate in favor of those who have the appropriate prior experience and against those who do not have it. The vision is to provide instructional task sequences that are designed to build up the requisite experience.

One might ask, “Don’t we do this already?” Let’s consider a couple of frequently used approaches. The use of manipulative materials and other physical or iconic representations is often thought to create the experiential base for conceptual learning. These tools are useful and have potential beyond their current uses. However, there is insufficient theory guiding the use of physical and iconic representations. Teachers often have students initially solve problems using these representations. The students produce solutions that are isomorphic, *in the mind of the knowledgeable adult*, to formal solutions. However, these “concrete solutions” in themselves do not produce conceptual understanding and do not embody the vision articulated in the last paragraph.

A second approach is the pedagogical use of a *series* of problems. This is an attempt to create a series that allows students to generate ideas, but where the steps from one problem to the next are within the students’ grasp, that is novel problems that are only a small change from the prior one. Although there is not much theory to guide the development of such series, these series at their best might approximate what is described by the vision presented. However, it seems that in many cases, key problems in the sequence are only solved by a minority of the students.

In contrast, in our work, the intention is to identify (goal-directed) activities in which students are already capable of engaging, from which they predictably can abstract the new ideas. There is no point at which we *hope* that they can do or see something that is key to the new mathematics. There is no point at which their learning is based on solving a novel problem that they might not be able to solve. The vision involves a shift from provoking learning to engineering learning (albeit not in a deterministic sense).

One of the basic tenets of this vision is that children are born with an ability to learn concepts and they do this through their activity. Let us take two well-known examples. First, most people have probably observed that children, after learning the rules and basic moves of a game (e.g., chess, video games), often develop sophisticated concepts for playing the game without instruction from anyone. They are certainly more sophisticated than learning simply what move has a positive effect and what move has a negative one. Do we understand how these concepts are developed? Could this ability be harnessed?

This second example involves mathematics learning. One of the greatest mathematical learning achievements in the life of any individual is the development of a concept of number. This is generally accomplished without professional teachers although parents figure prominently. There are many types of activities in which parents can and do engage their young children. However, there is one that is ingenious – counting. Counting activities, in which children engage in coordinating the touching of an object with the reciting of the next number name in the learned number name sequence, result in major conceptual gains. The child is not trying to solve a problem or even trying to learn something mathematical. They are most likely trying to imitate the adult, enjoy the play, and gain the adult's approval. Counting is a specific activity that leads to important abstractions of number concepts. Our vision is to understand the process underlying learning to count and an array of other mathematical concepts and to develop pedagogical design principles based on this understanding.

How Does This Work Potentially Contribute to and Fit into Mathematics Instruction?

In classrooms in which students initially work in small groups (and/or individually) and then convene in whole-class discussions, we envision our work informing the design of sequences of tasks for students' small group and individual work. Envisioned task sequences would provide the experience (requisite activity and opportunities for abstraction) that would allow students to have significant insight into the mathematics at hand. The purpose of the classroom discussion would not be to *bring* students to the intended ideas, but rather for students to share their insights developed through their work with the tasks, make new ideas explicit, provide justifications, and develop shared language and symbols for the ideas (as in *situations of institutionalization* (Brousseau, 1997). Teachers, in addition to leading class discussions, can interact with small groups of students who are in the process of abstracting a new idea.

It may not be necessary to employ this type and level of didactical engineering to all conceptual learning in the classroom. However, there are particular mathematical ideas taught in elementary and secondary school that many students never learn or never learn well. It is towards these pedagogical challenges that this approach is particularly directed.

I have described this approach to fostering learning as not involving problem solving. Certainly, the mathematics classroom must promote and engage students regularly in problem solving. However, having an approach to foster new concepts that does not rest on each student's ability to solve novel problems would be a useful pedagogical tool.

Current Project

In our last project, we developed a methodology for studying students learning. The methodology is an adaptation of teaching experiments with individual students (Simon, et al., 2010). We are now embedding that methodology in a 5-year project, Measurement Approach to Rational Number (MARN).[8] The project combines two main goals, continuing our inquiry into students' learning through activity and developing approaches to teach some of the most intractable concepts in the domain of fractions and proportional reasoning. Therefore we are studying learning in the context of fractions and decimals, and we are using our emerging understanding of how students learn through their activity to design tasks for promoting fraction and ratio understanding. The design of instruction builds on a foundation of measurement concepts modifying and extending the approach of Davydov and his colleagues (c.f., Davydov, & Svetkovich, 1991). Our hypothesis is that measurement-based activities can provide the specific basis for students' abstractions in these key mathematical areas.

MARN Methodology

The MARN design research will occur in two phases, individual teaching experiments and whole-class teaching experiments. The purpose of the first phase is to develop knowledge of promoting intended abstractions through task sequences. The resulting task sequences and hypothesized learning processes will constitute a significant part of the hypothetical learning trajectories for the whole-class teaching experiment.

As mentioned, the methodology we developed for studying students' learning through their mathematical activity involves individual teaching experiments. The design of the project is also predicated on the potential value of the individual teaching experiments to inform the whole class work on learning fractions and ratio. Our expectation of this potential is not shared by many in the mathematics education research community.[9] The MARN Project gives us a chance to examine this methodological issue empirically.

Rationale for Individual Teaching Experiments

> How do changes in children's thinking occur? Focusing on change . . . will require reformulation of our basic assumptions about children's thinking, the kinds of questions we ask about it, our methods for studying it, the mechanisms we propose to explain it, and the basic metaphors that underlie our thinking about it. (Siegler, 1996, p. 218)

Our goal for studying learning (understanding the mechanism by which conceptual understanding develops) is seen by many as impossible. Indeed it is both difficult and the success of any study is uncertain. The methodology for data collection is critical to producing a set of data from which warranted inferences about the learning process can be made.

We have found that the most important feature of the data collection is that it produces reasonably continuous evidence of the student's activity (mental and physical). Whereas observing physical activity is relatively straight forward, inferring mental activity requires attention to physical activity in conjunction with encouraged regular verbalization on the part of the student. Inference of students' mental activity has been part of qualitative research for several decades. What is different in this research is trying to infer the ongoing evolution of the thinking as opposed to key snapshots.

The main obstacle to continuous evidence of students' activity is instances when the students are listening to someone else who affects their subsequent activity. For this reason, we found that we could not use even 2 students together in a teaching experiment. When one person watched and listened to the other pursuing an idea, it often changed the flow of the observing student; however the researchers had no evidence of what went on in the mental activity of that student. For similar reasons the researcher avoids hints, suggestions, and leading questions. This data collection approach also allows us to focus on what aspect of the abstraction process can take place without extensive interaction.

Conclusions

The research program I have described is based on a simple idea: the more we understand about the learning of mathematical concepts, the better we will be able to promote conceptual learning. Bransford, Brown, and Cocking (2000, p. 221) asserted, "A scientific understanding of learning. . . provides the fundamental knowledge base for understanding and implementing changes in education. Our research program focuses on students' learning through their mathematical activity in the context of series of mathematical tasks. It rests on two important claims. First, learning can be studied directly and to productive ends Second, learning can be engineered in ways that do not depend on novel problem solving on the part of students. Third, engineering learning opportunities that allow students to build abstractions upon their mathematical activity (engendering the requisite activity) would increase equitable access to high-quality conceptual learning. Because this research program pushes the boundaries of what is generally believed to be possible, this program of research, meets with skepticism. In particular, the following questions are raised about the research.

1. Can data be produced to make useful inferences about the learning process?
2. Can empirically based constructs be developed which are useful for a variety of mathematical concepts for a variety of students in a variety of contexts?
3. Can design principles for task and task sequence creation be developed across concepts?
4. Can analyses of individual concept learning usefully inform design for classroom lessons?

Our research program represents a conjecture that the answers to these questions are, "Yes." As mentioned this is an extremely difficult and uncertain undertaking. Let me speculate (optimistically) about the potential payoff of this endeavor.

Contribution to Research

Design research is a productive and increasingly used methodology in mathematics education. It figures prominently in the generation of learning progressions, an exciting and growing area of current research. The problem with design research is that researchers' ability to study the learning of particular concepts is limited by their ability to promote the learning they wish to study. A greater understanding of students' learning through their mathematical activity (developing abstractions) and concomitant design principles for generative task sequences could provide a basis for more consistently productive design research.

Contribution to Curriculum Development

Whereas recent curricula tend to increase students' opportunities to learn, they tend to be uneven (within each curriculum) in quality. Part of the unevenness may be the variation among the authors, but much of the unevenness seems to be due to lack of task design principles grounded in an understanding of student learning processes. Strong lessons reflect an author's insight into a particular area. However, there is insufficient theory to guide the majority of lessons.

Contribution to Teaching and Teacher Education

In the context of ongoing mathematics education reform efforts, teachers seem to have derived both constraints on and recommendations for their teaching. As a result they try to refrain from telling students what they want them to learn and giving answers. They tend to use a variety of strategies: classroom discussions, small groups, non-routine problems, multiple representations, manipulatives and computer tools. However, none of this gives them a clear understanding of how to help students learn a new concept. As a result, teachers often fall back on strategies that do not differ *fundamentally* from traditional teaching, such as asking leading questions (trying to get students to say what the teacher would say if they were not avoiding telling) or having the student who already has the concept tell the others. Classroom discussion is a powerful tool. However teachers are too often working from a vague plan of conducting a classroom discussion so the majority of the students, who do not understand the new concept, understand it. Teacher education aims at strategies, skills, and dispositions, but neglects, for the most part, to help prospective and practicing teachers understand fundamentally new ways to promote the learning of particular concepts.

The research program described is aimed at providing a partial basis for filling the voids in each of these areas. However, while remaining optimistic, some tempering is in order. It is reasonable to expect that what is learned through basic research should be useable by researchers (e.g., in design research). However, the effect on teaching and teacher education will require additional research and development. What a researcher learns after 10+ years of intensive investigation is not necessarily accessible to practitioners.[10] We must ask of every product of basic research, "What part or version of this can practicing teachers understand with a realistic level of support?" And another set of questions not often asked about adult learners (e.g., teachers, doctoral students) is, "How can we understand the learning trajectory with respect to these new ideas (support experiences and learning process)?"

Finally, there is good reason why few research groups endeavor to study learning directly. It is difficult and success in any particular study is uncertain (Simon et al, 2010). The ambitious program of research that I have outlined will require the efforts of many research groups who take part in shaping the program and contributing results. Further, as a community, we will need to continue to make a strong case for support of basic research in mathematics education in an era dominated by a demand for "results now."

Endnotes

1. Ron Tzur and I collaborated on the initial work of this research program. We built upon his dissertation work and my prior research. Other collaborators have included Luis Saldanha, Evan McClintock, Tad Wattanabe, Gulseren Karagoz Akar, Ismail Zembat, Karen Heinz, and Margaret

Kinzel. Our current project includes Barbara Dougherty, Zaur Berkaliev, Arnon Avitzur, Nicora Placa, and Jessica Tybursky.

2. We use a social lens to examine interactive aspects of the classroom and the constructs of social and sociomathematical norms to examine opportunity for learning

3. Focus on *abstraction* is often seen as the province of constructivist theoretical approaches. However, Russian activity theory, derived from the theory of Vygotsky, uses abstraction as a key construct (c.f., Davydov, 1990).

4. In case the reader is sceptical about whether there was a shared meaning for "bigger," the same problem has been done in interviews in which the squares represented cookies that the interviewee liked and the question was "Which piece would you rather eat?" and the reasons for the answer were probed. The same phenomenon was observed.

5. This process could be investigated and explicated further, but it is not within the aims of this paper.

6. Answering this thought question empirically would present significant methodological challenges.

7. There is widespread conviction that engaging students in developing new mathematical ideas is more effective than giving them the ideas in a lecture. However, given classrooms in which students are engaged in generating ideas, there is little or no attention to the differential contributions of students and the effect on the quality of their learning.

8. The Measurement Approach to Rational Number (MARN) is supported by the National Science Foundation under grant no. DRL-1020154. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author and do not necessarily reflect the views of the National Science Foundation.

9. Case in point was some protracted arguments on this point during our first project advisory board meeting.

10. Often other researchers struggle to deeply understand the results of lengthy, focused investigations.

EXPLAINING STUDENT PERFORMANCE THROUGH INSTRUCTION

Jennifer Czocher
The Ohio State University
czocher.1@osu.edu

Lack of satisfaction with the quality of the mathematical knowledge of non-mathematics majors has led to the design of new curricular materials. In this study, a mixed methods explanatory design was used to compare the performances of two groups of engineering majors enrolled in two courses on differential equations and investigate their written work in light of differing curricular and instructional approaches.

Introduction

Calls for curriculum and instructional reform have been expanded to include collegiate mathematics education (American Mathematical Society, 2011). Lack of satisfaction with the quality of mathematical knowledge of students completing service courses in the mathematics department has raised considerable concerns regarding how these courses are taught. Among many such courses, Differential Equations (DEs) entertains a particularly prominent role since it caters to a variety of clients from engineering areas. Skills fostered in a traditional theory-driven DE course have been claimed to be of little value to these degree programs. For instance, in a survey, Varsavsky (1995) found that engineering faculty value skills like modeling over technical competencies like differentiation and integration. Indeed, engineering and physical science faculty recommend that service courses in mathematics be made more relevant to their students and suggest incorporating an engineering viewpoint (Czocher, 2010; Pennell, Avitable, & White, 2009; Varsavsky, 1995). These perspectives have motivated the design of new curricular materials that aim to frame student learning in meaningful contexts (eg, Rasmussen and King, 2000). Despite such curriculum development efforts, little is known about the actual impact of such curricula on student learning. The primary motive of the present study was to address this gap. To this end, I compared the performances of two groups of students enrolled in two different sections of an introductory course on DEs to see what differences, if any, existed in their work on various types of tasks due to exposure to differing curricular and instructional approaches. One section followed a standard commercial textbook while the other used a reform-based curriculum with a conceptual orientation that was built around contexts central to engineering fields.

Context and Background: The Case of Differential Equations

The study of DEs is a unique point in the trajectories of engineering and physical science majors. In some instances, it serves as a capstone to the calculus sequence. On the other hand, an introductory course on DEs might be the first time that these students are exposed to material that is specialized for their disciplines. Many introductory undergraduate courses strip the equations of their natural contexts in order to treat the equations abstractly and then treat DEs deductively. That is, a general equation is presented, its solution is derived, and applications from the physical sciences related to the target equation can then be handled by manipulating the generic solution.

Researchers have argued that curriculum and instruction must align in order to support students' transitions to studying advanced mathematical topics. The study of DEs poses special challenges to building and implementing supportive curricula since the "switch from conceptualizing solutions as numbers to conceptualizing solutions as functions is nontrivial for students" (Rasmussen, 2001, p. 67), and students' documented difficulties with function extend to the form of the initial conditions (ICs) (Raychaudhuri, 2008). Others have shown a related aversion to the use of boundary conditions (Black and Wittmann, n.d.).

"Unifying" views of introductory DEs range from the use of linear operators to physical approaches that emphasize formulation (see West, 1994) to models and derivations from first principles (Myers, Trubatch, and Winkel, 2008). Scholars have studied student performance on procedural and conceptual components of DE knowledge (Arslan, 2010) and on contextual and de-contextualized problems (Upton, 2004), whose analyses graded student responses as either "right" or "wrong;" a method too coarse to account for different heuristics or representational schemes potentially nurtured in instruction. Donovan (2004), in a pair of case studies, demonstrated the variety in students' conceptualizations of linear DEs and their representations, but did not address the bases for student reasoning. In contrast, Black and Wittmann (n.d.) studied students' reasoning strategies and identified important connections between the physical and mathematical interpretations of the DE model that influence student performance. Bingolbali, Monaghan, & Roper (2007) found that the teacher's proclivity for a particular interpretation of derivative was adopted by students. Indeed, it is likely that the student is heavily influenced by the values placed on types of knowledge (Hedegaard, 1998).

These considerations guided the development of the curricular materials whose impact on learning was examined in this work. The reformed curricula, Baker's (n.d.) text, supports a unifying solution strategy with physical reasoning by showing how a guess-and-check heuristic for formulating the solution mimics the physical system's response to the forcing term in the DE. Additional considerations, regarding the contextual domains provided for students' investigations, motivated the development of examples and contexts used in the text, as well as how content was sequenced. The curricula are described more fully in a later section of this article.

Methods

Participants

The participants were 51 undergraduate students enrolled in an introductory DE course and the two postdoctoral lecturers who taught them. The course is intended for non-mathematics majors and all 51 students were engineering majors. Of the 51 volunteers, 30 were in Lecture 1 (L1) which used a custom edition of *Elementary Differential Equations and Boundary Value Problems* by Boyce and DiPrima and 21 were in Lecture 2 (L2) which used "An Introduction to Differential Equations for Scientists and Engineers," a set of course notes written by a member of the math department faculty. There were 25 males and 5 females in L1 and 15 males and 6 females in L2. Typically, students were in the end of their freshman or sophomore years, depending on their level of high school mathematics preparation. However, many of the students had earned enough college credit to have junior standing. The students carried, on average, between 10 and 11 credit hours in addition to their course on DEs, the equivalent of two or three additional classes. The mean grade point average (GPA) for the participants was 3.29 (SD = 0.44) and their mean mathematics GPA was 3.14 (SD = 0.61). Their collegiate mathematical preparation, in terms of coursework, was uniform. All had completed single- and multivariable calculus, but not linear algebra. In addition, all had completed at least the first two quarters of their engineering and physics sequences. The two groups had similar backgrounds relative to the number of incoming credit hours, the number of quarters enrolled, the number of credit hours earned, the number of credit hours carried, overall GPA, math GPA, and the number of math, science, and engineering credit hours taken.

Both lecturers held postdoctoral positions and both were familiar with their respective curricula. L2 had some mathematics education experience and coursework during his graduate studies. L1 was a nonnative speaker of English.

Data Collection Instrument

Three tasks were created toward the end of the observation period from material common to both lectures and embedded in the groups' respective final exams. To establish content validity, the items were drafted and revised five times with input from both lecturers, and finally from the course coordinator. This type of negotiation when designing data collection instruments that measure student learning has precedence in mathematics education (Boaler, 2008). The values of parameters were different for the two classes since final exams were administered on different days. The problems were written with the conventions used in each class, eg, derivatives were denoted by y' in L1 and by *dy/dt* in L2. Values for parameters were selected in order to simplify calculations while maintaining structural similarity between the matched problems. Students in both classes were allowed graphing calculators. A brief description of each problem is offered below.

Problem 1 (P1): A first-order linear, constant coefficient, nonhomogeneous mixing problem.

Part (a) asked the students to find the amount of contaminant in a tank for any time t, supposing that initially the tank was full of pure water. In part (b), the flow of the contaminant is turned off at time $t = \tau$. The students were asked to find the amount of contaminant for times $t > \tau$.

L1 wanted his students to derive the differential equation, while L2 did not want to test that knowledge. Both lecturers decided to abbreviate P1, cutting out a third part that asked the students to interpret their solutions in terms of the physical situation. Thus, this problem is contextually situated, but is not an application of DEs to an engineering context. Since these tasks were not identical for the two groups, I do not compare the students' scores on this item beyond including it in the total score for the tasks. However, some information, such as students' handling of the ICs, is intact and relevant to the analyses presented here.

Problem 2 (P2): A second-order linear, constant coefficient, nonhomogeneous DE:

$4u''+u = 4e^{-t/2}$. Given the DE, part (a) asked students to find the general solution. In part (b), students were asked to suppose that $u(0) = u_0$ and that $u'(0) = 1$ and then to find a value of u_0 so that the amplitude of the steady state solution was 5.

The model in P2 represents a system that oscillates with no dampening, subject to forcing that is like an exponentially decreasing pulse. The focus is on the connection between ICs and long-term behavior of the system.

Problem 3 (P3): Separation of variables. Students were asked to use the separation of variables method to replace $m(t)u_t - n(x)u_{xx} = 0$ with a pair of ordinary DEs.

In both lectures, PDEs were most commonly treated with constant coefficients. P3 was designed to indicate whether students were able to use the method of separation of variables in a novel setting or if their knowledge was limited to a sequence of steps specific to the case $m(t) = n(x) = 1$.

Data Collection and Analysis

Since this study followed a mixed methods explanatory design (Creswell & Plano Clark, 2011), quantitative analysis of the exam tasks was followed with qualitative analysis of the students' responses. Quantitative data were generated through the grading of exams for accuracy. Tasks were graded independently from the lecturers so that data transformation decisions would not affect students' grades. The quantitative design was a prospective causal-comparative study and an ANCOVA was selected to analyze the total scores on the constructed tasks while controlling for the students' prior mathematics achievement, as measured by their math GPAs. Other numerical transformations involve frequencies and percentages. Qualitative data were generated through the observation of 24 (out of 29) sessions of each lecture and the detailed inspection of the students' responses to the tasks.

Student responses were examined first to establish what kinds of solutions they attempted. For each problem, a rubric was created to account for the level of difficulty of each stage of the solution process, and each stage was subdivided into steps. For example, one step of solving the DE by the method of integrating factor would require evaluating an integral. This step would not be broken down to diagnose the student's performance on integration by parts in order to avoid assessing prerequisite knowledge.

Each step of a student's response was assigned a value of "correct" (1) or "incorrect" (0), but responses were graded so that step $n+1$ was graded for consistency with step n. This decision prevented minor mistakes from compounding and so errors in student thinking could be diagnosed instead of tabulating wrong answers. There were a total of 14 steps in P1, 13 steps in P2, and 7 steps in P3. The value of each task, and so its parts, were scaled to 14 points to assign equal weight to each in the total score.

24 class sessions of each section was observed over one academic term. Lectures were 48-minutes long and met three days a week. Two 48-minute recitation sections were held on the other two days. Field notes included the instructors' and the students' comments, the instructors' board work, and my overall impressions of how lessons progressed. In analyzing observational records, I focused on lesson content, context, and pedagogy (Saroyan & Snell, 1997), noting lesson structure, the number and quality of examples used in each session, the number of connections made among topics made within and outside of mathematics, interactivity among the instructor and the students, and the mathematical behaviors that were modeled by the instructor.

Curriculum and Instruction

Both instructors used a traditional lecture format and both classes treated the same set of topics. L1 used Boyce and DiPrima's text (T1), which intended to provide exposure to the theory of differential equations with "considerable material on methods of solution, analysis, and approximation" (Boyce & DiPrima, 2009, p. vii). T1 follows an exposition-example-exercise format, where new topics are introduced formally through definitions and formulae, organized around analytic techniques with topics grouped into modules to allow for flexibility in usage. Theorems are stated precisely in symbols and are sometimes proved rigorously and sometimes through example. T1 does not assume familiarity with linear algebra, but many theorems rely on linear operators. Exercises tend to drill for procedural fluency and theoretically oriented problems have step-by-step directions or ask only for verification. In either case, the solution path is evident from the problem statement. Separate sections are devoted to applications, such as mechanical vibrations, and these are placed after the sections that develop techniques for solving the relevant DEs.

L2 used Baker's (n.d.) text (T2) which uses a modeling approach and the author's goal is to draw on common problems in the practice of science and engineering to motivate the creation and solution of DEs. It follows an example-exposition-exercise format where physical considerations precede mathematical formalism in each section. T2 does not contain "theorems," but instead offers "principles" which are written in English. Some principles are proven rigorously and some are justified through examples. Among the rigorously proved theorems, T2 uses English explanations while T1 relies on symbolic proof. There are few truly concrete examples or exercises, as most have at least one parameter. In comparison to T1, there are fewer exercises and these tend to be less technically difficult and less computationally oriented. Only one solution technique is presented throughout T2: guess-and-substitute (G&S), which is similar to the method of undetermined coefficients.

L1 followed the development of topics from abstract to concrete. The lectures were content-driven and L1 made every effort to convey the material on the syllabus. He drew examples from the text's exposition or from exercises that were similar to the assigned homework problems, with a focus on computation. Between one and seven examples were presented each lecture, with an average of between three and four per lecture. The examples followed presentation of theory. L1 held a goal orientation toward problem solving in that examples were considered complete when an answer was reached. He selected examples to maximize variety in technical complexity and sequenced them logically so that the adjustments in parameters from one example to the next were evident. The steps taken in each example were clearly labeled in order to provide guidelines to help structure student thinking about the problems. Taken together, these pedagogical choices yielded high intra-lesson coherence. Mathematics was communicated through symbolic representations and summary formulas. Students were encouraged to ask questions, and they did so regularly but infrequently.

L2 followed the development of topics through the text, but he did not regularly devote class time to explicit discussions of theory. Lectures were context-driven, in that all abstractions were derived through applications. Class time was spent on the structure of the physical problem, recognizing and articulating assumptions, deriving a model from first principles, and justifying its appropriateness, so the sessions had high inter-lesson continuity. Each example modeled a simplified real-life physical problem and each took between one-half and three sessions. L2 focused on building students' awareness of symbols and formulae as tools to represent quantities and relationships. The pace of the session was driven by L2's questioning, but the students were highly interactive, both posing and answering questions, while pursuing systematic exploration of the relationships between physical properties and their reflections in the model. Examples rarely ended in formulae; instead L2 would ask metacognitive questions. Thus, L2 held a process-orientation toward modeling. He wrote very little on the board, instead communicating mathematics verbally.

Findings

Numerical Results

P1 was missing from one student's exam in L1 and so his data are not included in the numerical analyses. Students in L1 scored a mean of 27.55 (SD=1.76) out of the 42 points available (Range: 3.08, 42). The mean score in L2 was 31.89 (SD = 1.90, Range: 6.38,42). A fixed effects ANCOVA model was selected with Lecture as the independent variable and Math GPA as the covariate. All statistical tests were performed at the $\alpha = .05$ level and the data satisfied all assumptions for the model. A homogeneity of slopes test revealed no significant interaction between Lecture and Math GPA. The ANCOVA summary is shown in Table 1. The main effect for Math GPA is statistically significant $(F_{GPA} = 27.191, df = 1,47, p < .001)$ and the adjusted main effect for Lecture is also significant $(F_{Lec} = 5.972, df = 1,47, p = .018)$ with a moderate effect size and showing only moderate power (partial $\eta^2 = .113$, observed power = .668). Thus, when taking prior mathematics achievement into account, the L2 student performed better on constructed tasks.

Source	Sum of Squares	*df*	Mean Square	*F*	Sig.	Partial η^2	Observed Power
Lecture	324.366	1	324.366	5.972	0.018	0.113	0.668
Math GPA	1476.928	1	1476.928	27.191	0.000	0.367	0.999
Error	2552.881	47	54.317				
Corrected Total	4259.339	49					

Table 1. ANCOVA summary table

Solution Strategies

Three techniques can be used to solve the DE in P1: the methods of integrating factor, separation of variables, and G&S. The G&S method is the only method appropriate to solving the DE in P2. In L1, the method of undetermined coefficients was presented in the context of second-order linear DEs of the form**Error! Not a valid embedded object.**. After two lessons, *f(t)* was allowed to be nonzero and L1 explained the method symbolically and procedurally. The students, in the text and in class, were given the form of the particular solution as $t^s e^{\omega t}\left[\sum A_k t^k \cos\beta t + \sum B^k t_k \sin\beta t\right]$, in which they had to set the parameters *s*, ω, and β to match the form of each of the summands of *f,* and then apply the DE to determine the weights A_k and B_k. In L2, the method was explained physically as follows: when written in standard form, the right hand side of the DE represents the external force applied to the physical system (the "forcing term") and that the system responds to the forcing (the "response") in kind. Thus, the form of the response (ie, the solution) must match the form of the forcing. Table 2 illustrates the frequencies of solution strategies used by the students, from left to right, they are: method of integrating factor, separation of variables, guess-and-substitute, and did not attempt (DNA).

	Int. Factor		Separation		G&S		Other		DNA	
	L1	L2	L1	L2	L1	L2	L1	L2	L1	L2
App (a)	26	–	2	1	–	20	1	–	–	–
App (b)	4	–	16	–	–	18	1	–	6	3
Concept (a)	2	–	–	–	28	18	–	–	–	3

Table 2. Chosen solution strategies

Almost all of the L2 students used the G&S strategy. This is not surprising since it was the only strategy they were shown, but they did use it more successfully than L1 students used the other methods. Again, this is not surprising since the L2 students had more practice with the method in various settings. What is surprising is that the L2 students were able to successfully adapt the G&S strategy to the procedural problem, more often than did the L1 students. Many L1 students either set $m(t) = n(x) = 1$ or else incorrectly applied the equation to the guess $u(x,t) = X(x)T(t)$ indicating that the "substitute" part of the strategy was not as prominent for the L1 students. The G&S method highlights the relationship between the solution and the DE by framing the DE as a condition on the solution in much the same way as an algebraic equation is a condition upon its solution. This perspective may be lost with techniques that reduce the relationship between the DE and the solution to a sequence of steps.

Initial Conditions

In P1 part (b), the IC does not correspond to the level of contaminant at time zero, but rather to when the flow of contaminant is halted. Thus, the solution function is piecewise differentiable. Nine students (31%) in L1 handled the ICs correctly in this case as compared with 13 (62%) of the students in L2. The most common mistake committed was to neglect the constant of integration and was made solely by L1 students. The second most common mistake was not ensuring that the pieces of the solution were matched at τ, caused by using $t = 0$. In P2, the ICs determine specific properties of the long-term behavior of the solution so that amplitude is formulated in terms of the unknown ICs. Sixteen students (53%) of the students in L1 handled the ICs correctly as opposed to 19 students (90%) in L2. Many students who arrived at one correct IC did not find the other since they did not extract both roots of the condition squared. However, the most common mistake, among both groups, was to apply the ICs only to the homogeneous solution. The second most common mistake was to apply the ICs to the steady state solution. This points to an interesting conception, since it amounts to setting $t = 0$ after letting $t \to \infty$, but it is not pursued further here.

Both lectures introduced ICs as “another condition on the solution to the DE.” ICs are an important part of the DE model, since they contain parameters that determine how the transient solution adjusts to the steady state solution. One key difference between how the two lectures treated ICs was that in L2, ICs were driven by context and each time were derived from the physical situation during the derivation or the discussion of the model. In contrast, the ICs in L1 were either stated outright at the beginning of the initial value problem or were selected by considering the neatness of the solution.

Discussion and Conclusions

The students in L2 were more successful with the G&S strategy, which can be attributed to a number of reasons. First, there were fewer strategies from which they could choose when solving problems. In L2, guessing was an allowed heuristic. Lastly, the G&S was developed on physical grounds, which allowed for alternative ways of understanding the solution strategy (Harel & Koichu, 2010). One could also argue that since G&S does not require memorization then the strategy is easier to access and implement. In a test-taking situation, the take-the-best heuristic (see Gigerenzer, 2008) might be the only accessible approach to the test taker. In this light, L1 students needed a greater amount of time to search through all possible integration techniques in order to recognize a discriminating cue. The fast-and-frugal nature of the G&S heuristic favors the L2 students whose allowable solution-space includes the G&S method, which mimics the familiar educated-guess-and-check strategies.

In P1 and P2, students needed to attend to the ICs in novel ways. In P1, the ICs join solutions from distinct, non-overlapping time periods. The difficulty exhibited here by L1 students may be less an indicator of correctly applied ICs and may instead be symptomatic of their discomfort with piecewise functions. In comparison, L2 students' success in handling ICs suggests that contextual treatment of ICs both places them appropriately within the solution procedure and strengthens conceptual connections among the components of the mathematical model in a sensible way. Alternatively, L2 would close each example, not with a formula, but by modeling how to justify the solution process by matching properties of the solution with assumptions made at the outset of the example. The looking-back heuristic thus reinforces ICs as relevant to the model. The application orientation of L2 and its text provides a foundation for relational understanding (Skemp, 1987) and legitimizes physical intuition as a way of understanding (Harel & Koichu, 2010) when working with ICs.

Overall, the students in L2 performed better on the constructed tasks than did the students in L1. While there may be a number of extraneous factors contributing to this finding, evidence from a closer analysis of the students' responses reveals two main reasons for the difference in performance. The students in L2 were more adept at treating ICs and they were more successful in selecting and applying solution techniques. While results merit further investigation, such as a larger sample size and more varied instrumentation, they do point to the potential of conceptually- and contextually-oriented curriculum and instruction for enhancing student learning of DEs.

HOW ARE GRAPHS OF TWO VARIABLE FUNCTIONS TAUGHT?

This is a study about how graphs of functions of two-variables are taught. We are interested in particular in the techniques introduced to draw and analyze these graphs. This continues previous work dedicated to students' understanding of topics of two-variable functions in multivariable calculus courses. The model of the "moments of study" from the Anthropological Theory of the Didactic (ATD) is used to analyze the didactical organization of the topic of interest in a popular calculus textbook, and in a typical classroom presentation. In so doing we obtain information about the institutional dependence of findings in previous studies.

Antecedents

Despite its importance, there are not many published articles in the mathematics education research literature that deal with the particularities of functions of two variables. The first published article we found that explicitly treats functions of two variables is by Yerushalmy (1997). In it he insisted on the importance of the interplay between different representations to generalize key aspects of these functions and to identify changes in what seemed to be fixed properties of each type of function or representation. Kabael (2009) studied the effect that using the "function machine" might have on student understanding of functions of two variables, and concluded that it had a positive impact in their learning. In other work, Montiel, Wilhelmi, Vidakovic, & Elstak (2009) considered student understanding of the relationship between rectangular, cylindrical, and spherical coordinates in a multivariable calculus course. They found that the focus on conversion among representation registers and on individual processes of objectification, conceptualization and meaning contributes to a coherent view of mathematical knowledge. Martínez-Planell and Trigueros (2009) investigated formal aspects of students' understanding of functions of two variables and identified many specific difficulties students have in the transition from one variable to two variable functions. Using APOS theory, they related these difficulties to specific coordinations that students need to construct among the set, one variable function, and R^3 schemata. Finally, in a study about geometric aspects of two variable functions, Trigueros and Martinez-Planell (2010) concluded that students' understanding can be related to the structure of their schema for R^3 and to their flexibility in the use of different representations. They gave evidence that the understanding of graphs of functions of two variables is not easy for students, that it can be related to the structure of students' schema for R^3, and in particular, that intersecting surfaces with planes, and predicting the result of this intersection, plays a fundamental role in understanding graphs of two variable functions and was particularly difficult for students.

The way students are taught, and the way mathematical topics are introduced in the textbooks used by students plays an important role on what they learn. In this study we analyze the way graphs of functions of two variables are presented in a widely used textbook, and in standard university classrooms. Our research questions for the part of the study we present here are:

- How is the topic "graphs of two-variable functions" introduced in a widely used textbook?
- How is this topic taught in a university class?
- Are conversions among representations favored?
- What relationships can be found between the above mentioned students' difficulties, the presentation used in the textbook, and the selected classrooms?

Theoretical Framework

In this article we incorporate Anthropological Theory of the Didactic (ATD) as a tool for the epistemological analysis of the textbook and classrooms. In this theory the mathematical activity and the activity of studying mathematics are considered parts of human activity in social institutions (Chevallard, 1997; Bosch and Chevallard, 1999). The theory considers that any human activity can be explained in terms of a system of *praxeologies*, or sets of practices which in the case of mathematical activity constitute the structure of what is called *mathematical organizations* (MO). Mathematical organizations always arise as response to a question or a set of questions. In a specific institution, one or several techniques are introduced to solve a task or a set of tasks. Tasks and the associated techniques, together form what is called the *practical block* of a praxeology. The existence of a technique inside an institution is justified by a technology, where the term "technology" is used in the sense of a discourse or explanation (*logos*) of a technique (*technè*). The technology is justified by a theory. A theory can also be a source of production of new tasks and techniques. Technology and theory constitute the *technological-theoretical block* of a praxeaology. Thus a praxeology is a four-tuple ($T/\tau/\theta/\Theta$) (tasks, techniques, technologies, theories), consisting of a practical block, (T/τ), the tasks and techniques, and a theoretical block, (θ/Θ), made up of the technological and theoretical discourse that explains and justifies the techniques used for the proposed tasks. Typically, a praxeology gives raise to new praxeologies as new problems are explored, techniques are generalized and different ones are introduced, the range of application of technologies expand, and the theoretical basis grows to encompass more general phenomena. This gives raise to mathematical organizations consisting of interrelated sets of praxeologies.

Within an educational institution a mathematical praxeology is constructed by a didactic process or a process of study of a MO. This process is described or organized by a model of six moments of study (Chevallard, 2002) which are: *first encounter* with the praxeology, *exploratory moment* to work with tasks so that techniques suitable for the tasks can emerge and be elaborated, *the technical work moment* to use and improve techniques, the *technological-*

theoretical moment where the technological and theoretical discourse takes place, the *institutionalization moment* where the key elements of a praxeology are identified, leaving behind those that only serve a pedagogical purpose, and *evaluation moment* where student learning is assessed and the value of the praxeology is examined. It is important to clarify that the order of the moments is not fixed. It depends on the didactical organization in a given institution, but independently of the order it can be expected that there will be instances where the class will be involved in activities proper to each of the "moments".

This didactic model is used in this study to describe the mathematical organization related to functions of two variables presented both in the textbook used by students and in the work done in class. This description will be helpful when looking for relations between results of the analysis and students' difficulties and constructions found in the literature. The use of results of this endeavor can be helpful in the design and analysis of activities of a didactic sequence in terms of their institutional suitability with the purpose to help students understanding the concept of two variable functions.

Methodology

This study is related to a project being conducted by the authors in two universities in different countries. A textbook was selected by the researchers to be analyzed considering that it is used in both universities involved in the study, and widely used in other universities. Two researchers independently reviewed the text in terms of the theoretical framework and negotiated their findings until agreement was reached. One of the researcher observed several classes where the topic was introduced by different teachers, took notes about the way functions of two variables was taught by different teachers and interviewed some of them. After transcription of observations and interviews, data was analyzed again by two researchers and results negotiated between them. Results obtained were compared with those found in previous studies and with the genetic decomposition suggested in Trigueros and Martinez-Planell (2010) in terms of the constructions this model proposes for the learning of the topic in order to look for possible relations of constructions found to be made by students and the way functions of two variable are introduced in the text and in classrooms.

In this study we concentrate on results related to graphs of two variable functions. For this purpose, we take into account the analysis of the selected textbook and the classroom observations and interview from one of the teachers who represent the way most of the observed teachers taught this topic to their students.

Analysis of a Textbook Based on the ATD Moments of Study

Graphs of functions of two variables are introduced in courses of multivariable calculus to help students construct a richer mental model to reason about them, and to illustrate the important concepts of multivariable differential and integral calculus.

In the selected text, Calculus: early transcendentals by James Stewart, 6th edition (2006), multivariable functions are introduced in the text in chapter 14 devoted to partial derivatives. However, fundamental planes (that is, planes parallel to the coordinate planes), considered as a prerequisite to understand these functions, are met before, in Section 12.1, where the three-dimensional coordinate system is introduced. This is done through the introduction of the tasks of graphing the planes $z=3$ and $y=5$. This can be considered a *moment of the first encounter* with graphs of two variable functions. These tasks remain isolated since they are not afforded any special role in relation to their use in understanding other subsets of R^3 (by forming intersections, for example), and are not met again until the exercises at the end of the section. Its only connection with a mathematical organization is their appearance in a section devoted to three-dimensional space. There is another *moment of the first encounter* for the topic of graphing functions of two variables in Section 12.6 where the graphs of quadric surfaces are shown for the first time. Even though quadric surfaces are not always graphs of functions of two variables, the task of graphing an ellipsoid with equation $x^2 + y^2/9 + z^2/4 = 1$ is introduced, and the technique to do the task explained: *"By substituting $z = 0$, we find that the trace in the xy-plane is $x^2 + y^2/9 = 1$, which we recognize as an equation of an ellipse"*, and immediately generalized to a families of traces: "*In general, the horizontal trace in the plane $z = k$ is $x^2 + y^2/9 = 1 - k^2/4$* ... " . We found another example of a *moment of first encounter* in Section 14.1 where after defining functions of two variables, the text presents the first examples of graphs of functions. A linear function and the top half of a sphere are graphed by recognizing their types of equations (no use of traces), then a graph is generated by a computer without using or mentioning traces, and finally an elliptic paraboloid is presented, one that had been presented before, by making reference to its prior appearance.

We can observe an absence of questions generating the need for graphing functions, nor the importance of understanding how to graph them. These facts, together with the isolation of the tasks presented, are not conductive to a mathematical activity where techniques arise in a productive way in terms of students' learning.

In the *exploratory moment* in Section 12.6, the tasks of graphing five quadric surfaces are introduced, perhaps not as an end in and of itself, but as a means to establish the technique of traces that expectedly is to be further developed with the continued exploration of other tasks. Although at first sight this number of might seem quantitatively adequate, the examples and their accompanying explanation require students from the outset to recognize and place in space a family of curves, a task that has not been introduced before. The tasks in this exploratory moment are not adequate to prepare students to use traces as a technique to draw the graphs of two variable functions. The exploration continues in Section 14.1, where the text mentions the use of traces in computer generated graphs and shows four such graphs with hardly any comment. Here, the technique of using traces to draw graphs of function is related to tasks done with technology, but the way it is presented makes it difficult for students to interpret how the technique works in this mathematical organization.

As we can see the textbook's moment of exploration does not present students with opportunities to encounter relevant tasks which can help them make sense of what the traces shown are about, they also are not given real opportunities to explore the tasks in order to find regularities or properties which can help them make sense of the technique that is being introduced.

To examine the *moment of practice of the technique* we found that in Section 12.1 there are some exercises that make direct or indirect use of fundamental planes to describe regions in three-dimensional space. Only a few of them are assigned exercises in the syllabus of both courses. Further and more importantly, these exercises do not provide the opportunity of exploring the result of intersecting fundamental planes with subsets of R^3 and to relate these intersections with the technique of traces introduced before. Then, in Section 12.6, relatively few exercises at the end of the section require using sections to produce the graph of a surface, and only six of them are assigned in the courses' syllabus. In Section 14.1 we found some exercises that require using cross-sections to draw the graph of a two variable function, most of them are presented in terms of matching problems. This kind of problems would be useful to exercise the technique of drawing graphs of surfaces if they required students to justify their selections using cross-sections. As they are presented, students attempt using other strategies, frequently without success, and hence these tasks do not really give students the opportunity to practice the technique introduced. Exploratory moments are not integrated and systematic; the text has hardly any task where interpretation or justification of the technique is needed. It introduces other techniques, i.e. recognition of the algebraic form of quadric surfaces, but unrelated with the use of traces.

We can say that the text does not provide enough opportunities for the students to work on the practical block of the praxeology and no ground is set to develop consistently the theoretical part of the praxeology related to graphing functions and converting flexibly among different representation registers.

As discussed in Chevallard (2007), the *moment of development of technology and theory* is closely interrelated with each of the other moments of study. This is clearly seen to be the case in this topic. The technology of using traces or cross-sections to draw the graph of a function of two variables is introduced in the moment of first encounter and developed with scant opportunities to do task explorations, as discussed above. In the book, there is not an explicit discussion of the fact that substituting a number for a variable in an equation with three variables corresponds to intersecting a fundamental plane with the graph of the equation. Hence, there is hardly an explanation about cross-sections, projections, and contours. The examples discussed in Section 12.6 assume that students can readily recognize families of curves and place them in space; the reader is left to make sense by him or herself, or resort to a memorized table of surfaces and formulas to answer questions about graphs of two variable functions.

From the point of view of ATD, the lack of a technology to make sense of the technique introduced leaves the mathematical organization ungrounded. Students may not understand why the graph of a function of two variables is important, why it is a surface and how to make sense of even computer generated graphs. The mathematical organization constructed consists of isolated ideas. It does not have coherence.

Consider now the *moment of institutionalization.* From the point of view of the two educational institutions, as documented in the course syllabus, this is a topic to be mastered. Differential and integral calculus of functions of two variables is to a large extent based on reducing problems of functions of two variables into problems of functions of one variable by holding a variable fixed and analyzing the resulting one-variable function. The textbook can be considered as the reference for the institutionalization of those elements of the mathematical organization that are considered as mathematical objects. However, as discussed before, the way graphs of functions are presented does not provide any ground for students to be aware of the importance of this idea. Moreover, quadric surfaces are not used again in any substantial way after their introduction in Section 12.6, their importance and their role is never clarified. They remain isolated from the rest of the mathematical organization being presented in multivariable calculus. Even if it appears that the intention was to use them, as a means to introduce sections in graphing surfaces, this goal is not achieved as we have seen. They are not reinforced in Chapter 14 where functions of two and three variables are introduced. The *moment of institutionalization* of this topic is not clear.

The *moment of evaluation* of what is learned by students is done by the instructors teaching the course. Although the textbook includes some review questions and a test, for the most part they are not related with graphing functions of two variables, and they are not used by the teachers. If we review the courses' syllabus we find that students are evaluated using three or four partial examinations and a final examination. In one of the universities the topic of graphing surfaces comes late in the semester of Calculus II, and is not included in a partial examination, so it accounts for no more than 3% of the final grade but in Calculus III the topic is evaluated more thoroughly. At the other university the topic is covered at the beginning of Calculus III and is evaluated in a partial examination. Despite the fact that the analysis of graphs of two variable functions by considering its restriction to fundamental planes is pervasive throughout the study of calculus of two variables, its introduction through the textbook and in evaluations, does not stress that importance. Students get the impression that this is not an important topic and may not pay attention to it. There is not a clear presence of the *moment of evaluation* of the technique itself in the textbook.

Analysis of the Teaching of the Graphs of Two Variable Functions

As can be expected, professors in their class complement the information given in textbooks. We now use the moments of study to analyze the data we obtained from observing the classes of a particular professor during the two weeks he devoted to the teaching of functions of two variables, as an illustration of how the teachers work in class, since we found out many similarities in the work of all the teachers observed, even though they teach in different countries. Again, we focus here on their graphs.

After a brief discussion of one variable functions where the teacher emphasizes graphs of these functions, in particular linear and quadratic functions, he introduces functions of two variables as an extension of functions of one variable and asks students how they would graph this type of function and what kind of geometrical object the graph would be. After discussion with the whole group the teacher leads the students to the fact that the graph should be a surface. He introduces the equation of a plane in R^3 and its relationship to the graph of the plane, using fundamental planes in the analysis. Students are given a few tasks where they have to draw planes parallel to the coordinate planes and to find their equation. The *moment of the first encounter* with two variable functions is presented in terms of the relationship between functions of one and two variables and the question of how the graph would look like. Fundamental planes are introduced but there is no justification of why they are needed.

Later on, the class as a whole discusses quadric surfaces; the tasks for discussion consist in finding the conic curves that combined give raise to different surfaces. Then tasks are given to the students where they have to find intersections of a surface with fundamental planes in order to graph a given function and find its domain and range.

Thus the *moment of task exploration* consists of a series of tasks designed for the students to be aware of the difficulties involved in graphing functions of two variables and how they can use some strategies, such as using fundamental planes, including intersections with the coordinate planes to help them doing so. Graphs of functions are also linked with other properties of functions of two variables. An example of a task is: draw the graph of the function $z=2-y^2$ by using different planes of the form $x=k$. It is interesting to note that when students use the planes, the equation remains the same, so they have to discuss the difference between the graph of the function and the intersection curves. The teacher then gives homework where students can use computer generated graphs to relate the equation of quadric surfaces with their graphs. In the moment of task exploration students work with graphing functions of two variables using fundamental planes. The technique is introduced as a means to facilitate graphing the functions and it is also linked to the domain and range of the given functions. We consider that up to this point, the teacher is constructing the practical part of the praxeology. We noticed, however that this moment is not expanded to the homework; it goes back to graphs and equations of quadric surfaces without connection to the introduced tasks.

The *moment of practice of the technique* is quite restricted. After introducing the technique the teacher goes back to the definition of function of two variables and gives students some tasks where they have to find domain, range and graph of several functions. Students can either use what they have reviewed about quadric surfaces and their graphs, or fundamental planes. Most of the tasks are related to quadric surfaces.

Students do not have enough opportunities to work with the technique, although it seems clear to them that the use of fundamental planes is related to finding these graphs.

While working with the technique there is some explicit discussion of the fact that substituting a number for a variable in an equation with three variables corresponds to intersecting a fundamental plane with the graph of the equation, and some explanation about contours and projections. However, since the number of tasks worked by the students is reduced, in our opinion, the *moment of the development of the technology* is not well developed, this may leave students with a superficial idea of the importance of the technique, although they may be able to use it with simple functions. The technological-theoretical block of the praxeology is not well developed in this class.

The professor works with other examples when finding graphs of functions, and each time he makes clear that fundamental planes, contours and projections are useful to understand how the function “behaves”. This repeated emphasis can be considered as the *moment of institutionalization* of the topic we are concerned with.

In the first partial exam the teacher asks students to draw the graph of a simple function using fundamental planes. He also asks a question where students have to find the intersection of a fundamental plane with a given surface and they have to graph the resulting curve in the plane. This can be considered *the evaluation moment*.

Discussion and Conclusions

Results of the previous analysis show that even though curriculum and teachers underline the importance of the graphs of functions of two variables in relation to their study, the components of the praxeology are presented in an isolated and incomplete form in the textbook used and in the analyzed classrooms: its *practical block* is presented in a very superficial way, there are very few opportunities for students to do *tasks* where they can establish relationships among different representations, and the *technological-theoretical block* is absent. This presentation is bound to be ineffective, in terms of learning. Its importance is also not communicated to the reader. We can also see that although professors, as demonstrated by the one described here, present this praxeology with more elements, including more work on *tasks* relating representations, in terms of the *moments of study,* this presentation is also incomplete. It consists of quite isolated elements, since the *technique* introduced is not practiced enough and is not clearly related to a *technological* discourse.

In previous research Trigueros and Martínez-Planell (2009, 2010) investigated the relationship between students’ notion of subsets of Cartesian three-dimensional space, and their understanding of graphs of two-variable functions with students who had taken courses as the one described here and used the textbook as a reference, using APOS theory and Duval’s theory of representations as a theoretical framework. Results from these studies showed that understanding of two variable functions is not easy for students and can be related to the structure of their schema for R^3 and to their flexibility in the use of different representations. In particular, it was shown that students who had completed a multivariable calculus course present many difficulties with constructions involving fundamental planes and surfaces in Cartesian space. Most of the interviewed students had difficulty relating information about two variable functions in different representation registers, did not use fundamental planes to draw graphs, showed confusion between surfaces, curves and solids in space and only one of them was found to be able to intersect surfaces with planes and predict the result of this action. Results also demonstrated that most students have many difficulties understanding functions of two variables, their domain and range, and that the generalization of understanding of one variable functions to two-variable functions, in particular in the case of graphical representation, is not direct. The study showed, for example, that many students do not readily convert the action "substituting $z = 0$" , which is a *task,* into that of intersecting a fundamental plane with the surface, so they are not ready to consider families of traces. They need more opportunities to work on tasks that help them interiorize actions into processes, and thus build the necessary *techniques*.

Results of the present study, together with those of the previous ones, show a more complete and detailed picture of observed phenomena. It is not surprising that students do not learn how to use traces to draw graphs of two variable functions. It is also comprehensible why they have difficulties to distinguish different subsets of Cartesian space and do not clearly understand the importance of being able to analyze graphs of these functions. Results obtained from the analysis of the *moments of study* of the mathematical activity associated with this topic demonstrate that not enough opportunities are given to students to master the *techniques* and *technologies* needed to analyze and use graphs of two variable functions. So, an effort needs to be done to balance activity in class so than all the moments of study are present in the study of these functions and help students deepen their understanding. It is true that students can use technology to see the graphs of functions, but without the necessary tools to make sense of the information contained in them, they may not "see" what the teacher intends to show.

Taken together, results of both studies give information about what needs to be done. We have started some work in this direction. We have designed sets of activities aimed at helping students to construct a better understanding of functions of two variables. Activity sets are available on the internet at http://math.uprm.edu/~rafael/. The design of these activities follows the constructions modeled in the refined genetic decomposition described in Trigueros and Martinez-Planell (2010), and also takes into account the characteristics of the two universities where the studies took place.

INVESTIGATING RELATIONS BETWEEN ABILITY, PREFERENCE, AND CALCULUS PERFORMANCE

Erhan Selcuk Haciomeroglu
University of Central Florida
erhansh@mail.ucf.edu

Eric Chicken
Florida State University
chicken@stat.fsu.edu

The goal of the present study was to report an instrument designed to determine students' mathematical performances and preference for visual or analytic thinking for the calculus derivative and antiderivative tasks as well as examine the relationships among students' cognitive style, cognitive ability, and mathematical performance in calculus. Data were collected from 150 Advanced Placement calculus students. The results suggest that the instrument is measuring an important component of cognition and has the potential to be a measure of performance and preference for visual thinking in calculus.

Introduction

Researchers have been interested in identifying the preference and ability components of cognitive style for several decades (e.g., Clements, 1979; Bishop, 1980, 1989; Hegarty & Waller, 2005). The visualizer-verbalizer distinction in particular has been an area of interest for researchers in various disciplines (e.g., Hadamard, 1945, Kozhevnikov, Hegarty, & Mayer, 2002; Paivio, 1971; Richardson, 1969, 1977). The goal of the present study was to report an instrument designed to determine students' mathematical performances and their preferred mode of thinking for the calculus derivative and antiderivative tasks as well as examine the relationships among students' cognitive style, cognitive ability, and mathematical performance in calculus.

Background

Krutetskii (1976) identified types of mathematical giftedness based on students' preferences for two cognitive processes: verbal-logical or visual-pictorial. Following the work of Krutetskii (1976), Moses (1977), Lean and Clements (1981), Suwarsono (1982), and Presmeg (1985) have recognized that individuals could be placed on a continuum (i.e., degree of visuality) according to their preference for visual processing. In designing instruments —Problem Solving Inventory (PSI) and Mathematical Processing Instrument (MPI)—consisting of algebra word problems to determine students' preferences, and in their work, Moses and Suwarsono defined visuality as the extent to which a learner prefers to use visual processes to solve mathematics problems. That is, visualizers are considered as learners who prefer to think with images and visual strategies, and analyzers (or verbalizers) as learners who prefer not to think with images and visual strategies when there is a choice on a specific task. In this study, we used the visualizer-verbalizer distinction as a lens to determine students' preferred mode of thinking. However, in the remainder of this paper, we have used the terms "analytic" and "analyzer" interchangeably to describe verbal-logical processing or verbalizers.

There have been studies of cognitive abilities and styles in mathematical performance in different content areas. Battista (1990) with high school students found that spatial visualization and logical reasoning were significant factors of geometry achievement and geometric problem solving, and that spatial visualization was related to the use of visual and analytic problem solving strategies (i.e., analytic, visual without drawing, and visual with drawing). A similar finding was reported by Ferrini-Mundy (1987), who found a correlation between spatial ability and certain aspects of calculus. However, other research has shown divergent perspectives. Studies including MPI, developed by Suwarsono (1982) and later modified by Presmeg (1985) as a measure of visualizer-analyzer cognitive style have found either a weak relationship or no relationship between either mathematical performance or cognitive abilities and mathematical visuality. For instance, Galindo-Morales (1994) compared mathematical visuality indicated by MPI and performance of students enrolled in three calculus courses using different instructional approaches (i.e., graphing calculator, Mathematica, and no technology) and concluded that there was no significant relationship between the degree of visuality and calculus performance in any of the three groups. Hegarty and Kozhenikov (1999) administered the MPI to measure sixth grade students' problem solving performance and preference for visual thinking. Their results revealed that mathematical visuality did not correlate with problem solving performance and was negatively associated with the cognitive abilities—verbal ability, nonverbal reasoning, and spatial ability.

Our contention is that calculus requires visual thinking and adequate understanding of visual representations, and that aspects of visuality (or visual imagery) that play an important role in calculus performance may not be measured accurately by existing questionnaires consisting of tasks that do not involve calculus. Moreover, research has shown that the nature, complexity, or novelty of a task influences the degree of visuality (or visual imagery) a student uses when solving the task (e.g., Dean & Morris, 2003; Lowrie & Kay, 2001; Massa & Mayer, 2006; Paivio, 1971; Richardson, 1977). Although various tasks and questionnaires have been designed to measure cognitive styles and learning preferences related to the verbalizer-visualizer distinction (e.g., Mayer & Massa, 2003; McAvinue & Robertson, 2006-2007; Riding, 2001), no adequate instrument for Calculus is available. Thus, there is a need for a calculus instrument designed to determine students' mathematical visuality. We believe this demands research examining the role of cognitive abilities and styles in calculus performance. The present study extends existing research on cognitive styles by examining the relationships among calculus students' preferred modes of thinking, cognitive abilities, and mathematical performances and provides measures of visualizer-analyzer style dimension and mathematical performance in calculus.

Method

Participants

The participants were 169 high school students who were enrolled in Advanced Placement (AP) calculus courses at four high schools in two school districts in Central Florida in the United States at the time of the study. All 169 students agreed to participate in the study. Nineteen students who failed to take all tests were excluded from the data. Of the 150 students, 55 percent of the students were males, and 45 per cent were females.

Materials

The six tests, measuring spatial orientation (Cube Comparisons (CC) and Card Rotations (CR)), spatial visualization (Form Board (FB) and Paper Folding (PF)), and logical reasoning (Nonsense Syllogisms (NS) and Diagramming Relationships (DR)) abilities, are part of the KIT of Reference Tests for Cognitive Factors (Ekstrom, French, & Harman, 1976). Cognitive style tests consisted of a revision of Mathematical Processing Instrument for Calculus ([MPIC], Haciomeroglu et al, 2009) and a modified version of Mathematical Processing Instrument

([MPI], Suwarsono, 1982). The students' scores on the Advanced Placement (AP) Calculus Exam were collected from teachers at the end of the study.

Spatial Ability Measures

The Cube Comparisons Test consists of 21 items and requires the participant to view two drawings of a cube and determine whether or not the two drawings can be of the same cube. The Card Rotations Test consists of 10 items, each of which presents a two-dimensional figure and eight other drawings of the same card. The participant indicates whether each of the eight cards, without reflecting, is the same or different from the original figure. The Form Board Test consists of 24 items. Each item presents five shaded drawings of pieces and requires the participant to decide which of the shaded figures, from two to five, can be used to make the given geometric figure. The Paper Folding Test consists of 10 items each of which illustrate folds made in a square sheet of paper and a hole punched in it. The participant selects one of the five drawings that shows the position of the holes when the paper is completely unfolded.

Logical Reasoning Ability Measures

The Nonsense Syllogisms Test consists of 15 items. Each item is a formal syllogism, in which statements are nonsense and cannot be solved by reference to past learning. The participant determines whether conclusions drawn from the statements show good reasoning. The Diagramming Relationships Test consists of 15 items. In each item, the participant selects one of five diagrams, which illustrates the interrelationships among sets of three objects.

Cognitive Style Measures

Two cognitive style tests, a revision of Mathematical Processing Instrument for Calculus ([MPIC], Haciomeroglu et al, 2009) and a modified version of Mathematical Processing Instrument ([MPI], Suwarsono, 1982), were used to determine the degree to which students preferred visual or analytic thinking.

The MPIC and the MPI consist of two parts. The first part of each instrument is a test consisting of mathematical tasks: there are 10 derivative and 10 antiderivative tasks (i.e., 7 graphic and 3 algebraic tasks in each test) on the MPIC and 8 algebra word problems on the MPI. The second part is a visualizer-analyzer questionnaire consisting of a visual and an analytic solution for each task on the MPIC and at least 3 or more visual or analytic solutions for each task on the MPI. Upon completion of each test, the students were given the visualizer-analyzer questionnaire and were asked to choose for each task a method of solution that most closely describes how they solved the tasks.

In this study, the MPIC was used to measure the students' preference for visual thinking and mathematical performance for derivative and antiderivative tasks presented graphically or algebraically. Thus, it yielded two performance and two visuality scores for each student: performance (P-G) and visuality (V-G) scores from 14 graphic derivative and antiderivative tasks, and performance (P-A) and visuality (V-A) scores from 6 algebraic derivative and antiderivative tasks. The MPI was used to measure mathematical visuality, but not performance because it consisted of algebra word problems and may not reflect the differences in their mathematical performance. The internal reliability of the MPI visualizer-analyzer questionnaire was 0.225. The internal reliability of the V-G (14 graphic tasks) and V-A (6 algebraic tasks) visualizer-analyzer questionnaires were 0.918 and 0.71 respectively.

Calculus Performance Measures

Three calculus performance scores were included in the analyses. The students' scores on the AP Calculus Exam were collected from teachers at the end of study. The AP Calculus Exam is an important standardized test. High school students who perform well can earn college credit and advanced placement. It covers differential and integral calculus topics, and scores are reported on a 5-point scale (5 is the highest and 1 is the lowest). The students' calculus performance was also assessed by the MPIC Derivative and Antiderivative tests presented graphically and algebraically. The internal reliability of graphic (P-G) and algebraic (P-A) tests were 0.801 and 0.36 respectively.

Procedure

All students received standardized instructions and were tested in groups of 12 to 30 in their classrooms. All participating students gave their informed consent and were debriefed at the end of the study. Four school visits were made during semester, and the tasks were administered in the following order: At the first visit, Form Board, Card Rotations, and Diagramming Relationships were administered. At the second visit, Paper Folding, Cube Comparisons, and Nonsense Syllogisms were administered. The students had completed MPI test prior to the third visit, and they were first given MPI questionnaire and then MPIC Derivative test and questionnaire at the third visit. At the fourth visit, MPIC Antiderivative test and questionnaire were administered. The students were willing to participate in the study and enjoyed most of the tests under classroom conditions. We were unable to administer fewer tests per day due to the time restrictions. Results might have been higher under research conditions. The students were given 8 minutes for FB, 4 minutes for ND and DR, and 3 minutes for CC, CR, and PF. Completion of MPIC and MPI was not timed. The total scores for CC, CR, FB, and NS tests were determined by subtracting the number of incorrect answers from the number of correct answers. Since there were 5 response options for each item on PF and DR, the total scores were determined by subtracting one-fourth the number of incorrect answers from the number of correct answers.

Scoring of MPIC and MPI

In determining preference for visual or analytic thinking, the primary goal was to identify the students' methods as visual or analytic; whether their answers were correct or incorrect mattered less than their method(s) in measuring mathematical visuality. On the MPIC visualizer-analyzer questionnaire, to determine the students' visual preference scores for the derivative and antiderivative tasks, they were given a score of 0 for each analytic solution and 2 points for each visual solution. If a solution does not give any indication of method or both methods were used, a score of 1 was given. On the MPI visualizer-analyzer questionnaire, to determine the students' visual preference scores for the algebra word problems, they were given a score of 0 for each analytic solution and 1 point for each visual solution. Thus, for the derivative, the antiderivative, and the MPI questionnaires, the total possible scores were 20, 20, and 8 points respectively.

In assessing students' performance on the MPIC Derivative and Antiderivative tests, the students were given a score of 0 for each incorrect answer and 1 point for each correct answer. Thus, for each of the two tests, the total possible score was 10 points. To illustrate the use of the MPIC, we give an example of one of the derivative tasks (see Figure 1) and the corresponding item in the questionnaire. We consider thinking as visual when individuals prefer to use visual methods and thinking as analytic when individuals prefer not to use visual methods when there is a choice on a specific task. Analytic solutions are generally equations-based. An analytic solution to a task presented graphically typically may involve translation to an equation, computing the integral of the equation, and then using this new equation to draw the antiderivative graph.

Graph is shown. Please sketch the graph of the derivative.

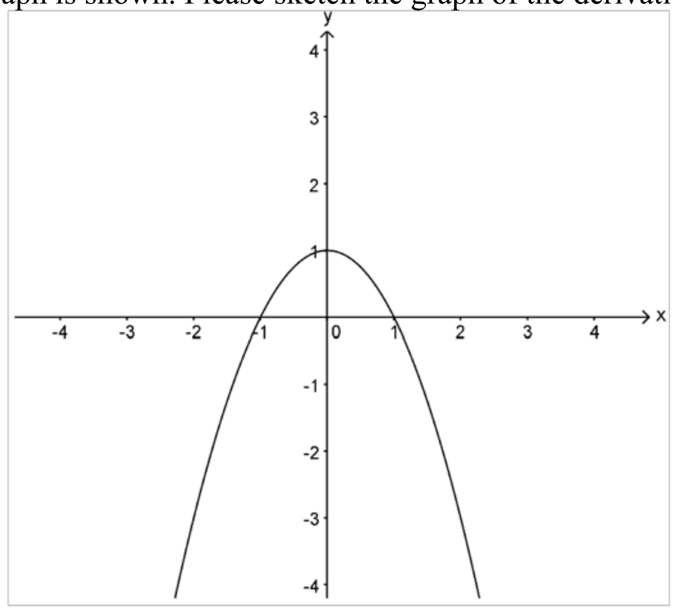

Figure 1. Derivative task.

We observed that instead of estimating equations precisely, analytic students referred to basic groups of functions such as linear, quadratic, or cubic functions and their derivative graphs associated with odd or even powers of x respectively. The following is the analytic solution given on the questionnaire for the derivative task in Figure 1: *I estimated the equation of the graph (or recognized the equation of the graph). For example: This could be the graph of* $f(x) = -x^2$ *so I computed the derivative as* $f'(x) = -2x$ *and drew the derivative graph using this equation.*

Visual solutions are image-based. They are able to visualize the changing slopes of tangent lines to the function and accordingly are able to construct an entire derivative graph with no need to consider individual parts of equations at critical points or intervals. These individuals are able to determine the shape of derivative graphs based on their visual estimates of slopes. The following is the visual solution given on the questionnaire for the derivative task in Figure 1: *From the graph I estimated the slopes (or the slopes of tangent lines) at various points on the graph of the function and used this to draw the graph of the derivative. For example: The slopes of tangent lines are positive and decreasing as x approaches 0 from the left. The slope is zero at x = 0 because the graph of the function has a horizontal tangent line at (0, 1). The slopes of tangent lines are negative and decreasing as x approaches positive infinity.*

For the tasks presented algebraically, we consider thinking as visual when students prefer to draw the graph of the given function on paper (or in mind) and estimate the slopes of tangent lines at various points on this graph to draw a possible graph of the derivative or antiderivative. On the other hand, we consider thinking as analytic when students prefer to calculate the derivative or integral, and used this equation to draw a possible graph of the derivative or antiderivative. For instance, one of the algebraic tasks requires sketching a possible graph of the antiderivative, given $f'(x) = 3x^2 + 1$. An analytic solution involves computing the integral as $f(x) = x^3 + x^2 + c$ and drawing the graph of f(x) using this equation, whereas a visual solution involves drawing the graph of $f'(x) = 3x^2 + 1$ on paper (or in mind) and using the y values to estimate the slopes to draw the graph of the antiderivative.

Results

Means and standard deviations for each of the ten measures appear in Table 1. In order to determine between cognitive styles as assessed by the MPIC and the MPI visualizer-analyzer questionnaires and the other variables, Pearson product-moment correlations were computed. The correlations between cognitive styles, abilities, and mathematical performances are presented in Table 2.

Correlational Analysis

There was a significant correlation between the three measures of calculus performance. The correlations between MPI and the other two measures of cognitive style V-G and V-A were non-significant and negative. Of the three measures of cognitive style, V-A significantly correlated with AP and P-G. There was a significant but small correlation between V-A and P-G. The MPI had non-significant negative correlations with the three performance measures. The correlations between the three measures of cognitive style and the measures of spatial and logical reasoning abilities were either negative or non-significantly low.

Among the spatial ability measures, only FB had a significant correlation with P-A. CC and CR had the lowest correlations with the performance measures. FB, PF, NS, and DR significantly correlated with AP and P-G. The correlation between CC and P-G was significant, but CR was correlated neither with AP nor with P-G. It can be seen from the correlations of cognitive ability tests, except CR and FB, the four measures of spatial ability significantly correlated with each other. The two measures of logical reasoning ability significantly correlated with each other. DR correlated three of the four measures of spatial ability, CC, FB, and PF, whereas NS only correlated with FB, suggesting that FB was the only spatial ability measure correlating with both measures of logical reasoning ability.

Conclusions

This study contributes to the existing research by examining the relationships between cognitive styles, cognitive abilities, and mathematical performances in calculus. The correlational matrix revealed that spatial orientation ability, measured by Card Rotation and Cube Comparisons tests, did not correlate with calculus performance. Unlike spatial visualization and logical reasoning ability, spatial orientation seems to be unrelated to calculus performance although visualizing mathematical objects from different perspectives is crucial to understanding calculus. The significant correlation between spatial visualization and calculus performance could be partially attributed to the tasks that require sketching derivative or antiderivative graphs; however, this trend is also evident in consideration of correlations with AP test scores. The MPIC and MPI visualizer-analyzer questionnaires did not correlate with spatial ability and logical reasoning ability measures, suggesting that cognitive abilities do not influence students' preference for visual or analytic thinking, and vice versa. This is consistent with previous research (Hegarty & Kozhevnikov, 1999; Lean & Clements, 1981; Moses, 1977; Suwarsono, 1982). Krutetskii (1976) also observed that gifted students do not possess strong spatial abilities and might prefer not to use visual methods.

A factor analysis on the twelve variables in Tables 1 and 2 provides interesting results. Using the varimax rotation, eleven of these variables load onto four easily interpretable factors: a calculus performance factor with AP (0.582), P-G (0.721), P-A (0.612); spatial ability factor with CC (.717), CR (.639), PF (.523), FB (.495); logical reasoning factor with DR (.76), NS (.416), and cognitive style factor with V-G (.729), V-A (.522), P-G (.426). A modified version of Mathematical Processing Instrument ([MPI], Suwarsono, 1982) was used to measure the calculus students' visual preference. The MPI did not did not load on any of the four factors and did not correlate significantly with any measure. On the other hand, the MPIC test and questionnaire regarding derivative and antiderivative tasks presented graphically loaded substantially on the cognitive style factor and correlated significantly with calculus performance measures, suggesting that the MPIC is measuring an important component of cognition. Our results are consistent with those of Galindo-Morales (1994), who reported that visuality as assessed by the MPI was not related to calculus performance. However, when calculus derivative and antiderivative tasks were used to measure mathematical performance and visuality, significant correlations can be found. Moreover, most calculus students have acquired a deep conceptual understanding of mathematics and might have characteristics that distinguish them from others (Ferrini-Mundy, 1987).

Our work with AP calculus students has generated new information about ability, style and mathematical performance in calculus. We believe that analyses of data obtained with the MPIC have produced results worthy of continued study, and that the MPIC has the potential to be a measure of performance and preference for visual thinking in calculus.

HOW DO STUDENTS CREATE OPPORTUNITIES TO LEARN MATHEMATICS?: REPRESENTING STUDENTS IN RESEARCH ON CURRICULUM USE

Amanda Jansen
University of Delaware
jansen@udel.edu

The purpose of this paper is to argue for increased attention to students' experiences in research on mathematics curriculum. I call for examining students' roles in the process of curriculum use to complement studies of student data to assess the outcomes of curriculum use. I present a framework that illuminates students' roles in the process of curriculum use.

Opportunities to learn are considered to be the strongest influence on what students learn (Hiebert & Grouws, 2007). One way to think about creating opportunities to learn is through a process of curriculum construction. When students are represented in studies of mathematics curriculum, student performance (and, more rarely, attitudes or dispositions) is assessed as an outcome indicator. However, students are less frequently represented in research studies as explicitly part of the process of constructing curriculum. The purpose of this paper is to argue for an increase in research on how students play roles in creating opportunities to learn mathematics. In this paper, I present a framework for the ways in which researchers have represented or might represent students as part of the *process* of curriculum construction, beyond representing students as outcomes of teachers' curriculum use.

The need for more complex representations of students in research on mathematics curriculum has been requested previously. Smith and Star (2007) argued for broader conceptualizations of impact of mathematics curriculum. They recommended that researchers look beyond achievement outcomes to include students' disposition measures as outcomes and to examine interactions between indicators of impact when studying the effects of curriculum. The Research Advisory Committee [RAC] of the National Council of Teachers of Mathematics [NCTM] (Confrey et al., 2008) called for examining subgroups of students to assess *for whom* various curriculum materials and approaches are more and less effective (and why). The RAC suggested that a more complex representation of students would involve accounting for race, socio-economic class, and gender when studying the effects of curriculum materials. Erickson and Shultz (1992) noted that when researchers have investigated students' experiences in classrooms, they rarely accounted for subject matter. In this paper, I extend these calls for more complex representations of students in research on mathematics curriculum by emphasizing a focus on students' roles in the *process* of creating opportunities to learn mathematics.

Why is it valuable to consider how students are represented in research on mathematics curriculum? In the context of post-No Child Left Behind, so much emphasis is on "what works." Students are represented in terms of achievement scores, as outcomes in the process of implementing instructional innovations (including particular curriculum materials or teaching practices). Yet we realize that students are more than their test scores. Classrooms are social contexts, and all of the participants – including students – affect the unfolding of social events. As the social event of a lesson unfolds, it usually does not do so exactly as a teacher planned; changes are often made to the lesson in the moment, as the participants respond to one another. In this way, among others, students can play a role in constructing what can be learned during a lesson.

In this paper, I present a framework for characterizing how students influence their opportunities to learn mathematics. I take up the following questions in this paper: How have students been represented in research on mathematics curriculum? How *might* students be represented in research on mathematics curriculum? What are the affordances and constraints of these different constructions? My analysis of current research on mathematics curriculum suggests the need for further research on the role of students in the *process* of curriculum use.

Theoretical Framework

To describe my general perspective on research on mathematics curriculum, first I define what I mean by "curriculum." Then, I share some of the purposes for studying mathematics curriculum use in past research, and I discuss how students have been represented in this area of research. The Mathematical Tasks Framework (Henningsen & Stein, 1997) is presented for the insights it provides about how students are constructed and might be constructed in research on curriculum.

Curriculum

Following Stein, Remillard, and Smith (2007), I view curriculum broadly as "the substance and content of teaching and learning – the 'what' of teaching and learning (as distinguished from the 'how' of teaching)" (p. 321). I view curriculum construction as a dynamic & flexible process. Opportunities to learn mathematics in a classroom involve teachers and students participating with written curriculum materials and each other (Remillard, 2005). These learning opportunities are shaped by the tasks in the written materials, how teachers implement the tasks, and how students engage with the tasks.

Purposes of Research on Mathematics Curriculum

Mathematics educators whose research addresses mathematics curriculum have examined (1) comparative effects of new curriculum materials (evaluation studies) and (2) how features of curriculum and pedagogy shape these effects and influence students' learning (Star & Smith, 2007). Across studies that evaluate the effects of curriculum materials, the focus has been either upon demonstrating that newer materials ("Standards-based" materials designed to help teachers implement lessons aligned with the NCTM Standards) do no harm or can more effectively promote students' learning of content aligned with NCTM Standards, compared to other curriculum materials (e.g., Huntley et al., 2000).

Research on mathematics curriculum has evolved toward representing teachers' roles with greater complexity. Researchers from the QUASAR project illustrated that teachers' implementation of mathematics tasks could transform tasks that were written to be challenging to become less demanding or teacher could maintain the level of challenge through task implementation (Henningsen & Stein, 1997). Tarr et al. (2008) studied the effects of the use of middle grades curriculum materials along with instructional practices (Standards-Based Learning Environment) on student achievement; they found that curriculum materials converged with teachers' instructional practices to foster students' achievement. Across studies, results suggest the importance of teachers' roles in constructing students' opportunities to learn from curriculum materials.

There is a need to represent students in research on curriculum with greater complexity as well, including how students help create opportunities to learn from particular curriculum materials. In a recent review of the research literature on how curriculum influences student learning (Stein, Remillard, & Smith, 2007), students' roles are discussed for less than a page (p.

355), which suggests a lack of research on their role in the process of curriculum use. If students are represented typically at the "end" of the curriculum use process, specifically in terms of what they have learned, students may be represented as having a relatively passive role in curriculum use – as receiving the curriculum. Following Goodlad (1979), it is possible that the teachers' instructional approaches and written curriculum materials (or, in Goodlad's terms, the intended, perceived, and operational curriculum) may not be aligned with what students experience (the received curriculum). Thus, capturing students' perspectives in relation to curriculum use would provide insight on constructing opportunities to learn mathematics. Not only might students receive a curriculum that may not be aligned with what the teacher intends or implements, students' engagement with a mathematical task can influence their learning.

Stages of Curriculum Use and Students' Roles

Stages in the Mathematical Tasks Framework (Figure 1) provide insights about how students have been represented in research on curriculum use. The first stage is the mathematical task as represented in curricular/instructional materials, or the written curriculum. Teachers then plan to use written tasks in the form of lessons. Teachers implement these lessons, which would be the second stage – mathematical task as set up by the teacher in the classroom. The third stage represents students' interactions with mathematical tasks – mathematical task as implemented by students in the classroom. The fourth stage represents students as *outcomes* of curriculum use.

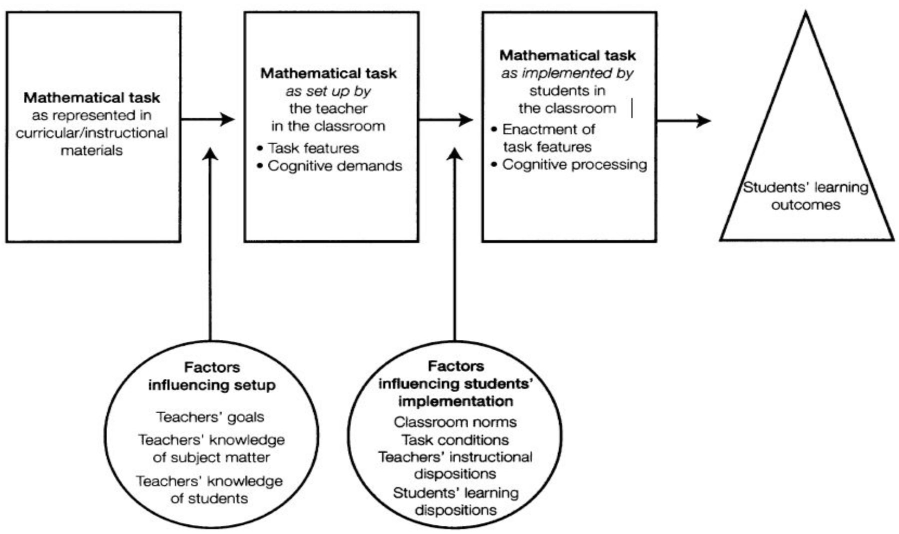

Figure 1. Mathematical Tasks Framework (Henningsen & Stein, 1997, p. 528)

Note that students also appear as factors influencing how teachers set up tasks (teachers' knowledge of students) and how students implement tasks (students' learning dispositions). The Mathematical Tasks Framework suggests that students' roles in the process of curriculum use include influencing teachers' planning and implementation of mathematical tasks, students' engagement with tasks, and, potentially (if there was an arrow creating a cycle from student learning outcomes to teachers' implementation of the task again in the future) students could influence how teachers revised their lessons based upon these mathematical tasks.

The idea that students play a role in influencing opportunities to learn is not new. Borasi (1990) wrote about students as the "invisible hand operating in mathematics instruction" (p. 174), and she illustrated that students' conceptions and expectations can influence their learning. Erickson and Shultz (1992) argued for the need to capture variation in students' subjective experiences of curriculum. Although some mathematics education researchers have examined how student engagement shapes their opportunities to learn (e.g., Nasir & Hand, 2008), these studies are either set outside of school or not in relation to tasks in specific curriculum materials. To support mathematics educators in moving toward more complex representations of students in research on mathematics curriculum, there is a need for a framework to describe students' roles in the process of curriculum use.

Methods

To develop this framework, I purposefully selected research literature to examine for this paper. I used the following criteria to select articles: To discuss how students have been represented to date, I drew upon peer reviewed publications. To consider how students *might* be represented, I drew upon a wider range of texts and looked beyond peer reviewed publications to include conference papers and book chapters. The Mathematical Tasks Framework provided a structure for locating research on students' experiences with curriculum use. I examined research with representations of students in the second stage (mathematical task as set up by the teacher), the third stage (mathematical tasks as implemented by students), and, if there could be a feedback loop between student learning outcomes and selection of mathematical tasks, I examined research that represented students in the process of teachers revising opportunities to learn as well.

Results

In this section of the paper, I explore how students have been represented in the process of curriculum use within a framework (Table 1), and components of this framework serve as inspiration for how students might be represented in future research on the process of curriculum use in mathematics education.

Processes	How *are* students represented in curriculum research?	How *might* students be represented?
When *teachers plan* lessons based upon curriculum materials	• Students' mathematical thinking as resources to draw upon when designing opportunities to learn. • Students' funds of knowledge as resources to draw upon when designing opportunities to learn.	• Students' voices as a factor that influences selection of curriculum materials or other aspects of curriculum design.
When *teachers implement* lessons based upon curriculum materials	• Students as texts to be "read" by teachers during instruction (to inform in-the-moment revisions) • Students' engagement as a factor that influences cognitive demand of mathematical tasks (maintenance or decline).	• Students' engagement as a factor that influences *increase* in cognitive demand.
When *students implement* mathematical tasks	• Variations in how students engage with the same mathematical tasks.	• In terms of strengths in students' engagement in balance with opportunities to improve their engagement.
When *teachers revise* lessons based upon curriculum materials	• Students' mathematical thinking as a factor that influences revisions of opportunities to learn.	• Students' voices (attitudes or other perspectives toward curriculum) can be a factor that influences revisions of opportunities to learn.

Table 1. Students' Roles in Constructing Opportunities to Learn

Students as Resources when Planning Lessons

Students play a role in the process of constructing opportunities to learn when they are draws upon as resources for teachers when selecting tasks or designing and planning to implement mathematical tasks in their classroom. In *Child and the Curriculum*, Dewey (1902) argues for "psychologizing" the curriculum. This process involves constructing educative experiences for learners that originate from the child's present experiences and move into the logic of academic disciplines. Research on curriculum design (designing, selecting, and planning curriculum) is conducted in the spirit of psychologizing the curriculum when it represents students as resources to inform the process.

Some ways that students have been represented as resources in the process of curriculum design or planning to implement tasks has been in the form of local instruction theories (Gravemeijer, 2004) or students' "funds of knowledge" (Bartell et al., 2010). Local instruction theories (Gravemeijer, 2004) describe a reflexive relationship between hypotheses about how students learn, think, and reason about a given topic and the means of instructional support to help students understand that topic. Students' thinking is a resource for task design with the goal of moving students' thinking toward a particular mathematical learning goal. Some researchers promote a view of curriculum design that draws upon home and community-based funds of knowledge (knowledge, skills, and experience found in students' homes and communities). Bartell and colleagues (2010) describe how pre-service elementary teachers designed lessons that built on their own students' funds of knowledge after learning more about the students' lives (e.g., participating in a tour of the students' communities led by community members). In this research, students play a role in curriculum construction because the opportunities to learn in these pre-service teachers' classrooms would differ or be adjusted depending on what they learned about their students' lives outside of school.

Additionally, students could be represented in research on the process of curriculum design in settings where curriculum materials (or tasks or content goals) were chosen (at least in part) based upon students' input. How frequently are students consulted as stakeholders in the process of selecting and designing opportunities to learn? After all, education is *for* students (Levin, 2000), so their voices about the materials and tasks could be represented by research and considered when making instructional decisions. For instance, researchers could investigate the criteria students use to select mathematics curriculum materials or tasks.

Students as Resources when Implementing Lessons

Teachers' interactions with students could influence how teachers implement tasks in the classroom. For instance, teachers "read" their students when implementing mathematical tasks, which can lead to improvised curriculum construction, such as changing tasks or ending a task early (Remillard, 1999). Additionally, mathematical tasks have been observed to either maintain their level of challenge and difficulty (maintain cognitive demand) or become less challenging (cognitive demand decreases) as teachers and students interact (Henningsen and Stein, 1997). Students may pressure teachers to reduce ambiguity in order to reduce their anxiety about being successful on a challenging task. Students shape their learning opportunities as they influence teachers' implementation of tasks.

Future research could examine whether and how students can play a role in raising the level of cognitive demand of a task. It is possible that students could push the level of cognitive demand higher if teachers are open to students' mathematical wonderments. As students have opportunities to pose their own mathematical problems (Brown & Walter, 2004), they may start asking increasingly challenging questions. Students may make connections that the teacher had not intended, perhaps even during a lesson that was not headed toward making connections, taking a lesson that was initially focused on procedural fluency toward a lesson that examines meanings behind and connections between procedures.

Students' Implementation of Mathematical Tasks during Lessons

Prior research has examined how students engage differently with tasks from the same curriculum materials. Two studies of seventh grade students in classrooms that used NCTM Standards-based curriculum materials (Lubienski, 2000; Jansen, 2008) illustrate variations between how different students take up the same mathematical tasks. SES differences appeared to moderate how students engaged with open, contextualized mathematical tasks as set up by the researcher-teacher (Lubienski, 2000). Higher SES students engaged with more confidence and with an eye toward the intended mathematical ideas when working on open, contextual tasks. Lower SES students preferred more external direction and approached problems in a way that led to missing some of the intended mathematical points. Jansen (2008) examined how students' beliefs moderated their participation in classrooms with Standards-based curriculum materials. Students who believed whole-class discussions were threatening avoided talking about mathematics conceptually, yet these students participated by talking about mathematics procedurally. Additionally, students' beliefs about appropriate behavior during mathematics class appeared to constrain whether they critiqued their classmates' solutions. Waddell (2010) investigated African-American elementary school students' engagement in classrooms that implemented Standards-based materials over three years and identified ways in which the student's engagement converged with and diverged from the patterns of engagement promoted by their teachers' instructional practices. These studies illustrate that students' engagement and participation, as moderated by SES, cultures, or their beliefs, influences their opportunities to learn from mathematical tasks.

It is helpful to examine a range of patterns in student engagement with mathematical tasks, because teachers would benefit from increased awareness of variations in students' engagement with tasks. Teachers can more effectively support students' engagement if they have knowledge of how students might engage. When researchers investigate student engagement, one dilemma involves how to discuss ways to improve students' engagement without placing blame upon students for not participating productively. (Henningsen and Stein (1997) appear to navigate this dilemma by focusing upon how teachers can influence students' engagement.) Future research should continue to uncover different ways in which students engage with the same mathematical tasks, especially highlighting positive qualities of students' engagement that lead to productive learning opportunities. Results of such studies could support more teachers as they read their students while implementing tasks. Knowledge about how students engage can help teachers as they intervene to support students to engage productively (or encourage students when they do engage productively).

Students as Resources when Revising Lessons

Teachers can use their knowledge of their students to revise their lessons based upon their curriculum materials. Referring back to Gravemeijer's (2004) local instruction theories, these theories are considered to be revisable. Teachers can develop and take these theories as conjectures about how and why curriculum materials or mathematical tasks (and instructional moves to use when implementing the tasks) are effective, then test and modify them in their own classrooms. When teachers learn or develop new understandings about students' mathematical thinking, evidence suggests that they may change their instruction (Fennema et al., 1996). Thus, students are represented in the process of research on mathematics curriculum revisions by descriptions of their mathematical thinking and their influence on curricular (and instructional) decisions.

It is also possible to imagine research in which opportunities for students' learning are revised based on students' feedback. Some researchers have attempted to solicit students' perspectives about their experiences with particular curriculum materials. In a report written by high school students and their teacher (Holt et al., 2001), students shared their perspectives on their experiences in classrooms with Standards-based curriculum materials. These students reported an appreciation of the participatory aspects of these classrooms and reports that the teachers' supportive stance toward the materials improved their experience. Bay, Beem, Reyes, Papick, and Barnes (1999) assessed over 1,000 middle school students' reactions to Standards-based curriculum materials after a year of use by asking students to write letters about their experiences with the materials. Students were generally positive about the materials and appreciated the hands-on activities, real-life applications, and collaborative work. Students' perspectives on curriculum materials have been investigated, but researchers could follow up on this line of work by studying the effects of implementing students' recommendations or the selection of materials chosen with students' input.

Discussion

Just as complex representations of how teachers use curriculum materials provide insight on creating opportunities for students to learn, additional representations of students are needed in research on mathematics curriculum. Currently, students are represented primarily as outcomes of curriculum use. Researchers could continue to investigate the role of students as a factor that influences teachers' planning and implementation of curriculum, as a factor that influences revisions of lessons, and as a diverse group that engages differently with similar tasks. Advances in research on mathematics curriculum could include studies of students as active participants as decision-makers about curriculum and representations of students' strengths when engaging in mathematical tasks (including ways in which students play a role in raising the cognitive demands of tasks).

Explicitly investigating and highlighting students' roles in the process of curriculum construction can provide insight into social processes of learning to consider not only whether but *how* the use of curriculum materials shapes learning. Although there are political pressures to use curriculum materials that are proven to be "effective," it is important to understand the conditions that lead to productive uses of these materials. Students' roles in the process of constructing opportunities to learn are conditions that mathematics educators need to understand more fully to gain a broader perspective on how curriculum materials support students' learning. For these reasons, I hope for more complex representations of students to play an increasingly central role in future research on mathematics curriculum materials.

MIDDLE SCHOOL ALGEBRA FROM A FUNCTIONAL PERSPECTIVE: A CONCEPTUAL ANALYSIS OF QUADRATIC FUNCTIONS

Amy B. Ellis
University of Wisconsin-Madison
aellis1@education.wisc.edu

This study presents a model of three conceptual advances in understanding quadratic functions based on a teaching experiment with 6 8th-grade students. Using a covariation approach, students investigated quadratic growth as a coordinated change of x- and y-values. Qualitative analysis yielded three major shifts in students' understanding: a) developing an understanding of the first and second differences for y as rates of growth with Δx implicit; b) explicitly coordinating Δx with the constant second differences; and c) coordinating covariation and correspondence views through meanings for the parameter "a" in $y = ax^2$.

Objectives

Calls for "algebra for all" have grown in frequency in recent years, influencing district policies nationwide. For instance, the National Mathematics Advisory Panel (2008) recommends that districts prepare to enroll increasing numbers of students in algebra by Grade 8. Similarly, the NCTM (2000) Principles and Standards calls for including algebraic ideas throughout the K-12 curriculum and recommends that middle school students in particular focus on learning concepts in algebra. Successful implementation of "algebra for all", however, depends on finding ways to help students understand fundamental algebraic concepts such as equality, the use of variables, and functions. Research suggests that traditional courses focused on strategies for manipulating symbols, simplifying expressions, and solving equations yield poor results in overcoming students' well-documented difficulties in understanding algebraic relations (e.g., Knuth et al., 2006). These limitations have led to efforts to expand notions of what constitutes school algebra, and one major set of recommendations emphasizes a functional perspective as a central concept for organizing algebra instruction (Schliemann, Carraher, & Brizuela, 2007), with the early introduction of functional relationships in the elementary and middle grades. Placing functions at the center of algebraic reasoning can support students' abilities to make sense of quantitative situations relationally and provide an important foundation for future success in mathematics.

Given the importance of functional understanding for developing algebraic reasoning, one of the critical challenges remains better understanding how students' early function conceptions develop. As Asquith et al. (2007) noted, the challenges in learning more about students' reasoning "are particularly relevant at the middle school level, at which time the transition from arithmetic to algebraic thinking is arguably most salient" (p. 250). This paper presents an investigation of middle school students' emerging understanding of quadratic growth, presenting a model of three conceptual advances students experienced when studying quadratic function. It closes with a discussion of the implications for algebra understanding.

Students' Understanding of Quadratic Functions

Quadratic functions represent the basis of the more advanced mathematics to come at the secondary level and as such can act as a transitional topic for supporting students' developing algebraic reasoning. However, attempts to effectively introduce quadratic relationships have proved difficult. Students struggle to understand the role that the parameters "a", "b", and "c" play in $y = ax^2 + bx + c$, and have difficulty describing the effects that changing the parameters can have on a function's graph (Zazkis, Liljedahl, & Gadowsky, 2003). Studies have also documented students' tendencies to inappropriately generalize from linearity in order to make sense of quadratic relationships (Chazan, 2006), including using linear interpolation and attempts to find a slope and a point (Ellis & Grinstead, 2008; Eraslan, 2007). The phenomenon of generalizing from linearity suggests a need to consider introducing non-linear functions earlier in students' algebraic reasoning. One aim of this study was to identify the concepts that middle school students developed when investigating quadratic relationships from the perspective of reasoning about quantities.

Conceptual Analysis and the Development of Models of Students' Thinking

Conceptual analysis as a tool in mathematics education can be employed to satisfy a number of different goals. One can develop a conceptual analysis in order to specify the mental operations required to obtain a particular set of concepts or to analyze ways of understanding a body of ideas based on describing the coherence between their meanings (Glasersfeld, 1995; Moore, 2010). Thompson (2008) identified four uses of conceptual analysis: a) to build models of what students actually know at a specific time and in specific situations, b) to describe propitious ways of knowing for students' mathematical learning, c) to describe ways of knowing that might be problematic to students' understanding of important ideas, and d) to analyze the coherence of various ways of understanding a body of ideas. The purpose of this study is compatible with (a); its aim is to build a model of what students understand about a particular type of quadratic growth. In so doing, the model introduces advances in understanding quadratic growth that may be favorable for fostering a deeper understanding of functional relationships.

Following Glasersfeld's theory of radical constructivism (1995), the analysis presented here is based on the understanding that a student's knowledge is fundamentally unknowable, and thus any conceptual model is simply a researcher's tool for making sense of the student's mathematics. From this perspective it becomes important to refine tentative models over time. The use of the teaching-experiment methodology (Steffe & Thompson, 2000) supported the creation, testing, and revision of models of students' mathematics over multiple iterations. One aim of the teaching experiment was to investigate the viability of an introduction to quadratic function that emphasized the covariation approach (Confrey & Smith, 1995) within a quantitatively-rich setting. Within this approach, students examine quadratic growth as a coordinated change of x- and y-values. An open question was whether students could make quantitative sense of the phenomenon of constant second increases for y coordinated with uniform increases for x, and whether this understanding could support a more robust view of quadratic function that could be meaningfully connected to the correspondence rule $y = \mathrm{a}x^2$.

Methods

Participants and the Teaching Experiment

The study occurred at a public middle school with 6 8th-grade students, whose teachers identified them as high performers (2 students), medium performers (2 students), or low performers (2 students). Students across a range of performance were included in order to create a heterogeneous group in terms of mathematical backgrounds, knowledge, and skills. The students participated in a 15-day teaching experiment, which met for 1 hour a day. The students worked with a computer simulation of growing rectangles in Geometer's Sketchpad, in which they could manipulate the size of the rectangle. By adjusting the rectangle's height, the length would adjust automatically, preserving the height/length ratio (Figure 1):

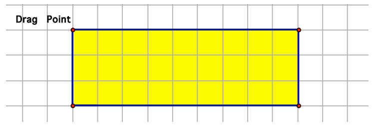

Figure 1: Image Capture of a GSP growing rectangle script

The students explored relationships between the heights, lengths, and areas of various rectangles by using scripts in Geometer's Sketchpad and by creating their own drawings, tables, graphs, and equations. The author taught the sessions, which were observed by two project team members who offered reactions and commentary after each session.

Data Sources and Analysis

All sessions were videotaped and transcribed, and additional data sources included students' written work and the author's written reflections on each session. Data were analyzed via the constant comparison method with an open and axial coding technique. Retrospective analysis (Steffe & Thompson, 2000) of the videotapes supported the creation of an initial model of each student's evolving understanding of quadratic growth. The development of the initial models of conceptual change led to the identification of 4 major categories of interest across all students: (a) students' meaning for the first differences; (b) students' meaning for the constant second differences; (c) the coordination of the increases in height with the increases in area; and (d) the relationships between the constant second differences, the rectangle's dimensions, and the parameter "a" in $y = ax^2$. Identifying the students' operations for each category led to the development of the model presented below.

Results: A Three-Stage Model of Students' Conceptual Development

Three major conceptual advances occurred during the teaching experiment that shifted the students' evolving understanding of quadratic growth. Figure 2 provides an overview of each of the conceptual advances and the sub-categories of shifts that occurred within each stage.

Stage 1: Understanding differences as rates of growth with Δx implicit	*1a*: 1st Differences as the rate of growth of the area
	1b: 2nd Differences as the rate of rate of growth of the area
Stage 2: Understanding differences as rates of growth with Δx explicit	*2a*: There is a relationship between Δx and the 2nd differences
	2b: Connecting the 2nd differences to the rectangle
	2c: Identifying how Δx is related to the 2nd differences
Stage 3: Coordinating the covariation and correspondence views	*3a*: Viewing "a" as change in length per 1-unit change in height
	3b: Viewing "a" as the ratio of the change in length to the change in height
	3c: Understanding "a" as ½ the 2nd differences (Δx implicit)
	3d: Understanding "a" as ½ the 2nd differences (Δx explicit)

Figure 2: Three stages and sub-categories of conceptual advances

The following table is one student's record of a 2 cm by 3 cm rectangle:

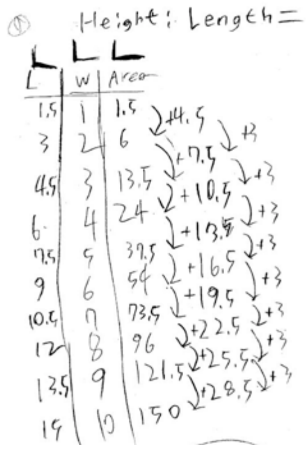

Figure 3: Table of length/width/area values of a growing rectangle

All of the students' discussions about quadratic growth relied on the growing rectangles context. The students created tables of data to record the height, length, and area values they observed in Geometer's Sketchpad such as the one seen in Figure 3. The students' propensity to represent data in well-ordered tables in which the height or the length values increased by uniform 1-cm increments encouraged a focus on what is often referred to in textbooks as the "first differences" and the "second differences" for *y*. The first transition the students experienced was one in which they shifted from understanding these values as differences to understanding them as rates of growth.

Stage 1: Understanding Differences as Rates of Growth With Δx Implicit

1st differences. The students initially focused only on the differences between successive area values without coordinating with the way the height or the length grew. For instance, when describing the first differences for height/area table of a square that grew by 1-cm increments, Jim explained, "it goes 1 and then 3 and then 5 and then…and then you go to 3, 5, 7,…just keeps going." Attention to coordinating the growth in area with how the height grew was absent from Jim's description. The teacher-researcher asked the students to draw diagrams of growing rectangles that depicted the increases in area. Figure 4 shows Ally's 2 x 3 rectangle that grew to become a 3 x 4.5 rectangle and then a 4 x 6 rectangle:

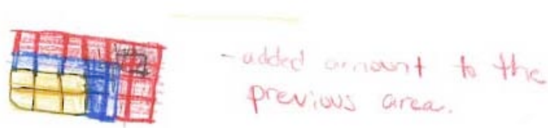

Figure 4: Ally's depiction of the additional area produced as the rectangle grows

Ally explained, "So we added 7.5 to this part [pointing to the 2 x 3 rectangle], we added 10.5 to this part [the 3 x 4.5 rectangle], and then, because it's the difference, it's [the second differences] how many more squares you had to add to this one [the 3 x 4.5 rectangle], instead of compared to this one [the 2 x 3 rectangle]." In this depiction Ally began to coordinate the number of squares making up the additional area to each time the rectangle "grew". The increments were not explicit for Ally, but she and the other students began to attend to the fact that the first differences represented the growth of the area for each increase in the rectangle's size. The next day, Jim more generally stated that the first differences represented "How many new squares it's gaining every time it grows." Jim's use of the term "every time" suggests that he was coordinating the growth in area with some growth in height and length, but did not explicitly attend to the unit of growth.

2nd differences. The students initially described the second differences as "the second level sort of thing", or "the new outside area." Ally's picture in Figure 4 helped her explain that "every time it grows it adds 3", but it was unclear whether she saw this as the rate at which the rate of growth of the area grew.

A continued emphasis on creating drawings helped the students clarify the meaning of the second differences. For instance, Bianca explained that they represented "the area of the next shape minus the area of the previous shape", or the "amount added to the amount added to the area." Jim noted that the students should name this value, stating, "I think we should give it names, like, the amount added to the amount added is so confusing!" Ally suggested "Difference in the Rate of Growth" and the students settled on this term, eventually shortening it to the "DiRoG". Jim characterized the DiRoG as, "So the rate of rate of growth is how many square units it's gaining from the rate of growth."

When the students created a table for the height, length, and area of a 1 x 2 growing rectangle, Jim found the DiRoG to be 4 square units, and then exclaimed, "it's going up by the rate of the rate…the rate that the rate of growth is growing!" Elaborating, he said, "When I add that new shelf thing [referring to increasing the size of the rectangle], there's 4 left over instead of 3." At this point Jim began to connect the DiRoG to an increase in the rectangle's size, but the unit of increase remained implicit. The connection to the manner in which the rectangle grew was limited to conceiving of how the area grew "each time", rather than for a specific value for which the height or length increased.

Stage 2: Understanding Differences as Rates of Growth With Δx Explicit

Δx and the 2nd differences. If the students were not coordinating the DiRoG with the value of Δx, they would likely not anticipate that the DiRoG would change for a table in which Δx was something other than 1. In order to test this prediction, the teacher-researcher asked the students to create tables for a 2 cm x 5 cm growing rectangle, anticipating that some students would increase the height value increased by 1 cm, and others would increase the height value by 2 cm. This did occur, for instance, Daeshim created a table in which Δx was 2 cm, and Jim created a table with Δx as 1 cm.

The students argued about whether the DiRoG should be 5 cm^2 or 20 cm^2 until Jim realized that it depended on Δx: "He's [Daeshim] going by 2's, but I'm going by 1's." After a class discussion in which the students agreed that the DiRoG could legitimately be 5 or 20, Jim asked, "So your rate of growth can change no matter what?" At this stage the students understood that the DiRoG depended on how the rectangle grew, but had not yet determined how the DiRoG was dependent on Δx.

Connecting the 2nd differences to the rectangle. Because the students struggled to determine how Δx would predict the DiRoG, they decided to consider the DiRoG in relationship to the rectangle's dimensions. Daeshim drew a picture to show that the DiRoG would be twice the area of the original rectangle for a 4 cm by 14 cm rectangle (Figure 5):

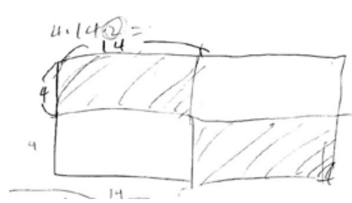

Figure 5: Daeshim's drawing of a growing 4 cm x 14 cm rectangle

Daeshim iterated the height so that the next rectangle became an 8 cm by 28 cm rectangle. He explained that this effectively created an additional area equivalent to 3 of the original rectangles, and repeating this process again would produce an additional area equivalent to 5 of the original rectangles, so the DiRoG, representing the difference in the rate of growth of the area, would be equivalent to the area of two of the original rectangles. Daeshim produced a corresponding table in which the Δx value was 4, and the DiRoG was 112 cm^2.

In contrast, Jim decided that the DiRoG would be equivalent to twice the length of the rectangle when the height was 1 cm: in this case, that would be 7 cm^2. He explained, "You reduce the height until 1, and then you can just multiply the area, or length, by 2. Because at 1, length and area are the same." He was aware that this depended on the rectangle growing in 1 cm increments for the height. Bianca agreed with Jim's method, but characterized it differently, stating "It's the length when the height is 2." Jim and Bianca imagined a rectangle that was a 1 cm x L cm rectangle. In this case reducing a general H x L rectangle to 1 cm for the height would produce a length of L/H. The area of that rectangle would be L/H, and thus the DiRoG would be $2 \times L/H$, which is equivalent to twice the length (or area) of a rectangle when its height is 1 cm.

Δx and the 2nd differences. The different table configurations for the 4 cm x 14 cm rectangle led to the two DiRoG values, 7 cm^2 and 112 cm^2. Tai explained that both values were correct, "Because one the height is growing by 4, and for the other one, height's growing by 1." Daeshim then explained that when the DiRoG, 7, is multiplied by the square of the Δx value in the other table, 4, the result is 112: $7 \times 4^2 = 112$. In general terms, if the Δx value increases by h units instead of 1 unit, the DiRoG must be multiplied by h^2. After working with many different table configurations, the students decided that this relationship was true, but were not able to explain why. It was at this point that shifting to a correspondence view became necessary to move the students' thinking forward.

Stage 3: Coordinating the covariation and correspondence views

Viewing "a" as the change in length per 1-unit change in height. The students examined a table of height and area values and had to predict the area when $h = 82$ (Figure 6).

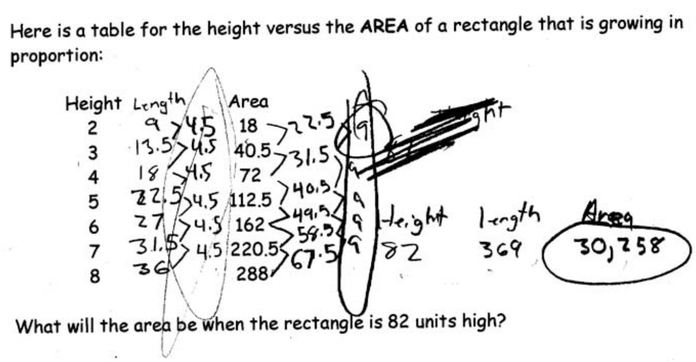

Figure 6: Student's work on a far prediction problem

The students introduced a third length column and found length values by dividing the area by the height. Tai explained, "The area divided by the height is the length. And if you can find out the length, then for this then you can find out the area." The constant increase of 4.5 cm in the length helped the students create a general strategy. Jim explained, "It would go over 4.5 for every time you go up the height 1." Jim determined that he could find the area by multiplying the length by the height, i.e., "$n \times 4.5 \times n$", which the students then shortened to $4.5n^2$. Jim and the other students' ongoing attention to coordinated changes even as they identified a general correspondence rule marked the beginning of their coordination of the covariation view and the correspondence view.

Viewing "a" as the ratio of the change in length to the change in height. Once the students created equations in the form $y = ax^2$, they began to examine connections between "a" and the quantities height and length. The parameter "a" can be thought of as the ratio of the rectangle's length to its height. However, this view did not gain purchase with the students, who were entrenched in a dynamic view, preferring to think about how the heights, lengths, and areas changed as the rectangle grew. Tai explained, "The number in the front is always the difference in the length divided by the difference in the height." Daeshim formalized this as "dL/dH", where "dL" and "dH" referred to the constant differences in successive length and height values. The students' ability to relate "a" to a coordinated change in height and length values served to further connect the covariation and correspondence views.

Understanding "a" as ½ the 2^nd differences (Δx implicit). The students noticed that the "a" in $y = ax^2$ was half the DiRoG. This is true only for tables in which Δx is 1, but the students did not initially attend to this limitation. After creating the correspondence rule $A = 0.75h^2$, Jim explained, "The difference of the rate of growth, half of that is here [points to .75]." After working with multiple tables, the students agreed with Jim's conclusion and Bianca formalized it as "DiRoG/2 = a". At this point, the students understood the parameter "a" in two ways: as half the DiRoG (although this depends on the height growing in 1-cm increments), and as the ratio of the change in length to the change in height. This led Bianca to realize that they could determine the DiRoG by finding $\Delta L/\Delta H$ and multiplying it by 2. However, the students could not easily explain why their generalizations were true, and they were not aware of the fact that their generalizations were limited to the case in which height increased by 1 cm.

Understanding "a" as ½ the 2^nd differences (Δx explicit). In order to help the students re-focus their attention on the change in height values, the teacher-researcher introduced tables with varying Δx values. The students examined a new table with a Δx value of 4 in which the correspondence rule was $y = 4.5x^2$. The students were instructed to consider, "What does the 4.5 have to do with the DiRoG?"

It was through a re-consideration of the quantities height, length, and area that the students eventually began to connect the DiRoG, the "a" value, and the Δx value. The students initially predicted that "a" would be equal to DiRoG/2. They quickly determined that this was incorrect and at that point recalled Daeshim's conjecture that if the Δx value increases by h units instead of 1 unit, the DiRoG must be multiplied by h^2. Bianca realized, "Length over height! It's length over height, times DiH (Δx) squared, times 2 equals the DiRoG of the area." Bianca realized that "a" was the ratio of the length to the height of the rectangle. She knew that typically, twice this value is the DiRoG, but she also realized she needed to compensate for the Δx value being 4 instead of 1. Multiplying by Δx^2, which she called "DiH", provided the correct compensation. Eventually, the students formalized this connection as "a = (DiRoG/2) × DiH^2".

Discussion

The students experienced little difficulty transitioning to tables that did not increase by uniform height values. The images of the changing height and length values in the growing rectangle supported their ability to make sense of these tables and create correspondence rules. Moreover, the students were able to make meaningful connections between correspondence rules and graphical representations by relying on images of coordinated changes between height, length, and area. For instance, all of the students correctly predicted that the parabola for $y = 5x^2$ would be narrower than the parabola for $y = 0.5x^2$, because the former represented a larger rectangle at each specific height value that would add more area with each increase in height.

The students' conceptions about quadratic growth were not without limitations. It was challenging for them to coordinate the growth in area with corresponding growth in height and length, and the students did not appear to reach a point at which they viewed the quantities as varying continuously rather than in repeated discrete increments. Nevertheless, the students developed a number of important threshold concepts (Meyer & Land, 2003) during the course of their investigations. They conceived of the first and second differences as rates of growth, and coordinated the growth of area with growth in height and length values. Their coordination of the covariation view with the correspondence view also fundamentally changed their understanding of the role of the parameter "a", and aided their abilities to create meaningful correspondence rules to represent data.

Lobato et al. (2009) remarked that a common view of conceptual analysis is that it should be based on analyzing the understanding of mathematically sophisticated adults, if participants are included at all. When student thinking is mentioned, its value is relegated to providing a window into the psychology of mathematics rather than as a source for articulating the substance of mathematics. But analyzing student reasoning, particularly at the middle-school level when students confront complex functional relationships for the first time, can inform the construction and refinement of a set of conceptual learning goals. The results of this study suggest that a covariational approach to quadratic relationships can provide a foundation for understanding the nature of quadratic growth and can support a meaningful transition to correspondence relationships.

AN ANALYTIC FRAMEWORK FOR REPRESENTATIONAL FLUENCY: ALGEBRA STUDENTS' CONNECTIONS BETWEEN MULTIPLE REPRESENTATIONS USING CAS

Nicole L. Fonger
Western Michigan University
nicole.m.lanie@wmich.edu

To better support students' conceptual understanding of algebra in the information age, we need an improved understanding of how students interpret connections between multiple representations using CAS as a representational toolkit. This research centers on the development of an analytic framework for categorizing students' connections between multiple representations, an indicator of students' representational fluency. Videotaped task-based interviews with high school algebra students solving equations using CAS were analyzed to generate the proposed analytic framework, which has a hierarchical structure based on the direction and purpose of students' translations between representations.

Purpose of the Study

Each mathematical representation is a glimpse into a version or phase of a particular mathematical object, and when taken together, multiple representations offer complementary perspectives of a mathematical object, which can help to reveal its structure. Flexibility in multiple representational approaches is an indicator of more sophisticated mathematical competencies (Brenner et al., 1999). Despite an emphasis on multiple representations in standards and curricula, school algebra students' difficulties with translating between multiple representations have been well documented (e.g., Dreyfus & Eisenburg, 1996). In technology-intensive approaches, some researchers have found that school algebra students can use multiple representations in solving tasks and are successful in translating between multiple representations (Ruthven, 1990) while others attest to the persistent difficulties students face in using multi-representational approaches with flexibility (Huntley & Davis, 2008).

CAS-intensive trends in school mathematics, and algebra in particular, that were pioneered in the late 1980s and 1990s have finally infiltrated contemporary curricula and classrooms (e.g., Davis & Fonger, 2010). Congruous with the perspective that the coordination of multiple representations is an indicator of conceptual understanding, issues of linking or connecting mathematical representations are significant concerns. Indeed, although CAS environments can act as representational toolkits, Heid and Blume (2008) report that, "students do not necessarily connect representations when operating in a multiple representation environment" (p. 98). Indeed, Heid and Blume (2008) articulate a "need to better understand how students move between, connect, and reason from multiple representations" (p. 98).

With the integration of CAS in school algebra, researchers and practitioners alike need to know how high school students link multiple representations while using CAS technology (Arbaugh, et al., 2010). In addressing this gap, the purpose of this study is to gain insight into the ways in which students connect multiple representations during task-based partner interviews using TI-Nspire CAS. Specifically, this study seeks to answer the following research question: When solving equations using CAS as a representational toolkit, how can students' connections between multiple representations be characterized?

Theoretical Framework

Janvier (1987) defines the psychological conversion made from one type of representation to another as a translation process. In other words, the meaning of a source representation is interpreted in reference to a target representation perspective. Adapted from Huntley, Marcus, Kahan, and Miller (2007), a useful framework for investigating multiple representations is the "Rule of Four" model, which involves symbolic, verbal, graphic, and numeric representation systems, with arrows indicating translations between them. Morgan, Mariotti, and Maffei (2009) posit, "converting between different systems of representation is a critical cognitive activity for developing understanding of a mathematical object" (p. 247).

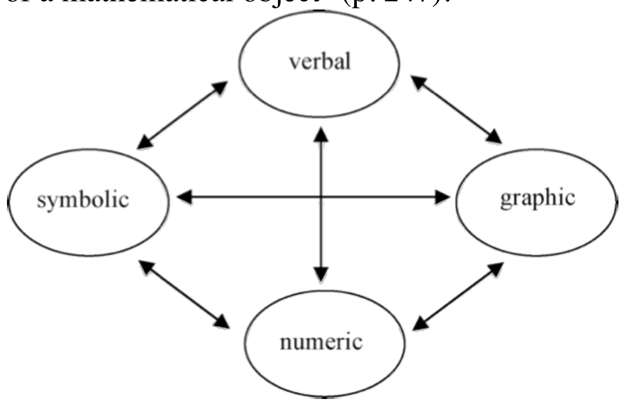

Figure 1: Rule of Four illustrating translations between representations.

The design of the TI-Nspire CAS Touchpad (OS v2.0) houses representations on separate types of "Pages" with a pre-determined structure and main representation for each (including Calculator, Notes, Graphs, Table). For clarity in determining students' use of representations, the Page type and corresponding prominent representation are integrated: symbolic-calculator (S), verbal-notes (V), graphical-graphs (G), and numeric-table (N).

In this context, the construct of representational fluency serves as a tool to characterize students' multi-representational activity. Inspired by Sandoval and colleagues (2000), representational fluency (RF) is the ability to construct, interpret, translate between, and link multiple representations. It is implicit in this definition that both the construction of representations on CAS (inscriptions) and discourse about these representations (e.g., interpretations) are of importance for accessing students' RF. Specifically, I focus on the connections (links) students make between representations to be an indicator of students' RF.

For purposes of this study, a student(s) is said to *make a connection between multiple representations using CAS as a representational toolkit* if they give a correct interpretation of multiple, mathematically equivalent, representations that are evident in their CAS activity or reflection on CAS activity or inscription(s). In other words, for a student to make a connection they must verbalize that they are coordinating information (i.e., invariant features of the object in question as evident in mathematically equivalent representations) in their interpretation of one representation in terms of another, or a pair of representations.

Methodology

Participants and Context

The study was conducted at a Midwest high school that drew accelerated students from several area high schools for mathematics and science coursework only. The school and classroom context was chosen based on the requirement that students have access to TI-Nspire CAS technology, and use this technology regularly in their second year algebra classroom. Of the 25 students in the targeted class, four volunteered to participate in the study and were interviewed. These ninth grade students had taken algebra in middle school and would take geometry after passing their current algebra class. By the beginning of the data collection for this study, students had been using CAS as a regular part of their mathematics instruction for seven weeks.

On three separate occasions prior to interviews with students, the researcher observed the enacted curriculum of students' classroom and took field notes on students' and teachers' use of CAS with regards to multiple representations and use of the adopted textbook, the third edition of the University of Chicago School Mathematics Project *Advanced Algebra* (Flanders et al., 2010). The main purpose of these site visits was to inform the design of instrumentation for the CAS-based task structured interviews; it was necessary to understand the enacted and written curriculum in this classroom to design tasks that involved accessible yet non-routine mathematics and familiar CAS functionality. The classroom observations, reviews of the written curriculum, and conversations with the teacher verified that all student participants had opportunities to learn mathematics through a variety of representations. Moreover, through the use of hypothetical or imperative language, the teacher and textbook often recommended or expected that students use CAS to create representations.

Data Sources and Instrumentation

The main data sources were digital video recordings of task-based interviews conducted with two pairs of students. The teacher determined pairs of students based on students' ability to work well together while engaged in mathematics tasks. Coincidentally, same sex pairs were formed (one male, one female), and the teacher reported that despite the high-ability of all students at this school, there was some variability in these four students' mathematical abilities. On two separate occasions during Fall 2010, each pair was interviewed for 50-minutes during class time. Partner interviews were conducted based on the rationale that richer data would be generated than what might transpire in interviews with individuals. In partner situations, students' interactions with each other and their CAS were perceived to be more authentic to their classroom experiences in which tablemates were observed to regularly communicate about mathematics and CAS technology.

During the interviews, students were prompted to solve two equations, Task R and L (see Figure 2). Both tasks were presented in an initial verbal representation, while Task L also included a graphic representation. These tasks were designed so that various constraints and affordances of the initial representation(s), the context, the mathematics, and/or the technology, might prompt students to construct and/or translate between representations.

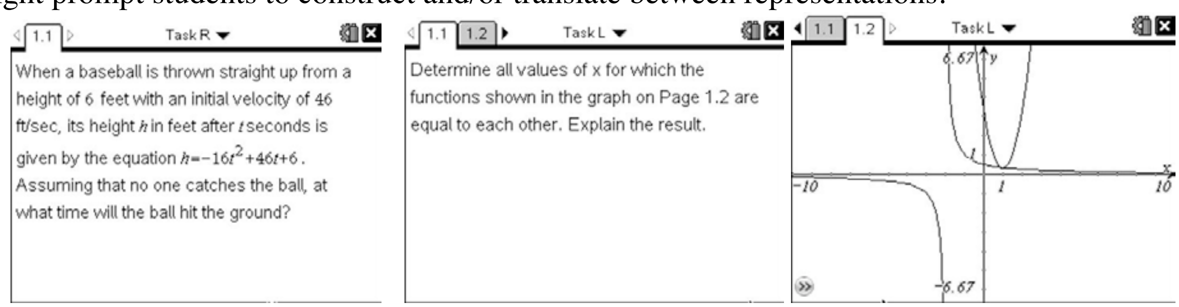

Figure 2. Tasks presented to pairs of students on CAS and in paper form.

Each task was stored and saved as a TI-Nspire document that each student accessed electronically on a handheld CAS. Participants were encouraged to use CAS for the entire interview, but they were also provided pencils and paper copies of screen shots of the tasks (as shown in Figure 2). Data from saved electronic documents of completed tasks and paper and pencil work (if any) were collected at the close of each interview.

During the task-based interviews, participants were encouraged to follow a "think aloud" protocol, openly conversing with one another throughout the interview, providing verbal explanations to accompany their CAS activity as they completed each task. To guard against the researcher changing the cognitive demand of the tasks, a collection of interview prompts was prepared to provide parameters for the interactions between the researcher and participants. The overall intent of these prompts was to elicit further explanations from the students regarding the meaning of their solution approaches with respect to multiple representations.

For instance, "Linking Probes" were given after students had considered the solution and/or solution process from multiple representations (e.g., "How is what you see/did here the same or different from what you see/did here?"). In some cases, students considered multiple representations on their own; in other cases, the researcher encouraged the use of multiple representations through probes (e.g., "Could you solve this in another way?"). In other words, if the students did not self-prompt the use of multiple representations or got stuck in an approach for several minutes, the researcher suggested students consider an alternative approach. Although it is possible that these prompts encouraged students to elicit connections between multiple representations that would not have otherwise been verbalized, this was deemed appropriate because the focus of the study was on the connections students were able to make, rather than on those they chose to verbalize.

Data Analysis

Two video files per interview—one per student in a pair that captured each student's CAS screen—were synchronized into one timeline for video analysis using Studiocode (SportsTec, 1997-2010). The merging of video files allowed for a data analysis method that accounted for both individual and taken-as-shared understandings (cf. Cobb & Yackel, 1996) of the pair of students while they solved equations using CAS. Seed ideas for an analytic framework for linking multiple representations were developed a priori to data analysis, yet the cyclical process of coding, developing, and refining an analytic framework occurred in several stages.

Initial rounds of analysis involved coding and memoing using a grounded-theory inspired approach in which the code categories and descriptions were developed in response to student data. Instead of inventing new terminology in all cases, a conflation of existing terminology was determined to be more beneficial. Specifically, the analytic framework was shaped by the analysis of data and was also purposefully crafted as an amalgamation of existing categorizations and descriptions of students' connections from the literature. A mathematics educator who was familiar with the study and related literature critiqued a refined version of the analytic framework. The entire data set was then reexamined and all instances of connections were coded, memoed, and transcribed, allowing segments of data to be revisited as the analytic framework was being developed. With all connections instances coded, emerging categories, sub-categories, and definitions for the framework were further refined into a hierarchical structure.

Results

The proposed framework for representational fluency is hierarchical in terms of the direction and number of students' translations between representations and the nature of their connections with respect to the perceived goals of students' problem solving activity. Specifically, connections are categorized to be *uni-directional*, *bi-directional*, *multi-directional*, or *abstract*. Both bi-directional and multi-directional connections necessarily involve uni-directional connections. The difference between bi-directional and multi-representational connections is that the former involve a pair of representations (to and from two distinct representations), and the latter involve more than two different representations (and may include a bi-directional pair). Abstract connections go beyond specific reference to types of representation to generalizing the underlying mathematical objects/principles (e.g., equations/equality). Table 1 outlines the framework levels with brief descriptions; connections can be categorized as *one* of: I, IA, IB, II, IIA, IIB, IIC, III, or IV. Transcript excerpts are discussed next to exemplify select levels and sub-levels including: *uni-directional justification*, *bi-directional reconciling*, *multi-directional connection*, and *abstract connection*. The examples were chosen to distinguish between justification and reconciling codes, and also to give more detail on each of the four directional categories, highlighting the hierarchical nature of the framework.

Level of Connection	Brief Description
I. Uni-directional Connection	Translation; interprets meaning of a given source representation in reference to a target representation (Janvier, 1987).
IA. Representational Resourcefulness	Uses a representation to overcome a barrier (Jon Davis, personal communication, 11/18/2010).
IB. Uni-directional Justification	"Use representations as justifications for other claims" (Sandoval et al., 2000, p. 6).
II. Bi-directional Connection	Translation and complementary translation (Janvier, 1987).
IIA. Bi-directional Justification	Pair of representations are used to (dis)confirm an approach (Sandoval et al., 2000).
IIB. Bi-directional Reconciling	Coordinated activity; checking the solution between two representations (Kieran & Saldanha, 2008).
IIC. Reflection on Reconciled Objects	Reflection on the compatibility of a result between a pair of representations (Kieran & Saldanha, 2008).
III. Multi-directional Connection	More than two representations are related by translation processes.
IV. Abstract Connection	A generalization is made across different representations.

Table 1. An analytic framework for representational fluency based on sophistication of connections between multiple representations.

In a *uni-directional justification* connection type, students "use representations as justifications for other claims" (Sandoval et al., 2000, p. 6). In other words, a representation is used to confirm or disconfirm a conjecture or solution approach in another representation. This code is not the same as checking the end result or product of a solution approach against another (i.e., reconciling), instead, the emphasis is that some information from a source representation is used to inform the solution approach in a target representation before the solution is obtained. For example, students from the first interview, attempted to solve Task R using the graph and relate the points where the graph crosses the x-axis to the verbal problem situation in which it only makes sense to have a positive value for time.

Researcher: So how can you use this graph to solve?

Student A: …There are there's two points where it crosses the x-axis [taps finger on desk

twice].
Student B: Right.
Student A: So it'd have to be the positive number and not the negative number because you can't have a negative time.
Student B: True.

In the exchange above, a contextually-based verbal representation is used to justify what is reasonable for a solution on the graph. This is not considered representational resourcefulness because the students were not stuck in using the graph, thus the reference to the verbal representation was to inform their graphic solution.

At the second level of the framework, instances of *bi-directional reconciling* are specific events of coordinated activity in which the student(s) is moving back and forth between two representations. For example, the results of equation solving processes are reconciled between a pair of representations in the second interview while students completed Task L.

(1) Student C: Oh, wow, there's more to the equation. [re-executes solve command on calculator page: solve(1/(x+2)=3*(x-1)^2+0.3,x), ENTER, yields x=-1.96245 or x=0.873499 or x=1.08895]
(2) Student C: … [traces x=1.09 on graph] Yeah look at that, it works now. I got, I got them to equal at 1.09 just like it does in the equation [looks at calculator page, mistakenly points to x=-1.96245].
(3) Student D: At x=1.09? [traces on graph]
(4) Student C: Oh wait. It's very close to 1.09, it just rounds up [comparing approximated values on calculator screen, x=1.08895 and rounded values on graph; continues to compare other values]
(5) Student D: [traces near x=1.11…x=1.08 on graph] So they're basically the same.

In the above excerpt, both students reconciled the results between the symbolic and graphic representations. Student C reconciled the solution from symbolic to graphic (lines 1-2), back to symbolic (line 4), a complementary translation. The utterance from Student D in line 5 is interpreted to mean that the solution of 1.09 was reconciled to be the same in both the graphic and the symbolic representations, taken as evidence of a bi-directional connection in which the solution is checked between two representations.

A student(s) is said to make a *multi-directional connection* when more than two different representations are related by translation processes. The example below from the first interview is a taken-as-shared multi-directional connection between graphic, verbal, and symbolic representations.

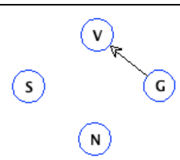
(1) Student B: It's [the graph] actually telling you it would hit the ground at 3 seconds, where as with the calculator you can make so many mistakes when figuring out the problem …
(2) Student A: I'm going back and I'm putting three in for the answer and I'm seeing if it comes out zero [typing 0=-16(3)^2+46(3)+6 then ENTER in the calculator page yields “true”]. Which it says it's true, so—
(3) Student B: [types h(3), ENTER, yields 0] Yep.
(4) Researcher: So what does that help you to understand about the problem?
(5) Student A: That the point that we got is the time it took for it to hit the ground.
(6) Student A: And then when we plugged it back into the calculator it told us that the equation is equal to zero and that's what we were looking for.
(7) Student B: Yup, and it basically reassured the fact that the graph, that that point was right.

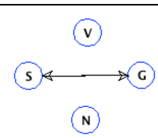
Consistent with the definition, lower levels in the framework are evident within the dialogue of the above example. Student A interprets the graphical solution in terms of the verbal representation, a translation (line 1). Both students reconcile the solution obtained from the graphic representation with a symbolic representation (lines 2-3, 7). Third, the students reflect on the results that had been reconciled between the graphs and calculator pages and relate this to the verbal representation (lines 4-6). In sum, the students have related more than one pair of representations by a translation process. The fact that uni-directional and bi-directional connections are identified within the multi-directional connection is also evidence of the hierarchical nature of the framework, yet instances were not double-coded.

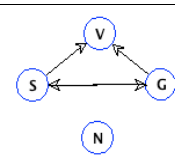
A student(s) is said to make an *abstract connection* when they make a generalization across different representations. In particular, a student demonstrates flexibility in solving equations from multiple representations and is able to generalize the process of solving equations from a functions-based perspective in which an equation is viewed as two expressions, interpreted as functions, which can be viewed from symbolic, graphical, and/or numeric representations. At this level of a connection, the notion of equality is understood from multiple representations. For example, the students in the first interview were asked to reflect on the fact that they had obtained a solution using the graphs page, but hadn't obtained a solution using the calculator page for Task R. This led Student B to generalize that "Because the graph is just a symbol of the equation [switches from Graphs page to Calculator page] or like the diagram of the equation so you should have been able to get the same thing." Moreover, when solving a given equation, Student B articulated that, "If you did it correctly you should have gotten the same answer." So at this point in the interview, even though the students had only successfully solved the task using the graphic representation, Student B was able to articulate that the same solution should be obtainable using a symbolic representation. This is evidence of a generalization across different representations.

Discussion

Students' difficulties in connecting representations of algebraic objects have been well documented. The definition of a connection and the analytic framework for representational fluency proposed here are the building blocks for future research aimed at understanding students' strengths in connecting representations and for instruction designed to foster richer connections among multiple representations using CAS. Using connections between multiple representations as an indicator, students' representational fluency can be categorized in a hierarchical manner per the direction and purpose of students' translations between representations. The results and examples discussed above can be illustrated using the Rule of Four framework, showcasing the four distinct levels in the proposed analytic framework (see Table 2). By teaching topics in algebra using pairs and sets of representations, and emphasizing bi-directional and multi-directional connections through the use and reflection on CAS inscriptions, students may develop representational fluency and in turn come to a more robust conceptual understanding of the mathematical object(s) in question.

Uni-directional	Bi-directional	Multi-directional	Abstract
			






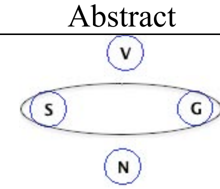


Table 2. Illustrations depicting levels of connections using Rule of Four framework.

The proposed framework and schematic representations mask some of the intricacies of the nature of students' connections as others have studied them. It would serve well to use the framework for analyzing data from a larger sample size. Specifically, the multi-directional connection category might be expanded to account for students' problem solving goals, analogous to the subcategories for the bi-directional level. Additionally, future research might employ the use of the analytic framework to elucidate types of opportunities afforded by written curricula to make connections between multiple representations with CAS. This framework would also be useful in the design of instructional intervention or tasks aimed to foster sophisticated connections between representations through the use of directionally linked dynamic technology environments.

We report findings of research that deals with secondary students' interaction with a digital microworld, eXpresser. eXpresser is designed to support students in constructing general figural patterns of square tiles and expressing the algebraic rules that underlie them. Our focus is on the sense production that emerges as students use eXpresser. In order to analyze student productions, we adopt a semiotic perspective based on a broad notion of mathematical sign systems. We identify in the analysis, critical moments that illustrate the emergence of algebraic expression in eXpresser's alternative sign system. These moments are constituent elements of the process of deriving a general rule and support the development of the notions of dependent and independent variable.

Introduction

The findings of various studies that deal with pattern recognition and expression have led to conceiving of mathematical generalization as a gateway to learning algebra for pre-algebraic students. This approach seeks not only for students to become competent in recognizing regularities in numerical or figurative sequences, but that they also can imbue the corresponding algebraic expressions with meaning and sense (Noss & Hoyles, 1996, Mason, 2008; Bednarz, 1996; Kieran, 2007; Lee, 1996). Many research experiments have used this generalization approach to algebra while working with digital learning environments, and these have been shown to help students along that path, such as studies undertaken using Logo (Hoyles & Sutherland, 1989) and using spreadsheets (Sutherland & Rojano, 1993). Yet one of the greatest obstacles reported concerns the move from recognizing and analyzing a pattern to expressing it symbolically. The MiGen project (1) has developed a microworld, *eXpresser*, designed specifically to support students in generalizing rules based on structure, in this case of the structure of figural patterns of square tiles (Noss et al., 2009). The *eXpresser* microworld includes construction objects and a set of actions that can be carried out on them so that students can build models made up of these patterns and test their generality through animation.

In this paper we focus on the potential of students building a rule that represents the structural regularities of a pattern, while also being able to exploit a symbolism for exploring the performance of the pattern in general. This symbolism is closely tied to the nature of the sign systems made available by *eXpresser* for rule-building. The affordances of *eXpresser* features were directly used in the study reported here in order to design generalization and symbolization activities, which were investigated with groups of secondary school students, aged 11-13, in England and Mexico (2). The study aims to analyze the sense production processes that were triggered when students were on the path toward building a rule, which represented the structure

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

of the patterns that together made their model. Episodes of in-class experimental sessions in which the students were interacting with *eXpresser* were analyzed from the basis of a semiotic perspective in which the notion of Mathematical Sign System (MSS) plays a central role (Puig, 2008).

Theoretical Perspective: Mathematical Sign Systems and Sense Production

Since mathematical texts are produced with a heterogeneous set of signs, the notion of Mathematical Sign System (MSS) dealt with in Filloy et al. (2010) and used in our analysis entails not only the signs considered as specifically mathematical, but also those pertaining to natural language, figures, diagrams, as well as the signs of digital learning environments. Hence that notion of MSS does not refer to a set of mathematical signs organized in a system, but rather to a system of signs –specific to mathematics or not- that is of a mathematical nature (i.e. the system is conceived as of a mathematical nature rather than the individual signs). It is crucial to take the system as a whole because the use (or uses) of the system is the responsible for meaning and sense making. Moreover the notion is not limited to socially established sign systems, but includes signs, sign systems or strata of sign systems that students produce in order to make sense of what is presented to them in a teaching model, in an interview situation or in a mathematics task.

Thus, sense production in mathematics activity comes about by way of chains of reading and transformations of actions that are undertaken on texts expressed in an MSS (Puig, 2003). Thus in the particular case of work with *eXpresser*, our interest lies in analyzing the sense production of students related to the expression of rules that correspond to figurative models built in an environment in which they interact with its MSSs through reading and transformation actions. In *eXpresser,* students have access to increasingly abstract set of MSSs, as evident below.

***eXpresser*: A Digital Microworld to Express Generality**

In *eXpresser*, students are asked to construct a general model and to develop a rule that determines the total number of tiles in the model. The students construct the model by visualizing its structure and determining appropriate patterns of repeated building blocks that together make up the model. The students have to make explicit rules to calculate the number of tiles in each pattern, which are colored if and only if the rule is correct and then combine the rules for the different patterns to obtain the total number of tiles in the model. Of course there is more than one way to construct a model, each of which leads to a "different" rule for the same model.

Figure 1 shows a snapshot of the *eXpresser* with what is known as the Train-Track model already constructed (shown top left of the screen labelers My World). A C-shaped building block (A) has been created (by dragging and dropping separate tiles and grouping them) and is repeated by placing each repetition two squares across and zero places down (When making a pattern, the translations across and down for each repetition of a building block, as well as an initial number of repetitions has to be specified). When the C-shaped building block (A) is made, its properties are shown in an expression (B). The building block is repeated as many times as the value of a variable called ‘Model Number’ (D), in this case 4.

Patterns are colored by calculating and then allocating the *exact* number of colored tiles to its construction. In the case of the pattern made of C-shapes, using the expression for construction (B) and the number of times the building block is repeated, the rule for the total number of tiles in this pattern is ‘7×Model Number’, in Figure 1 (E). As students build their constructions in ‘My World’, a second window is seen alongside (the ‘General World’). This mirrors exactly My World until the student unlocks a number in their model, the metaphor for making a variable, at which point the General World chooses randomly a 'general' value for the variable. In Figure 1, the value of the Model Number in the General World is randomly set to 9, resulting in a different instance of the model (F). The General World is only colored when students express *correct* general rules in the 'Model Rule' area of the screen (G). Students cannot interact directly with the General World. They are, however, encouraged to click the play button (H) to animate their general model to test its generality.

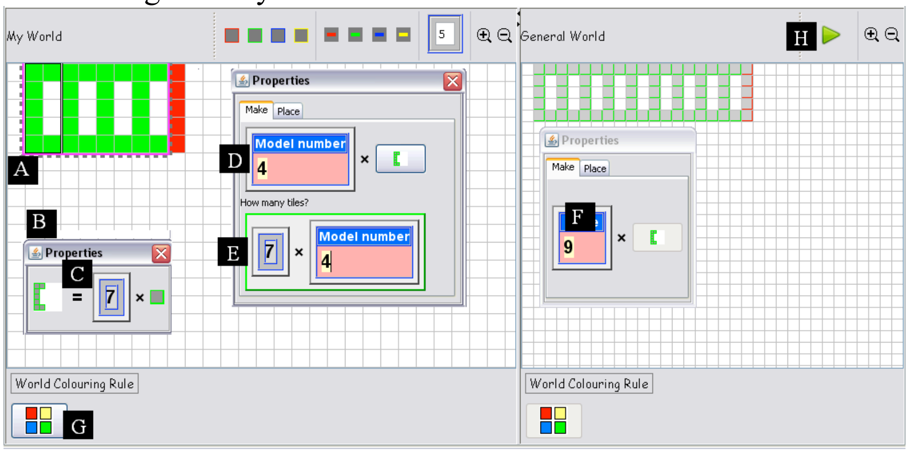

Figure 1. Constructing a model and expressing its rules in *eXpresser*. (A) Building block. (B) Expression of construction of the building block. (C) The number of tiles of the building block. (D) The number of repetitions of the building block. (E) Number of tiles required for the pattern, with general rule. (F) Any variable used in 'My World' takes a random value in the 'General World'. (G) A general rule that expresses the total number of tiles in the whole model. (H) Play button for animating patterns.

The construction objects in *eXpresser* are structurally related to the elements of the symbolic rule as follows: a) the number of building blocks is associated with the variables and constants; b) the number of tiles in each block is associated with the coefficients of the variables in the expression; c) the patterns constitute the terms of the expression; d) and the model is associated with the complete expression. In particular terms in the task referred to in this article, the students were asked to build a model associated with a symbolic expression that had linear and constant terms. In other words, the model had to be made up of several patterns that together would serve to represent a Train-Track model, which, if properly built, could be "extended" as student wanted. The students were asked to use different colors for each of the patterns that made up the model, in order to highlight the way they perceived the structure. The students were also required to answer questions that are aimed at provoking reflection on the model-formula structural relations that they had constructed.

Experimental Work with eXpresser

The data presented in this paper refer to the work of 11 to 13 year old students (14 Mexican and 22 English students) who began to study algebra in secondary school. Although the students worked on several activities throughout the study, this report only includes an analysis of the Train-Track activity. Data was compiled from videotapes of classroom sessions, written reports of the students on worksheets and computer files produced by the students registering their interactions with the software. Our attention was focused on analyzing the role of the different sign systems proposed in *eXpresser* in the sense production processes. In England, the task was presented fully computerized and students answered some reflective questions presented through digital worksheets. In Mexico, the students worked with *eXpresser* and with paper and pencil worksheets.

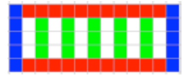
Results – MSSs in eXpresser

In building models, the students moved from working with MSSs associated with visual perception to more abstract MSSs, such as numerical and in some cases algebraic MSSs. During the process it was possible to see how the students made sense of the elements of a symbolic expression by associating them with the specific elements that made up their figurative model. Thus the generalization processes consisted of searching for a structure that could be transformed from the figurative model to a symbolic expression by means of the structure of the task-pattern, and then a rule could be derived based on the perceived structure. Data analysis made it possible to identify critical moments of generalization activity, which characterized aspects of work in *eXpresser* related to the nature of the different MSSs available in the setting. These aspects include, *inter alia*: a) constructing building blocks from unit tiles; b) unlocking numbers in order to vary them; c) numerical articulations among the different patterns that make up the model; d) building model rules using the *eXpresser* language; e) building different patterns based on the perceived structure to produce different models; f) analyzing the relations between the particular construction and the general models that it is possible to see in *eXpresser*. In this paper we focus only in the affordances of *eXpresser* that were designed to aid the transition from pattern construction to arithmetic expression and its transformation to algebraic expression (aspects b) and d), for which we have used analyses of student working on the Train-Track activity.

Building Blocks, Patterns and Models

A building block is an object that belongs to a MSS that is more abstract than that of individual tiles, albeit both are of a figurative nature. First, the students must become aware of the need to determine a building block in order to make a pattern. Analysis of the videotapes and of the files saved automatically by the software when the user interacts with it enabled us to follow up on student actions in their attempts to build their patterns and models. Although the students had no trouble defining the building blocks, records of their work in both countries showed that some had a tendency to simply produce the pattern tile by tile. In this case, they were helped by redirect their attention to the building block they had been in fact implicitly repeating while dragging tiles, thus helping the students identify their own building blocks (see Noss et. al., 2009). Ten different forms of constructing the Train-Track model were identified, see Table 1.

Locked numbers
Unlocked numbers

A	B	C	D	E
1Mexican & 2 English students	4 Mexican & 3 English students	3Mexican students	1Mexican student	1Mexican & 9 English students
				


Two patterns: $5n + 2(n - 1)$	Three patterns: $3n + (2n - 1) + (2n - 1)$	Three patterns: $5n + (n - 1) + (n - 1)$	Five patterns: $3n + (2n+1) + (2n+1) + 5 + 5$	Two patterns: $7n + 5$
F	G	H	I	J
1 English student	1 English student	1 English student	4 English students	1 English student
				Three patterns: $5n + 2n + 5$	Three patterns: $4n + 3(n+1) + 2$	Three patterns: $6n + n + 5$	Three patterns: $4n + 3n + 5$	Two patterns: $7n + 12$

Table 1. Different forms of constructing the Train-Track by students participating in the study. To better communicate each model's structure, in the bottom line the corresponding algebraic rules are shown (*n* is the number of one of the building blocks in the model). It should be noted that this not mean that the participant students could produce such an expression in the algebra MSS.

From Arithmetic Expressions to Algebraic Rules

One important step in the generalization process toward the use of an abstract MSS is that of deriving a symbolic rule (arithmetic or algebraic) that makes it possible to obtain the overall number of tiles in a pattern (dependent variable) in terms of the number of building block repetitions (independent variable). The microworld provides immediate visual feedback when, for a given pattern, the production rule is correct: that is by coloring all of the tiles used in the particular construction (see Figure 2).

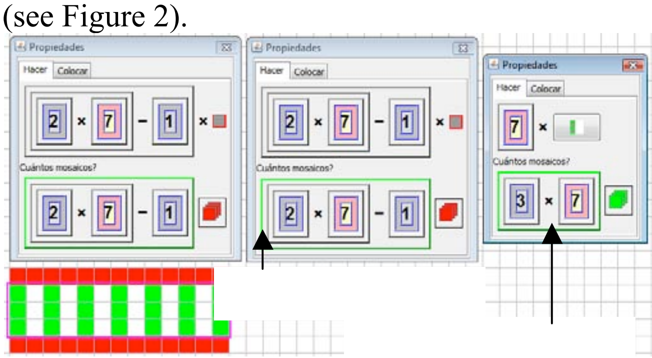


Figure 2. Arithmetic rules for the three patterns that constitute the model (top (red) line), bottom (red) line and vertical (green) line)

Different types of numerical expressions (texts) can be seen in the image on the left of Figure 2, including: locked numbers (constants) and unlocked numbers (generalized numbers) in which the values can change. Identification of the role played by these types of numbers in the figurative model is essential to the construction of algebraic rules. Although indicating the overall number of tiles that constitutes a pattern is sufficient for it to be colored, a rule must be provided in order for the pattern to remain colored for *any* number of repetitions of the building block (so that the Train-Track can, in turn, be extended or reduced). Most students in both Mexico and England used initially a specific number to indicate the number of tiles in each pattern. Despite introductory tasks in *eXpresser*, the persistence of this student strategy shows (unsurprisingly given previous research) a common reluctance to articulate a relationship and to express it in a general way. To overcome, the teacher (3) had to intervene and encourage students to use a building block. The intervention relies on repeatedly changing the variable in the number of repetitions of the building block and therefore 'messing-up' the coloring of the pattern– drawing on the vocabulary used by students in a dynamic geometry setting. The visual feedback challenged students to find a general rule that according to Gregg (one of the students in the English trials) "tells it [the *eXpresser*] how many tiles it needs for any number in the pink [unlocked] box". However, some students (9 in Mexico) when answering the worksheets sometimes but not always made a numerical formula for some of the patterns in the model. For example, Figure 3 shows the work of Sofia indicating two formulas: one with an operation (7×5) and other with a constant number (6) in the case of model C in Table 1. Sofia also forgot to indicate the arithmetic expression for one of the patterns, since the last one was not built with the pattern construction tool, she used the tool copy-paste to include it in the model.

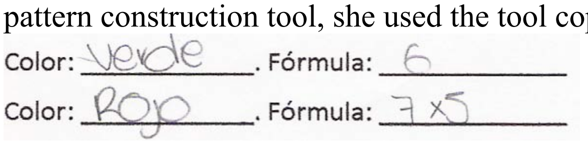

Figure 3. Construction of one numerical formula and one constant to indicate the number of tiles in two patterns (Verde – Green; Rojo – Red)

Eventually, most of the students managed to make symbolical formulae for their patterns, though many were isolated and not interrelated. For example, in the worksheet in Mexico, Diego constructed a formula with two variables (a×5 + 2b), for the model (C) in Table 1 he did not seem to see the relationship between a and b ($b = a - 1$) and it was only after teacher intervention that he (and another two students) were able to construct a formula with one independent variable (see Figure 4).

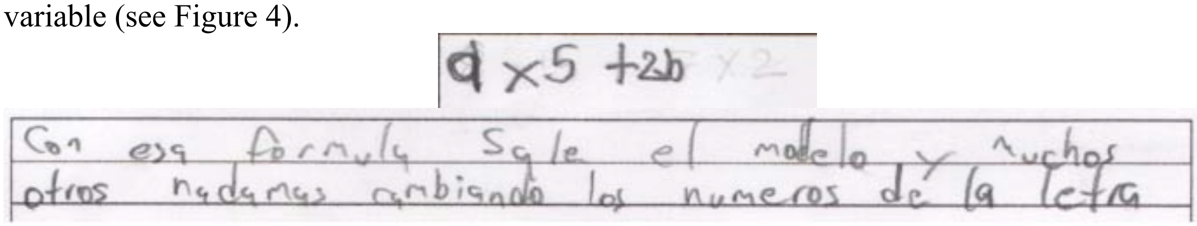

Figure 4. A student's work on expressing the formula to calculate the number of tiles in the Train-Track model. Student writing: "With this formula I get the model and many more when I change the numbers of the letter"

An effective intervention capitalizes on drawing students' attention to the General World. Models that use patterns with more than one independent variable, are 'messed-up' in the General World since, for each variable, the microworld chooses random values likely to be different so the models do not maintain their structural coherence. Figure 5 shows Connor's work, an English student; he has unlocked both the 5 and the 3 as the number of repetitions in his two patterns, but has not specified any explicit relationship between them. The teacher asked him many times to choose several different random values for the number of green building blocks and find the number of red building blocks. Connor painstakingly repaired the model each time when it was no longer colored. He had implicitly identified a relationship but could not express it in general terms. After several repetitions of the same prompt, when the value of repetitions of the green block was 8 and that of the red had to become 15 (2×8 – 1), Connor verbalized his rule: "You times the 8, you times the number of green tiles by 2 […] and then take away 1", and used *eXpresser* to represent explicitly the relationship between the two patterns in his model.

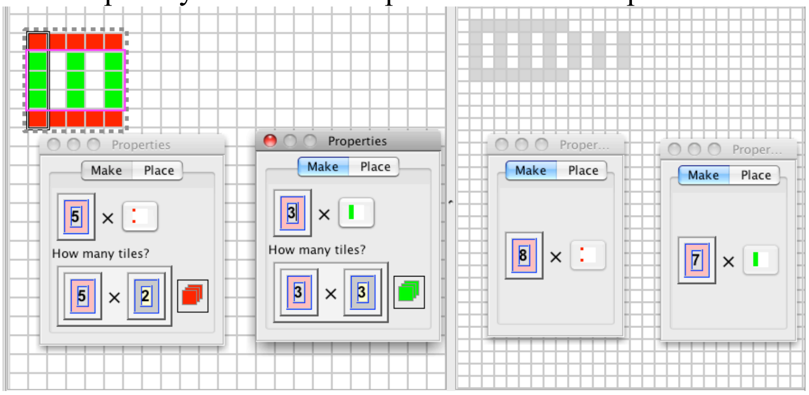

Figure 5. Connor's model is messed-up in the General World

In *eXpresser*, numbers are perceived as objects to which a value can be assigned, that can be locked or unlocked and given a name. Hence, in their capacity of being concrete objects, numbers are associated with one single screen position. If that number is required in order to construct a rule (simply being represented by the same variable is sufficient in the MSS) then it must be a part of two different relations, thus forcing the student to make a copy of it and not simply defining another number (or variable) that has the same value. As such, in Figure 2, the object-number shown with a numerical value of 7 was copied five times in order to construct and relate the rules for the three patterns that make up the model. Determining this fact is one of the most important characteristics of building a formula in the MSS of algebra because the subsequent symbolization only consists of assigning a name to that number.

Differentiating specific numbers from general numbers and number-objects means that *eXpresser* substantially changes the activity of mathematical expression of patterns and thus makes the passage from generalized numbers to use of letters more natural within the digital environment. As such, students are able to reflect upon establishing relations among objects that, despite belonging to different strata of MSSs, all have a figurative referent that enables the students to imbue those relations with sense. We assert that this characteristic made it possible for the majority of students participating in the study to express a rule corresponding to the Train-Track model in an algebra like MSS. Figure 4 shows part of the worksheet of Diego on which he has expressed the formula for calculating the overall number of tiles in the Train-Track model, as well as his interpretation of that formula (expressed in words).

Students in England were asked to reflect on their derived rules in *eXpresser* by writing some arguments to support their rules' correctness or not. A 12 year old student, Nancy, whose model/rule is shown in Figure 6, wrote: "My rule is correct because each "block" has 7 squares. So however many blocks there are, there are 7 squares for each one so you multiply the number of blocks by 7. But, at the end there is another block to finish the pattern off. In this block there are 5 squares so you add the number of squares (the blocks multiplied by 7) to the final block (the 5 squares). This rule should apply to this pattern each time". Nancy showed a good understanding of each term in her derived rule and seemed to understand the generality of her rule. She was able to identify how the coefficients in her rule were derived and expressed clearly what her variable was, i.e. the number of blocks. In her own words, the term ‘any’ was referred to as ‘however many’.

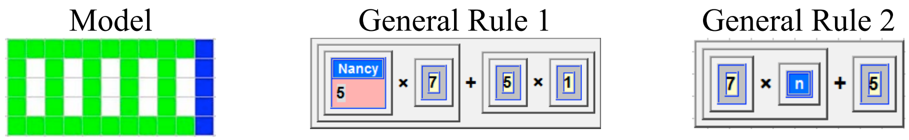

Figure 6. Nancy’s model and rules in eXpresser

Another 12 year old student, Connor (model (B) in Table 1), wrote: “My rule is correct because it worked without fault and the color stayed on the General World. (6×3) + [(6×2)–1] ×2 this is my rule. The 6×3 is the green tiles and how many of the green blocks we need times the how many tiles are in each block. The 6×2–1 is the red tiles and the -1 because otherwise the red tiles would go over how many you need and ×2 at the end is because I’ve got 2 lots of the red”. Even though Connor might think generally, he still used the specific value 6 for his variable when he wrote down his general rule- a generic example maybe. It is evident that he also had a clear understanding of each term in his rule supporting his rule’s correctness by reference to the feedback from the *eXpresser*, i.e. his model stayed colored for any model number.

Discussion

The availability in the environment of an increasingly abstract set of MSS strata to work with specific numbers, general numbers and number-objects made it possible for the students participating in the study to formulate rules that generated different patterns and to inter-relate them by way of one single independent variable. This was we argue a critical moment in a generalization task and helped students to develop and distinguish the notions of independent and dependent variable. We assert that the relationship among these generative rules is the result of the acts of reading and transforming that the students undertake on their own productions in *eXpresser* when trying to formulate one single rule to calculate the total number of tiles in the figurative model that was made up of different patterns. Production of sense arises in those acts with respect to expression of the rule in an algebra-like MSS. Nonetheless some of the students were able express generality in their own and *eXpresser*’s language, but still found it difficult to express it algebraically, a move supported by later collaborative tasks.

Endnotes

1. The MiGen project is funded by the ESRC/EPSRC Technology Enhanced Learning programme; Award no: RES-139-25-0381). For more details about the project see http://www.migen.org.
2. The experimental work in Mexico is funded by CONACYT (Grant No. 80359).
3. In England, the students were supported by either the teacher or the intelligent support component of the MiGen system, which provides prompts based on students’ interactions and helps them reflect and decide about their next step in solving the task

Third- through fifth-grade students participating in a classroom teaching experiment investigating the impact of an Early Algebra Learning Progression completed pre- and post-assessments documenting their abilities to represent or describe unknown quantities. We found that after a sustained early algebra intervention, students grew in their abilities to represent related unknown quantities using letters as variables.

Algebra has historically served as a gateway to higher mathematics that—due to high failure rates—has been closed for many students. These failures have been due in large part to a narrow treatment of algebra as an exercise in symbol manipulation without much regard for the symbols' underlying meanings (Kaput, 1998). Mathematics education researchers (e.g., Davis, 1985; Kaput, 1998; Olive, Izsak, & Blanton, 2002) have argued that addressing this issue requires us to view algebra not as an isolated eighth- or ninth-grade course, but as a continuous strand spanning the entire K-12 curriculum. This is not to be interpreted as a call to shift traditional instruction in symbol manipulation to earlier grades, but rather as one to consider broadening our notions of what it means to think algebraically and introducing elementary school students to important ideas of algebra in the context of their study of arithmetic.

In response to this call, we are presently drawing from research findings and curricular resources in the area of early algebra to develop an Early Algebra Learning Progression (EALP) organized around five "big ideas": 1) Generalized Arithmetic, 2) Equations, Expressions, Equality, and Inequality, 3) Functional Thinking, 4) Proportional Reasoning, and 5) Variable.

We are conducting a one-year classroom-based study in grades 3-5 to gather initial efficacy data regarding the impact of EALP-based classroom experiences on elementary students' developing understandings of these big ideas. The focus of this paper will be our initial findings regarding students' developing understandings of particular aspects of variable. We will share pretest and mid-year assessment data documenting students' performance using variables to represent unknown quantities. We will additionally have end-of-the-year posttest data ready to share at the conference.

Theoretical Framework

While traditional treatments of algebra often present the subject as one about "manipulating symbols that do not stand for anything" (Kaput, 1999, p. 134), we must acknowledge that much of algebra's power comes from the ability to represent unknown and varying quantities succinctly and manipulate these expressions without constant reference to their underlying meaning. The concept of variable must thus play a critical role in early algebra (Schoenfeld & Arcavi, 1988). Schoenfeld and Arcavi argue that rather than asking students to practice symbol manipulation and solving for unknowns, teachers should encourage students to view variables as shorthand tools for expressing already-understood ideas about varying quantities.

Despite its importance, variable is a concept with which many students struggle. Documented difficulties include believing that variables stand for names, labels, or attributes (e.g., *h* stands for height, *w* stands for weight) (Booth, 1988; Clement, 1982; Knuth, Alibali, McNeil, Weinberg, & Stephens, 2005; MacGregor & Stacey, 1997; Weinberg et al., 2004) and being unable to operate with or even consider unknown quantities rather than specific values (Blanton, 2008; Carraher, Schliemann, & Schwartz, 2008).

While variables can take on several meanings in different mathematical contexts (Kieran, 1991; Küchemann, 1978; Usiskin, 1988), in this paper we focus on students' abilities to use variables to represent unknown quantities. We draw from Carraher et al.'s (2008) work, in which third-grade students were asked to represent the number of candies in two sealed boxes—one of which had three additional candies resting on top. The majority of the students initially assigned particular values to the amounts in each box (e.g., 3 and 6), suggesting they were unable to work with indeterminate amounts. Given a similar context, Blanton (2008) found that the presence of unknown quantities led students to consider such problems unsolvable. By drawing attention to multiple possible solutions to the *Candy Box* problem and encouraging students who refrained from assigning particular values to contribute to the discussion, Carraher et al. found that students' representations—which included drawings, tables, and verbal comments—were enriched and that eventually variable representations (e.g., N and $N + 3$) were accepted.

Kinzel (1999) asserts that students' difficulties with algebraic notation originate from narrow conceptions of variable (e.g., viewing the symbol as a label) and that if algebra is to be viewed as a meaningful representational tool, further attention should be given to symbolizing and interpreting variables in classrooms. Carraher et al.'s (2008) work illustrates that young elementary students are capable of representing unknown quantities in sophisticated ways when these representations build on their informal representations and understandings.

Method

Participants

Participants include 301 students in grades 3-5 from two elementary schools in southeastern Massachusetts. The school district in which these schools reside is largely white (91%) and middle class, with 17% of students qualifying for free or reduced lunch. Six classrooms (two from each of grades 3-5 and all from one school) are serving as experimental classrooms and 10 classrooms (four grade 3, four grade 4, and two grade 5, all from both schools) are serving as control classrooms.

Classroom Intervention

Students in the experimental condition are participating in an EALP-based classroom teaching experiment for approximately one hour each week for the majority of one school year. A member of our research team—a former third-grade teacher—is serving as the teacher during these interventions. Additionally, each lesson is observed by a member of the research team as a way to identify characteristics of students' thinking and issues of instructional design. The project team also meets twice weekly, once on-site to discuss initial observations about the teaching experiment, and once off-site to connect initial findings to the proposed EALP and revise the EALP. A typical one-hour lesson consists of a "jumpstart" at the beginning of class to review previously-discussed concepts, followed by group work centered on research-based tasks aligned with our EALP (see Figure 1 for an example). These tasks are designed to encourage students to reason algebraically in a variety of ways and justify their thinking to themselves and their classmates. All classroom tasks and assessment items presented in this paper are adapted from Carraher et al. (2008).

> Jack and Ava both have a box of candy. Each box contains the same number of pieces of candy, but we don't know how many in each. Ava is given four more pieces of candy.
>
> a) How could you represent the number of pieces of candy Jack has?
> b) How could you represent the number of pieces of candy Ava has?

Figure 1. The Candy Boxes task

Students in the control condition are participating in their usual classroom activity with their regular classroom teachers. District-wide, all classroom teachers are using "Growing with Mathematics" (Iron, 2003) curriculum materials. This curriculum does not include a particular focus on early algebra or tasks similar to the ones included in our intervention.

Data Collection

A pretest and (identical) posttest along with a shorter "mid-year" review were designed to measure students' understandings of algebraic topics identified across the five "big ideas" in the EALP. The constructs measured on our assessments are closely linked to the EALP. Item construction was research-based where multiple internal reviews of all assessment items were conducted by the authors in order to ensure consistency, coherence, and fidelity to that of the constructs mentioned in the EALP.

From these assessments, we will focus in this paper on two tasks—the *Piggy Bank* task from the pretest/posttest (see Figure 2) and the *Silly Bands* task from the mid-year review (see Figure 3)—that investigated students' abilities to represent unknown quantities in relation to other unknown quantities.

> Tim and Angela each have a piggy bank. They know that their piggy banks each contain the same number of pennies, but they don't know how many. Angela also has 8 pennies in her hand.
>
> a) How would you describe the number of pennies Tim has?
> b) How would you describe the total number of pennies Angela has?

Figure 2. The Piggy Bank task

> Carter and Jackson each have the same number of silly bands, but we don't know how many they have. Carter earns 3 more silly bands for cleaning her room.
>
> a) How would you represent the number of silly bands Jackson has?
> b) How would you represent the total number of silly bands Carter has?

Figure 3. The Silly Bands task

The pretest was administered to all participants prior to the start of the teaching intervention in early September 2010. The posttest will be administered at the intervention's conclusion, in May 2011. In this paper, we will be able to share results of the pretest and the mid-year review administered in late November 2010, after eight intervention lessons. Because the purpose of this mid-year review was to offer the research team formative feedback on the impact of the intervention, it was only administered in the experimental classrooms. As such, our focus in this paper will be exclusively on the experimental students' growth representing unknown quantities as evidenced in their performance on the aforementioned assessment items. A more complete experimental-control comparison will be included in the presentation as we will have posttest results to share by that time.

Data Analysis

Each item on the pre-test and mid-year review was first scored dichotomously (i.e., correct or incorrect). A response was scored as correct if a variable expression was written that correctly conveyed the given relationships (e.g. Jackson has J silly bands; Carter has $J + 3$ silly bands), if a correct statement was made about the relationship between the items in question (e.g., "Carter has 3 more silly bands than Jackson" or even "Carter has more silly bands than Jackson"), or if a student stated a need to use a variable but did not specify a particular one (e.g, "I would represent Tim's number of pennies with a letter"). In addition, there were a few instances in which students wrote equations rather than just expressions that were scored as correct (e.g., "Jackson has $a + 3 = b$"). Equations such as $a + 3 = a$ were scored as incorrect because the same variable was used to represent two different quantities.

Next, each item on the pre-test and mid-year review was given an appropriate strategy code. For part a on both assessments, responses were assigned the code *Letter* if a student used a variable to represent the unknown quantity (e.g., "Tim has x candies"), *Value* if a student assigned a specific value to the unknown quantity (e.g., "4 candies"), and *Picture* if a student drew a picture to represent the unknown quantity. Student responses in which the quantities in the task were compared using words and specific quantities (e.g. "Tim has 8 fewer pennies than Angela") were coded as *Comparison with Quantity.* Responses in which comparisons were made using words but no specific quantities (e.g., "Tim has fewer pennies than Angela") received a *Comparison without Quantity* code.

Responses to part b were coded in the same way as part a, with additional attention paid to whether the responses were related to part a or independent of part a. For example, if a student responded that "Tim has x pennies" in part a and "Angela has $x + 8$ pennies" in part b, this second response would receive the code *Related Letter*. If, instead, a student responded that "Angela has y pennies," this second response would receive the code *New Letter*. "I don't know" or blank responses received a *No Response* code, and all other responses were coded as *Other*. A chi-square analysis was conducted to check for a significant association between the correctness of responses on the pre-test as compared to the related mid-year review item.

To assess reliability of the coding procedure, a second member of the research team coded a randomly selected 20% sample of the pre-test data. The mid-year review data was fully scored by two coders. Pre-test scoring agreement between coders was 92% for both correctness and strategy on part a and 90% for correctness and 92% for strategy on part b. Mid-year scoring agreement between coders was 87% for correctness and 82% for strategy on part a and 81% for correctness and 84% for strategy on part b. All differences in scoring were discussed by the coders and resolved.

Results and Discussion

In this section, we report experimental student results from the *Piggy Bank* task (see Figure 3) and the *Silly Bands* task (see Figure 4). There was a significant association between the correctness of responses for all items on the pre-test as compared to the mid-year review. For part a, $\chi^2(1) = 85.85$, $p < .001$ where it was 15.08 times more likely for a participant to get *Silly Bands* part a correct on the mid-year review than to get *Piggy Bank* part a correct on the pre-test. For part b, $\chi^2(1) = 52.33$, $p < .001$ where it was 7.46 times more likely for a participant to get *Silly Bands* part b correct on the mid-year review than to get *Piggy Bank* part b correct on the pre-test. Both results were statistically significant.

Percent of students who gave correct response and percent of students who used a variable correctly on part a on Piggy Bank and Silly Bands tasks

	Grade 3	Grade 4	Grade 5
Piggy Bank (Pre-test)	(n = 39)	(n = 42)	(n = 42)
Gave correct response	5.1%	23.8%	33.3%
Used variable correctly	0%	0%	0%
Silly Bands (Mid-year)	(n = 39)	(n = 41)	(n = 41)
Gave correct response	79.5%	80.5%	80.5%
Used variable correctly	61.5%	63.4%	68.3%

Table 1. Part a results

Percent of students who gave correct response and percent of students who used a variable correctly on part b on Piggy Bank and Silly Bands tasks

	Grade 3	Grade 4	Grade 5
Piggy Bank (Pre-test)	(n = 39)	(n = 42)	(n = 42)
Gave correct response	5.1%	23.8%	35.7%
Used variable correctly	0%	0%	0%
Silly Bands (Mid-year)	(n = 39)	(n = 41)	(n = 41)
Gave correct response	66.6%	70.7%	68.3%
Used variable correctly	51.3%	48.9%	58.5%

Table 2. Part b results

From Tables 1 and 2, one can see that students initially struggled to produce correct representations or descriptions of unknown quantities, even with very liberal criteria. None of those students who did produce a correct representation or description used variables to represent the unknown. However, a majority of participants at all grade levels were able to use a variable correctly on part a and close to over half were able to use a variable correctly for part b by the time of the mid-year review. Furthermore, participants tended to use the same variable in part b of the *Silly Bands* task that they used in part a, showing an ability to consider the relationship between two unknown quantities. Tables 3 and 4 show the percent of students using the previously-discussed strategies in response to the pre-test and mid-year review tasks.

Percent of students using each strategy in response to part a on Piggy Bank and Silly Bands tasks

	Grade 3		Grade 4		Grade 5	
Strategy	*Piggy Bank* (Pre-test)	*Silly Bands* (Mid-year)	*Piggy Bank* (Pre-test)	*Silly Bands* (Mid-year)	*Piggy Bank* (Pre-test)	*Silly Bands* (Mid-year)
Letter (as variable)	2.6%	89.7%	0%	75.6%	0%	85.4%
Value	33.3%	5.1%	45.2%	12.2%	42.9%	4.9%
Picture	0%	0%	0%	2.4%	0%	4.9%
Comparison with Quantity	5.1%	5.1%	11.9%	9.8%	23.8%	4.9%
Comparison without Quantity	0%	0%	11.9%	0%	7.1%	0%
Other	5.1%	0%	14.3%	0%	16.7%	0%
No Response	53.9%	0%	16.7%	0%	9.5%	0%

Table 3. Part a strategies

First, in response to part a, note that participants demonstrated no prior knowledge of representing an unknown quantity using variables, preferring instead to assign specific values. However, by the time of the mid-year assessment, at least 75% of students at all grade levels attempted to represent the unknown quantities using a variable, with the majority of them doing so correctly. We had predicted that students would use a pictorial representation (e.g., a piggy bank) or an empty box to represent an unknown amount, especially prior to instruction. However, only a small number of these pictorial and box representations surfaced. The decline in *No Response* codes was dramatic, especially in grade 3.

Percent of students using each strategy in response to part b on Piggy Bank and Silly Bands tasks

	Grade 3		Grade 4		Grade 5	
Strategy	*Piggy Bank* (Pre-test)	*Silly Bands* (Mid-year)	*Piggy Bank* (Pre-test)	*Silly Bands* (Mid-year)	*Piggy Bank* (Pre-test)	*Silly Bands* (Mid-year)
Related Letter	2.6%	59.0%	0%	53.7%	0%	61.0%
New Letter	0%	28.2%	0%	22.0%	0%	26.8%
Related Value	25.6%	2.6%	35.7%	9.8%	35.7%	4.9%
New Value	18.0%	5.1%	11.9%	4.9%	2.4%	0%
Related Picture	0%	0%	0%	2.4%	0%	2.4%
New Picture	0%	0%	0%	0%	0%	0%
Comparison with Quantity	5.1%	0%	16.7%	7.3%	21.4%	4.9%
Comparison without Quantity	0%	5.1%	7.1%	0%	9.5%	0%

No Response	41.0%	0%	14.3%	0%	14.3%	0%

Table 4. Part b strategies

In response to part b, we noted a shift in responses from assigning a specific value on the pre-test (related or non-related to the response in part a) to using a variable on the mid-year review. Well over half of participants across the grades wrote an expression using the same variable used in part a, with the majority doing so correctly. No students left this task blank or responded with "I don't know" on the mid-year review.

One particular category of response caught our attention. Some participants used variables but represented the unknown quantities with equations rather than expressions. For example, in response to the *Piggy Bank* task, one student represented the number of Angela's pennies as $n + 8 = n$. Such a response recalls Booth's (1988) assertion and Carraher et al.'s (2006) similar finding that students may struggle with "lack of closure" and feel the need to "simplify" or come to a "single term" answer. Such students appear to have difficulty holding operational and structural views of expressions simultaneously. As Linchevski and Herscovics (1996) suggest, expressions such as $n + 8$ are difficult for students because the addition operation cannot be performed. The expression must be viewed as the result of the operation and not merely a process. This tendency among some students to write incorrect equations was present even after several months of our instructional intervention, with 10.3%, 4.9%, and 2.4%, in grades 3, 4, and 5, respectively, answering in this manner on the mid-year review.

Conclusion

As Blanton (2008) asserts, "It is as children work with symbols that they acquire meaning for them. They will experience a natural progression in their thinking that begins with a limited understanding of symbols and symbolizing" (p. 66). While students initially exhibited great difficulty representing unknown quantities in a general way (i.e., without assigning a specific value), over half of our participants at each grade level exhibited the ability to use a variable to represent an unknown quantity by the time of the mid-year review. While we have indications that several students had difficulty viewing variable expressions as objects not in need of further simplification, overall the majority of students seem to be learning to use variables in meaningful ways that were unknown to them at the start of the school year.

The goal of this study was to understand errors that student make when simplifying exponential expressions. College students enrolled in four college mathematics courses were asked to simplify and compare such expressions. Quantitative analysis identified three persistent errors: interpreting negative bases, negative exponents, and parentheses. Qualitative methods were used to examine why they made these errors. Analysis indicated that students frequently misinterpret the negative sign when attached to the base of an exponential expression. We theorize that students' concept image of the negative sign must move beyond rule models to correctly interpret numbers in exponential expressions.

Students entering post-secondary schools often need frequent reminders on how to use algebraic properties while solving problems in pre-calculus and calculus classes. Algebra provides the foundation to advanced mathematical thinking; and proficiency in algebraic manipulations is essential for students if they want to enter STEM careers (Liston & O'Donoghue, 2010). The terminology and rules of algebra contain little meaning to many students and appear arbitrary (Demby, 1997; Kieran, 2007). Rules are memorized and are considered to be similar to the rules of a game. Many students have difficulty keeping track of memorized rules that appear to be contradictory at times.

Interpreting the equal sign is one example that has been studied extensively. For example, Knuth et al. (2006) found that an operational conception of the equal sign, the idea that the equal sign was a signal to do something, was more commonly held among middle school students than a relational conception of the equal sign. Students with a relational conception understood the equal sign as representing congruence between the expressions on either side of the equal sign. They found middle school students with the relational understanding were much more successful at solving algebraic equations. Thus, the misconception of the equal sign as a prompt to do something interfered with students' mathematical development.

Carraher and Schliemann (2007) described the difficulties students have bridging arithmetic to algebra and in particular interpreting mathematical symbols. Kieran (2007) expanded those notions by further discussing the development of algebraic thinking in middle and high school. She noted that considerable research exists that describes the ways in which students use variables, expressions, and equations. However, there is relatively little research on students' interpretation of the negative sign which is interpreted as either an operation (subtract) or a negative number. This research paper is part of an on-going study in which the authors are examining pedagogical approaches and interventions that increase precalculus students' achievement. Here we investigate how college students interpret a negative sign that is embedded in exponential expressions.

Previous Research

Students must overcome numerous obstacles to become fluent in algebra, including the interpretation of operations implied by the positioning of symbols next to each other (Lee & Messner, 2000). Research (Chalouh & Herscovics, 1983) on concatenations indicated that many students had difficulty interpreting both mixed numbers where addition is implied or algebraic expressions of the form *3a.* After many years of high school experiences learning that multiplication was implied in concatenations (*3a*), some college students applied multiplication with mixed numbers. They simplified $3\ \frac{2}{3}$ to be $3 \times \frac{2}{3} = 2$. Clearly, these students over generalized one set of meaning that is appropriate for expressions like *3a.* Matz (1980) noted that many students did not know how to interpret a negative sign and exponents. For example, students frequently confuse whether -3^2 is 9 or -9.

Vlassis (2004) examined how middle school students interpreted negativity. The eighth-grade students conceptualized negativity as a process, linked to the binary operation of subtraction. Negative nine made sense to these students, for example, in an expression such as $n - 9$ but -9 was more difficult to explain. She concluded that the different uses of the negative sign are counterintuitive and an obstacle for students to overcome.

Teachers often use a textbook to guide their instruction; Lee and Messner (2000) examined opportunities for students to work with the negative sign in sixth- through ninth-grade mathematics curricula. Lee and Messner found that textbooks typically provide multiple opportunities to work with positive and negative integers but seldom offer experiences with negative fractions, exponents, decimals, and mixed numbers. To support students' understanding of $-n$, some textbooks use colored chips in which red is negative and black is positive (wikiversity, 2010). For example, to combine -9 and $+4$, students take nine red chips and four black chips. The four black chips annihilate four of the red chips with the result of five red chips, negative five. Here, students develop the notion that the negative sign indicates an entity that neutralizes a positive chip with the net result of zero.

We theorize that students encounter the notion of additive inverse but it is not always clearly articulated or connected to the idea of an identity. Without discussion on the different interpretations of the negative sign, many students have difficulty interpreting the negative sign in concatenations. Kieran (2007) suggests that additional research is needed to understand the reasons for this difficulty.

Theoretical Framework

A mathematical concept can be thought of as a complex web of ideas constructed by each individual from mathematical definitions and mental constructs (Tall & Vinner, 1981; Vinner, 1992). Tall and Vinner described these two components as concept definition and concept image. A concept definition is a set of words that is used to specify the concept. The definition may be phrased in language accepted by the mathematical community or in everyday language taught by teachers who create short mnemonics to help students remember procedures.

For example, teachers and textbooks often use the phrase *opposite of* rather than the mathematical term *additive inverse* to describe the relationship between a number, its negative and the additive identity, zero. A concept image includes "all of the mental pictures and associated properties and processes." (Tall & Vinner, 1981, p. 152). For additive inverse, the image may include $4 + (-4) = 0$ as (a) four jumps to the right and then 4 jumps to the left on a number line or (b) two numbers positioned equidistant but on the opposite side of zero on a number line. Thus, the concept of additive inverse is a synthesis of the concept definition and images associated with it. Vinner (1992) suggested that individuals create idiosyncratic images that may interfere with the development of new concepts.

Concepts develop over time and are important for advanced mathematical thinking (Tall, 1991). They allow for generalization, inference, different levels of abstraction, cognitive economy, and communication (Palmeri & Noelle, 2003). Palmeri and Noelle theorized that a concept image becomes more sophisticated through three stages: rule model, prototype model, and exemplar model. During the stage of the *rule model*, conceptual rules are carefully worded definitions that are internalized by students and used to carry out procedures or to determine whether an object is a member of a set. The *prototype model* indicates the stage in which an individual recognizes nuances that distinguish individuality among the members of a set. For example, if we consider the set of all triangles, members may look quite different with different side lengths and angles; however, all have exactly three sides. These images become prototypes that allow the individual to check whether an object is a member of the set. Through the prototype model, the concept image becomes more sophisticated and includes both a concept definition and a variety of concept images that illustrate diversity. The *exemplar model* enables individuals to synthesize information about both the commonality and variability of category exemplars and indicates a structural understanding of the concept. Through the exemplar model, the concept image becomes yet more complex and the concept definitions and images are intertwined. For example, students in this stage might recognize how changing the coefficients of a function changes features of its graph. The individual compares the symbolic representation with prototype images and manipulates the images in such a way to describe the effect of the new coefficients. The individual is aware of the nuances between different members and can modify them at will through an understanding of the underlying mathematical structure.

Methods

For this study, we assessed 904 students enrolled in college algebra, pre-calculus, and first and second semester calculus for their ability to simplify and compare exponential expressions. The assessment contained 19 problems involving exponential expressions. Quantitative methods were used to identify the problems that a large number of students missed across the four class levels. There were four problems in which more than 40% of students at all levels solved incorrectly. We labeled these problems as indicators of persistent errors.

To understand why students consistently made these errors, we sought to interview 50 students. However, only 19 students agreed to the interview with a $10 stipend paid for the half-hour interview. These 19 students were enrolled in college algebra, pre-calculus or calculus 2. During the interview, students were asked to read and resolve each of the four problems and explain their reasoning aloud as they solved them. Questions were asked to help identify the concept definitions and images that students used while solving the problems. Conceptual cross-case matrix analysis (Miles & Huberman, 1994) was used to characterize students' explanations to identify commonalities among student explanations.

Findings

Through quantitative and qualitative analysis, three persistent errors emerged around the following concepts: interpretation of a negative sign preceding a base; the role of parentheses in an exponential expression; interpretation of a negative exponent. This paper is based on our qualitative analysis of the first two errors which are related. Students' difficulty distinguishing between a negative number raised to a power and the additive inverse of a number raised to a power became evident by examining their explanations of three problems. Two of the problems required students to simplify exponential expressions and the third problem involved comparing two exponential expressions.

Interpretation of a Negative Sign Preceding a Base

Two problems on the assessment required students to simplify an expression where either a negative sign preceded the base or was part of the base. One asked students to simplify $(-8)^{2/3}$ and the second to simplify $-9^{3/2}$. All of the students who incorrectly simplified the first problem read, "Negative eight raised to the $\frac{2}{3}$ power." Most of the students who incorrectly simplified the second problem read, “Negative nine raised to the $\frac{3}{2}$ power.” Other variations of the second problem were, “I’m not sure how to read that [pointing to $-9^{3/2}$]. It’s different from that [pointing to $(-8)^{2/3}$] because it has parenthesis.” and “I never know whether the negative sign is included.” The reading of these two problems with a negative sign was similar. Students read both problems as if the negative sign was part of the base. They did not differentiate when the negative sign indicated the additive inverse or a negative number. Only one student who misread the expression proceeded to solve the problem correctly. She wrote on her paper, “ $-9^{3/2} = -\sqrt{9^3} = -\sqrt{9 \times 9 \times 9} = -\sqrt{81 \times 9} = -\sqrt{729}$.” She did not finish simplifying the expression because she “always used a calculator.” It is interesting to note that she did not find the square root of nine before cubing it. We interpreted her solution strategy as a reliance on rules, first raise the base to the indicated exponent then find the root of the number.

All of the other students who misread $-9^{3/2}$ and attempted to solve it made the same error. They interpreted the negative sign as attached to the nine before any power was taken. They wrote “$\sqrt{-9^3}$” or stated that the answer was an imaginary number and could not be solved. Four students further simplified $\sqrt{-9^3}$ and their answers resulted in: $3i$, $i\sqrt{729}$, or $(3i)^2 = -81i$. Clearly, they made additional errors in simplifying the expression; however, the error we were most interested in was the initial one of interpreting $-9^{3/2}$ as $(-9)^{3/2}$ rather than the additive inverse of $9^{3/2}$.

Two students correctly interpreted the expression, $-9^{3/2}$. One pre-calculus student correctly stated the steps to follow to simplify it, “Take nine then cube it, then square root it, then make it negative.” She read the problem by translating it into the procedure to simplify the problem rather than the more precise reading that a calculus student made, “Take the negative of nine to the $\frac{3}{2}$ power.” Both of these students recorded the correct answer.

Only one student we interviewed recognized that taking the square root first and then cubing the result would make the computation easier. It appears most students learned an order of operation that begins with applying the power indicated by the numerator in the exponent followed by computing the root indicated by the denominator in the exponent regardless of the efficiency of this order.

Role of Parentheses in Exponential Expressions

The assessment required students to compare two expressions, $(-17)^8$ and -17^8. Five of the 19 students interviewed had a correct answer and gave a similar explanation, “Negative 17 to the eighth [pointing at $(-17)^8$] is larger than negative 17 raised to the eighth power [pointing at -17^8] because the [even] power of a negative number is positive. Negative 17 to the eighth [pointing at $(-17)^8$] is a positive number and larger than negative 17 to the eighth [pointing at -17^8].”

In contrast, the students who were incorrect read both expressions as “negative 17 to the eighth” claimed that these two numbers were equal. Six students stated, “Parentheses don’t matter.” When probed, they explained that parentheses matter only when there are more terms. With additional terms, the parentheses indicate what operations should be completed first. One student reasoned, “Parentheses tell you the order of operation, what needs to be done first. You only need them for something like $4(17-9)$. They tell you that you have to subtract before multiplying.” The other students who gave incorrect answers explained that both expressions were raised to an even exponent and thus both were positive and that –17 and 17 were the same distance from zero, thus the same. Clearly, the concept image of $(-17)^8$ and -17^8 were identical because –17 and (–17) had identical meaning.

The probing questions that we asked about whether the two numbers were the same prompted one calculus student to retrieve a kernel of forgotten mathematics. Reflecting, he explained that -17^8 could be thought of as -1×17^8. Thus it was a negative number and smaller than the other expression. Immediately after completing this problem, he said, “I made a mistake. I don’t know why I did that. I saw the negative sign in that problem [pointing to $-9^{3/2}$] and the square root and automatically wrote it off.” At this point, he went back and correctly simplified the previous expression, $-9^{3/2}$. We suspect that the reason for his mistake was not an oversight, rather it indicated an important misconception that was linked to his concept image of negative numbers. The negative sign was irrevocably linked to a number and was interpreted as an indicator of a negative number unless it followed a number or variable.

Discussion

Consistent with findings of previous researchers (Chalouh & Herscovics, 1983; Lee & Messner, 2000; Matz 1980), college students in this study had difficulty interpreting the negative sign in concatenations. Many students did not distinguish a negative number raised to a power from the additive inverse of a number raised to a power. Their concept image was limited to a rule model in which they carried out a procedure to interpret any number with a negative sign, regardless of other mathematical symbols that were next to it. The concept image of $-n$ was limited to a negative number and its meaning did not change when it was raised to an exponential power.

Parenthetically, none of the students that we interviewed used the language of additive inverse when discussing problems on the assessment. Conceptualizing -9 as an additive inverse of 9 suggests a relational interpretation; however, students frequently failed to extend this relational understanding to more complex expressions. In particular, they failed to recognize the symbol $-9^{3/2}$ as the additive inverse of $9^{3/2}$. However, in an operational context such as $1 - 9^{3/2}$, students recognized that $9^{3/2}$ was to be subtracted from the number one. In this mathematical context, students first simplified the exponential expression then found the difference.

When asked if there is an inconsistency between these two interpretations, these college students explained that “…the minus sign means to minus when a number precedes it.” Here it is clear that many students may not think of the negative sign as indicating an additive inverse that can be applied to more complex expressions. Without recognizing the mathematical meaning of an additive inverse that is linked to the concept of an additive identity, these students did not develop a more sophisticated concept image of the negative sign. In addition, this may explain why students do not recognize n^{-1} as the multiplicative inverse of n.

Removed from a procedural context, students tend to misinterpret the symbol $-9^{3/2}$. Negative numbers become mathematical objects that are located on the number line. The associated concept image of a negative number is a dot on the number line to the left of zero, equidistant from zero as its positive counterpart. Students fail to separate the negative sign and the base, it becomes an inseparable object. This was made explicit by several of the students as they explained the meaning of -17^8 and $(-17)^8$. Students interpreted both expressions as a negative number that is raised to the power 8. To them, the parentheses were unnecessary because the negative sign and 17 are combined to form an inseparable object, -17. They correctly recognized -17 and (-17) as the same mathematical object but erroneously extended this to -17^8 and $(-17)^8$. The rule for interpreting a negative sign was resistant to recognizing that its meaning can change when other mathematical symbols are added.

The concept image that these college students developed was different from the eighth-grade students in Vlassis's (2004) study. Vlassis found that the eighth-grade students interpreted negativity as the operation of subtraction. They saw the negative sign as an indication to conduct a procedure. In contrast, the college students in our study interpreted negativity as a mathematical object or entity with a distinct location on a number line. These students associated the negative sign as an operation when it was preceded by a number. In this case they interpreted it differently. Thus, in one sense, these college students were moving toward a concept image with two definitions. We theorize that simultaneous recognition of these two concept rules would lead to a prototype model in which students recognize similarities and differences in the concept images. Thus, they could select the appropriate concept image for a given context. Integration of these images would lead to an exemplar model and students could flexible apply these images in different concatenations. Students using an exemplar model would understand the function of the negative sign to indicate the multiplicative or additive inverse of a number and extent this meaning to more complex situations.

We theorize that students' concept image of negative numbers is not sufficiently well developed to enable them to recognize the negative sign as a relational concept (additive inverse) when the number in question involves an exponent. However, if the number is embedded in an operational context, they generally interpret it correctly.

From our experience, this problem continues to show up in advanced mathematics classes. Students interpret $-x$ as a negative number regardless of the value of x. For example, if students are told that (a, b) is a point in Quadrant II then asked, "In which quadrant does the point $(-a, b)$ lie?" they fail to interpret $-a$ as a positive number. We theorize that it is critical for students to develop a more sophisticated concept image of $-x$ that includes the concept definitions of a negative number and the additive inverse to correctly interpret the negative sign in concatenations.

Implications

The goal of this research project was to understand the fundamental reasons why students have difficulty simplifying exponential expressions. We found that a limited concept image of a negative number was a confounding factor. This inflexible image led students to misinterpret the negative sign in concatenations. We suggest that teachers need to introduce the language of "additive inverse" and "multiplicative inverse" into the class room to help student develop a more sophisticated understanding of the negative sign. In addition, students need more time investigating the interpretation of the negative sign in different concatenations.

We found it interesting that eighth-grade students in Vlassis's (2004) study created a concept image of negativity as an operation. As students mature this image seemed to be replaced by negative numbers as entities unless it was preceded by another mathematical expression . Additional research is needed to understand how students' concept of negativity develops over time. The goal is to help students create more sophisticated concept images that are based on exemplar models rather than rule-based models. We agree that colored chips can be helpful to students as they investigate the meaning of the negative sign but over reliance on one interpretation of the negative sign can hinder students' development of a more sophisticated concept image. They need to spend more time on different interpretations of the negative sign in concatenations. This can be accomplished by creating mathematical contexts that produce cognitive conflict forcing students to reexamine their prototypes for consistency. Continued research is needed to better understand the reasons behind persistent errors that students make when interpreting the negative sign in this and other contexts.

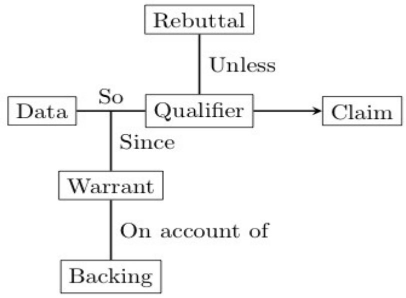
We observed a student teacher's practice as she taught one unit of instruction. Using a modification of Toulmin's (1958/2003) diagrams, we analyzed her support for collective argumentation by examining questions she asked, parts of arguments she contributed, and the kinds of warrants her students contributed. Our findings suggest reasons she was identified as an exemplary student teacher and support moves that may be applicable to other teachers' practice.

As part of a larger study, we observed several student teachers as they each taught one unit of instruction. Our research team identified one of the student teachers, Bridgett (a pseudonym), as exhibiting practices more commonly seen in experienced teachers. Bridgett's facility for engaging in frequent, prolonged, and mathematically significant discourse with her students presented an opportunity for investigation into how collective argumentation might be supported by teachers. In this paper, we characterize her teaching moves in support of collective argumentation to answer the following question: In what ways did an exemplary student teacher support collective argumentation as she taught a geometry unit?

Background

Recent work in mathematics education has highlighted argumentation as an important part of classroom discourse. Building on Toulmin's (1958/2003) model of argumentation, mathematics educators, following Krummheuer (1995), examined collective argumentation in classroom settings. Collective argumentation involves people arriving at a conclusion, often by consensus. This avenue of research is an extension of Toulmin's work, as he examined argumentation in the traditional sense of one person convincing an audience of the validity of a claim. Some work in mathematics education examines individual construction of arguments (e.g., Hollebrands, Conner, & Smith, 2010; Inglis, Mejia-Ramos, & Simpson, 2007), but we build on studies addressing collective argumentation. Current work in collective argumentation involves examining student learning through this lens (Krummheuer, 2007) as well as examining how ideas become "taken as shared" (Rasmussen & Stephan, 2008).

An argument, as described by Toulmin (1958/2003) and currently used in the field, involves some combination of claims (statements whose validity is being established), data (support provided for the claims), warrants (statements that connect data with claims), rebuttals (statements describing circumstances under which the warrants would not be valid), qualifiers (statements describing the certainty with which a claim is made), and backings (usually unstated, dealing with the field in which the argument occurs). Toulmin conceptualized an argument as occurring with a specific structure (see Figure 1) in which these parts of arguments relate to one another in specific ways. In practice, arguments are often more complicated in that, for example, statements offered as data may also need support, thus functioning as both data in one argument



and a claim in a sub-argument[1].

Figure 1: Diagram of a Generic Argument (adapted from Toulmin, 1958/2003)

Our research answers Yackel's (2002) call to examine the teacher's role in collective argumentation by focusing on both the parts of arguments he or she provides and the teaching moves that prompt or respond to parts of arguments provided by students. Previous research has shown that facilitating mathematical discussions, of which collective argumentation is a part, is difficult for teachers, particularly when students have been engaged in tasks that may have multiple solution paths (Hufferd-Ackles, Fuson, & Sherin, 2004; Stein, Engle, Smith, & Hughes, 2008). Hufferd-Ackles et al. suggested creating a "math-talk learning community" (p. 81) in a classroom as one way to ameliorate the difficulties of facilitating productive discourse, while Stein et al. described five practices that are useful when facilitating discourse particularly around cognitively demanding tasks. Our research examines the role of one student teacher as she and her students engage in collective argumentation.

Methodology

We observed and videotaped one exemplary student teacher, Bridgett, for seven consecutive class periods, covering the bulk of a geometry unit within an integrated and accelerated freshman mathematics course. Members of the research team transcribed each of the video recordings. Field notes, class video recordings, and relevant written class materials supplemented the transcripts. We identified and diagrammed episodes of argumentation within the transcripts, purposefully ignoring non-mathematical classroom talk and arguments that were largely definitional (such as deciding how many sides a nonagon has) or pedagogical in nature. Individual or paired members of the research team created diagrams, and the entire team vetted each proposed diagram after intense discussion and frequent

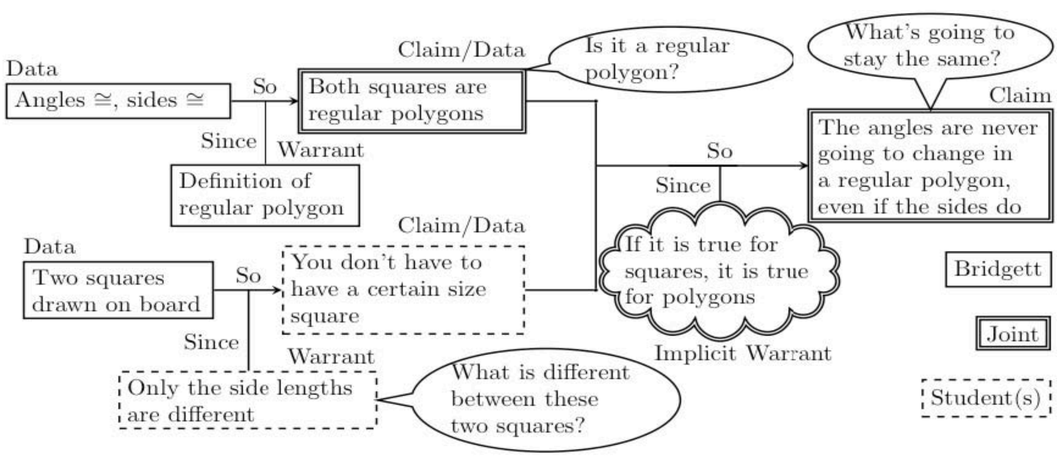


Figure 2: Diagram of Argument about Regular Polygons

We used a modification of Toulmin's (1958/2003) diagrams to document the collective argumentation. We color coded[2] the diagrams to record whether Bridgett, the students, or both Bridgett and students together contributed a given component (as in Conner, 2008) and recorded Bridgett's actions in support of argument components. These practices allowed for a finer nuance in identifying who contributed a specific part of an argument and how that contribution came about. See Figure 2 for an example of Bridgett's support for argumentation. In addition, when a part of an argument was implied but not directly stated by the class, we included it in the diagram, labeling it as an implicit part. Most of these parts were warrants (see the "cloud" in Figure 2 for an example of an implicit warrant.

We categorized Bridgett's questions, other support and direct contributions across all the diagrams. We analyzed Bridgett's supportive acts in light of the structure of the arguments and their mathematical context. Our identified patterns of support constitute the core of the present results.

Results

Bridgett engaged in many different activities to support the collective argumentation in her class. She asked questions that prompted students to provide various parts of arguments, she responded to students' contributions in various ways (sometimes verbally acknowledging the contribution, sometimes recording the contribution on the board for future use), and she directly contributed parts of arguments. On a more global scale, she negotiated norms in her class that applied to all members that involved supporting claims with data and warrants. Our analysis of Bridgett's support for argumentation is ongoing; this report focuses on the parts of arguments prompted by Bridgett's questions, the particular kinds of warrants that were contributed by students, and the parts of arguments that Bridgett herself contributed. Through the analysis of these aspects of Bridgett's support for argumentation, we aim to provide a description of what is possible, even in a student teacher's classroom, and to describe the moves that Bridgett used that might be productive in other teachers' classes.

The episode of argumentation chosen to illustrate our points in two of the following sections (Figure 2) occurred during a whole class discussion about polygonal angle formulas. The class was engaged in an attempt to derive the formula for the measure of the interior angles of (regular) polygons. The class had already discussed various ways to partition particular polygons into triangles, in order to sum all the interior angles, and the observation was made that each angle in the polygon needed to be congruent if a general formula for the interior angle measures was to be found. Bridgett recognized that many of the students had only an intuitive understanding of regular polygons, and that the definitional properties of regularity were not explicit in some of the students' minds. Therefore, she explored with the class what should be true of "regular" polygons.

Questions as Support for Collective Argumentation

As a method to analyze Bridgett's support, our research team identified the various questions Bridgett posed that supported collective argumentation within the classroom. Examining her questions across the collection of arguments, we recorded 290 questions from Bridgett that directly supported a part of an argument. We then analyzed who contributed the various parts of the arguments and found that her questions prompted a total of 156 student contributions, 119 contributions from both the students and Bridgett, and 15 contributions from Bridgett. This first level of analysis reflects two important norms within Bridgett's support for collective argumentation. First, Bridgett's support facilitated a significant amount of student contribution. Second, due to the significant amount of student contribution, Bridgett rarely needed to respond to her own questions; rather, the support she provided by asking appropriate questions elicited meaningful student participation. These findings seem to substantiate our assumption that classified Bridgett as an exemplary student teacher.

To further our analysis, we differentiated among the various parts of arguments prompted by Bridgett's questions. For example, her questions prompted more contributions of data than any other part of the argument. She asked 82 questions that prompted students to provide data, 67 that prompted data to which both Bridgett and her students contributed, and 6 that resulted in Bridgett herself providing data. Included in these numbers are parts that were coded as data alone and parts that were coded as both data and claim, as illustrated in Figure 2. The statement, "Both squares are regular polygons" was coded as both data and claim because it first was a claim, made by Bridgett and her students together, that the squares on the board were regular polygons. It was then used, together with "You don't have to have a certain size square" as data for the main claim in the argument. Although this large proportion of data supported by Bridgett's questions corresponds to the proportion of data provided within the arguments, this finding demonstrates how Bridgett's questions required students to provide the facts needed to support their development of mathematical claims. Bridgett's questions prompted many of the parts of arguments that were contributed, but not all contributions were prompted by questions. In the next section, we explore similarities and differences in student contributions of warrants prompted and unprompted by Bridgett.

Student Contributions of Warrants

Many of the questions posed by Bridgett supported students in making their reasoning explicit. Bridgett also supported students' reasoning in other ways, such as marking a diagram or encouraging the students to continue their thought processes. Of the 57 instances in which Bridgett provided any support for a warrant, 48 of the warrants were explicit and only 2 could be attributed solely to Bridgett. In contrast, of the 175 warrants that were unsupported, 63 warrants were explicit and Bridgett provided 15 of the explicit warrants. Thus, when Bridgett provided support for a warrant, students were more likely to make their reasoning explicit, either in collaboration with the teacher or on their own. However, when Bridgett did not provide support, the students were less likely to make their reasoning explicit, and Bridgett may have contributed the appropriate reasoning. These conclusions align with Toulmin's (1958/2003) suggestion that warrants are typically left implicit unless specifically requested, or, in our case, supported by the teacher. In addition, these conclusions speak to the importance of the teacher's role in collective argumentation; specifically, assisting students in making their reasoning available to the class.

Although it was typical for students to leave their reasoning implicit in the absence of support, there were 25 instances in which the students made their reasoning explicit without specific support from Bridgett. For this reason, we focused our analysis on the types of warrants provided by students with and without Bridgett's support. Our analysis yielded three categories of warrants: mathematical concepts (i.e., definitions, theorems, and properties), procedures, and observations. Of the 24 explicit warrants provided exclusively by students in conjunction with support from Bridgett, 8 were categorized as concepts, 12 were categorized as procedures, and 4 were categorized as observations. One example of an argumentation episode in which Bridgett provided support for a students' warrant was made while the class was reviewing homework. Bridgett posed the question to the class, "Is it possible to have a triangle with side lengths 3, 4, and 7?" The class responded, "No." Bridgett then asked, "Okay, why not?" One student reasoned, "[Be]cause the two smallest sides have to be as long as the longest side. [Be]cause 3 plus 4 equals 7 and 7's not larger than 7." This argument is illustrated in Figure 3a. The student's warrant was categorized as concepts because the student's reasoning made use of the triangle inequality theorem although it was not precisely stated. Bridgett supported the warrant by asking the question, "Why not?"

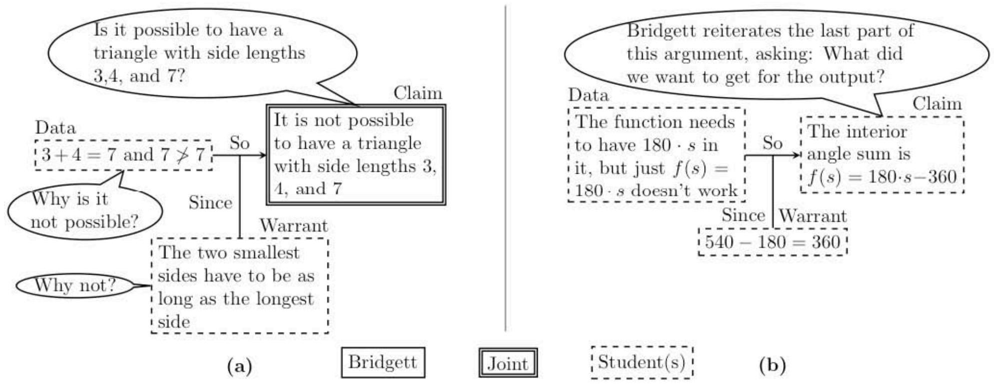

Figure 3: Arguments about (a) Triangle Side Lengths and (b) Polygon Angle Sum

In comparison, when students provide explicit warrants in the absence of support from Bridgett, 8 were categorized as concepts, 12 were categorized as procedures, and 5 were categorized as observations. For example, one episode (see Figure 3b) in which Bridgett did not provide support for a student's explicit warrant was made while the class determined the function for the sum of the measures of the interior angles of a polygon given the number of sides. A student was at the board explaining how he developed his formula. Claims that had entered into the collective up to this point include the linearity of the function, the slope of the function is 180, and 180(3) = 540 but the sum of the interior angles of a triangle is 180 degrees. The student claimed the function needed to have 180 as the slope, but 180 "doesn't work out right." He then stated, "But then I just subtracted 180 from 540 and it equals 360. Yeah. So, subtract 360." While making this statement, he wrote on the board $f(s) = 180s - 360$. The student's warrant was categorized as a procedure. Although Bridgett provided support for the claim, she did not provide support for his warrant.

Students provided the same types of warrants with the same approximate frequency, regardless of the presence of support. We draw two conclusions from this comparison. First, it appears that Bridgett negotiated classroom norms regarding the appropriate types of justification and provided support for warrants involving each of the types of reasoning. Second, the minimal amount of variation in the number of warrants in each category suggests Bridgett was not selective in the types of warrants she supported. Her choice of when to provide support may be due to many factors, including the complexity of the argument, the perceived mathematical abilities of the student(s) providing the claim, or the context of the argument. Further analysis is warranted and ongoing. Although we can only speculate as to why Bridgett may have chosen to provide support in particular circumstances, we can analyze the contributions she makes to an argument.

Bridgett's direct contributions

Bridgett directly contributed only 100 parts of arguments (out of more than 800 parts), slightly less than one per episode of argumentation, during the seven days included in this analysis. In addition, we attributed an additional 15 parts of arguments to her (coded as implicit contributions). Of her 100 explicit contributions, 59 were coded as data, with only seven of these being coded as both data and claim. When a part of an argument serves as both data and claim, it is either presented as an intermediate claim that serves as data for a later claim, or it serves as a claim's support (data) that is later challenged. It is significant that most of Bridgett's data contributions were coded exclusively as data because it is indicative of the purposes they served in the arguments. In many cases, when Bridgett introduced a problem to the class, her contribution was coded as data because it included information necessary to solve the problem (and/or specified what the problem was). For instance, in the argument diagrammed in Figure 2, Bridgett started the episode of argumentation by asking, "What is different between these two squares?" after she had drawn two squares on the board. The two squares drawn on the board were coded as data because they were used in this way in the argument; they were attributed to Bridgett because she drew them. In fact, without these two squares, the argument would not have occurred. It is different in contribution than the student's contribution that is coded as claim/data. The student's claim/data used Bridgett's data to make a claim that was then used as data for the final claim. Thus, while Bridgett's drawings of squares initiated the argument, the crux of the argument depended on claims and data contributed by students.

The other data attributed to Bridgett in this argument was more aligned with the data provided by the students and was characteristic of the other kind of data provided by Bridgett. Bridgett pointed out that their definition required that all angles were congruent and all sides were congruent. This was not challenged by anyone. Perhaps in this simple case there was no possibility of a challenge, but in general, when Bridgett contributed a piece of data, there was no challenge by students that would provoke a sub-argument. The one major exception to this rule was an argument initiated by Bridgett after a student disagreed with her claim that a circle was not a polygon. In this one episode, in which almost all of Bridgett's data/claim contributions occurred, Bridgett engaged the class in a proof by contradiction, a proof method with which the students were not particularly familiar, and she was challenged at various points in the argument by her students. This episode, although different in several respects from typical classroom discourse in Bridgett's class, showed us several important things. First, students were not afraid to challenge Bridgett's statements, even though they chose not to do so under normal circumstances. Second, when the class was doing something that was clearly unfamiliar, Bridgett contributed more parts of the argument. Finally, norms in this class applied to both the teacher and the students. The students held Bridgett to the same standards of argumentation, in particular, justifying claims. This unusual episode shows the consistency of the kinds of data contributed by Bridgett. Bridgett's data remained unchallenged except when students were very unfamiliar with the method of argument and strongly disbelieved her claim.

Discussion and Conclusions

The expansion of Toulmin's (1958/2003) model provides researchers an effective tool for the examination of collective argumentation (Conner, 2008). Through the systematic dissection and classification of what often feels like "messy" discourse, we are able to more clearly discern patterns and recognize the contributions of the various actors in collective argumentation. Important considerations, such as by whom claims are made, who provides justification for those claims, and the extent of student and teacher contributions, are quantified, which allows for a more focused qualitative analysis. It is through this analysis method that we are able to pinpoint characteristics of Bridgett's teaching that suggest that it is exemplary.

Though defining "good teaching" is beyond the scope of this paper, Bridgett's student-centered classroom aligns with the view of effective mathematics teaching espoused by many teacher preparation programs and policy documents (Wilson, Cooney, & Stinson, 2005). She is unusual in this regard, as previous studies have found that such practices, and the beliefs that drive those practices, often diminish once prospective teachers enter the classroom (e.g., Eggleton, 1995). Bridgett's emphasis on and willingness to flow with students' contributions greatly enriched the mathematical discourse in her classroom. The students eagerly participated in discussions by making claims and providing data, and they also demonstrated their acceptance of the resulting learning style by holding Bridgett to the same standard of justification by demanding warrants and providing rebuttals to claims they considered dubious. In short, Bridgett's teaching was exemplary from many points of view, especially in light of her status as a student teacher.

An important characteristic of good mathematics teaching is the ability to develop a classroom environment that engages students in doing mathematics (Wilson et al., 2005). Lampert and Cobb (2003) explained the importance of mathematical discourse within such an environment, "classrooms [can] not be silent places where each learner is privately engaged with ideas… [learners] need to talk or write in ways that expose their reasoning to one another and to their teacher" (p. 237). Lampert and Cobb emphasized the important role of the teacher in facilitating and supporting such productive mathematical discourse; however, the authors contend that much less is understood regarding the teacher's role. The case of Bridgett provides a glimpse into some of the important aspects of the teacher's role in supporting mathematical discourse through collective argumentation. Our detailed analysis of the collective argumentation within Bridgett's classroom introduces examples of teacher moves that promote student engagement in doing mathematics. The questions Bridgett posed as well as the additional support she provided encouraged her students to significantly contribute to the development of mathematical arguments. Therefore, Bridgett's teacher moves promoted collective argumentation in the truest sense of the word *collective*, for the entire classroom continually worked together to arrive at mathematical conclusions.

The foregoing analysis has revealed many aspects of Bridgett's mathematical discourse with her students. The types of data she provided and the situations in which she required warrants seem consistent with a high level of student-centered discourse. However, it is worth asking if the relationship is causal. Would mimicking Bridgett's argumentation style lead to similar outcomes for other teachers with other students? A definitive answer to this question is currently unknown, as there are several other characteristics that might reasonably have contributed to Bridgett's teaching style and subsequent classroom interaction. Two possible mechanisms not examined here, but included as part of the larger study whose final results are forthcoming, are Bridgett's belief structure (Cooney, Shealy, & Arvold, 1998) and her beliefs about mathematics, teaching, and proof (Conner, Edenfield, Gleason, & Ersoz, 2011). Nevertheless, Bridgett's propensity to request and expect warrants from her students, as well as her reluctance to directly provide intermediate data and claims in arguments, are practices that could conceivably enhance the mathematical discourse in other classrooms by encouraging fuller student participation, resulting in more authentic argumentation. Further research on the transferability, as well as the causality, of argumentation mechanics is needed in order to confirm or disprove this hypothesis.

Endnotes

1. Toulmin (1958/2003) called these "preliminary arguments" or "lemmas" (p. 90). We use sub-argument to indicate that these may not come before the other argument in terms of time and to avoid lemma, which has a specific mathematical meaning.

2. Color is represented by line style in diagrams in this paper.

TEACHER PERSPECTIVES ON MATHEMATICS CONTENT AND PEDAGOGY: DESCRIBING AND DOCUMENTING MOVEMENT

Diana B. Erchick	Michael D. Dornoo	Manjula P. Joseph
Ohio State University Newark	Ohio State University Newark	Ohio State University
Erchick.1@osu.edu	Dornoo.1@osu.edu	Joseph.239@buckeyemail.osu.edu

In this paper we report on a study examining how teacher perspectives on mathematics content and pedagogy changed after the teachers' schools participated for one year in the Mathematics Coaching Program. Teacher narrative responses to questions about student work samples provided qualitative data for analysis. Questions asked for teacher input on student thinking and instructional decisions. Responses reveal teacher change in the area of the program goals of movement toward an integrated procedural/conceptual perspective on content and a learner responsive perspective on pedagogy.

Purpose of the Study

We know that teachers bring to their classroom practice many factors that influence their pedagogy. They bring knowledge, skills, and understandings of mathematics that impact student learning (Adler & Davis, 2006; Ball, Lubienski, & Mewborn, 2001; Fennema & Franke, 1992; Hill & Ball, 2004; Hill, Rowan, & D. Ball, 2005). They also bring into their classrooms perspectives on the nature of mathematics and how it should be taught. Perspectives on mathematics include whether it is a procedural or a conceptual activity, whether it is necessary to know mathematics both conceptually and procedurally, and whether there is some combined way to know mathematics (Baroody, Feil, & Johnson, 2007; Star, 2005). Perspectives on mathematics pedagogy include whether it is better taught with a teacher-directed or more learner-responsive approach, or if one can use and apply both approaches. In this paper we report on a study exploring teacher change in terms of perspectives on mathematics and pedagogy with teacher participation in a professional development project. We examine these particular perspectives because the program serving as the context for this work has among its goals to support teacher movement along a continuum from a strict and superficial procedural perspective on content to a more richly connected and integrated procedural/conceptual perspective; and along the pedagogy continuum from a teacher-directed to a learner responsive perspective.

In the following paragraphs, we define the perspectives on mathematics and pedagogy that are central to this work, and review the literature on which those definitions are based. We then describe the methods utilized in our study, including the context of the work, the nature of the data, and data analysis procedures. Finally, we discuss findings and closing thoughts.

Theoretical Framework

Supporting teachers' practice toward students' mathematics learning necessitates consideration of multiple concepts brought to the teaching of mathematics. The area of teacher mathematics content knowledge already has a deep base in the literature. What we bring to the discussion are teachers' perspectives on mathematics content and pedagogy is a distinction between perspectives and what is generally understood in the literature as 'disposition'. Scholars define dispositions as traits that lead a person to follow certain choices or experiences (Damon, 2005) or as tendencies to exhibit frequently a pattern of behavior directed to a broad goal (Katz, 1993). For Gresalfi and Cobb (2006), the word "disposition" encompasses ideas

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

about, values of, and ways of participating with a discipline, identifying with it, and how it is realized in the classroom. A dictionary definition of disposition describes it as “a person's inherent qualities of mind and character” (New Oxford American Dictionary, 2005). Similarly, a perspective is defined as “a particular attitude toward or way of regarding something; a point of view; the state of one’s ideas” (Oxford Dictionaries, 2010). Perspective, although sometimes related to attitudes and beliefs in the literature, is usually recognized as being a result of experience, and that it can change, and that it influences practice. (e.g. Ross, 1986; Ross & Smith, 1992; Zeichner & Tabachnick, 1983).

In our work we did not chose to name the mathematics and pedagogy concepts we study dispositions because definitions of dispositions as cited above suggest less the likelihood that they can change than does the meaning of perspective. As educators, we believe that the perspectives teachers bring to bear on mathematics and pedagogy are not “inherent” but have been learned through lived experiences in and out of school. Additionally, our work in professional development relies in part on the belief that professional development can result in teacher change in terms of perspectives on content and pedagogy.

Mathematics Content and Pedagogy Perspectives

Contrary to what many in the general public believe, the content of mathematics is much richer than only arithmetic or computation; and learning mathematics content with understanding is a more complex endeavor than merely knowing the “how to do” of mathematics (Heibert et al., 1997). These and other perspectives are on the opposing “sides” of what Jon Star (2005) calls the “so-called math wars” (p. 404), about which he cites Judith Sowder’s statement that “Whether developing skills with symbols leads to conceptual understanding, or whether the presence of basic understanding should precede symbolic representation and skill practice, is one of the basic disagreements” (1998, as cited in Star, 2005). Star clearly advocates for procedural understanding, but does so from the position that both procedural and conceptual understandings are viewed too simplistically: Conceptual understanding as rich and concrete and procedural as superficial and lacking connections. Star suggests a framework where both knowledges are studied for their rich, connected, and deep relationship and integrated qualities.

Baroody, Feil, and Johnson (2007) suggest a conceptualization that is consistent with Star’s “recommendation to define knowledge type independently of the degree of connectedness” (p. 123). Baroody et al. propose the following definitions of procedural and conceptual knowledge: a) Procedural knowledge refers to “mental ‘actions or manipulations’, including rules, strategies, and algorithms, for completing a task” (de Jong and Ferguson-Hessler, p. 107 as cited in Baroody et al., p. 123); b) Conceptual knowledge is “knowledge about facts, [generalizations], and principles” (de Jong and Ferguson-Hessler, p. 107 as cited in Baroody et al., p. 123).

Baroody et al. (2007) distinguish their conceptualization with degrees of depth/superficiality, connectedness, and mutual dependence/independence and note: “depth of understanding entails both the degree to which procedural and conceptual knowledge are interconnected and the extent to which that knowledge is otherwise complete, well structured, abstract, and accurate” (p. 123). We take our content perspectives from this literature, and assign a range of conceptualizations, from procedural to integrated procedural/conceptual, to form a continuum of perspectives on mathematics content for our study.

The NCTM, particularly by way of its standards publication (2000), puts forth a vision of school mathematics “where all have access to high-quality, engaging mathematics instruction. There are ambitious expectations for all … Knowledgeable teachers have adequate resources …

The curriculum is mathematically rich, offering students opportunities to learn important mathematical concepts and procedures with understanding" (NCTM, 2000, p. 3). This vision, which includes learning mathematics with understanding (Heibert et al., 1997), has been embraced by much of the mathematics education community. It is in direct contrast to what one might describe as traditional teacher-directed mathematics instruction that often includes less visible engagement in the learning process. That is not to say that students are not cognitively engaged; but it does mean that students are not communicating mathematical ideas, not drawing on reflective practices and deep understanding. Instead, the teacher directs students on what to do, on what and how to learn, playing the dominant role; and students respond to the teacher by following instructions (Eccles, Midgley, & Alder, 1984; Gmitrová & Gmitrov, 2003).

Student-centered instruction is that which is "[d]esigned to elicit and build on students' ways of understanding mathematics" (Empson & Junk, 2004, p. 122) and is often problem-based (Ma & Zhou, 2000). Student-centeredness includes the teacher talking less and the learner talking more, with the learner doing the mathematical thinking and having opportunities to self-correct and generate knowledge through rich mathematical practices.

The project context of our work had a goal to move teachers beyond student-centered instruction to learner-responsive pedagogy (LRP). As in student-centered pedagogy, the LRP teacher makes decisions based on the learner's interests and focused on the learner's active engagement in the lesson. But LRP includes two additional distinctive qualities a) a shift, or expansion of each constituents' responsibilities and roles in the learning process from teacher as authority to authority shared by teacher and learner; and b) action: a resulting and deliberate instruction based on teacher knowledge of learner thinking and understanding. On-going analysis of student thinking is a fundamental component of LRP so instructional decisions can be made in direct response to the learners' understanding and action in making pedagogical choices based on the learner's needs is an intentional move. These pedagogy perspectives form a continuum from teacher-directed to learner responsive perspectives in our study.

Methodology

Participants, Sampling, Context, and Data Source

Participants in this study are teachers in schools enrolled in a mathematics coaching program during the 2008-2009 academic year. All are certified or licensed teachers, and are credentialed to teach in any of grades one through eight; some also are credentialed to teach kindergarten. They teach in elementary, intermediate, or middle schools served by the coaching program. Teachers were free to choose whether or not to participate in the research, and are solicited to allow access to their data from the coaching program for research and evaluation purposes.

In the 2008-2009 project year, 143 teachers consented to participate in the research. Of the 143 consenting teachers, 100 responded to student work items in the autumn and again in the spring of the academic year, as pre- and post responses. From the set of 100 participants with both pre and post responses, we created a purposeful, random sample (Patton, 2002) of 20 participants for analysis. We based our sampling strategy on the following principles:

a) Include all responders with narrative responses on all items making the sample purposeful in its inclusion of only full sets of extended responses (Patton, 1990).
b) Randomize within the purposeful sample to assured a representative set.
c) Limit participation to 20 participants: 20 participants, each with 20 response in each of two administrations generated 800 data points for analysis, a significant number of data points

for qualitative analysis, given the practicalities of time constraints, collaborative coding, and inter-rater reliability goals of the work (Patton, 2002).

The context of the study is the Mathematics Coaching Program, a statewide program training mathematics coaches to work in elementary, intermediate, and middle schools. Program goals include teaching movement : a) toward richly connected procedural/conceptual perspective on mathematics and away from a strict (and superficial (Star, 2005)) procedural perspective; and b) toward a learner-responsive and less teacher-directed pedagogy perspective.

The data source used for our analysis is a questionnaire generating teacher analyses of student work. Participants provided narrative responses to two questions for each of ten student work samples. One question asked for teacher interpretation of the student's thinking and the second asked for teacher suggestion of next instructional moves. For example, one item provides the following student work: Bobby was given the problem 17 – 9 = __ and solved it as follows: 17 – 9 = 17 – 10 – 1. Teachers were asked to a) Provide a rationale to describe what Bobby was thinking; and b) provide an explanation of what to say or do to help Bobby further his thinking.

Data Analysis

Participant extended responses were coded through two lenses on the autumn (pre) and spring reviews (post), and also compared for pre and post results. Responses on student thinking were coded for content on a continuum from Procedural to Conceptual to Integrated Procedural/ Conceptual perspectives. Responses about instruction were coded on a continuum from Teacher Directed to Problem/activity-based and Student Centered to Learner Responsive Pedagogy. See the abbreviated codebook of Table 1 for the list of codes. One or more content codes was assigned to each student thinking response; and one or more pedagogy codes to each instruction response. Multiple researcher reviews of sample responses, collaboration on coding assignments, and comparisons to coding by an outside reviewer (Morse, Barrett, Mayan, Olson & Spiers, 2002) helped reach inter-rater reliability goals of 85% in the analysis.

Table 1. Abbreviated Codebook

Results: Movement in Content and Pedagogy Perspectives

Table 2. includes results of the coding analysis of participant perspectives on mathematics content, showing movement or lack thereof on a P to C to IPC continuum. Data points are best viewed as clustered around or tending toward a particular position, allowing for some variance in the content and pedagogy perspectives, while still describing a location.

As the data in Table 2 shows, 25% of the participants tended to exhibit positive movement from P to IPC. Consider an example teacher response: Jenny uses the following method to find

28% of 60,000 mentally. 20% is 1/5 and 1/5 of 60 is 12, so 20% of 60,000 is 12,000. One percent of 60,000 is 600, and that times 8 is 4800. So the answer is 12,000 + 4,800, which is 16,800. We coded a teacher's response of "When finding answers to problems mentally it is easier to break it down into easier chunks," as P because the response only commented on what one would do. Later in the year, that same teacher responded "Jenny broke apart the problem into easier chunks. She understands the relationships between percents and fractions and understands that you can divide 60 by 5 to show 1/5" coded IPC because it included both procedural and conceptual component; and that conceptual and procedural components are connected.

Another problem showed a toothpick aligned with a ruler between 8" and 10.5" and a student's response that the toothpick measured 10.5" in length. We coded a response of "I think she doesn't understand that you start at the beginning of the ruler to measure" as a P response, while a second response of "She seems to be able to read the ruler but is struggling to understand how to measure when an object doesn't begin at 0" was coded as an IPC response because of the teacher's analysis that notes the concept of the starting point of a measure.

On a division of fraction problem where the student used a mathematically valid alternative algorithm to find a correct answer, negative movement is exampled by a teacher's analysis of "It seems she made common denominators." This was coded C because it simply mentioned a conceptual component. It did not suggest a procedure, and thus could not be P or IPC. Later, that same teacher responded with "Common denominators are used for adding or subtracting fractions. She doesn't understand that you divide fractions by multiplying the reciprocal of second fraction," coded as P because it focused on the procedure, without explaining meaning.

Positive Movement	Percent of participants	Negative Movement	Percent of participants	No movement	Percent of participants
P to C	5%	IPC to P	15%	Remain P	20%
P to IPC	25%			Remain IPC	10%
				Remain P & IPC	25%

Table 2. Participant Movement on Mathematics Content Continuum

Table 3 includes the proportional results of the coding analysis of the qualitative data on participant perspectives on mathematics pedagogy. These results show percentages of movement on the TD to PSC to LRP mathematics pedagogy continuum. In Table 3 25% of the participants revealed positive movement from TD to PSC, and PSC to LRP. An example of such positive movement from Bobby's 17-9= __ problem cited above starts with "By using his own explanation I could: 1. verify his mistake as I see it and 2. allow him to discover his own error and then he could recognize his error in the future" which is coded PSC because it does focus on helping the student realize his error. Later in the year that same teacher's response becomes "I would have him solve both sides using pictures or models and compare his answers. Using this method Bobby could see that his process is wrong. He can visualize the need to add that 1 back in the equation." This end of the year instructional suggestion is coded LRP because the teachers knows and helps the student discover his errors, by having the student compare and reflect upon his own work. The teacher and the student share the authority in the experience.

An example of the 15% of the participants who showed negative pedagogical movement is as follows: A teacher's first response about Bobby's problem was, "Bobby I like how you rounded the 9 to 10. Now we have to subtract 17-10=7 and add 1 back to get to the 9. Let me show you with our cubes what I would do." We coded this response TD, but with expectation of movement at the post administration because of the potential in the use of manipulatives. However, at the post administration, the same teacher responded, "If Bobby explains his answer to me then I would correct him when he explains -1 and tell him he needs to +1 because the problem was 17-9 and show him with base 10 blocks - 9 cubes is less than 10 cubes or 1 long (10 cubes).” Bobby’s use of manipulatives was clearly still from a teacher directed perspective, and perhaps even more TD in the language of “I would correct him,” “tell him,” and “show him.”

Positive Movement	Percent of participants	Negative Movement	Percent of participants	No movement	Percent of participants
TD to PSC	20%	LRP to PSC	10%	PSC	40%
PSC to LRP	5%	More TD	5%	TD	15%
				LRP	5%

Table 3. Participant Movement on Mathematics Pedagogy Continuum

Analysis by Mathematics Content Strands

An additional review of the data by mathematics content strand revealed interesting results for two different NCTM content standards: number and operations; and data analysis and probability. Two of the items drawn from the number and operations content standard provided student work showing unusual solutions. The first was one in which the student reduced the fractions to common denominators and divided along the numerators, using a mathematically valid approach. Seventeen out of twenty teachers did not accept this as a valid method, insisting that the student should have used the “invert and multiply” strategy. One other responded that the student “got lucky.” The second item is a three-digit subtraction problem for which the student developed his own alternate algorithm. Thirteen of the twenty teachers refused to accept this student’s mathematically valid solution as a legitimate solution. In both of these items, although the teachers who doubted the solutions did not necessarily lack content knowledge, they were unwilling to accept the alternative strategies. This suggests a reluctance to value student thinking, which would hinder the use of a learner-responsive pedagogical approach.

Two items in the sample drawn on the data analysis and probability standard also revealed interesting findings. One item included student interpretation of a graph that had no labels or numbers. The student explanation described a representation of distance against time, but every teacher in the sample of 20 viewed the graph as representing only speed against time. Hence no teacher interpreted the student’s explanation as correct. On a different problem, focusing on probability, 20% of the teachers responded with thorough explanations revealing an understanding of the mathematics; but most offered responses that were clearly incorrect or with what we might call “non-answers” circumventing the topic and suggested little to no knowledge of the relevant content. In both cases, data suggest that even those with overall PSC or LRP pedagogical perspectives did not know this particular mathematics well enough to question students through explorations or help students come to a mathematically valid understanding.

Closing Discussion

As noted earlier, the MCP context for this research study has among its goals to support teacher movement in mathematics content and mathematics pedagogy perspectives. We find that the program impacts teacher perspectives and that our coding helps document and describe that movement. That we can capture even small movement with data on only one year in the MCP suggests a useful methodology in capturing the subtleties of incremental change. As opposed to definitive, consistent, permanent positions, teachers are positioned in-between categories, tend toward a position, or contribute data that shows only slight movement toward a position. In the day-to-day work that the MCP coaches do with teachers, being able to identify subtle changes and the nuances of individual teacher's perspectives is critical to the coaches' work. That a set of teachers may fill in many different positions on the continua does not suggest more codes are needed, but, rather, that the continua represent the realities of teacher growth. They are practical and useful tools for describing fluid movement, being flexible enough to capture the teachers' sometimes daily and often small, incremental changes in perspectives. Many teachers also are likely to be positioned differently for some content than for others, so connecting this work to teacher content knowledge can reveal additional directions for professional development.

Finally, this work has implications for equity pedagogy (Erchick, Dornoo, Joseph, and Brosnan, 2010). A teacher's strict and superficial procedural perspective on mathematics limits students' opportunities for the rich mathematical learning of the integrated procedural/conceptual perspective; and examples of limitations of content knowledge that emerged in this work also hinder students' access to the mathematics. A teacher directed perspective as we define it in this study is akin to Friere's " 'banking' concept of education" (1973; 1989, p. 58), where the teacher transmits, deposits, and "the scope of action allowed to the students extends only as far as receiving, filling, and storing the deposits" (p. 58) and does not allow for the shared authority, and the accompanying learning, that is necessary for Learner Responsive Pedagogy.

THE INFLUENCE OF A TEACHER'S DECENTERING MOVES ON STUDENTS ENGAGING IN REFLECTIVE THINKING

In this paper, we discuss how a teacher's decentering moves influence the discourse in her classroom. Research has revealed decentering to be a valuable construct in characterizing the interactions in a professional learning community. Our research explores the role of decentering in a teacher's ability to support student learning in the classroom. Specifically we focus on how a teacher's decentering moves influences her students' propensity to reflect on their thinking and solutions. Our findings illustrate how a teacher's improved decentering ability supports student reflection and achieving a conceptually oriented classroom.

Introduction

Researchers have found the construct of decentering to be a useful construct in analyzing a facilitator's ability to support mathematical discussions in a professional learning community (PLC) of secondary teachers (Carlson, Moore, Bowling, & Ortiz, 2007). The authors observed that as a facilitator increased her or his propensity and ability to discern the thinking of her or his peers, the mathematical discourse in the PLC became more substantive and conceptual. In this paper we adapt decentering to analyze a Precalculus teacher's interactions with her students. We discuss how a teacher's decentering actions relate to her students' opportunities for reflecting on their responses and thinking. We also characterize transitions in students' tendency to engage in reflective thinking in relation to the teacher's decentering actions.

Theoretical Framework

Piaget (1955) described decentering as the act of adopting a perspective that is not one's own. Steffe and Thompson (2000) built on Piaget's work in describing how one individual adjusts his or her behaviors in order to influence another individual, or a group of individuals, in a particular manner. Specifically, Steffe and Thompson used decentering to characterize the interactions betweens teachers and students.

A teacher decentering assumes that the student's behavior has a rationality of its own and tries to discern the mental actions driving the student's behaviors. As the teacher decenters, they build a model of the student's thinking, and then base his or her actions on this model. To contrast, a teacher not decentering interacts with students assuming that her or his thinking and the student's thinking are identical. Over the course of a conversation, a non-decentering teacher may notice that the student's thinking is different, but the teacher does not construct a model of the student's thinking, therefore acting in a non-decentered way.

Researchers (Carlson, et al., 2007) found decentering to be a key tool for facilitators to achieve successful discourse in secondary mathematics and science PLCs. When characterizing the PLC facilitators' decentering actions, the authors determined various Facilitator Decentering Moves (FDMs) in order to classify the PLC interactions. The decentering moves ranged from the facilitator acting entirely in a non-decentered way (FDM1), representing the lowest end of the spectrum, to the facilitator building a model of PLC members' thinking and how the members were interpreting her or his actions while adjusting her or his actions based on these models

(FDM5), representing the highest end of the spectrum.

Teuscher, Moore, and Carlson (2011) made further connections between a teacher's level of decentering and the student discourse in the classroom. In studying one teacher's use of research based curriculum, the authors noted that the teacher's question types and purposes changed as the teacher began to focus on her students' thinking and understanding of the concepts independently of her way of thinking about the tasks (decentering). We believe that student knowledge is unique to each individual and we conjecture that a decentering teacher will support her or his students' learning by enabling the students to build and reflect on their thinking and actions. We predict that classroom discourse will also shift toward more opportunities for student reflection as a teacher is decentering. When teachers promote student reflection and thinking, the students are placed in situations that Hiebert and Grouws (2007) call *opportunities to learn*.

Hiebert and Grouws (2007) suggested that the type of curriculum influences opportunities for students to learn and we conjecture that the curriculum may influence teachers' pedagogical decisions. A curriculum emphasizing a conceptual orientation may influence a teacher's pedagogical goals to promote an environment of conceptual discourse. On the other hand, a curriculum emphasizing a procedural orientation places value in students gaining procedural fluency. In characterizing these two goals of learning, procedural and conceptual, Hiebert and Grouws (2007) note two types of teaching patterns: teaching for skill efficiency and teaching for conceptual understanding. Teaching for skill efficiency means providing students with opportunities to practice and master mathematical procedures quickly and accurately. Teaching for conceptual understanding means providing students with rich mathematical tasks that support them making mental connections between mathematical ideas, procedures, and facts. Teaching orientations impact the nature of classroom discourse, promoting either a calculational or conceptual orientation (Thompson, Philipp, Thompson, & Boyd, 1994).

Stigler and Hiebert (1999) noted that even though an element in the system (in this case the teacher) may change, the system itself resists sudden change and will "rush to repair itself" due to cultural scripts. The system they refer to includes teachers, students, administrators, and parents. Cultural scripts are unwritten "rules" or behaviors that are shared by members of a society; in the context of teaching and learning, it is the expected role of teachers and students. Due to these constraints in achieving classroom shifts, we hypothesize that a teacher's decentering ability and corresponding changes in her or his students' activity will occur in gradual shifts.

For the present study, we investigate the following research questions:

1. How does students' discourse shift toward more opportunities for reflection as a teacher's decentering levels increase?
2. How does the nature of student reflection change when the teacher promotes and the curriculum supports a conceptual orientation in mathematics?

Methods

Claudia is a secondary mathematics teacher at Rover High School. Previous to the study, Claudia had a total of 20 years teaching experience including elementary, junior high and high school. At the time of this study, Claudia was assigned to teach Precalculus for the second time in her career. All mathematics and science teachers at Rover High School participated in a National Science Foundation Math and Science Partnership (MSP) project (No. EHR-0412537) designed to support secondary mathematics and science teachers in improving their instruction and their students' learning. The project leaders designed and implemented school-based interventions including graduate courses, workshops, and leadership for school-based PLCs at

Rover High School to support teachers in using inquiry-based instructional methods and a conceptually oriented curriculum. To support Claudia's efforts, the project leaders gave Claudia the opportunity to use a newly developed research-based conceptually oriented Precalculus curriculum (Carlson & Oehrtman, 2010), which we will refer to as the Pathways curriculum. In this curriculum, covariational reasoning, rate of change, proportionality, and problem solving are emphasized.

Claudia's two Precalculus classes used the Pathways curriculum and were videotaped daily to observe the interactions and discourse between Claudia and her students. Videos were digitized and viewed by the research team, with select videos analyzed to examine shifts in Claudia's interactions with her students. Three exemplary videos were selected for coding: one from the first week of class (August), one from five weeks into the school year (September), and one from five months into the school year (December). The research team coded the teacher-student interactions for students' mathematical reflections and the degree to which Claudia was decentering while interacting with her students.

To code student opportunities for reflection, the last two levels of descriptor C.9 "The teacher encouraged students to reflect on the reasonableness of their responses" from the Middle Tool Observational Tool was used (Reys, 2004; Tarr, et al., 2008). We first coded each teacher-student interaction that provided students' the opportunity to reflect on the reasonableness of their or someone else's responses. The second level of coding was within each interaction, the teacher moves depending on the whether the teacher encouraged or discouraged conceptual understanding (see Table 1) by either promoting a calculational or conceptual orientation (Thompson, et al., 1994).

Student Opportunity	Teacher moves
Student reflection on answers	1. The teacher asked students if they checked whether their answers were reasonable but did not promote discussion that emphasized conceptual understanding, or 2. The teacher encouraged students to reflect on the reasonableness of their answers, and the discussion involved emphasis on conceptual understanding.

Table 1. Student Opportunities (adapted from Reys, 2004)

To characterize Claudia's decentering, we used the construct of the facilitator decentering moves (Carlson, et al., 2007) in the context of interactions between Claudia and her students. Table 2 displays the construct of facilitator decentering moves (FDM); in the context of our study we referred to the teacher-student interactions as teacher decentering moves (TDM).

Decentering Codes	Description
TDM1	The teacher shows no interest in understanding the thinking or perspective of a student with which he/she is interacting.
TDM2	The teacher appears to build a partial model of a student's thinking, but does not use that model in communication with the student. The teacher appears to listen and/or ask questions that suggest interest in the student's thinking; however, the teacher does not use this knowledge in communication.
TDM3	The teacher builds a model of a student's thinking and recognizes that it is different from her/his own. The teacher then acts in ways to move the student to her/his way of thinking.
TDM4	The teacher builds a model of a student's thinking and acts in ways that respect and build on the rationality of this student's thinking for the purpose of advancing the student's thinking and/or understanding.
TDM5	The teacher builds a model of a student's thinking and respects that it has a rationality of its own. Through interaction the teacher also builds a model of how he/she is being interpreted by the student. He/she then adjusts her/his actions (questions, drawings, statements) to take into account both the student's thinking and how the teacher might be interpreted by that student.

Table 2. Characterization of Teacher Decentering Moves (adaption from Carlson, et al., 2007)

Results

In this section we discuss the quantitative and qualitative results from the analysis of Claudia's three classroom videos. Each classroom session lasted 50 – 54 minutes. Table 3 displays the number of minutes of class time that was coded as a teacher-student interaction in which students reflected on their responses. The percentage of student contribution to these reflective interactions is listed after the minutes, measured as the time Claudia was not speaking during the interaction. Each instance of student reflection was coded according to whether or not the discourse promoted conceptual understanding (e.g., making connections between mathematical ideas).

Reflection type	August (minutes)	September (minutes)	December (minutes)
Did not empathize conceptual understanding	4.43 (28.91%)	0.00 (0.00%)	0.00 (0.00%)
Emphasized conceptual understanding	1.87 (28.91%)	5.39 (46.62%)	12.69 (52.10%)

Table 3. Teacher-student interactions categorized by reflection type

The percentage of total class time in which interactions included student opportunities to reflect on answers was 11.50% in August, 9.90% in September, and increased to 25.3% in December. The percent increase of time spent in these interactions, determined as the difference in minutes between August and December relative to the total class time in August, was 11.93%. The increase in student reflection on their mathematical responses is evident, but the table only conveys the percentage of class time for which this occurred. In August, the 11.50% spent in reflection was based on interactions that consisted of Claudia questioning her students during a whole class discussion. When students worked in small groups during the same lesson, the research team did not observe opportunities for student reflection. In both the September and December videos all student reflections occurred during work in small groups as the teacher circulated and visited with groups.

Although the time in which opportunities for student reflection increased from August to December, this data alone does not illustrate the quality or nature of these questions. In an attempt to provide a deeper characterization of Claudia's questioning, we analyzed her classroom videos to determine the role of decentering in her questioning, as well as transitions in the nature of her questioning and student thinking elicited by her questioning. The following three excerpts give examples of student reflection in the context of Claudia's interactions with her students.

In Excerpt 1a (August) Claudia read student responses to a recent quiz on average rate of change and asked students to determine what was missing or incorrect in the responses. In the transcript, '…' is used to indicate one speaker interrupting another speaker.

Excerpt 1a

C: Listen to this one and I'm going to tell (you?) the comment I wrote. Average rate of change is the overall distance, divided by the amount of time that tells you the average amount of miles per minute from p1 to p2. Now what's wrong with this answer? What is it actually telling me?
S1: How to find it.
C: So it's telling me the what? How to find it, but what about how to find it?
S2: The math.
C: The math, the formula, okay? So when it says what's the meaning of the average rate of change? It doesn't mean tell me in words what the formula is, it means: tell me what it means.

In Excerpt 1b (August) Claudia discussed with the class the meaning of the average rate of change of a diver's height from the water with respect to time using a table of values. Claudia and her students changed the time interval to half a second on the calculator and discussed the meaning of a rate of change of zero between two successive values in the table.

Excerpt 1b

C: Okay, so that would mean that what would happen, the person jumps off the board?
S1: Floats there for a second.
C: Okay, so is the diver suspended in mid-air for a half a second?
(Some students in class say no.)
S2: He wasn't suspended but…
S3: …went back in.
(Some students in class are making gestures of a concave down parabola.)
C: Oh, so he went up and back down, okay, but we're not seeing that right here in this table. But the way you could find out is change your interval again and what could we change it to this time?
S4: One-quarter.

13	C: Point two five, or you could do smaller, you could do point two, whatever.

In Excerpts 1a and 1b, we characterize Claudia's actions at the TDM1 level because she was focused on students arriving at a specific answer with no indication that she was interested in the thinking or perspective behind the students' responses (Excerpt 1a: lines 6, 8-10; Excerpt 1b: lines 9-11, 13). Although she initiated the opportunity for student reflection (Excerpt 1a: lines 1-4; Excerpt 1b: lines 1-2, 4), meaningful discussion did not follow (Excerpt 1a: lines 5-7, Excerpt 1b: lines 5-8) and Claudia proceeded without pushing the students for further explanation (Excerpt 1a: lines 8-10, Excerpt 1b: lines 10-11). The opportunity for student reflection in Excerpt 1a did not promote conceptual understanding (lines 6-8). Although Claudia made an attempt to promote conceptual understanding in Excerpt 1b (lines 1-2, 4), she did not try to create a model of student thinking. Claudia instead questioned her students in ways that suggested she was seeking an answer, which did not promote deep or meaningful reflection.

In Excerpt 2, which occurred during a September class, students were in groups of three to four students. Claudia gave her students a task stating: "A local hotel currently rents an average of 28 rooms per night. The hotel management estimates that for every \$5,550 spent on hotel renovations they will be able to rent an additional 6 rooms each night. Sketch a graph that represents the relationship between the number of rooms that can be rented in terms of the amount of money spent on renovations." (Carlson & Oehrtman, 2010, Module 2) This question was part of a unit on linearly and proportionality. Claudia circulated the room monitoring the students' activity and asked questions of students in different groups as they engaged in the task. Claudia's conversation with two students is presented in Excerpt 2.

Excerpt 2

1	C: So if you can pay for one room at a time that would mean, as soon as you pay the
2	next 925 dollars you would get an additional room. Right?
3	S1: Correct.
4	C: Okay, what kind of relationship is that?
5	S1: (*thinking*)
6	S2: Step function.
7	C: (*Laughing*) No.
8	S2: It is not proportional.
9	S1: It is not proportional and it is not linear because…
10	C: Okay, why is it not proportional?
11	S1: Because you start at 28, and you can't spend negative money on the next room.
12	C: Are the changes proportional though?
13	S1: No.
14	C: So for each additional room built are they always going to pay nine hundred?
15	S1: I don't know, we are trying to think about how to describe this.
16	S2: Well you presume, because they're not only going to build half a room.
17	S1: If for every apple you need one orange and you have half an apple then you need
18	half an orange, but this is not the case here because you spend half the money
19	here you are still going to get one, or you can't spend half the money here.
20	C: Okay, are you assuming that you have to spend the 5,550 dollars in your graph, is
21	that what you are assuming?

In Excerpt 2, we characterize Claudia's interactions with her students as TDM3 level because she made moves to guide Student 1 to her own way of thinking (lines 1-2, 4, 10, 12, 14).

Specifically, she was prompting the students to describe that there was a proportional relationship between the two quantities. Although her questioning (lines 1-2, 4, 10, 12), initiated opportunities for her students to reflect on their solution it did not support their reflections. In providing these opportunities, however, the students' utterances indicated that their thinking was different than Claudia (lines 6, 8, 9, 11, 13), and they persisted because they were convinced of the reasonable of their response. As the interaction progressed, Claudia's question in line 14 gave the students another opportunity to more fully verbalize their thinking. They justified why the situation with the hotel renovation was not proportional based on their understanding of proportionality (lines 16-19). By the end of the excerpt, Claudia began to reflect on the rationality of the student's thinking (lines 20-21). Immediately after Excerpt 2, Claudia allowed her students to describe their way of thinking, and this led her to accept their solution as a viable alternative to be respected (TDM4). She then asked Student 1 to present her solution to the class as one of the acceptable approaches to solving the problem.

In Excerpt 3 (December), students were in groups of three to four students discussing a problem about the relationship among the arc length, radius and angle. The context of the problem is a bug traveling on a fan blade with the unit of measure in radians and students are to explore the relationship between arc length, radius, and angle. The concept emphasized in the previous lesson was that one radian of angle measure corresponded to the arc measure of one radius length. Claudia circulated the classroom monitoring students' discussions as they engaged in the task. In Excerpt 3 Claudia was conversing with students in one group regarding the question: How does the angle measure change if the radius of the fan is changed, but the distance the bug travels (0.765 radians) is not changed?

Excerpt 3

C: Okay, in radians is not changed though. You are thinking of the arc length, you are thinking of the distance the arc length.
S2: That's not a distance the bug traveled that's the angle of the distance.
C: But can we take an arc length and change it to a radian measure?
S1: Yeah.
C: Okay, so?
S2: But that isn't the distance that the bug traveled.
C: But if the arc length of an angle is given, can we find the distance the bug traveled?
S2: If it is given in radians.
C: Yes, if you have a radius and an angle you can, so you are just saying that the way the question reads, how does the angle measure change if the radius of the fan is changed, but the distance the bug travels in radians is not changed? Is because of how it is worded, he is thinking the arc length. Okay so if the…
S2: But the bug travels would be, they say the units that they give you to use and the quantity they ask you to measure do not match.
C: True.
S2: That would be like, what is the gas mileage in liters, and it's like (*inaudible*).
C: (*laughs*) Okay yeah, okay so let me look at this for a minute – how does the angle measure change if the radius of the fan is changed, but the distance the bug travels, 0.765 radians, is not changed? Well can you say that a linear measurement is 0.765 radians? Can I say that?
S1: No, but that is what it says here.

24	C:	What is 0.765 radians, what does that represent for any circle?
25	S1:	The openness of the angle.
26	C:	But what does the actual 0.765 radians measure, what does that mean?
27	S1:	How– it's proportional to the radius so it is that much of the radius around the
28		circle.
29	C:	Okay, so we could say that this is 76.5% of one radian in length? Could we say
30		that?
31	S1:	Yeah.
32	C:	S2 what do you think? So if the measurement is 0.765 radians then the length of
33		the arc is 76.5% the length of the radius.

In Excerpt 3, we characterize Claudia at the TDM4 level. She acknowledged understanding how Student 2 interpreted the question and made moves to help both Student 1 and Student 2 reach a common understanding of the question, based on her model of the students' thinking about the question (lines 1-2, 11-14). Claudia's questioning (lines 4, 6, 8-9, 21-22, 24, 26, 29-30, 32-33) initiated opportunities for student reflection (lines 3, 5, 7, 10, 15-16, 18, 23, 25, 27-28, 31). Specifically, she prompted the students to reflect on a misconception that the radius length could be only used to measure the angle subtended by an arc, as revealed through the comments of Student 2 (lines 15-16, 18). Claudia made moves to resolve this misconception by linking mathematics concepts from the prior lesson in regards to the correspondence between radian measure of the circle and its radius. The questions Claudia asked (lines 21-22, 24, 26, 29-30, 32-33) required the students to continue to reflect on reasonableness of their thinking until both students reached a common understanding (which was reached after this excerpt).

Conclusions

Hiebert and Grouws (2007) identified two critical features of classroom teaching that foster conceptual understanding : (1) explicit attention must be made to the connections between facts, procedures, and ideas of mathematics; and (2) students must "struggle" with mathematics, not in the literal sense, but in the sense that they need to put an effort in making sense of the mathematics. Excerpts 2 and 3 display Claudia supporting her students' thinking by questioning them in ways that led to their reflecting on the mathematics (Excerpt 2: lines 6, 8, 9, 11, 16-19, Excerpt 3: lines 3, 5, 7, 10, 15-16, 18, 23, 25, 27-28, 31). In these excerpts Claudia modeled a higher level of decentering (TDM3, TDM4) when compared to Excerpts 1a and 1b (TDM1), in which no decentering was present. Claudia's higher level decentering actions enabled mathematically rich conversations emphasizing conceptual understanding while generating more opportunities for student reflection. Also, classroom discourse shifted from a calculational orientation towards a conceptual orientation as students were asked to explain their thinking. Stigler and Hiebert (1999) had noted a system resists sudden changes due to cultural scripts. We had hypothesized that the changes in classroom norms would be gradual. Just as Claudia's progression in decentering was gradual as the semester progressed, so too was the students' propensity to reflect on their thinking.

Future studies should continue to investigate teachers' decentering abilities and how these abilities support student learning. Such studies should also include a focus on the attributes (e.g., content knowledge, attitudes, and beliefs) of a teacher that support shifts in her or his decentering abilities. Although one of the observational scale descriptors was adapted from the Middle School Observational Tool (Reys, 2004), the other descriptors should offer further insight in the decentering actions of a teacher and the learning and actions of students.

Teacher Educator's questioning strategies are essential in maintaining the level of cognitive demand of tasks for preservice teachers' learning of mathematics for teaching. Classroom discourse has been known to maintain the level of cognitive demand of tasks. However, qualitative differences exist in the use of discourse. This study focuses on comparing instructors' questioning strategies with two groups of preservice elementary teachers using the same cognitively challenging task on surface area, where in one group the level of the cognitive demand of the tasks is maintained while in the other it is lowered. We highlight effective questioning strategies during whole group discussion.

Introduction

The purpose of this study is to investigate the role of instructor's questioning strategies in facilitating discourse in mathematics methods classes for preservice elementary teachers. We analyze the role of questions used by teacher educators in setting up a classroom community that emphasizes justification and explanation (evidence and warrants). Our analysis targets specific types of discourse that teachers use and how they affect the flow of the discourse within the whole class discussion. While classroom norms have been found to affect the quality of discourse (Cobb, 1999), the role of the teachers is key to orchestrating the whole class discussion. What and how the teachers ask questions affect the course of the discussion, whether building towards key mathematical understandings as opposed to merely sharing ideas. This paper contributes to the literature in extending our understanding in supporting teacher educators to facilitate whole-class mathematical discussions with preservice elementary teachers. We share an analysis of two instructors who were using the same cognitively demanding task designed to support preservice elementary teachers' understanding of surface area and generalized across prisms and cylinders.

Theoretical Framework

The theoretical framework of this study is derived from a sociocultural perspective, whereby mathematics teaching and learning is inherently social and embedded in active participation in communicative reasoning process (Lerman, 2001). Lerman (2001) deems that learning is a consequence of social interactions, which "along with physical and textual interactions can cause disequilibrium in the individual, leading to conceptual reorganization" (p. 55). He argues that "consciousness is constituted through discourse" (p.88) and associates speaking mathematically with learning mathematics and learning to think mathematically. Communication in mathematics classrooms provides opportunities for students to engage with ideas, refine understandings, and share insights and strategies. Walshaw and Anthony's (2008) review of current literature on discourse indicates that "students' active engagement with mathematical ideas will lead to the development of specific student competencies and identities" (p. 516). Rich mathematics discourse is at the center of constructing and connecting knowledge in mathematics. In classrooms where students explain and defend their ideas, analyze and evaluate the ideas of others, justify solutions, and explore multiple perspectives through conversations with peers, students deepen their own conceptual understandings and further their learning in mathematics. Classroom discourse has the potential to develop and deepen students' conceptual understanding of mathematics. The quality and type of discourse are crucial to helping students think conceptually about mathematics (Kazemi & Stipek, 2001; Lampert & Blunk, 1998; Nathan & Knuth, 2003; van Oers, 2002; Van Zoest & Enyart, 1998).

Teacher discourse, i.e. what teachers say and how they say it, has a significant influence on how and what students learn (Knott et al., 2008). Teacher discourse can influence both the amount and the quality of learning that takes place, and may often inadvertently lower the level of the mathematical task from cognitively demanding to one of rote application of procedures (Stein et al., 2000). Particularly during whole class discussion, in the collective act of abstraction that occurs for students during the course of the lesson, the teacher facilitates and choreographs the mathematical discourse through the use of a wide range of meta-mathematical discourse moves (Knott et al., 2008). They are meta-mathematical in a sense that "they do not directly supply mathematical content but rather they are about mathematics, and employ the language or 'register' of mathematics" (Knott et al., 2008, p. 95). For example, teachers use moves such as steering, probing, redirecting, clarifying, validating, prompting, rephrasing, re-voicing, and generalizing during the interaction with students engaging in the mathematical tasks. Although these discourse moves are not directly mathematical content discourse, they are important in making mathematics learning happen in the classroom, by encouraging students to participate in shaping their own learning.

The use of discourse with preservice teachers poses additional challenges to mathematics educators. Specifically, preservice teachers have experienced mathematics lessons throughout their schooling and often enter their preparation program with an expectation of learning to become better at what they think mathematics teachers do (Nichol, 1999). One recommendation to rectify this problem is to focus on using problems and dilemmas of practice "as springboards for investigation of mathematics teaching and learning" (Nichol, 1999, p. 48). Morrone et al. (2004) found that instructors who consistently pressed for understanding and used scaffolded discourse to facilitate preservice elementary teachers' learning when using a series of challenging tasks were able to generate mathematical knowledge about content and teaching.

In this study we analyze how these discourse types might be associated with the development of preservice elementary teachers' mathematical explanation and justification. We attend to instructors' tactical moves that encourage preservice elementary teachers to attend to the content by tracking teacher educators' questioning strategies and noting the kinds of opportunities to engage with content that are offered to students during whole class discussion (Gresalfi & Williams, 2009).

Methods

Participants and Setting

This study is part of a larger project, the Elementary Preservice Teachers Mathematics Project (EMP), developing a series of cognitively demanding mathematical tasks (Stein et al., 2000) for preservice elementary teachers. The tasks were developed across several mathematical topics (Number Theory, Fractions, Ratios and Proportions, Geometry, and Geometric Measurement) where the questions were appropriately scaffolded and supported by classroom discourse in both small group and whole class discussion. In the pilot study, participants consisted of 32 undergraduate students at a major New England University, majoring in elementary education, special education, or deaf studies. The participants were in two classes taught by two different instructors, who were doctoral candidates in mathematics education in their third year of the program. Both instructors strove to develop their students' understanding but used different methods. Preservice teachers in the two classes first worked on the mathematical tasks in small groups followed by whole class discussions. However, the two sections differed during the whole class discussion. In one section, the instructor only went over answers whereas in the other section, the instructor also included a discussion about the big ideas of the key concepts and procedures.

The study was conducted midway through the second semester of a two-course sequence for elementary education majors. Both sections had previously experienced using discourse and sense-making to discuss mathematical problems in small groups and to work toward justification. The task being used in this study was part of the EMP geometric measurement strand. It focused on surface area and covered two class periods. The preservice teachers examined the lateral and total surface area of prisms on the first day and examined similar ideas around cylinders with an emphasis on drawing connections between prisms and cylinders on the second. Specifically, the participants were introduced to a different way of finding the surface area of prisms and cylinders by considering the lateral surfaces and bases separately. They discovered the perimeter of the base of a prism or cylinder multiplied by the height of the figure is equivalent to the area of the lateral surface area. This study focuses on a question (Figure 1) in which the preservice teachers were asked to determine which of three figures (two prisms and cylinder) had the largest surface area. By this point, they should have noted that the lateral surfaces areas had the same dimensions and so the base areas were the only difference. Prior to the whole class discussion, the preservice teachers had explored and discussed the questions in their small groups both with and without the instructor.

15. The following nets show the lateral surface rectangle but not the bases of a triangular prism, a square prism, and a cylinder, respectively. Which one has the greatest surface area? Explain.

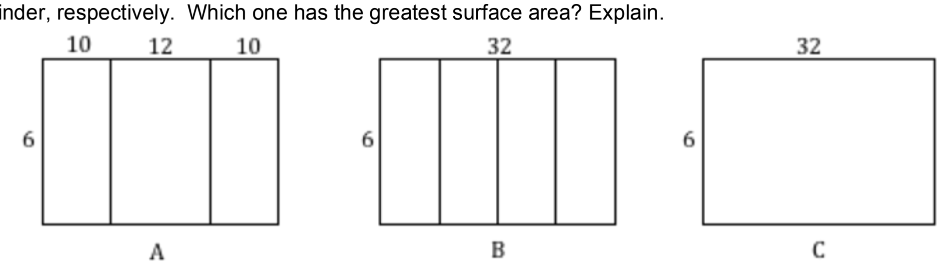

Figure 1. Question 15 from the EMP Task on Surface Area

All lessons were videotaped and transcribed. The tasks were coded using the Instructional Quality Assessment Academic Rigor (IQA-AR) Rubric for Potential of the Task (Boston & Smith, 2009) to assess the levels of cognitive demand of the mathematical tasks as they were intended to identify questions at a high level. The transcripts were coded using the Instructional Quality Assessment Academic Rigor (IQA-AR) Rubric Implementation of the Task (Boston & Smith, 2009) by pairs of coders to ensure inter-rater reliability.

Using the rubrics, we identified questions that have high levels of intended cognitive demand. We then analyzed the transcripts for instances when the level of cognitive demand was maintained or dropped during the implementation. Question 15's level of cognitive demand was high but then was dropped in the first group and maintained in the second group.

In order to analyze and compare instructors' discourse moves, we adapted existing analytical frameworks (Fraivillig, Murphy, & Fuson, 1999; Knott, Sriraman, & Jacobs, 2008) to attend to teachers' discourse moves, especially the use of questioning strategies. We deemed it necessary to adapt these frameworks because there are differences in context between K-12 and preservice education settings. Table 1 shows the analytical framework used in our study.

Table 1. Analysis Framework for Teacher Educator's Discourse Moves

Purpose of Move	Questioning Strategy	Description
Eliciting	Probing	To elicit students' prior knowledge
	Rephrasing/Re-voicing	To validate students' mathematical thinking
	Prompting	To provide background knowledge
Supporting	Steering	To move the discourse in a particular direction based on students' engagement in and demonstrated level of understanding of the task
	Re-directing	To steer the discourse back when the discourse is moving towards irrelevant or incorrect mathematical assumptions
Extending	Challenging	To demand explanation and justification of students' claim
	Generalizing	To push students to move beyond the particular to the general case

Findings

Comparing the transcripts from the two instructors orchestrating the whole class discussions around question 15, we identified differences in their use of tactical moves in framing the whole class discussion, orchestrating discourse, and connecting and extending the preservice teachers' thinking. Table 2 shows the frequencies of each of the discourse strategies used by each instructor during their whole class discussion around question 15. Both instructors used moves that elicit and support preservice teachers' thinking, but the second instructor included moves that extend preservice teachers' understanding (Challenging and Generalizing) to think beyond what was explicitly asked in the question, and pushed them to explain and justify their mathematical thinking.

Table 2. Frequencies of whole class discourse moves for question 15

Discourse Moves	**Instructor 1**	**Instructor 2**
Probing	13	17
Rephrasing/Re-voicing	1	0
Prompting	0	0
Steering	1	3
Re-directing	0	0
Challenging	1	6
Generalizing	0	1

Framing of the Whole Class Discussion

The way an instructor frames a whole class discussion affects how the discourse that follows will unfold. The first instructor (I1) in this study immediately steered the preservice teachers' attention to the shapes of the bases and dismissed the lateral surface area to be unimportant. Instructor 2 (I2) begins the discussion with an open question, "What did you guys discover in question number 15?" setting up a tone of inquiry, followed by a probing question, eliciting preservice teachers' knowledge of the three lateral surface rectangles.

Instructor 1	Instructor 2
On question 15 let's start and just talk about how we would go ahead and find the bases of those 2 shapes. Before we do that, we were asked which has the greater surface area. Was it necessary for us to find the lateral surface area of each of those shapes?	Let's talk about question number 15, where maybe I think the difference in calculating the bases comes out. What did you guys discover in question number 15? We had 3 lateral surface rectangles. What was the first one? What kind of prism was the first one?

Orchestrating the Whole Group Discussion

Both instructors led preservice teachers in a whole class discussion as they validated solutions for finding the area of the bases in question 15. They used discourse to help preservice teachers synthesize the information. Although both instructors were eliciting preservice teachers' solution methods and leading similar discussion, Instructor 2 used tactical moves that established important norms for discussion in the classroom, which maintained the level of cognitive demand of the task and pushed for clarity. Instructor 2 employed the Challenging and Generalizing tactical moves which led preservice teachers to make claims and provide justifications. Instructor 1 relied more on Probing and Steering moves that led to brief preservice teacher responses, often without justification.

In one episode, Instructor 1 asked a closed question that led to an answer, without justification, and steered the discussion back to question 15 and asked, "So which one of our three shapes is going to have the largest surface area?" The preservice teachers responded to his question with a one-word answer, "cylinder," followed by the instructor providing them with an explanation, in which he was relating and connecting the mathematics ideas that emerged from the problem.

Instructor 2 led the preservice teachers to step back and think about the purpose of the task by asking, "What's the big idea here? Why did I have you guys calculate the area of these bases? What do you notice?" The emphasis on the "big idea" and the push for explanations encouraged the preservice teachers to consolidate their ideas.

I2:	So, what's the big idea here? Why did I have you calculate the area of these bases? What do you notice?	Generalizing
S9:	In order to find the area of each of the bases, you have to find out which one has the greatest surface area or the greatest lengths of total surface area.	
I2:	Oh, why is that?	Challenging
S9:	Because the prisms and cylinders that we're making out of paper, they all have the same lateral surface area. And so the only differences are the area of the bases.	
I2:	Can someone just repeat what S9 just said? She just made a really good point.	Re-voicing

S10: You only need to find the area of the bases because all of the prisms have the same lateral surfaces rectangle, so that measurement is going to be the same. So by finding the measure of both of the bases or just one of the bases, you can find out which one has the biggest surface area.

Connecting/Extending Preservice teacher Thinking

We found that the instructors' questioning strategies played an important role in extending preservice teachers' thinking and leading them to make connections. In both of these classroom exchanges, the instructors encouraged preservice teachers to make connections to their past experiences in working with the idea of determining the figure with the greatest area with fixed perimeter. Instructor 1 steered the preservice teachers to make the connection, and when a preservice teacher was unsure of her connection to the geoboard to explain why, with a fixed perimeter, a circle would have the largest area, there was no push for clarity. There was no clear indication that the preservice teachers were able to generalize that the circle would have the greatest area given that the perimeter was fixed. When the preservice teacher (S2) suggested that a square would have the largest area, the instructor steered the conversation to address that the figure should not be limited to rectangles (including squares), but could extend to circles.

I1:	If we have a fixed perimeter, which rectangle has the largest area?	Probing
S2:	The one that's closest to a square.	
I1:	The one that's closest to square if we are using tiles. If we are not using tiles then we would want to find the perfect square. So in a similar case here we are looking for the most ideal shape here, which is a circle. …if I'm taking my piece of paper, pretend this is a 6 by 32 piece of paper for a second [folds paper], we want to find the smallest surface area possible, we could just fold this in half and have the surface area on the top and bottom have zero right here. As we think about it and get further and further away from this line we are going to a circle, we are getting a larger and larger surface area as we move forward from that direction.	Re-directing

However, another preservice teacher's (S11's) choice of using a geoboard for the explanation, presented a challenge to explain why the circle would have the greatest area, but the instructor's choice of discourse move failed to provide support to push for clarity in the preservice teacher's explanation and justification.

S11:	One way I thought about it was like if you were using a geoboard, the closer it got…I don't know it's hard for me to explain, but you could tell with something that has the same perimeter as a circle it's not going to be as large of an area because it won't fill up the space as much. I don't know, maybe that doesn't make any sense at all.	
I1:	So you're saying that a circle wouldn't be as large?	Rephrasing
S11:	No, a triangle wouldn't be as large because it wouldn't fill up the same…I don't know. I mean it makes sense in my head.	

In contrast, the preservice teachers in Instructor 2's class connected their past experiences and suggested several strategies (using strings, physically fitting prisms and cylinder, and using drawings) to explain why the circle would have the greatest area.

S5 I was thinking the day we were doing strings, for all of them we have to form the base, we have the same length of string and we form it in 3 different shapes. So it's cool that even though the perimeter is always going to be the same, the circle is always going to have the greatest area according to like the way we set it up…

I2: Interesting. What do you guys think about what S5 just said? Do you think she's correct? — Challenging

S1: We took the cylinder and put the rectangular prism in it…it should fit inside it and there should be the square with little arcs, pieces missing from it, showing that it would have the same perimeter or circumference, but with a bigger area for the circle because the square can fit inside of it.

The instructor further challenged them to generalize the idea by introducing a hexagonal prism and pressed the preservice teachers to provide justification.

I2: S3 has the circle drawn around the square, and the square is drawn around the triangle. So what does this imply? What if I gave you guys the same lateral surfaces rectangle here, another 6 by 32, and I said make me hexagonal prisms? Where do you think its total surface area would fall amongst these 3? — Generalizing

S3: Between the square and the circle.

I2: Why must it be this way? — Challenging

S4: We discussed that it must go between the square and the circle because the more sides you add to the figure, the closer it gets to a circle. So whereas the square has 4 sides, the hexagon has 6, and it just keeps breaking down the paper into closer of a circle.

S2: So if you would fit the hexagon into the cylinder, like the hexagonal prism into a cylinder, there would be less area left over on the outside than the square.

Finally, the instructor steered back the conversation to highlight the connections that the preservice teachers had made.

I2: Okay … S5 mentioned something that kind of relates back to a task we did in the beginning with area and perimeter, do you remember with string? How does this connect to that, some of the big ideas we did in that task with the string? S2 had mentioned it and I want to make sure everyone kind of makes that connection because making that connection is really important. — Steering

S4: Is the connection just that we're dealing with a fixed length [makes string with hands], like with a fixed length of string, and forming it into different shapes? The same thing with the fixed length of the piece of paper?

I2: S5 what do you think, you brought it up? Is what S4 saying what you were trying to say? — Challenging

S5: Yeah. I mean it's a general idea. They kind of brought up the same idea with fitting the paper. It's interesting that clearly constructing the figure with the exact same shape and as we said the lateral surface area is the same but…and the perimeter is the same but we're using one of the lengths from the lateral surface, but it creates a completely different area for each figure.

These interactions led preservice teachers to make claims and warrants about their solutions. Big ideas and connections were emphasized. The discourse in Instructor 2's classroom maintained the level of cognitive demand of the task.

Conclusions

When working on mathematical tasks, preservice teachers tend to focus too much on getting the "correct answer" and fail to step back and look at the big ideas for which the tasks are intended. This is especially true because of their familiarity and experiences with certain procedures or algorithms. It is the role of the instructor to draw out the idea that getting only the correct answer is not sufficient and that it is more important to examine the mathematical structure and the ideas behind the tasks. Teacher educators can accomplish this goal by focusing on questioning strategies built around challenging student assertions and creating generalization rather than simply steering and rephrasing student responses (Knott et al., 2008). By emphasizing this ideal, preservice teachers in Instructor 2's class were involved in more active engagement with mathematical ideas (Walshaw & Anthony, 2008) and participation in a communicative reasoning process (Lerman, 2001). Instructor 2's questioning strategies led to preservice teacher discourse that maintained the high level of cognitive demand of the surface area task. Preservice teachers' own educational backgrounds often lack sufficient mathematical understanding, therefore it is critical that the cognitive demand of tasks remain high so that they can provide effective instruction in the future. Questioning strategies that elicit strong discourse among preservice teachers is one way to ensure rigorous learning of mathematics content and specialized content knowledge in preservice elementary teacher classrooms.

THE EVOCATION AND ENACTMENT OF CONCEPTUAL SCHEMES: UNDERSTANDING THE MICROGENESIS OF MATHEMATICAL COGNITION THROUGH EMBODIED, ARTIFACT-MEDIATED ACTIVITY

Timothy Charoenying
University of California, Berkeley
timothykc@berkeley.edu

When instructional designers develop content-targeted pedagogical situations, their practice can be theorized as engineering students' development of conceptual schemes. To account for the contributions of students' prior schemes and situated experiences towards their development of conceptual schemes, I suggest a distinction between the evocation of schemes and enactment of situations. The former suggests that the design of an instructional situation can activate students' prior schemes. The latter suggests that the structure of students' activity in an instructional situation determines the nature of newly constructed schemes. I contextualize my views using empirical data from a case study of early fraction instruction.

Background and Objectives

An established principle of reform mathematics education is to foster students' understanding of mathematical concepts and reasoning skills through problem-solving activities (e.g., NCTM, 2000). These activities are often designed as scaffolded interactions between teacher and student, whereby the teacher presents students with an instructional situation and attempts to guide them to realize a particular instructional goal (e.g., Newman, Griffin & Cole, 1989). In many cases, instructional artifacts are also introduced to support students' appropriation of a particular mathematical concept/scheme (e.g., Dienes, 1964).

For better or worse, the measure of a successful instructional activity is often defined by whether or not the interaction leads students to successfully appropriate the targeted learning objective. While this statement should appear self-evident, various national performance indicators (e.g. National Mathematics Advisory Panel, 2008), as well as the research literature on students' 'misconceptions' (e.g., Smith, diSessa, & Roschelle, 1993) can be interpreted as indirect evidence that our collective understanding of design practice remains underdeveloped.

Indeed, the challenges that students have learning fraction concepts have been well documented (see Lamon, 2007), and a major concern in early rational-number instruction is that many students cope with the topic's inherent challenge by progressively learning to rely primarily on their ability to perform procedural algorithm, enacted as symbol manipulation, which they apply as a means of demonstrating their competence in this mathematical subfield (e.g., Freudenthal, 1983, Chapter 5). The pitfalls and limitations of relying on purely procedural fraction knowledge are poignantly demonstrated in the case of Liping Ma's (1999) elementary school *teachers*: While perfectly capable of performing the appropriate arithmetic procedures for solving fraction-division problems, these teachers were unable to explicate their solution procedures in the form of mathematically accurate scenarios.

Consequentially, more work is needed to explicate the rationales underlying the otherwise tacit design choices that inform instructional practice, as well as to understand the effects that these choices can have upon students' cognition and learning outcomes. A primary objective of this paper will be to explore how the design of an instructional situation can influence students' mathematical cognition, so as to inform a general framework for both fostering and analyzing students' interactions with instructional artifacts and/or activities.

The claim to be advanced is that an instructional activity may be designed so as to purposefully and productively *evoke* students' existing funds of knowledge, and/or to *enact* situations that support students' development of targeted concepts/schemes.

This thesis emerged from, and will be supported by empirical data from a number of case studies involving the implementation of an experimental unit that leverages multimodal activity to support students' learning of fraction concepts (Charoenying, 2010). The specific pedagogical content area involves fundamental notions of rational numbers (specifically, part-to-whole conceptualizations of the *a/b* fraction form). My analysis will explore how the material embodiment of a mathematical task (in the form of an instructional activity) contributes to students' subjective cognitive schema. The functional unit of analysis guiding this examination is the interplay between students' *schemes*, and the instructional *situations* that both influence and give rise to them (Vergnaud, 2009).

Theoretical Framework

Expanding our Notions of Inter-Subjectivity

A socio-cultural perspective of learning is that instructors mediate the speech, actions and perceptions of learners (Vygotsky, 1978; see also Newman, Griffin, & Cole, 1989). Through this process, the learner appropriates and internalizes the socially established meanings of cultural forms such as mathematical signs and concepts.

Bartolini Bussi and Mariotti (2008) have elaborated upon the notion of mediation by characterizing the artifact mediated interactions between instructor and learner as a 'didactic cycle,' whereby the instructor progressively guides the learner to understand the link between the artifact used to complete a task and the formal mathematical meanings.

Although the inter-subjective dialectic between instructor and learner is clearly a vital component of teaching and learning, this framing essentially constrains any analyses along two dimensions—the knowledge, goals, and beliefs of the instructor (Schoenfeld, 1998; see also Ma, 1999); and the prior knowledge and cognition of the learner. Given the fact that not all instructional interactions are successful in supporting students' development of a targeted concept/scheme, a purely socio-cultural analyses would imply some failing on either the part of instructor or learner.

Rather than continue to problematize unsuccessful teaching and learning interactions in terms of the participants, I believe it may be more productive to problematize our existing theoretical frameworks for analysis (Smith, diSessa, Roschelle, 1993). Here, I suggest that a potential gap in socio-cultural accounts of learning is that they do not adequately address the contributions of learners' tacit multimodal activity underlying action and expression to cognition, or their prior knowledge to learning (cf., Abrahamson, 2009). A potentially more productive approach towards designing and understanding learning interactions, would be to incorporate a more nuanced examination of how the *intra*-subjective contributions of students' multi-modal perceptions and prior-funds of knowledge interact within a designed, instructional situation.

Evoking Schemes and Enacting Situations

I would begin by highlighting that whereas learners may experience some activities as conceptually "meaningless" and others as "meaningful," what can be common to these activities are the material objects students encounter, the operations they conduct upon and with them, and the discernable results of these actions.

Here, I propose utilizing the verb "to *evoke*" to refer to the activation of students' prior schemes. It is widely accepted that familiar artifacts, symbols, and signs can evoke an individual's pre-existing schemes. Similarly, students' schemes may be evoked upon their discovery of familiar features present in an instructional situation. Understanding and anticipating the schemes that are likely to be evoked by particular design features would position designers and educators to better interpret and address students' responses as they guide them towards the desired learning objective.

In tandem, I propose utilizing the verb "to *enact*" to describe how students' experience of a situation can be purposefully designed so as to support a particular learning objective. Bruner (1966) had originally used the term "enactive representation" to elucidate how children's actions and activities in the world contribute to their development of iconic and/or symbolic forms of representation. Bruner had suggested that only after "something" is first acted upon and experienced in the world, can it be referenced; first as an object of thought, and later as an icon and/or symbol (see also Hutchins, 2006). Following this reasoning, I argue that the educator/designer can guide students to enact a situation— to act upon, observe, and/or produce situated phenomena —the experience of which can form the basis from which students can subsequently "reverse-engineer" the targeted instructional schemes/concepts the educator wishes for them to develop.

In summary, given the prominent and established role that artifacts play in supporting early fraction instruction, it is important to understand how the design and utilization of these objects can influence students' mathematical cognition. I have proposed the constructs of evocation and enactment in order to further elucidate the relationship between the schemes that are activated when students' notice particular features of a design, the forms of interactions that the design supports, and ultimately, the contributions of situated activity towards mathematical learning. Finally, the instructional design presented herein is influenced in part by theoretical claims that cognition in general (Barsalou, 1999), and mathematical reasoning in particular (Lakoff & Núñez, 2000; Núñez, Edwards & Matos, 1999), are grounded and tacitly instantiated in real-world experiences. Therefore, an explicit design consideration was to provide students with activities that leveraged their multi-modal perceptions and embodied actions in situ to help mediate and modulate the appropriation of mathematical forms and modes of reasoning (Abrahamson, 2009).

Methods

Given the dual objectives of this project: to better understand student learning, and improve instructional materials, design-based research (Brown, 1992; Confrey, 2005) was selected as an appropriate investigative approach.

This work draws on a series of case studies conducted during an ongoing design-based research study examining how students learn through interacting with tangible mathematical objects. I acted as teacher–researcher-designer. Students from two grade general-education classes (n=54) and from a Grade 3-5 self-contained special-education class (n=7) participated in a series of small group and one-on-one, video-taped teaching interactions.

My design rationale for building the instructional artifacts was as follows: First, I sought a familiar physical object rather than a diagrammatic or computational illustration. I felt it would be important for students to be able to interact with the objects so as to experimentally create, confirm, and reverse mathematical conjectures. A second criterion aimed to encourage broad dissemination was that the design be inexpensive, easily procured, and simple to use.

The resulting instructional design is a tutorial session that engages students in problem solving activities involving water and standard kitchen measuring cups (see Figure 2a).

Through a premeditated sequence of problem posing and facilitated hands-on inquiry, students are guided to perform and report perceptual judgments, measure quantitative aspects of the situation, uncover patterns, and so doing reformulate their initial judgments of part-to whole relationships as aligned with mathematical algorithms and vocabulary. Along the way, the teacher challenges students to warrant/evaluate their claims using the available materials.

As with traditional instructional representations, such as area models and number lines, a key affordance of measuring cups is that they enable students to harness their visual modality to support their mathematical judgments. Thus, to compare the unit fractions 1/3 and 1/4, one could place the respective measuring cups side-by-side (see Figure 2b). More importantly, the measuring cup activities provide a tangible means for teachers to guide students to physically enact situations they believe are analogous to the mathematical schemes they wish students to develop. For example, to help students develop a part-to-whole scheme, students could be guided to enact a situation in which they iterated the same volume from a unit-fraction cup into a one-whole cup measurer until it was filled (see Figure 2c). These activities also provide opportunities for teachers to observe and assess student reasoning.

Figure 2a. Standard kitchen measuring cups.

Figure 2b. A side by side visual comparison of two unit fraction measures.

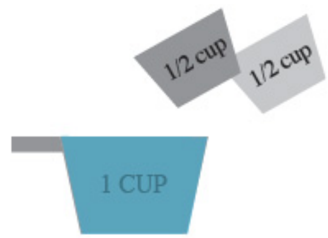

Figure 2c. Enacting a part-to whole scheme by iterating ½ cup measures into 1 cup.

The specific case study presented in this paper is from a one-on-one tutorial session with a Grade-3 special education student, hereafter referred to by the pseudonym "Manny." Pre-assessment data and consultation with the classroom teacher revealed that Manny was performing far below grade level in mathematics.

Results and Discussions

The pedagogical objective of the tutorial session was to guide Manny (age=8) to formulate a *qualitative* understanding of individual unit fractions and the part-to-whole scheme by using the measuring cups to physically enact mathematically analogous situations.

Enacting Mathematically Analogous Situations

After allowing him to familiarize himself with the measuring cups, I ask him how many scoops from the 1/2 cup measure are needed to fill the 1 cup measure. Manny correctly guesses two scoops. I then instruct him to enact his conjecture by iterating 1/2 cup measures of water into a one cup measure. While this instructional sequence would seemingly suggest some understanding of the part-to-whole scheme, his haphazard response to a similar question posed with the 1/4 cup measure reveals otherwise.

R: How many scoops do you need with this one [the 1/4 cup measure]?

M: Three, No four.
R: You need four of these? Why?
M: [Manny looks at the symbol for 1/4] It's one-half

His utterances suggest he has yet to understand the mathematical meaning signified by the fractional notations inscribed on the measures. I write 1/4 onto a slate.

R: No. Can you read one over four. Or you can say one fourth.

I then instruct Manny to iterate four scoops of water from the 1/4 measure directly into the one whole cup measure. He then reverses the operation by scooping water directly out of the one whole cup measure (into a separate reservoir of water) using the 1/4 measure.

R: How many of these guys? [I show him the 1/3 measure]
M: Three.
R: What do you call this one [the one third measure]?
M: I don't know.
R: One over three. Wait. Before you scoop, you have to write it. [Manny writes 1/3, and iterates the 1/3 cup measure into the one whole cup (figure 3)].

Figure 3. Manny iterating water iterating from the 1/3 measure into one cup

A Conflict Between Prior Knowledge and Perceptions

Having guided Manny to enact two situations I believe will support his understanding of the part-to-whole relationship of unit fractions, I purposefully attempt to dis-equilibrate his existing number scheme. I write 1/3 and 1/4 onto a slate.

R: Alright, question Manny. Which fraction is bigger? One third or one fourth?
M: That one [indicating the 1/3 cup measure].
R: You are correct, but why is this one bigger? Can you explain it to me. This is a one third cup [I hold the 1/3 cup next to its numerical inscription] this is a one fourth cup [I hold up the 1/4 cup next to its numerical inscription]. Why is it bigger? [I point again to the 1/3 cup] Why is one-third bigger?
M: Wait. [He matches the cups to the inscription. So this one's bigger! [M points back to the 1/4th cup measure]! No. This is!? [points again to the 1/3 cup measure] I don't know!
R: What do you mean you don't know? You can see with your eyes!

Interestingly, the prior number schemes that the numerical inscriptions evoke for Manny overrule his perceptual judgment. He picks up the 1/4 cup measure, physically nests it into the 1/3 cup, and again tentatively concludes that 1/3 is "bigger."

Evoking a Recently Enacted Situation

To reinforce Manny's intuitions and help him to appropriate a part-to-whole scheme, I guide Manny to reflect upon his earlier enactment of the mathematically analogous situations.

R: Okay. How many times do you need to scoop this one [How many times must the 1/3 measure be iterated to fill 1 cup?]

M: Three

R: And how many times do you need to scoop this one to fill this one.[How many times must the 1/4 measure be iterated to fill 1 cup?]

M: Four.

R: Do you understand why one third is bigger than one fourth yet? Let's see if you can explain why this fraction [inscription for 1/3 written on a whiteboard] is bigger than this one [inscription for 1/4 written on a whiteboard]

M: Because this one doesn't put too much water in it. [simulates scooping of water using the 1/4 measure into the 1 cup measure] And this one [points to the 1/3] can scoop a lot of water [more than the 1/4 measure].

Manny then examines each measurer in turn again, including the 1/2 measure. He physically simulates the pouring action with each into the one whole cup measure. I remove the measures and inscribe the fractional notation for 1/5 and 1/10 onto a board.

R: Which one would be bigger? [1/5 versus 1/10] Which one is going to be a bigger fraction? If these were cups, which would be bigger? [Manny attempts to locate a 1/5 cup and 1/10 cup measure] We don't have these cups...

M: Oh this one [he points to the 1/5 inscription]

R: Why? If this were a scooper…

Manny is initially unable to articulate an answer. He looks to the inscription of 1/10 and utters 11, which could suggest that the arrangement of numbers evoked his addition scheme. He looks again to the inscription of 1/5 before suddenly exclaiming:

M: Wait now I know! This one [the inscription for 1/5] only needs 5 cups, the small one [the inscription for 1/10] needs 10 cups!

Strikingly, the prior enactment of the mathematically analogous situation—which is arguably a function of the concrete, physical properties of the instructional artifact— provided an embodied point of reference for Manny's generalization (see also Pratt & Noss, 2002 on 'situated abstraction'). Manny's statement suggests that he has begun to build an experiential resource commensurate with the mathematical law that $a * 1/a = 1$. A generalized scheme has been abstracted from the situation. One is left to infer that the utility of an instructional situation is contingent on its capacity to support students' enactment of situations that are analogous to the scheme to be learned.

In many respects, Manny's initial interpretation of the 1/*a* form for fractions is typical of students his age, his learning disabilities notwithstanding. What differentiates this particular instructional activity from more traditional approaches involving drawn representations such as area models or number lines for example, is that Manny is able to physically enact both the composition and decomposition of fractional parts into wholes, and so doing, construct an understanding of fractions that is directly grounded in experience. Additionally, the physical medium allows me as teacher to design an activity I believe corresponds to the mathematical concepts/schemes I wish for him to appropriate. Just as importantly, it allows me to indirectly infer the changes in his conceptual understanding by directly observing his actions.

Summary and Conclusions

It is widely accepted that mathematical concepts can emerge through guided acts of representation, as students attempt to articulate emerging schemes in language and any other available means of objectification. While the contributions of a more knowledgeable other are instrumental to this process, I would argue that an analysis of an instructional interaction is incomplete unless one also accounts for the interplay between the instructional situation, and the cognitive and multi-modal perceptual resources that learner student brings to bear.

I have proposed two mechanisms for characterizing learners' interactions with an instructional artifact or activity. First, I highlight the fact that instructional activities are situations that can evoke pre-existing schemes in the mind of the learner. Awareness of this mechanism is arguably of vital importance for instructional designers. As a design heuristic, this notion of evocation leads the designer to consider how students might perceive and experience an instructional situation. Vitally, it prepares designers to better account for the otherwise unexpected ways that a student might make sense of a novel instructional situation. Knowing a priori that a particular design feature is likely to evoke a particular scheme for students (e.g., how the discrete units of an area model evoke counting schemes), would help to inform how an educator/designer chooses to mediate students' learning activities.

Second, I use the term "enact" to describe how students' situated activity can be structured so as to help facilitate their construction of a given scheme. Schemes are not constructed *ex nihilo,* but from students' encounters with, and assimilation of, new situations.

It stands to reason then that the manner in which students' situated activity is organized and orchestrated is central to their conceptual development. Instructional designers can selectively determine the experiences students have, and thereby influence the trajectory of students' cognitive development. Students' enactment of an instructional situation furnishes them with a set of experiences that may form the cognitive bases for the instructor's targeted learning objective.

Although evidence from only a single, brief case study episode is provided, the full corpus of data suggest that the Water Works design appeared to support students' articulation of their mathematical ideas by allowing them to physically enact a variety of representative situations. On the other hand, situations involving fractions for which there was no corresponding measuring cup such as 1/5, 1/100 etc., could not be directly modeled with the set of measurers. The students in the study did not appear to immediately transfer their newly constructed schemes (e.g., four scoops from the 1/4 measure to fill one cup) to the purely symbolic representations for which there had been no situation-specific analog. This is a clear limitation of the present design. In such cases, an abstract, drawn or computationally modeled representation of the scheme/situation might have been much more practical.

In conclusion, the argument advanced by introducing the constructs of evocation and enactment is this: Educator/designers effectively determine the actions and outcomes that arise from students' interactions with a particular situation. Therefore they influence in large part the schemes students construct. Conceptualizing instructional practice in terms of structuring learning situations may provide educators, designers, and researchers alike with new productive insights for anticipating and evaluating the effectiveness of a proposed instructional design.

Finally, the instructional design presented in this study is a low-cost, low-tech example of an embodied representational context that can be adapted by teachers in *any* classroom.

We examined how a student with learning disabilities (SLD) in mathematics constructed a scheme for differentiating, selecting, and properly operating on/with units that constitute a multiplicative situation, namely, singletons ('1s') and composite units (abbreviated UDS). Conducted as part of a larger teaching experiment in a learning environment that synergizes human and computer-assisted teaching, this study included 12 videotaped teaching episodes with a 5th grader (pseudonym-Sam), analyzed qualitatively. Our data provide a window onto the conceptual transformation involved in advancing from absence, through a participatory, to an anticipatory stage of a UDS scheme—a cognitive root for the distributive property. We postulate this scheme as a fundamental step in SLDs' learning to reason multiplicatively, and highlight the transfer-empowering nature of constructing it at the anticipatory stage.

Introduction

This study examined how students with learning disabilities (SLD) may construct a scheme for reasoning about multiplicative situations. Learning to reason multiplicatively is a major feat for elementary age children (Harel & Confrey, 1994; Kamii & Clark, 1996; Sowder, et al., 1998;

Steffe, 1994), whether or not they are identified as having learning disabilities/difficulties in math. Fostering it in all children is critical, because it provides a basis for understanding and properly using not only multiplication and division, but also fractional, proportional, and algebraic reasoning (NCTM, 2000, 2006). Lacking such a basis seems a key hurdle in SLDs' progress toward the latter, advanced concepts (Xin, 2008; Xin, Wiles, & Lin, 2008) and a cause for being and feeling 'stuck' in mathematics.

This study, a part of the NSF-funded *Nurturing Multiplicative Reasoning in Students with Learning Disabilities*[1] (NMRSD) project, examined SLDs' construction of a scheme for operating on, and coordinating, not just one but two sets of composite units (Steffe & Cobb, 1998) at a stage conducive to solving novel tasks ('transfer'). Such tasks may call for finding the sum or difference between two quantities (e.g., 'You have 7 boxes, 8 crayons each; I have 3 boxes, 8 crayons each; How many more crayons do you have?'). To solve such tasks in the absence of tangible 1s, a solver must identify and coordinate the units involved additively and multiplicatively. She either first multiplies (7x8=56, 3x8=24) to find the total of 1s in each set and then subtracts (56-24=32)—a *Totals-First* method, or first subtracts to find the difference in *composite units* and then multiplies the resulting, new set of composite units by the number of 1s in each (7-3=4; 4x8=32)—a *Difference-First* method. Our research question was how SLD may learn to differentiate, select, and operate on those quantities while forming a cognitive basis for what adults refer to as the distributive property (e.g., 8x(7-3) = 8x7 - 8x3).

Conceptual Framework of this Study

The NMRSD project is developing a software that draws on three research-based frameworks: a constructivist view of learning from mathematics education, generalization of word-problem underlying structures ('story-grammar') from special education, and machine (or statistical) learning from computer sciences. For this study the constructivist scheme theory (Piaget, 1970, 1985; von Glasersfeld, 1995) and its recent extension into the reflection on activity-effect relationship (*Ref*AER*) account (Simon et al., 2004; Simon & Tzur, 2004; 2004; Tzur, 2007, 2008) provided the cognitive lens. In particular, we used Tzur & Simon's (2004) distinction between the participatory and anticipatory stage in the construction of a new mathematical conception for designing instructional tasks and for assessing Sam's ways of operating. This stage distinction drew on von Glasersfeld's 3-part notion of scheme: (a) recognition of a situation, which sets the student's goal, (b) a mental activity associated with that situation and goal, and (c) an expected result. At the participatory stage, a learner forms a novel anticipation—an invariant relationship between the activity and a newly noticed/linked effect it brings forth. However, this *AER* is yet to be linked to a scheme's first part, and the learner can only access it if prompted for the activity, which regenerates the link (see Roig & Llinares, 2009). At the anticipatory stage, the learner links the novel *AER* with a host of 'structurally similar' situations, thus abstracting spontaneous (prompt-less) access to it across contexts (see Woodward, et al., 2009). We built on Tzur and Lambert's (in press) recent articulation of prompt features to guide decisions about sequencing tasks that could foster, and help assessing, transition to the participatory and then anticipatory stage of UDS.

The content-specific constructs of our framework draw on the *Initial*, *Tacitly Nested*, and *Explicitly Nested Number Sequences* (Steffe & Cobb, 1988)—three schemes a child uses in assimilating and operating on abstract composite units (CU). In the latter, the child conceives of smaller CUs as embedded within larger CU. For example, 3 CU of 8 singletons (3 boxes of crayons) and 4 CU of 8 singletons (4 boxes) are embedded within 7 CU of 8. Coordinating such same-size CU is key for early multiplicative reasoning in general and for children's construction of a UDS scheme in particular.

Methodology

Within the NMRSD project, this case study consisted of 12 videotaped teaching episodes in which Sam, a 5th grader, was jointly taught by the software and the second author. Sam was a strategic case, because RTI-like, problem-based pre-intervention assessment by the software and researchers indicated his 'readiness' for UDS. He had formed anticipatory stages of operating on CU multiplicatively to find the total of 1s (e.g., How many cubes are in 6 towers of cubes, 3 cubes each? Denoted $6T_3$ here) and additively to find CU sums/differences (e.g., You have $7T_3$; I have $4T_3$; how many more T_3 do you have?).

The software was designed based on results of previous (Tzur et al., 2009; Woodward et al., 2009; Xin et al., 2009; Zhang et al., 2009) and on-going teaching experiments with SLD. It presents students with problems in an interactive environment, and collects and analyzes data from the student's work (e.g., prompts needed, solution processes used) to select and present the next problem. This includes assessing if a student is ready to start the next level of problems. During our work with Sam, human teaching played a significant role to gain insight into software improvement—studying its impact (or lack thereof) on SLD learning of the intended mathematics.

Typically, software tasks commence within a context of producing, actually and/or mentally, a CU in the form of a tower made of several cubes (e.g., $7T_8$). One type of UDS problems asks the child to compare two different sets of same-size towers (e.g., $7T_8$ and $3T_8$). For example, the software may initially present those towers, then cover them, and pose the tasks: "*Jacqueline has a collection of 7 towers with 8 cubes in each. Mercedes has a collection of 3 towers with 8 cubes in each. How are these collections similar? How are they different? Who has more cubes and how many more?* A second type of problems switches the quantities, so two equal sets are made of different-size CU (e.g., $7T_8$ and $7T_3$). In teaching sessions in which the software was the primary source of UDS tasks, we often suggested to Sam to use one of the mini-tools available in the software (e.g., a calculator, a simulation of fingers that depict 'double-counting'). We also frequently asked Sam about the referent units of his solutions and how he figured these out.

We also used two interventions outside the software. First, Sam's work indicated that he did not have a conventional meaning for "*more*". For him, this term referred not to the difference between two quantities, but to the total of units in the larger quantity. Thus, we asked Sam to place two groups of Lego cubes (12 and 9), and then pair-off (1-to-1) as many cubes as possible. The researcher then clarified that (a) the number of non-paired cubes is the difference between the two sets (which Sam knew already) and (b) "more" refers to this number. This intervention seemed to create a shared, proper meaning for "more". The second intervention, which preceded Excerpt 2 (see Results), took place during the third UDS episode, as the software continued posing the first type of UDS problems. Sam seemed to struggle with operating on the various units, so we asked him to draw the two sets of towers on a paper. We said that a drawn tower could show each individual cube or just a schematic line/bar that Sam would label with the number of cubes it signified. Importantly, Sam felt the need to draw each cube in every tower (i.e., producing 1s), a need that was later diminished.

Data analysis occurred throughout the study. In our on-going analysis we discussed and recorded significant events after each teaching episode. We paid close attention to possible indicators (prompts needed) that Sam was in the participatory or anticipatory stage of UDS, and used our observations to plan for the next episode(s). In our retrospective analysis we began with those teaching episodes in which we previously identified segments when Sam was working in either stage of UDS. We transcribed and analyzed those episodic "snapshots" line-by-line to articulate advancements in Sam's mathematical thinking.

Results

In this section, we first briefly summarize data pertaining to Sam's lack of unit differentiation-and-selection (UDS) scheme. We then present and analyze data in support of claiming his transition to (a) the participatory stage and (b) the anticipatory stage of UDS. This includes his learning of a conventional meaning for 'more' or 'less', and a task in which he applied ('transferred') anticipatory UDS to a novel context.

Absence of a UDS Scheme

Once the NMRSD software determined that Sam has constructed an anticipatory stage of multiplication, and of *additively* operating on the *same* composite units (SUC scheme, e.g., you have $7T_8$ and I have $5T_8$; how many T_8 do we have altogether?), it moved to a UDS task: "Jacqueline has a collection of 12 towers with 8 cubes in each. Mercedes has a collection of 7 towers with 8 cubes in each. How are these collections similar?" He selected 'They both have 8 cubes in each tower'. Then, asked about difference, he selected 'Jacqueline (J) has more towers'. The software asked, "Altogether, who has more cubes?" Sam responded not with a name, but with an attempt to compute how many cubes J has (calculator). First, he multiplied 7x7=49, followed by 49x8=392, and noted "That's not right." The researcher (R) prompted, "Why did you do 49 times 8?" Sam calculated 7x8=56 (his *available* multiplication scheme) and stated that M has 56 cubes *in each tower* (unit conflation). Then, R said that the task asks *who* has more cubes, J or M. Sam responded by finding (calculator) 12x7=96 and stating, "Jacqueline." R asked if this makes sense; Sam nodded (yes), "Because J has more towers".

The software proceeded, "How many more cubes does Jacqueline have?" and R said that Sam could use the calculator. Sam re-read the task, stated he does *not* see how the calculator could be used, and after some thinking said, while inserting the numbers into the computer: "96 divided by fifty … (looks at R) Was it 58 or 56?" R, after saying "56," asked Sam why dividing. Sam said that this will give him the number he's looking for (clarifying this was "how many more cubes," and that multiplication would not work as it gives too high-a-number). R noted that Sam could have also used addition or subtraction. After a short pause to think of these options Sam keyed 96÷56, saw the answer (1.7142…) and responded in big surprise: "Whoa!" He noted that multiplication and division would not work, contemplated "96 minus … No," and added (calculator) while saying: 96+56=152. R asked him again why adding would be proper and explained to Sam the importance of his *reasoning* about the operation. In response, Sam stated that multiplication, addition, and division (!) gave him too large a number, calculated 96-56=40, and claimed this seemed correct.

The entire exchange indicated to us that Sam was not using an operation based on a reasoned choice (about difference). Rather, he tried one operation after another and judged the answer's plausibility on the basis of size/form. He also did not indicate any consideration of finding the difference in CU (towers) as a first step to be followed by multiplication (e.g., $12T_8$-$7T_8$=$5T_8$, 5x8=40 cubes). Thus, R began working with Sam on such a method and its link to the transposed one (e.g., 12x8–7x8), that is, on constructing UDS.

Participatory Stage of UDS

To foster Sam's construction of UDS, we realized he would first need to attribute a proper meaning—*difference*—to the terms 'more' and 'less'. An alternative meaning he seemed to attribute was evident in his responses to SUC tasks. For example, in the above situation (J has $12T_8$, M has $7T_8$), if asked how many more *towers* did J have, Sam would most often respond '12'. We briefly note that (a) such a meaning was found in other SLDs during the larger study and (b) it made sense to him because J has more *and* she has 12 so '12-is-the-more'. Sam quickly adopted the conventional meaning that R introduced through tasks about Lego singletons (1s). Thereafter, he consistently applied the terms to the difference between two quantities, either singletons or composite units, and strategically selected subtraction to find it. He seemed ready to construct UDS, which was fostered via tasks with 'easy' numbers.

The software stated: "John has a collection of 12 towers with 3 cubes in each, Sarah has a collection of 8 towers with 3 cubes in each." Sam playfully built the $12T_3$; he was asked and properly responded that both John and Sarah have 3 cubes in each of their towers. Asked how many towers each child had, he responded 12 and 8 respectively, responded that John and Sarah do not have the same number of towers, and that John has more cubes-in-all than Sarah. Excerpt 1 below provides what transpired next (C=computer, S=Sam, R=researcher).

Excerpt 1 (September 22, 2010)

S: [Reads the task in C out loud] "So, how many more cubes does John have than Sarah has?" and continues: Okay, so, take [away] 8. That's going to leave me with 4.

R: Four what?

S: Four towers; [and] 4 times 3 is 12.

R: You know that one, right?

[A little later, after R asked S to open the software Toolbox and use the calculator.]

R: If you do 12 x 3 and 8 x 3 … just to check the other way.

S: (Inserts 12 x 3 = while saying) 12 times 3 equals 36.

R: That's how many cubes - who has? [Pause] That's John, right?

S: (Inserts 8 x 3 = while saying) 8 times 3 equals 24. (Appears to think what's next) Twen … Twenty … Twenty-four (Inserts 24 and the *symbol for multiplication*, '*', while saying) times … [no] subtract, minus … [Clears calculator screen.]

[At this point, after R suggested to subtract the smaller number from the larger, S found 36-24=12 and, with a 'high-five' from R, they noted that it is, and must be, the same answer as Sam obtained by first subtracting the towers and then multiplying.]

Excerpt 1 indicates Sam's learning to operate in a UDS situation. He (a) differentiated the 1s (cubes) and unit-rate (3 cubes/tower) from the CU (towers), (b) selected the latter and operated on it to find the difference (via subtraction), (c) selected the unit-rate and used it as operand for (d) multiplying by the difference (4 towers) to figure out the number of cubes (12) that John had more than Sarah. Once prompted for solving the task in the alternative method, Sam's attempt to use multiplication indicated he was yet to establish UDS.

We argue that Sam's construction of UDS was at the participatory stage for a threefold reason. First, his execution of the *Difference-First* method, while proper and independent, followed R's teaching of using such a method earlier in that session. Thus, theoretically, the claim about anticipatory stage is not possible. Second, a fully established (anticipatory) UDS would consist of adeptly using either method. Excerpt 1 provides evidence that, initially, Sam thought of multiplying the totals in each collection (36x24) instead of subtracting. Third, data from the following two sessions showed that, when the software opened an episode with a UDS task Sam was unable to solve it via the *Difference-First* method without being prompted by R, although Sam himself stated it was easier. Excerpt 2 shows his choice of initial method (*Totals-First*) and incorrect operation (multiplying totals) after properly answering what's similar/different about J's and A's collections ($13T_9$ and $3T_9$ respectively). Because Sam's *single*, wrong method/answer was sufficient to *self-prompt* him for shifting to the alternative, *Difference-First* method, we consider his work as indication of high participatory stage.

Excerpt 2 (October 20, 2010)
C: Altogether who has more cubes?
S: (Selects 'Jacqueline'.)
C: How many more cubes does Jacqueline have?
S: (Pulls up the calculator tool. Inputs: 13 x 9 = 117; 3 x 9 = 27; 117 x 27 = 3159. He then clears the calculator screen and inputs: 13 – 3 = 10; 10 x 9 = 90.) Ninety!

Anticipatory Stage of UDS

We culminate with data that show Sam's UDS at the anticipatory stage. As *Ref*AER* stresses, a participatory and anticipatory stage differ not in the nature a scheme's parts (situation/goal, activity, effect), but rather in the learner's access to it—with or without prompt. Excerpt 3 shows Sam's prompt-less solution to a task presented outside the computer at the start of an episode 3 weeks after he indicated the high participatory stage (Excerpt 2). In the previous episode, he solved a tower/cubes UDS task without a prompt; here, we show how he applied ('transferred') it to a novel, realistic word problem with larger numbers.

Excerpt 3 (November 10, 2010)
S: (Reads the problem): "Evan's daughter (Sarah) needs to prepare 18 birthday bags. In each bag she plans to put 8 candies. Ron's daughter (Lihi) needs to prepare 7 birthday bags. She also plans to put 8 candies in each bag. Who needs more candies, Sarah or Lihi? How many more candies does that daughter need?" (He writes, 'Sarah needs')
R: Do you need a calculator?
S: (Nods yes): Hm-hmm. (Opens the calculator, inserts 18x8=144, comments it is the same as 12x12, clears the calculator and uses it for 18-7=11.) Eleven? Hmm. They are candies (clears screen). So what do I need to do here? I found the difference, which is 11. (Pauses, then shifts method again) Seven times … (calculates 7x8=56, then 18x8=144, and finally 144-56=88, so he exclaims): Eighty-eight!!
R: [After asking Sam to explain why he solved it this way, what did he find in each calculation, and Sam's writing 'Sarah needs 88 more candies' and stating he subtracted to find the difference in candies] Is there a different way to solve the problem?
S: [Appears to be thinking] Hmm …
R: I think you almost started one … Anything in your mind that you could have done?
S: Well, I did 18 minus 7, which is 11, and then 8 times 11 is 88! (Looks at R proudly.)

Excerpt 3 provides evidence that Sam has established the UDS scheme as an invariant way of operating in multiplicative situations where two quantities of the same unit rate (e.g., 8 candies per bag) are compared to find the total difference in singletons (1s). Establishing UDS at the anticipatory stage allowed assimilation of and operation on quantities given in a realistic situation. Interestingly, he considered solving the novel situation via the *Difference-First* method. However, he seemed to lose track of the second step (as he later explained to R's question). Yet, the anticipatory scheme empowered his resourceful, independent shift to and successful completion of the *Total-First* method. In turn, he could return to and successfully complete the alternative method, with proud awareness of the answer identity.

Discussion

This study makes a twofold contribution. First, it portrays cognitive changes in forming a unit differentiation-and-selection (UDS) scheme. UDS was articulated while studying how multiplicative reasoning evolves in students with learning disabilities/difficulties (SLD) in mathematics. For these students, and likely for their normal achieving peers, UDS serves as an intermediate cognitive step. It builds on a student's assimilatory scheme of multiplicative double counting, used for the goal of quantifying a total of 1s via distributing the given numerosity (unit-rate) of a composite unit over a number of such units (Steffe, 1994; Steffe & Cobb, 1998). It is constructed through and applied to solving problems in which the learner's goal is to *compare two such quantities*, each consisting of so many composite units (e.g., How many more marbles are in 11 bags with 7 each than in 6 bags with 7 each?).

Articulating UDS shows the need to foster SLDs' intentional identification of how two quantities are similar/different in terms of 3 types of units of a multiplicative situation. Sam, and often other SLD, could initially operate on just one level of units, that is, 1s. However, to strategically and effectively employ mental activities for finding the difference in total, one must distinguish singletons from composite units and operate on the latter while using two or three levels of units (Steffe & Cobb, 1988). The UDS scheme involves anticipating and coordinating *Difference-First* and *Total-First* methods. In the former, the child first selects and compares the two quantities in terms of the *numerical difference between composite units* (e.g., 5 more bags in the situation above). To this end, as Sam *taught us*, a child may have to re-learn a proper meaning for 'more' and 'less'. Then, the child has to re-select the numerosity of each composite unit (unit-rate) and anticipate multiplicatively distributing it over the difference found (e.g., 7 marbles/bag x 5 bags of the difference only = 35 singletons in the difference). This process requires simultaneous operation on at least two levels of units. In the latter, *Total-First* method, the child first selects and multiplicatively computes the total of 1s in each quantity—a step that *may* involve two levels of units (e.g., 7x11=77 marbles, 7x6=42 marbles). This turns the situation into an additive comparison, for which subtraction is called upon as a second step (e.g., 77-42=35 marbles). Our study shows that the anticipatory, well-coordinated stage of a UDS scheme empowers its application (transfer) to novel situations. We postulate it as a conceptual root of what knowledgeable adults call 'the distributive property of multiplication over addition' (e.g., 7x(11-6) = 7x11-7x6).

Second, our study shows that computer-assisted learning opportunities can be designed by using ongoing analysis of student understandings as a basis for task selection. In the NMRSD software, tailoring tasks to student assimilatory schemes is achieved by operationalizing constructs of the *Ref*AER* framework (Simon, et al., 2004; Tzur & Simon, 2004). In particular, software programming draws on Tzur and Lambert's (in press) work of linking the participatory stage to Vygotsky's notion of ZPD and identifying three parameters of a prompt: (a) its *locus*—whether self-generated within a learner's mental processes or by an outside entity, (b) its *focus*/*essence*—ranging along the continuum from generic (e.g., could you solve the problem in a different way) to specific (e.g., could you begin by finding how many more towers does J have?), and (c) *number*—ranging from one, to a few, to many prompts. Using these parameters, as well as the *time* it takes a student to solve each problem and the *computer actions* she or he is using (e.g., typing 11 and then hovering with the mouse over '*' before typing '-' and '6' followed by '='), the NMRSD software successfully determined and fostered Sam's progress. He started when seemingly not yet having constructed a basic scheme of multiplicative double counting. The software taught him that scheme and determined he had constructed it at the anticipatory stage, as well as a scheme for additively coordinating same-size composite units (SUC). It then shifted to UDS, gradually changing the prompts given to Sam to engender his progress to participatory and then anticipatory stage (including situations with different unit-rates, such as comparing $7T_3$ with $7T_5$, or all units differing, such as $7T_3$ and $9T_2$). While the software 'progressed' based on assessing Sam's thinking, its work was synergized with human teaching (e.g., detect non-conventional meaning for 'more', introduce novel, realistic tasks, provide social-emotional support). This synergy empowered not only transfer to novel situations, but also Sam's quite effortless learning of a more advanced, pre-algebraic scheme (e.g., "You have $9T_7$; you receive 28 more cubes; how many towers will you have once all cubes are put into T_7?").

tyson.4@osu.edu

In this paper we report on a project integrating social justice pedagogy in a professional development program training mathematics coaches to work in grades kindergarten through eight. The goal of our research was to study the coaches' growth in understanding of and commitment to social justice pedagogy in the mathematics classroom after participation in the social justice component of the three-year coaching training program. Findings reveal six progressions of coach growth.

Goals

Research, theory and practice around equity and diversity in mathematics education has grown to include more work in recent years that addresses liberatory education and social justice from both US and international perspectives (Burton, 2003; de Freitas, 2008; Frankenstein, 1987; Gutstein, 2003, 2006, 2008; Gutstein & Peterson, 2006, Sriraman, 2008). Within the scholarship we also find a body of work addressing the concept of resistance in social justice work (Gutstein 2006; Satterthwaite, Atkinson, and Martin, 2004; Filax, 1997). In this framework, action against the inequities, injustices, and oppressions in the world in which one lives is the resistance of social justice.

In this paper we report on a project integrating social justice pedagogy in a professional development program training mathematics coaches to work in grades kindergarten through eight. The coaches are trained to provide support and professional development opportunities for the mathematics teachers in their buildings. Most of the schools in the project are low-achieving schools representing a variety of groups underrepresented in mathematics education. Social justice is a component of the conceptual framework for the project, and is therefore an appropriate topic to be integrated into the training and support of the coaches. The goal of our research was to study the coaches' growth in understanding of and commitment to social justice pedagogy in the mathematics classroom after participation in the social justice component of a three-year mathematics coaching training program.

In the following pages we put forth the theoretical framework for our study; explain the research project, its methods and findings; and discuss the findings and their implications for mathematics education professional development around social justice.

Theoretical Framework

> The goal of social justice education is to enable people to develop the critical analytical tools necessary to understand oppression and their own socialization within oppressive systems, and to develop a sense of agency and capacity to interrupt and change oppressive patterns and behaviors in themselves and in the institutions and communities of which they are a part. (Adams, Bell, & Griffin, 2007, p. 2).

The first topic we have to acknowledge is that there is such a phenomenon as social justice and conversely that social injustice exists. A claim that we are teaching for social justice positions us at a point of recognizing sites of social injustice and teaching toward a goal of social justice. Given society's dynamic nature and the obscure manifestations of injustice, a condition of social justice is not easily obtainable; nor does working for social justice have a fixed end. Thus our goal is not necessarily to reach a state of social justice. Rather it is to develop the ability to identify social injustice, address it within school and community settings, and take actions to create change leading toward social justice. When we talk about developing ourselves as socially conscious catalysts for change, we acknowledge that we have a responsibility to play an active role in working toward social justice (DeVries & Zan, 1996; Green, 1971; Tom, 1984).

The second acknowledgement we make is that the nature of injustice in our society results in school-age students facing "persistent and profound barriers to educational opportunity" (Darling-Hammond, 1995, p. 465). Social injustice means that children are denied opportunities to learn and grow. When we work toward social justice, we acknowledge these barriers and make a commitment to transform the educational fabric toward a more fair and inclusive educational setting. "Without acknowledgment that students experience very different educational realities, policies will continue to be based on the presumption that it is the students, not their schools or classroom circumstances, that are the sources of unequal educational attainment" (p. 465).

According to Bell (2007), "The goal of social justice is full and equal participation of all groups in a society that is mutually shaped to meet their needs" (p. 1). Teaching for social justice means that in addition to using "good teaching strategies," we use these strategies within a context of working toward social justice. When we talk about socially just teaching the focus is on pedagogical practices to help all students succeed.

In mathematics education, indentifying issues of social injustice with links to curriculum topics is not necessarily difficult for the informed professional. However, for the teacher in development, moving social justice perspectives into practice can be a challenge. In the content disciplines, mathematics among them, content traditionally takes center stage and becomes the focus of pedagogy and the unit of analysis in assessing student learning. Thus, for teachers, attention to social justice is often interpreted as a shift away from the content, an uncomfortable position when one is accountable for student mathematics learning. These challenges for teachers to identify, explore and understand social injustices, to apply the practices of socially just teaching, and to see themselves as agents of change to address injustices in their world(s) was an influence in the development and implementation of the coaching program.

Methods

Participants, Context, and Data Sources

The participants in our study were twenty mathematics coaches who participated in the study across three years of their involvement in a MSP-funded mathematics coaching training program. All are licensed or certified teachers who are hired by school districts to serve as full time mathematics coaches, one per building, for the duration of the coaching training. Schools enrolled in the coaching program may be primary, elementary, intermediate or middle schools, and the project supports coaches across all of grades kindergarten through grade eight. Not all coaches continued in the program for all three years of available training, with funding issues being the primary reason schools dropped out of the program.

During the three years of the study, in addition to the mathematics education sessions in the coaching program, the coaches also engaged in nine professional development sessions focused on equity, diversity and social justice. The conceptual framework for the project includes pedagogical elements, mathematics content elements, and contextual elements; it is in the contextual elements that the equity, diversity and social justice component of the project rests. The goal of the social justice curriculum in the project is to teach the coaches about social justice, and to motivate them to bring social justice perspectives to bear on their daily work with teachers.

It is important to note three particular factors of this project in terms their impact in on the reliability of our data. Throughout the research project, the coaches were open and honest in revealing the limits of their knowledge of social justice in mathematics education. Given the potentially sensitive nature of the discussions, discomforts of revelations of non-awareness and acknowledgements of racism, we might have questioned the degree of honesty. But we trust the honesty and credit their openness to three factors:

- The nature of the professionals in the coaching program,
- The nature of the program as a whole, and
- The style of pedagogy practiced in the social justice lessons.

The professionals who participate in the coaching program are teachers who have chosen to enter a new field in mathematics education in its early stages of development. Taking a risk in leaving their classroom positions to embark on this professional growth opportunity suggests a strength of mind that distinguishes them from many of their peers. Additionally, the coaching program in which they are being trained is an intensive internship model where the coaches are coaching from the first day of their training. Participation includes a three-year expectation of training, involves whole group meetings for two days monthly, and small group meetings for two additional days monthly. The coaches come to know each other well, and bond to each other early in the program over the challenges of the work and the learning curve they experience. Finally, the social justice pedagogy responded at all times to the participants' needs and emerging growth, never judging, always understanding of the lack of awareness, the fears, and the resistances. Together these three factors made for group dynamics that resulted in trustworthy data.

Table 1. Data Sources

Our data sources included open response survey instruments administered prior to the project, part way through the project, and after the last lesson. Coach work products from sessions and researcher reflections on curriculum and teaching served as data sources as well. One particular discussion session was documented with verbatim notes because there was no other product from the session to capture the coaches' understandings. See Table 1. for all data sources. In this discussion of data sources, in order to distinguish this work from the work of the rest of the coaching program, we use the word project to refer to the social justice in mathematics research part of the training program, and program to represent the coaching training overall.

Near the end of year one in the program, coaches participated in a lesson introducing equity and diversity in mathematics education and were asked at that time for their feedback on equity and diversity efforts in their schools. Once the group started in year two of the project, they began a six-session series intended to teach them about social justice, and to motivate them to integrate social justice into their work with teachers and students in their schools. In year 3 of the project, the coaches participated in two follow-up lessons addressing their on own struggles and reflections upon their growth.

Data Analysis

Our data analysis focused on document analysis in reviews of the curriculum, coach responses on multiple surveys, observation captured in a transcript of a discussion, coach work products, and researcher field notes that included our reflections, notes from the sessions, and planning discussions. We should note here how every session included from four-six observers from the program, providing a kind of reliability check on our interpretations of the events. Follow-up discussion with these observers became a part of our researcher reflections.

To begin analysis we progressed through all documents that were coach work products, survey responses, and transcripts and researcher notes. We reviewed each coach's documents chronologically through all lessons. We compared coach perspectives, language, and quality of work products progressively coach-by-coach, looking for indications of the coaches' understanding of and commitment to social justice pedagogy. As is customary in qualitative research, successive readings across the data allowed the coaches' growth patterns to emerge.

Results

Our analysis allowed us to identify the initial positions of the twenty participants and six different progressions in the coaches' growth. We found that the coaches were clear about what they did not know from the first days of the project. Reflecting back to the methodological note about the reliability of the data, we believe coach revelations to be honest. As a whole, the group started with varying degrees of naiveté, some believing they were attentive to equity and diversity in their work, only to realize later how far they needed to come. However, there were three particular cases that were distinctive within the group. One coach, Marjani*, who we discuss later, was the most informed at the outset, and credited that to her lived experience of injustices. Another coach, Margaret, began the project as a disconnected spectator and was one of only two coaches from whom we saw no growth. A second from whom we saw no growth was Mitch, who also started with an articulation of a connection to mathematics that suggested a potential and particular barrier to accepting social justice pedagogy. Mitch wrote early in the project "Honestly, I don't know how it will impact me as a math coach. I teach all children who make up a classroom, so I am not consciously aware of social justice per se, while teaching mathematics or working with a fellow teachers." At the end of his experience with us, he wrote that the social justice work did not belong in the coaching program because it "took a lot of our time away from the [coaching] material." Nadine, whose growth is clear in the data we discuss below, started with the following perspective:

> I don't believe the mathematics classroom is the place to have this debate. The study of mathematics supersedes socio-political, cultural conditions. For me it explains and uncovers the wonders of the universe, the responses of humankind, the nature of mankind and the predictions of the future. It confirms the idea of intelligent design.

The overall results in terms of coach growth were encouraging to say the least, as all but two of the coaches demonstrated growth. That growth was individualized per coach, both in terms of the amount of growth and the nature of it. Through our analysis, we identified the following six growth progressions, where data reflected movement as follows:

- From mathematics to students and teachers to consideration of the context
- As a pivoting center (reference) from self to student to student within the context
- From spectator to participant
- From naiveté to deeper understanding
- From the self within a social justice context to expanding boundaries of social justice
- From validation to expansion into mathematics

A Shift in Paradigm

The first three examples of movement listed above collectively represent a shift in paradigm for each participant. For one coach, Jessie, the shift was one that moved her focus from mathematics to students and teachers and eventually to consideration of the context. She wrote,

> To be honest, social justice and mathematics education wasn't even on my radar when we first began this discussion… I was more concerned about treating all students with respect and trying to meet their academic and social needs… I now look at students and teachers and try to understand where they have come from and where they are now….Although I knew about social justice or thought about it in the past, I didn't think about how it plays a part in mathematics education.

Valarie's case is an example of paradigm shift representing a change in her pedagogical center from herself as a person and teacher to the student in context. "I always thought I was helping children be all that they can be, but it was in my eyes, not in each child's eyes….I am … more aware of children's backgrounds and what they bring socially and educationally… I believe I got here by our discussions and being able to see others' point of view."

Susan examples a shift from spectator to participant. She revealed her spectator status when she wrote "I have always thought that everyone regardless of background, race, economics etc. should have an equal opportunity to education. I never really thought (I know this now) how that was going to happen." She then wrote that she also did not know "how to make it make it happen. It just should" suggesting a shift to her role as a participant. Finally, she writes "Where I am now, there are so many things to learn about with regards to where people come from, background, economics, and to learn and know how to help provide this equal opportunity."

Deeper/Broader Understanding

The last three examples of movement listed above collectively represent movement to a deeper or broader understanding on the part of each participant. In her writing, Nadine characterizes a change from naiveté to deeper understanding, progressing from a starting with a naïve belief that she was aware to knowing how she has much to learn. She wrote:

> My definition for equity on the first day was 'equity means every child gets what he or she needs.' I was so proud thinking 'I really nailed <u>this</u>' and I was surprised when I shared my answer with the group that Cynthia didn't jump right up and say, 'Yes yes. That is a great answer.' Instead, she said 'Hmmmm' and without another word moved on to the next person… It was the movie about the group of men who came together to confront the issue of race that had the most significant impact on me. I was embarrassed for the Caucasian man and ashamed to see a little of myself in his naiveté about the disparity that exists even today between races, and how that disparity continues to live today in part because of ignorance that it exists at all. Today, at least I am aware that it exists to a greater degree than I fully understood and it is something I need to work on.

Rita's data revealed a case of broader understanding, moving from the self within a social justice context to expanded boundaries that now include a broader world of social justice understanding. She wrote,

> When we first began this discussion of social justice I considered myself to have already begun a self-reflective process prior to our start. Even knowing at that time I still had much growing to do, I had no idea how much growth that would entail… Discussions we have had … have overflowed to discussions with Nadine and Marjani outside of [the coaching program]… I appreciate the discussions greatly and feel I have gained a broader sense of humanity and equity, as my current beliefs are challenged by new information. I appreciate the fact that awareness of social justice has been heightened as I feel it has impacted my own perceptions of my self.

Rita's major growth was from a place of comfort in her definitions and the process. She became "much more analytical of actions, beliefs, etc., not only in the educational setting but in all areas of my life."

Finally, Marjani was a special case of a coach whose broadening and deepening change included an expansion into mathematics as a context. Additionally, she was the only coach who actually was comfortable taking her learning into her role of a coach. She found the social justice readings and pedagogy validating from the start.

As an African American woman teaching in a racially diverse urban school district, Marjani found the films, readings, and discussion validating. She wrote:

> The film was very informative and served to validate my experiences and the experiences of other people of color. I have been in conversation about racism and its effects for as long can remember. My career has been impacted by my choices to work with inner city youth and their instructors…Raising 3 African American young men with the help of my husband, and experiencing the difficulties of racism as it tried to hinder our success, makes me very sensitive to the issues… I thought and reflected on the film when I read chapter 3 of Eric Gutstein… As I work with my teachers I encourage them to reflect on their treatment/reaction to various students. I also try model respect and relationship-building with them.

Discussion

Each mathematics education professional development provider designs and delivers programs to meet the needs of their constituents. Those programs often include combinations of experiences with mathematics, viewing films, and engaging in activities, readings and discussions. Our project was no different in that regard. But the growth found in this project does suggest the value of three contextual elements. One contextual element was the on-going review of the data, and the revised curriculum that resulted from that. Significant to the changing process was the risk-taking that was necessary on the part of the project, to push discussions in very uncomfortable directions, especially in the context of mathematics, which many believed to be value free and socioculturally neutral.

A second contextual element contributing to the growth in this project was the intensive, prolonged, and community-like engagement of the coaches described earlier. That context provided us the opportunity to integrate our project over a longer period of time than we would have had in typical professional development projects or university coursework. With the growth we found taking all of the three years to become realized by the coaches, it is clear that summer and holiday breaks way from their work, time between social justice lessons, and a project that is sustained and coherent provided allowed room and time for reflection and growth in nearly all of our coaches.

The coaches had assignments to talk to someone outside of our sessions about some element of our work together. One group of coaches took that a little further, suggesting a third contextual element contributing to growth. Three coaches, Rita, Nadine and Marjani worked in the same urban school district, spent time together as colleagues outside of their schools, and became friends. On the long, monthly drives to and from the coaching program trainings, and in their additional sessions two more days each month, they talked to and challenged each other regarding social justice pedagogy. They became critical friends (Nieto, 2000; Zeichner and Hoeft, 1996), referencing in written reflections those drives and the friendship that developed over their growth around social justice pedagogy in mathematics.

We close with comment on one final growth element that relates to the social justice work to the coaches' role as professional development leaders in their schools. As the coaches entered the third year of the project, Marjani was the only one showing any evidence of taking her social justice learning into her role as a coach. Since that application of their learning was a goal in our teaching, and because we had so little time left in the project, we made an assignment to the group to push them to think more about that aspect of their coaching work. The coaches stopped us; they could not do what we were asking them to do, and clearly articulated the ways in which they were not ready for it, and what they needed to do before they could apply their understanding to their coaching work. They revealed self-regulatory and self-directed behaviors, an aspect of growth we had hoped for, had not seen, and had not planned for. They needed from us only the space to reflect upon, synthesize, and name what they found to be incredible personal growth. They believe that only then could they – and would they – take their growth into their work as coaches.

This paper presents our initial work to develop trajectories of preservice teachers' knowledge of teaching algebra for equity. We have developed two overlapping hypothetical learning trajectories (HLTs) for teachers' learning to engage and motivate diverse students to solve algebra problems. These HLTs are being used to guide the development of assessments, interviews, and learning activities for a pilot group of preservice teachers. The HLTs also serve as learning materials to help the preservice teachers understand how their future middle grade students learn to solve algebra word problems.

This paper describes work in the first phase of an NSF funded project whose goal is to enhance preservice teachers' knowledge for teaching algebra to diverse students. Specifically, the project focus is to design, develop, and test technology-enriched teacher preparation strategies to address equity in algebra learning for all students. The foundation for this work is a set of Hypothetical Learning Trajectories (HLTs) for teaching algebra for equity, which will be described in the paper.

Moses and Cobb (2002) stated that "the most urgent social issue affecting poor people and people of color is economic access. In today's world, economic access and full citizenship depend crucially on math and science literacy" (p. 5). Ladson-Billings (2009), citing Haberman (1996), notes that "a serious effort toward preparing teachers to teach in a culturally relevant manner requires a rethinking of the teacher preparation process" (p. 143). We agree with Moses and Ladson-Billings and we concur with researchers who conclude that traditional teaching methods are one source of difficulties that students of color have in school-based learning. Weiner (2005) found that success in the classroom only came after a shift in teachers' attitudes about teaching, learning, and culture. Research (Irvine, 1990; Lewis, 2009) has found that White teachers are sometimes not sensitive to the cultural needs of African-American students in the classroom. Both verbal and nonverbal interactions between the student and teacher are often misinterpreted and can lead to negative consequences for the African-American student (Lewis, 2009).

The gap in mathematics achievement between White, Hispanic, and African-American students has been documented since 1973. Data from the past 30 years show that White students have consistently outperformed students of color for each of the testing points (Cooper & Schleser, 2006). Although there has been recent improvement among Hispanic and African-American students, the achievement gap is still an issue (The Nation's Report Card, 2007). Furthermore, several "national and international comparisons of student achievement indicate that it is between fourth and eighth grade when U.S. students in general, and minority students in particular, fall rapidly behind desired levels of achievement" (Balfanz & Byrnes, 2006, p. 144). There are several probable causes for the continuation of the achievement gap in mathematics, including, “weak and unfocused curricula, shortage of skilled, trained, and knowledgeable mathematics teachers, unequal opportunities to learn challenging mathematics, and unmotivated students” (p. 144).

The importance of teacher quality has been identified as a key element to closing the mathematics achievement gap [now known as the opportunity gap] and increasing achievement of all students (Ladson-Billings & Tate, 2006, The Education Alliance, 2006). Teachers who are highly qualified and certified to teach mathematics have stronger pedagogical and mathematics knowledge, and therefore are more likely to have a better understanding of how students best learn mathematics. Highly qualified teachers will have better instructional practices than less qualified teachers (Darling-Hammond & Sykes, 2003). Teachers who are highly qualified and who have the ability and knowledge to effectively teach mathematics can “produce as much as six times the learning gains produced by less-effective teachers” (Singham, 2003, p. 589). Preservice education is the starting point for developing high quality teachers for all students. In a review of research on preparing teachers for diversity, Sleeter (2001) noted that while many White preservice students expect to work with children of another cultural background, most have little knowledge of or experience in cross-cultural settings. Preservice teachers acknowledge family support as a factor in their own previous success in mathematics education, but also hold the beliefs that mathematics ability is inherited from the parents, and that socio-cultural factors can restrict or promote learning (de Freitas, 2008). Sleeter stated that "the great bulk of the research has examined how to help young White preservice students (mainly women) develop the awareness, insights, and skills for effective teaching in multicultural contexts. Reading the research, one gains a sense of the immense struggle that involves" (p. 101). She concludes that many of the programs and courses aimed at general multicultural awareness and knowledge have had limited success, partly due to the limited opportunities for direct and relevant experience that preservice teachers have in confronting real issues of diversity in the classroom.

Teachers in Ladson-Billings’ (2009) Dreamkeepers project offered these suggestions for teacher preparation programs: recruit teacher candidates who have expressed an interest and a desire to work with African-American students; provide educational experiences that help teachers understand the central role of culture; provide teacher candidates with opportunities to critique the system in ways that will help them choose a role as either an agent of change or defender of the status quo; systematically require teacher candidates to have prolonged immersion in African-American culture; provide opportunities for observation of culturally relevant teaching; and conduct student teaching over a longer period of time and in a more controlled environment (Ladson-Billings, 2009).

In designing the HLTs, we reviewed the research literature to examine effective strategies for equity both for preservice teachers and for middle grades learners. Cognitive, affective, and cultural factors were included as primary criteria for identifying strategies that might be effective. An important underlying goal is to explore and develop activities and strategies that are effective both for preservice teachers and the students they will eventually teach in the classroom.

Teaching and Learning Algebra

Specific learning models for algebraic thinking are being identified and used to guide the development and design of HLTs. We began by identifying research-based learning trajectories for specific emergent algebraic thinking at the middle grades (Chazan & Yerushalmy, 2002).

Although there is considerable research on teaching algebra, the nature of preservice teachers' learning trajectories for developing deep algebraic thinking is less well known. Our research focuses on identifying, describing, and documenting these trajectories so that knowledge of algebra, often found to be deficient in preservice teachers (You & Kulm, 2008), can be addressed during preservice work. Learning activities will be constructed around the strategies for providing access and encouraging student engagement in challenging mathematical problems.

There are many studies on teachers' knowledge for teaching function concept. For example, Norman (1992) found that the secondary teachers tended to have inflexible images of the concept of function that restricted their abilities to identify functions in unusual contexts and to shift among representations of functions. The sampled teachers were able to give formal definitions of function, were able to distinguish functions from relations, and were able to correctly identify whether or not a given situation was functional but did not show strong connections between their informal notions of function and formal definitions. Consistent with Norman's findings, Chinnappan and Thomas (2001) found that all four pre-service secondary teachers in their study had a preference for thinking about function graphically, weak understanding of representational connections, and limited ability to describe applications of functions. Difficulty in constructing functions was also observed by Hitt (1994), who found that teachers had difficulty in constructing functions that were not continuous or were defined by different algebraic rules on different parts of the domain. Even (1993) found that many prospective secondary teachers did not hold a modern conception of a function as a univalent correspondence between two sets. These teachers tended to believe that functions are always represented by equations and that their graphs are well-behaved. None of the teachers had a reasonable explanation of the need for functions to be univalent and over-emphasized the procedure of the "vertical line test" without concern for understanding. On the other hand, Chazan, Yerushalmy, and Leikin (2008) found that teachers who were provided an opportunity to discuss and use alternative approaches were able to rethink their ideas about functions and equations.

Description and Specifications of Learning Trajectories.

The first phase of the project focuses on two interrelated research questions: What are the trajectories of middle grade students' knowledge and skill in algebra? and What are the trajectories of preservice teachers' knowledge of teaching algebra for equity? We believe that the basis of preservice teachers' knowledge for teaching algebra for equity rests on their knowledge of students' learning and motivation. We have developed two separate but overlapping hypothetical learning trajectories (HLTs) for solving algebra problems. One HLT characterizes the learning development of middle grades students. The second HLT characterizes teachers' use of strategies to engage and motivate diverse students in learning algebra. The trajectories follow the model of Simon and Tzur (2004), who provided the following set of assumptions about the characteristics and use of a hypothetical learning trajectory (HLT):

1. Generation of an HLT is based on understanding of the current knowledge of the students involved.
2. An HLT is a vehicle for planning learning of particular mathematical concepts.
3. Mathematical tasks provide tools for promoting learning of particular mathematical tasks and are, therefore, a key part of the instructional process.
4. Because of the hypothetical and inherently uncertain nature of this process, the teacher is regularly involved in modifying every aspect of the HLT (p. 93).

The HLTs facilitate building on existing knowledge and developing deeper knowledge of the topics. In order to describe how this knowledge is built, we began with the model of Lamberg and Middleton (2009) in constructing HLTs. This model contains (a) descriptions of the conceptual scheme at each level of learning, (b) summaries of the cause/effect mechanisms that characterize students' current knowledge, (c) cognitive interpretations of current knowledge, including possible misconceptions, and (d) intermediary understandings that are necessary for bridging to the next level of the learning trajectory (p. 237). Figure 1 provides a first version of the HLT for solving algebra problems. The trajectory, based on findings from research and best practice, begins with a direct translation scheme and provides rationales and cognitive interpretations of reasons for students using this approach. The last column provides possible steps to bridge to a more sophisticated scheme for solving problems. The intermediary schemes represent increasingly sophisticated problem solving strategies. The highest level scheme in this hypothetical model is a heuristic approach based on Polya's (1945) work and subsequent research that has applied that scheme.

Conceptual Schemes	**Cause/Effect**	**Cognitive Interpretation**	**Bridging Steps**
Direct Translation Scheme: Translate directly from words into expressions or equations.	Students have been taught that certain words stand for operations or equivalence. (Koedinger & Nathan, 2004; National Council of Teachers of Mathematics, 2000). Textbook word problems often to support this strategy.	Students who can read and comprehend text may be successful using this strategy for some word problems. (Chapman, 2006) However, errors in translation are common, and many problems do not lend themselves to the approach. (Pape, 2004)	Practice using heuristics to understand problems, such as draw picture or diagram, make a table, identify the data and unknowns (Johanning, 2004, 2007). Delay writing equations, then write the equations in words.
Textbook Four-Step Scheme: Read, identify data, identify unknowns, write the equation.	In an attempt to reflect Polya's four step approach Polya (1945), yet keep a simple procedure, textbooks often use this strategy with simple word problems that provide reasonable success in applying this approach.	Students can use the strategy with simple word problems, as an aid in analyzing the data and assigning variables to the unknown(s) (Johanning, 2004, 2007). The approach does little to support finding relationships needed to write an equation (Greer 1993, Johanning, 2004).	Practice using heuristics to understand problems, such as draw picture or diagram, think of a similar problem, use numbers to find examples.
Generalized Pattern Scheme: Generate numbers and generalize the pattern.	In early grades, students learn to "plug in" numbers to verify statements. Since numbers are concrete and familiar, they can be used to generate data that satisfy the conditions in a word problem.	Students are familiar with numbers and can use them to satisfy problem conditions. They can use inductive reasoning to generalize familiar patterns or arithmetic sequences. (Zazkis & Liljedahl, 2002)	Practice using heuristics to understand problems, such as draw picture or diagram. Use differences to identify the type of pattern (linear, etc.)
Heuristic Scheme: Apply heuristics to understand, plan, carry out, look back (Polya)	An heuristic approach addresses the need to focus on understanding the relationships and conditions in a problem and the need to plan how to solve it before attempting to write equations (Johanning, 2007, Polya, 1945).	Students can begin to use heuristics for identifying the data and unknown, drawing diagrams, and tables. (Bednarz & Janvier, 1996; Kieran, Boileau, & Garancon, 1996). Then can use subproblems, special cases and develop strategies such as remembering similar problems (Kieran, 1996).	Reflect on the solution to find another one, or a better or generalized solution. Think about other similar problems previously solved.

Figure 1. HLT for writing symbolic representations for verbal or non-routine problems.

The HLT presented in Figure 2 addresses the issue of equity through the use of conceptual schemes that have potential to engage diverse students in learning algebra and problem solving. A central focus of our current research is to collect and analyze data in order to further understand and revise the proposed schemes.

Conceptual Schemes	**Cause/Effect**	**Cognitive Interpretation**	**Bridging Steps**
Situated learning scheme: Provide an instructional context that allows students to have concrete and hands-on experiences with math knowledge and skills. Build math learning on realistic, open-ended, culturally relevant problems that students solve using a variety of skills, concepts, and tools.	Traditional math instruction focuses on symbolic representations exclusively, or moves too quickly from concrete to abstract lessons. This kind of transition results in poor skill development and limited conceptual understanding. (Hollar & Norwood, 1999; Karsenty, 2002; O'Callaghan, 1998)	Students develop math understanding by constructing their own culturally relevant knowledge (Ladson-Billings, 1994), building from more concrete to abstract ideas. Activities that apply math in contexts support effective learning (Pellegrino, Chudowsky, & Glaser, 2001). Student engagement in planning and carrying out the activity builds "ownership" and understanding (Silva & Moses, 1990).	Use concrete materials such as balances, algebra tiles, and everyday objects to provide concrete (Their, 2001) and hands-on experiences, before introducing formal symbols, definitions and rules. Problem solving activities can be used that gradually are more open-ended and provide opportunities for students to devise solution strategies.
Culturally relevant context scheme: Use contexts for activities that are based in and relevant to students' cultures and lives.	Many students do not see the relevance of math and have low self-expectations for learning math. Providing interesting and relevant contexts can be motivational. (Ladson-Billings, 1997)	Learning does not take place unless students are engaged in the lesson (Their, 2001). A "zone of proximal development" is necessary in which students can learn which enhances motivation for learning math.	Adapt math activities and problems that have relevant contexts, individualized to the interests of a particular class, group, or individual student (Ladson-Billings, 1995).
Critical pedagogy scheme: Provide learning activities in which students investigate the sources of mathematical knowledge, identify social problems and plausible solutions, and react to social injustices.	Many students do not see the social relevance of math. Providing interesting and relevant social contexts can be motivational. (Ladson-Billings, 1995)	Problem-based learning engages students in using math to address and solve problems that are drawn directly from possible social or community issues. The context can motivate and engage students (Boaler, 2000).	Adapt math activities and problems that have social contexts, individualized to the interests of a particular ethnic or interest group, or individual student (McLaughlin, Shepard, & O'Day, 1995; Stinson, 2004).

Figure 2. HLT for engagement in meaningful, interesting, and culturally relevant algebra problems.

These HLTs are being used by the project in two ways. They serve as frameworks to guide the development of assessments, interviews, and learning activities for a pilot group of preservice teachers. These data will inform the revision and further development of the HLTs and the learning activities aimed at developing preservice teacher knowledge of teaching algebra for equity (KATE). The HLTs also serve as learning materials, along with problem solving activities, to help the preservice teachers understand how their future middle grades students learn to solve algebra word problems. The teachers develop activities and lessons that address the bridging steps necessary to progress in the trajectories. Finally, they present lessons in Second Life to a simulated class of diverse middle grades students.

EXPLORING PRESERVICE TEACHERS' BELIEFS ABOUT THE MATHEMATICS EDUCATION OF ENGLISH LANGUAGE LEARNERS

Laura Kondek McLeman
University of Michigan – Flint
lauramcl@umflint.edu

Anthony Fernandes
University of North Carolina – Charlotte
anthony.fernandes@uncc.edu

This study explores preservice teachers' beliefs about the mathematics education of English language learners. In all, 164 preservice teachers responded to an online survey designed by the researchers. Through the use of descriptive statistics, the data shows that preservice teachers are open to the use of native language; believed that mathematics was devoid of culture; and were more empathetic to the experiences of English language learners if they themselves had experienced trying to learn a second language.

This pilot study sought to expand on research that examined teachers' beliefs regarding the instruction of English Language Learners (ELLs[1]) (e.g. Reeves, 2006; Torok & Aguilar, 2000). Our goal was to understand preservice teachers' (PSTs) beliefs about the mathematics education of ELLs; specifically we considered the following research question: What are elementary preservice teachers' beliefs toward (a) the use of language in the school context; (b) the interconnection of language and mathematics; and (c) teaching mathematics to ELLs?

With the increased number of ELLs that are currently mainstreamed into classrooms (Costa, McPhail, Smith, & Brisk, 2005), along with the projected 40% of school students that will speak a language other than English at home by 2030 (AACTE, 2002, as cited in Lucas & Grinberg, 2008), it is vital to prepare teachers to work with this specific population. Within mathematics education, this need is magnified when one considers how ELLs have fared on national high stakes tests. Historically a large percentage of ELLs have performed below the basic[2] achievement level on the National Assessment of Educational Progress (NAEP) mathematics exam. This trend continued in the latest iteration of the assessment. In 2009, 72% of the eighth-grade ELLs tested were below the basic level compared to just 25% for non-ELLs. At the twelfth-grade, the numbers were 80% and 35% respectively, and at the fourth-grade the numbers were 43% and 16% respectively.

While these percentages indicate that the assessments should be analyzed with a focus on accessibility for ELLs (Kieffer, Lesaux, Rivera, & Francis, 2009), they also support the argument that teachers at all levels need to understand and be willing to incorporate into their teaching practice specific methods of helping ELLs learn mathematics deeply. The National Center for Educational Statistics (2002) reported though that of the 41% of teachers working with ELLs in their classroom, only 13% received adequate preparation. While there are many avenues in which to strengthen this preparation, one important component is for teacher preparation programs to consider the beliefs that PSTs have regarding the mathematics education of ELLs. As Philipp (2007) defined, beliefs can be thought of as "lenses that affect one's view of some aspect of the world or as dispositions toward action" (p. 259). Thus, how a PST views the mathematics education of ELLs will affect how they design and implement mathematical experiences for ELLs in the classroom. By understanding what PSTs believe, teacher preparation programs can design meaningful experiences that will promote a critical analysis of their beliefs.

Theoretical Perspective

We used an on-line survey to ascertain PSTs' beliefs about the mathematics education of ELLs. While admittedly there are downsides to using surveys (as discussed in Ambrose, Clement, Philipp, & Chauvot, 2004), our reasoning for the use of a survey was two-fold. First, we were concerned that PSTs might answer in a manner they thought was expected of them if we used an interview setting. As Sapsford (1999) noted, "a straightforward question can all too easily evoke a rhetorical or ideological response" (p. 106). We hypothesized that through an anonymous, on-line survey, PSTs would be more honest about their beliefs. Second, a more qualitative approach (such as interviewing or observations) would have been more time-consuming. As such, fewer PSTs would have been able to participate in the study. This was an important consideration since we were interested in understanding the beliefs of a population of PSTs and not just a select few.

The survey instrument was constructed by the researchers due to the lack of appropriate instruments found. At the beginning of another study (Fernandes, Anhalt, & Civil, 2009), which sought to understand how PSTs' beliefs were challenged as a result of conducting two task-based interviews with ELLs and reflecting on the interviews in a structured report, the second author could not find any surveys that would be appropriate to use in the context of mathematics. While survey instruments that focused on teachers' beliefs about working with ELLs or teaching diverse students were found (e.g. Reeves, 2006; Tatto, 1996; Torok & Aguilar, 2000), none focused specifically on the beliefs of PSTs regarding the mathematics education of ELLs. This lack of direct focus was a point of contention for us as the context of mathematics was just as important as the context of working with ELLs. As Cooney, Shealy, and Arvold (1998) noted, beliefs that are central in one domain are not necessarily central in another. Thus we conjectured that framing the statements in the context of the mathematics classroom would encourage the PSTs to consider the nuances of working with ELLs in the domain of mathematics as opposed to in general.

The survey consisted of 14 questions. Each of the statements measured the strength of agreement or disagreement of PSTs' beliefs related to the mathematics education of ELLs with a 5-point Likert-type scale. Each respondent was asked to choose from one of the following choices: Strongly Disagree; Disagree; Undecided; Agree; Strongly Agree. Each of the statements used in the survey was based on research and/or adaptations from items found in other surveys[3]. Respondents also answered questions relevant to their demographic information such as gender, years of teaching experience, years of experience working with ELLs, spoken languages, and ethnicity.

Methods

We piloted the survey with elementary PSTs from a university in the south east of the country in spring 2010. All of the PSTs were working toward their teaching certification through an accredited teaching certification program and were enrolled in one of the two mathematics methods courses offered that semester. All students enrolled in both methods courses were invited to participate in the study. The second author discussed the study with the two methods teachers and asked each of them to announce the survey to their students. The PSTs were provided a web link that directed them to the survey that was hosted on http://surveyshare.com. At the beginning of the survey, individuals were asked to read a consent form detailing the specifics of the study. If the individual indicated consent, they were then provided access to the survey questions. Participants were not asked any identifying information such as name or address. Overall, 164 PSTs participated, a return rate of almost 100%.

To ensure the validity of the survey, the participants were asked at the end of the survey to answer questions pertaining to the readability and clarity of the survey. In particular, participants were asked the following questions:

1. Were there any ambiguous questions?
2. Was there anything that you did not understand?
3. Was there anything that we did not ask that we should have asked?

Comments from the PSTs about what they did not understand indicated that three were unsure about questions related to their knowledge of teaching and three wanted an option of student teaching/clinical experience to be included in the "Years of experience teaching ELL students." Related to the former, one respondent commented, "I'm not in the classroom full time, so how am I supposed to know about teaching [ELLs]?" This type of comment was echoed in answers to question 1. Here respondents discussed less the ambiguity of the wording of the questions and more that they were unsure of how to answer the questions based on their experience. All of the PSTs noted that in these cases, they clicked the choice 'undecided.' These responses from the PSTs did not reveal any obstacles to their understanding or ability to answer any of the survey items.

The survey results were imported into an MS Excel file that was used to do the analysis. We calculated the percentage of PSTs who agreed with an item by adding the percentage of those who either strongly agreed or agreed with a statement. Similarly, we calculated the percentage of PSTs who disagreed with an item. These percentages are shown in Table 1 for each item. To further understand the alignment of the PSTs' beliefs with the literature, we obtained a total score for each PST by attaching a numerical value for a response in the Likert-type scale: 1 for strongly disagree; 2 for disagree; 3 for undecided; 4 for agree; and 5 for strongly agree, while reverse coding some items if needed. For us, a score of 1 represented a response that was least aligned with the research literature regarding ELLs and 5 was the most aligned. For example, the statement "Students in the US should be taught in English only" was reverse coded with a PST strongly agreeing scoring 1 and strongly disagreeing scoring 5. Since beliefs can only be inferred, we conjectured that a PST who believed that all students should be taught in English only would be less open to the use of native language as a resource in the classroom. Items 1, 2, 5, 6, 7, 8, and 12 from Table 1 were reverse coded. In this survey, a PST could have obtained a minimum of 14 and a maximum of 70. Our next step was to order the scores and use quartiles to partition the 164 students into four groups, where G1 represented the lowest quartile and G4 represented the highest. Finally we compared the means of the scores from the PSTs in the upper quartile (G1) to those in the lower quartile (G4)

Results

We examined the results of the survey descriptively as we sought to answer our research questions and interpret the results in light of the existing literature. First we report on the demographic information collected about the participants to contextualize the population who responded to the survey. We then report on the percentages of participants that agreed, were undecided or disagreed with the individual statements by considering three main categories of belief statements related to our research questions: (a) beliefs about language in the school context; (b) beliefs about the interconnection of language and mathematics; and (c) beliefs about teaching mathematics to ELLs. These percentages are summarized in Table 1. Finally we report the findings from the comparison of different groups based on the quartile calculations.

Demographic Information

Of the 164 participants, 153 were female and 11 were male. Of the choices 'European American,' 'African American,' 'Hispanic,' 'Asian,' or 'Other,' 85% of the PSTs reported being European American/Caucasian/White. (Note that some PSTs chose the 'other' category and filled in Caucasian or White.) Of the other 15% of respondents, 7.32% self-reported as African American, 1.22% as Hispanic and 3.05% as Asian. Most of the PSTs either indicated no formal teaching experience or reported classroom observations and clinical teaching required in coursework as their only teaching experience. Finally, over 85% had limited to no experience to working with ELLs prior to the study.

Belief	% Agree	% Undecided	% Disagree
Language in the School Context			
1. Students in the US should be taught in English only.	21.37	13.4	65.2
2. It is more important for immigrants to learn English than to maintain their native language.	41.4	19.5	39
3. In a mathematics classroom, ELLs should be allowed to discuss course material with each other in their native language.	76.83	12.8	10.37
4. ELLs should be assessed in their native language on the State tests.	35.98	37.80	26.22
Interconnection of Language and Mathematics			
5. Mathematics uses symbols and ideas that are not associated with any language or culture.	52.44	23.17	24.39
6. Mathematics is an ideal subject for transitioning recent immigrant students into English.	55.49	33.54	10.98
7. If ELLs can hold a conversation in English, they should have no more of a problem, than non-ELLs, learning mathematics in an English only classroom.	29.88	21.34	48.78
8. Mathematics is not language intensive.	25	15.85	59.15
Teaching Mathematics to ELLs			
9. Whenever possible, ELLs should receive instruction in their native language until they are proficient enough to learn via English instruction.	67.07	15.24	17.68
10. When working with ELLs in a mainstream classroom, teacher lesson plans should incorporate content objects as well as language objectives.	69.52	33.54	5.49
11. Teacher should incorporate explicit language learning strategies in the mathematics lesson if they have ELLs in the class.	66.47	25	8.54
12. Teachers should use the same standards in evaluating the work of all students in the class.	48.18	18.29	33.54
13. It is important to incorporate aspects of the students' culture into mathematics teaching.	84.15	9.15	6.71
14. Culture plays a significant role in the learning and teaching of mathematics.	56.1	28.05	15.85

Table 1. PSTs' beliefs about the mathematics education of ELLs

Beliefs about Language in the School Context

A majority of the PSTs (65.2%) disagreed or strongly disagreed with the statement "Students in the US should be taught in English only." Moreover, 76.83% agreed or strongly agreed with allowing ELLs to use their native language when discussing mathematics content in the classroom. Given that most of the PSTs surveyed were monolingual in English (83%[4]), these results point to the PSTs being open to languages other than English being used in the mathematics classroom. However, even though PSTs seemed open to the use of native language for teaching and small group discussions in the class, they seem split on the importance ELLs should give towards learning English rather than maintaining their native language. Namely, 41.4% of the respondents agreed that it is more important for ELLs to learn English while 39% felt that learning English should not come at the expense of the ELL's native language. This agrees with the literature (e.g. Walker, Shafer, & Iiams, 2004; Reeves, 2006) where teachers may assume that the use of native language may interfere with ELLs learning English and thus, more importance should be given to learning English. Finally, the PSTs were about evenly divided when asked about the use of native language on exams, with 35.98% agreeing, 26.22% disagreeing, and 37.8% undecided when responding to the statement "ELLs should be assessed in their native language on the State tests." There are a number of possibilities for the large percentage of students who are undecided. For example, it is possible that PSTs had difficulty deciding between whether it was a beginning ELL or a more advanced ELL that was allowed to take the tests in their native language.

Beliefs about the Interconnection of Language and Mathematics

A little more than half (52.44%) of the PSTs agreed with the statement, "Mathematics uses symbols and ideas that are not associated with any language or culture," with 23.17% being undecided and 24.39% disagreeing. This is in line with beliefs about mathematics being a universal language that is structured and the same for everyone regardless of country or region (Kloosterman, 1999). Indeed, both authors have regularly had informal interactions with PSTs who claim that "2+2=4" is true in any language or culture. This view of universality may account for why a majority of PSTs (55.49%) agreed that mathematics would be ideal to transition recent immigrant students into English. About a third (33.54%) of the PSTs, however, were undecided. It is possible that the PSTs that comprised this percentage see mathematics as inherently difficult and challenging and thus felt that mathematics would not be ideal for any student, regardless of language ability. When asked to consider if ELLs who could hold a conversation in English would have no more of a problem that non-ELLs learning mathematics in an English only classroom, a little less than half of the PSTS (48.78%) disagreed. Moreover, almost 60% of the PSTs disagreed with the statement "Mathematics is not language intensive."

Beliefs about Teaching Mathematics to ELLs

More than two-thirds of the PSTs agreed that ELLs should receive instruction in their native language until they are proficient enough to learn via English. This view is in-line with research (e.g. Moschkovich, 2000) that suggests that educators should draw upon resources ELLs bring with them, such as their native language. Just about or above two-thirds of the PSTs also agreed that teachers should focus on language when working with ELLs be it through focusing on objectives related to language or enacting explicit language learning strategies. Of the PSTs that did not agree with these ideas, a majority (85.9% for objectives and 74.5% for enacting) were undecided suggesting perhaps that the PSTs might be unsure of how or why a mathematics teacher should focus on language. Less than half of the PSTs (48.18%) believed that teachers should use the same standards in evaluating the work of all students, with about a third disagreeing and 18.29% undecided. This distribution points to the fact that while PSTs want to be fair in assessing what their students know and can do, a majority at least question how that fairness should play out in the classroom. In regards to how culture should impact the teaching of mathematics, a large number (84.15%) of PSTs felt that it is important to incorporate aspects of the students' culture into mathematics teaching. While we cannot know for certain from this statement alone, it seems that PSTs did not consider the depth to which a student's culture should be incorporated. Instead, they may have felt that, for example, using a context with which an ELL may be familiar in a story problem constitutes incorporating a student's culture. Indeed, when asked if culture should play a *significant* role in the learning and teaching of mathematics, the percentage of respondents who agreed dropped to 56.1, a 33% decrease.

Comparison of Groups

The total scores of the PSTs were divided into quartiles, with Min=33, Quartile 1= 51, Median=55, Quartile 3=58, and Max=62. A box-plot of the scores is shown in Figure 1. Comparing PSTs in G1 (or the scores in upper quartile) to PSTs in G4 (or the scores from the lower quartile), we found the biggest differences in the means of items 1 (G1=3.93, G4=2.71), 7 (G1=3.66, G4=2.49) and 2 (G1=3.32, G4=2.27). This indicates that PSTs in G4 tended to put more emphasis on English only education and were also more likely to mistake conversational proficiency for academic language fluency than PSTs in G1. Items 6 (G1=2.63, G4=2.37), 9 (G1=3.78, G4=3.22) and 5 (G1=2.95, G4=2.32) had the smallest differences of means between G1 and G4. The means in item 6 and 5 were closer to 1 indicating that the PSTs may have felt that mathematics is a difficult subject for all students, independent of language and culture. Item 9 showed that PSTs from G1 and G4 believed that ELLs should receive mathematics instruction in their native language until they are proficient enough to learn via English instruction. Given the beliefs of PSTs from G1 towards language (as seen in items 1, 7 and 2), it is possible that these PSTs view the teaching of ELLs as the exclusive responsibility of the ESL teachers in the school and may be less open to making accommodations in their own classrooms. Demographically, PSTs from G1 and G4 were similar in terms of gender, ethnicity, and previous experience with ELLs, however, the two groups differed in their exposure to a second language. There were 18 PSTs in G1 that spoke English only, compared to 28 in G4; and 23 that spoke an additional language at varying levels of fluency in G1, compared to 13 in G4. Considering this difference, the alignment of the PSTs' beliefs seen in items 1, 7, and 2 to the research could be attributed to their experience in learning a second language.

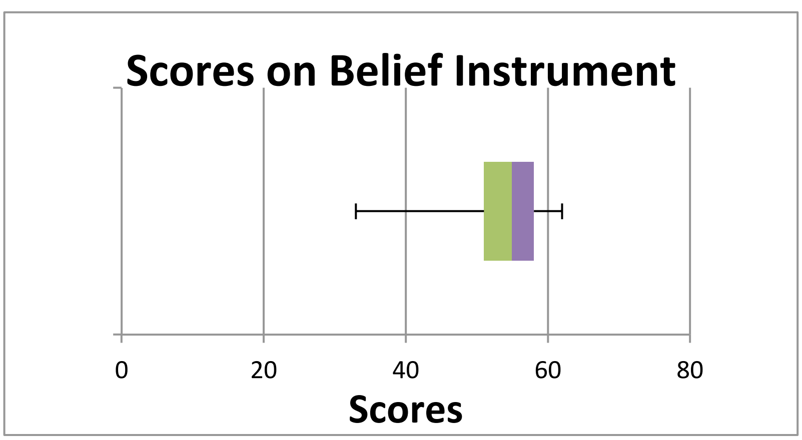

Figure 1. PSTs' overall scores on belief survey

Discussion

The calculation of percentages of PSTs who agreed or disagreed with a particular statement revealed some interesting connections among the PSTs' beliefs. One in particular concerns how PSTs may see culture within mathematics and mathematics teaching. An overwhelming 84% of PSTs agreed that a student's culture should be incorporated into mathematics teaching, with about 56% stating that culture should play a significant role in the teaching of mathematics. However, about 75% of the PSTs either agreed or were undecided that the symbols and ideas used in mathematics are not associated with any language or culture. These numbers indicate a possible disconnect for PSTs in the teaching of mathematics. One strategy for teaching ELLs suggested from research (e.g. Short & Echevarria, 2004) is to contextualize mathematics through the use of realia and the culture of ELLs in meaningful ways. The possible belief structure of the PSTs based on the percentage calculations suggests that even though PSTs may agree with the strategy suggested in the research, they may not understand how it is feasible to do so in the area of mathematics given that mathematics itself is devoid of context. If this is indeed the case, it sheds light on why teachers (both at the preservice and inservice levels) incorporate culture sometimes in seemingly superficial ways (e.g. changing the names of a story problem).

Finally, as seen in the comparison of groups, the PSTs who had beliefs that fell in the upper quartile (meaning that these PSTs had beliefs which were most consistent with findings from research) reported more experiences learning a language other than English than those PSTs who fell into the lowest quartile. It seems then that by experiencing the learning of another language, PSTs may have empathy for the experience that ELLs go through on a daily basis. However, this empathy may not translate into their teaching practice, as it is possible that they do not see it as their role as a classroom teacher to provide ELLs the type of support called for in research. If this empathy is cultivated, challenged, and nurtured though, PSTs that display the beliefs seen in this survey may develop the habit of mind and teaching practices that are consistent with best practices for teaching ELLs.

Closing Thoughts

While we acknowledge that beliefs are not static and in fact are affected by many factors at any given point in time, it is important that teacher preparation programs take into account what a PST is thinking regarding the mathematics education of ELLs. As can be seen through the findings and discussion from this pilot study, the use of a survey can provide a window into how PSTs may view the inclusion of language in the school context, the interconnection of language and mathematics and the teaching of ELLs. Mathematics teacher educators can use the valuable insight gained from the survey to design meaningful, relevant, and engaging experiences that challenge and confront PSTs' beliefs in an intellectual and respectful manner.

Endnotes

1. We consider English Language Learners (ELLs) as those students who are still developing a proficiency in English and consist of students who speak a language other than English at home.
2. The basic level is the lowest of the three levels a student can obtain on a NAEP assessment and is defined as "mastery of prerequisite knowledge and skills that are fundamental for proficient work" (NCES, 2009).
3. Proper credit was given in all cases where items from other surveys were adapted.

4. This percentage includes those respondents who either reported 'English' or 'English' plus an elementary/limited/brief amount of a different language when asked, "What languages can you speak? Please explain."

HIGH-STAKES STANDARDIZED MATHEMATICS TESTING IN URBAN HIGH SCHOOLS: AN EQUITY PERSPECTIVE

Laurie H. Rubel
City University of New York (Brooklyn College)
LRubel@brooklyn.cuny.edu

This article examines mathematics opportunities at two urban high schools in the context of high-stakes standardized testing. Case studies were conducted at two urban high schools in low-income neighborhoods. Data includes opportunities in mathematics offered to students at the school level, in terms of mathematics course sequencing, and at the classroom level in terms of task cognitive demand and participation modality. In particular, this article focuses on two related questions: 1) Do high-stakes standardized testing set high standards for all students? and 2) Do mathematics teachers "teach to the test" and if so, how?

Educational equity is often framed as a significant rationale for high-stakes standardized testing (Diamond & Spillane, 2004). Proponents of high-stakes standardized testing argue that the tests hold schools and teachers accountable to providing all students with a high quality education (No Child Left Behind Act, 2008). Others (e.g., Au, 2007; Koretz, 2008) contend that an emphasis on testing prompts schools and teachers to adapt their curricula to "teach to the test." The primary goal of this paper is to explore the two sides of this argument, in the context of mathematics education at two urban high schools that serve Black and Latino/a students from low-income families. While other studies explore the impact of standardized testing on teachers' instructional practice by strictly using a methodology of surveying or interviewing teachers (e.g., Barksdale-Ladd & Thomas, 2000), this study examines the potential relationship between high-stakes standardized testing and equity in mathematics education empirically, with data from classroom observations.

The paper begins with a presentation of the research context and description of data sources. It continues with a presentation of results organized around the dual themes of standardized testing as promoting high standards for all students and teachers "teaching to the test." The discussion section summarizes the study's findings and poses questions for further research.

Methods

Research Context

Urban school districts, because of their size, typically serve a diversity of students, along racial, linguistic, religious, and socioeconomic dimensions. However, while a city may be diverse across many dimensions, it is typically an aggregate of smaller neighborhood units, which are often homogenous in terms of race and socio-economic class. African American and Latino/a students from the lowest income families tend to be clustered in schools in particular urban neighborhoods (Lipman, 2004). The research described in this paper is conducted in two such neighborhoods in New York City, each with about 130,000 residents: Bushwick is primarily Latino/a (split among Puerto Ricans, Dominicans, Mexicans, and Ecuadorans), and Brownsville, about a mile away, is primarily African American. These neighborhoods are among the ten lowest income neighborhoods citywide; more than half of families in Bushwick and more than 2/3 of families in Brownsville are in the bottom two quintiles of city income levels (Furman Center, 2008).

Harwood and Carver are pseudonymously named high schools located in these two neighborhoods. At Harwood, in 2009-2010, just over two-thirds of students self-identified as "Hispanic or Latino/a," and the other nearly one-third self-identified as "Black or African American." About 90% of the school's families were recipients of public assistance. Carver also serves students from low-income families; about 81% of its families were recognized as recipients of public assistance. In 2009-2010, about 90% of Carver's students self-identified as "Black or African American," and the remainder of students self-identified as "Hispanic or Latino/a" (statistics cited in this paragraph are from New York State Education Department, 2010).

Harwood and Carver were the two partner schools for the Centering the Teaching of Mathematics on Urban Youth (CTMUY) professional development project in 2009-2011. CTMUY is an NSF-funded, integrated research and professional development project, focused on improving classroom-level opportunities to learn mathematics provided to students at high schools in underserved urban neighborhoods (for more details about the professional development project, see Rubel, in press and Rubel & Chu, accepted for publication).

Data Sources

Data for this analysis includes school-level data, teacher-level data, and classroom-level data, described in more detail below.

School data. Ethnographic school visits were conducted at Harwood and Carver in 2008-2009 and 2009-2010 as part of the schools' participation in CTMUY. Interviews were conducted with assistant principals and principals, as part of the data collection for that larger project about each school's course offerings in mathematics and rationale for those offerings. In addition, student standardized testing data was gathered from annual state report card.

Teacher data. Three focal teachers at Carver and four focal teachers at Harwood completed a Likert-scale survey which included items, among others, about the degree to which they emphasize a variety of objectives, such as preparing for standardized tests, increasing students' interest in mathematics, or preparing students for further study in mathematics.

Classroom observations. As part of the teachers' participation in CTMUY, each of three focal teachers at Carver and four focal teachers at Harwood were visited for ten classroom observations across the 2009-2010 school year. Observations were conducted in four clustered rounds across the school year. Each teacher's set of ten observations was conducted in the same class period, with the same group of students. Fieldnotes were taken during the classroom observations and were then expanded into detailed narrative descriptions. Two teachers each had single observations that were highly atypical, either because of teacher illness or student attendance, and those two observations were dropped from the data set.

Each lesson's main mathematical task was identified and then classified in terms of its cognitive demand, using categories from Henningsen & Stein (1997). Cognitive demand can be low-level, if the task presented to students relies strictly on memorization or if it is a strictly procedural task, that does not offer connections to concepts, understanding or meaning. Tasks that have a high level of cognitive demand might be complex and non-algorithmic ("doing mathematics) or procedural in nature, however, the task's procedures connect explicitly to concepts, understanding or meaning.

A second quantitative measure of each observed lesson pertains to the various participation modalities offered to students. I utilized a set of categories adapted from Weiss, Pasley, Smith, Banilower & Heck (2003): listening; investigating or problem solving; discussing; reading, writing, or reflecting; using technology; or practicing skills. Each lesson was subdivided according to the various participation modalities offered to students, and those modailities were quantified in terms of relative minutes of instruction.

Results

Results are presented in terms of two themes. First, I explore the notion of high-stakes testing as a mechanism that promotes high standards for teachers and students, using the examples offered by Carver and Harwood. Next, I analyze project data to investigate if and how teachers at Carver and Harwood "teach to the test" in the context of high-stakes standardized testing.

High Standards and/or Gatekeeper?

In New York, to graduate from high school, students must pass a state standardized exam in mathematics that corresponds with state courses in Algebra, Geometry, or Algebra 2/Trigonometry. However, because of the actual, or perceived, nature of mathematics as a strictly cumulative discipline, in practice, the state's entry-level algebra exam plays the dual role of functioning as the 'high standard for all students' and as the gatekeeper of high school graduation. Table 1 contains the percentage passing rates on the state's entry-level algebra exam, for the classes of 2009 and 2010 at Carver and Harwood at the end of their four years of high school. As shown, at Harwood, in both the classes of 2008 and 2009, only about half of its students passed the entry-level algebra exam by the end of high school. As a result, Harwood did not meet the Adequate Yearly Progress (AYP) thresholds determined by the No Child Left Behind Act in either year. After two years of not meeting AYP, Harwood was then labeled a "school in need of improvement (SINI)" and was subject to a state quality review of their mathematics program. In 2010, their results improved significantly and exceeded the AYP threshold, with 72% of the graduating class passing the state's entry-level algebra exam.

Carver High School, on the other hand, had relatively stable frequency of passing the algebra exam: 65% of students in the class of 2008, 72% of students in the class of 2009, and 66% of students in the class of 2010 passed the algebra exam by the end of high school. Carver's results exceeded the AYP threshold in 2008 and 2009. Although a higher percentage of students in the class of 2010 passed a mathematics exam than the class of 2008, in 2010, because of the changing nature of the AYP thresholds, Carver did not make AYP in mathematics (all data is from New York State Education Department, 2008, 2009, 2010).

	Class of 2008	Class of 2009	Class of 2010
Carver	65% (98)	72% (93)	66% (92)
Harwood	48% (105)	52% (102)	72% (97)

Table 1. Percentage of students passing entry-level algebra exam

As we see in Table 1, the percentage of seniors at Carver who passed the state algebra exam remained roughly constant, with a slight increase in 2009 and a corresponding decrease in 2010. Harwood, on the other hand, showed dramatic improvement in 2010. One interpretation of these results is that, after two years of low performance on the mathematics exams, the sanctions imposed on Harwood pushed the school and teachers to focus their efforts on preparation for the algebra examination. In fact, at Harwood, in 2009-2010, the school structured their staffing resources so that the eleventh and twelfth graders who had not yet passed the algebra exam had mathematics class two periods each day. This evidence suggests that the mechanism of the state standardized test, and the sanctions that come with poor performance, pushed Harwood to focus its resources on its struggling students, by offering them double the amount of instructional minutes in mathematics.

A second interpretation of this data focuses on the mathematics opportunities that result from an institutional emphasis on a *minimal* requirement. In other words, the accountability system does not rate schools in terms of the learning opportunities they provide to all students. Instead, the accountability system sanctions schools whose students do not meet a minimum requirement, in this case, passing an entry-level algebra exam. So at Harwood, in the 2008-2009 and 2009-2010 school years, students who did not pass the algebra exam at the end of their ninth grade year were placed in remedial “repeater classes” to retake the algebra course. Many students continued to cycle through the remedial classes all the way through their four years of high school. For instance, in the fall semester of 2009-2010, nearly 67% of all Harwood general education students were taking or re-taking the New York State entry-level Integrated Algebra course. So by the end of their four years of high school, while 72% of Harwood’s students from the class of 2010 passed the state’s algebra exam, many of these students (and of course, the 28% of the class who did not pass the algebra exam) were not given the opportunity to study geometry or any other mathematics as part of their high school education.

The case of Carver High School strengthens the interpretation of high stakes standardized testing functioning as gatekeeper. At Carver, during the 2008-2009 and 2009-2010 school years, students progressed through a sequence of Algebra, Geometry, Algebra 2/Trigonometry, irrespective of whether they passed the entry-level algebra exam. Those students who did not pass the exam were assigned to before school, after school, or Saturday sessions to continue to practice for that exam. However, once Carver did not make AYP in mathematics in 2010, Carver changed their course sequencing policy for their students in 2010-2011. While all students progressed from 9th grade algebra to 10th grade geometry, any eleventh or twelfth grade student who had not passed the entry-level algebra exam was removed from the mathematics course progression and tracked into a designated remedial “test-prep” mathematics class.

The analysis in this paper has, thus far, focused on school-level processes of course sequencing in the context of high-stakes standardized testing. In the next section, the analysis zooms in to the classroom level to examine the issue of if and how teachers at Carver and Harwood “teach to the test.”

“Teaching to the Test”

One way to examine the potential relationship between high stakes standardized testing and teachers’ pedagogical practices is to survey teachers. At the start of the CTMUY project, for example, all seven focal teachers at Carver and Harwood reported that they place moderate or heavy emphasis on preparing students for standardized tests. On the same survey, only three of the seven focal teachers indicated that they place moderate or heavy emphasis on preparing students for further studies in mathematics. Similarly, only three of the seven focal teachers indicated that they place moderate or heavy emphasis on increasing students’ interest in mathematics. Even though this is an extremely small sample of teachers, these results suggest that these teachers take the accountability system of high-stakes standardized tests seriously, mirroring findings of Barksdale-Ladd & Thomas (2000). I expand upon these findings to illuminate how a teacher’s emphasis on preparing students for standardized tests might be expressed in mathematics instruction. I build upon the definition of curriculum as presented by Au(2007) as including a) subject matter content knowledge; in this case, the mathematics content that is included in a curriculum, 2) structure or form of curricular knowledge; how mathematics is structured and presented within a curriculum, and 3) pedagogy; how that mathematical knowledge is communicated.

Mathematics content of curriculum. The high stakes standardized tests and the mathematics learning standards are both created and endorsed by the state and the school district, and they are therefore, assumedly, in direct correspondence. In the case of New York, high schools and their teachers are accountable to aligning the mathematical content of their 9th grade curriculum to the state’s algebra standards. Proponents of high-stakes testing argue that this standardizes the opportunities offered to students. So even in low-income neighborhoods like Bushwick and Brownsville, students are studying the same set of algebraic concepts and skills as everywhere else in the state. Seen in this way, "teaching to the test" pushes teachers to maintain high mathematics standards for their students by using the state's mathematics standards to guide the mathematical content of their curriculum.

Form of curriculum. In schools like Harwood and Carver, where students enter high school with a history of poor test scores, teachers are under enormous pressure for their students to achieve good results on high-stakes tests. Another interpretation of "teaching to the test," especially in contexts like these, is, therefore, that teachers will pattern the actual mathematical tasks they pose to students in the classroom, or the structure or form of mathematical knowledge, to precisely reflect the tasks that are offered on the standardized exams. By their very nature, standardized test tasks are limited to the types of questions that can be expressed in multiple-choice or short-answer form, have a single correct answer, and perhaps most importantly, can be completed in a very short time. These tasks typically require low-level forms of knowledge in that they tend to either require recalling a term or a executing a well-defined procedure (Williams, 2010).

I analyze this issue of "teaching to the test" first by examining the cognitive demand level of the mathematical tasks in the 68 observed classes at Carver and Harwood. Table 2 contains the distribution of cognitive demand level of these mathematical tasks in the 29 observed lessons at Carver and the 39 observed lessons at Harwood.

	Low-Level			High-Level	
	Memorization	Procedures without connections	Other	Procedures with connections	Doing mathematics
Carver	10	10		8	
Harwood	1	27	2	9	1
Total	11	37	2	17	1

Table 2. Task Cognitive Demand

As shown in Table 2, 50 of the 68 tasks were rated as low-level tasks, indicating that they were either memorization tasks (11), focused on procedures without connection to concepts, meaning or understanding (37), or were otherwise low-level (2). Only 18 of the 70 tasks were rated as high-level tasks, indicating primarily that they were tasks that focused on procedures with connection to concepts, meaning or understanding (17). In addition, 17 of these 18 high-level tasks were limited to only two of the seven focal teachers. In other words, the students in the classes of four focal teachers were offered only low-level tasks, in the 40 observed lessons of those teachers. These results strengthen the claim that teachers "teach to the test" by offering students low-level mathematical tasks, which correspond to the types of tasks found on standardized tests.

Pedagogy of curriculum. Another means of analysis as to if and how teachers are "teaching to the test" is to consider the forms of participation opportunities they make available to students in their mathematics classes. Table 3 contains the relative frequency of each participation modality offered to students in the 29 observed mathematics classes at Carver and the 39 observed mathematics classes at Harwood.

Teacher-centered modes of participation, such as listening to the teacher, practicing skills and “housekeeping” (taking attendance, collecting homework, distributing textbooks) dominated the observed lessons at both Carver and Harwood, as shown in Table 3. In fact, in the observed classes of four of the seven focal teachers, these teacher-centered modes of participation occupied more than 80% of the instructional time (not shown in Table 3). Notably, teachers organized classes, on average, for students to participate by “practicing skills” 37% of the mathematics time at Carver and 32% of the time at Harwood. At both schools, the “practicing” consisted of teachers distributing worksheets with tasks modeled specifically on previous state test items. Teachers created these worksheets using a free, Internet-based application, which consists of a search engine that generates such worksheets in printable form. Student-centered modes of participation, like whole-class discussion, listening to other students, problem solving or investigating, using technology, or writing were offered much more infrequently in the observed lessons, on average: only 26% of the time at Carver and 42% of the mathematics time at Harwood.

Forms of Participation	Carver 29 classes 60 min each	Harwood 39 classes 48 min each
Teacher-centered		
Listening to teacher	29%	22%
Practicing	37%	33%
“Housekeeping”	8%	3%
Total	74%	58%
Student-centered		
Discussing	10.%	12%
Listening to students	2%	3%
Investigating	9%	22%
Writing	4%	4%
Using technology	1%	1%
Total	26%	42%

Table 3. Frequency of Participation Modalities

There is a relationship between the cognitive demand of a lesson’s task and the participation modalities offered to students to complete that task. Low-level tasks, which typically require memorization of facts or execution of steps of a well-defined procedure, lend themselves to listening and practicing. The teachers in this study who exclusively offered low-level tasks to their students also nearly exclusively offered the teacher-centered forms of participation of listening to the teacher and practicing. In contrast, tasks with higher-level cognitive demands, in which students are challenged to detect patterns or make and communicate connections across mathematical representations, afford more varied opportunities for students. The teachers in this study who offered high-level tasks to their students also offered student-centered participation modalities like investigating or discussing.

Discussion

In this paper, I have presented dual themes related to mathematics education in a context of high-stakes standardized testing. In some ways, the current accountability system in New York forces high schools to maintain high standards for all students. While in the past, high school students could earn “local diplomas” without passing any state mathematics exams, current state mandates require that students pass a state mathematics exam in order to graduate from high school. In the context of schools in low-income neighborhoods, this mandate has had an impact in that schools are now required to place their 9th grade students in algebra courses, as opposed to primarily placing students in remedial level courses in "pre-algebra" or "consumer mathematics."

Although most of the students at Carver and Harwood pass their schools' 9th grade mathematics courses, most of the 9th grade students do not pass the corresponding state exam. This presents the schools with a dilemma: should the students retake a course that they have already taken and passed, should the students proceed through the high school mathematics curriculum, or should the school restructure its entry-level course to stretch over multiple years? The accountability system does not reward schools for having students take more or more challenging mathematics courses, and instead, sanctions schools for having students not meet the minimum requirement. Therefore, I argue that the accountability system encourages schools to follow the first option, i.e. cycle students through remedial courses, with a test-preparation emphasis, until they pass the test. The effect that this has had at Carver and Harwood is that this entry-level mathematics examination is positioned as a "finish-line" towards graduation, instead of a starting point for continued success. Students need knowledge in geometry and algebra 2/trigonometry to succeed in college placement tests or in college courses, so this inversion of a minimum requirement to function as an end goal ultimately does students a great disservice.

Others have claimed that "the weight of the high stakes testing environment falls heaviest on the shoulders of low income students and students of color" (Au, 2009, p.3). More specifically, Jones, Jones & Hargrove (2003, p.115) posit that low income students "are hit doubly hard (by high-stakes standardized testing) – not only do they tend to have lower scores on high stakes tests that may block them from subsequent opportunities, but the instruction that they receive might actually be worse than the instruction that they received before the testing policy was implemented." This claim is substantiated, perhaps, by this data and analysis.

While it remains hypothetical, of course, as to what the mathematics instruction at Carver and Harwood might resemble without high-stakes standardized testing, the observed structure and pedagogy of the curriculum at both Carver and Harwood are in alignment with standardized testing in several ways. Focal teachers most often presented students with tasks of low-level cognitive demand whose form corresponds to the low-level form of the state exams, typically involving recalling a vocabulary term or short, well-defined procedure. In addition, these low-level tasks were presented in a classroom pedagogical environment that privileges teacher-centered forms of participation. Students were typically expected to participate in mathematics, throughout the school year, by listening (to the teacher) and practicing, using worksheets created from a bank of test items readily available to teachers on the Internet. Opportunities for students to investigate patterns, to solve non-routine problems, to use technology to discover relationships, or to write or reflect about a mathematical concept or process were far more limited in the observed classes.

This preliminary analysis suggests that the context of high-stakes standardized testing is complex and merits analysis with an equity lens. A common perspective is that high-stakes standardized testing promotes equity by setting and enforcing high standards in mathematics. This analysis has demonstrated that we also need to consider the ways in which high-stakes standardized testing "exacerbates inequities" (Diamond & Spillane, 2004). This study has demonstrated the particular ways that high-stakes standardized testing also functions as a gatekeeper in urban high schools. In addition, this study provides description and nuance to how teachers "teach to the test" by providing students with low-level mathematical tasks using teacher-centered forms of participation.

THE GENDERING OF MATHEMATICS AMONG FACEBOOK USERS IN ENGLISH SPEAKING COUNTRIES

Helen Forgasz	Gilah Leder	Hazel Tan
Monash University, Australia	Monash University, Australia	Monash University, Australia
Helen.Forgasz@monash.edu	Gilah.Leder@monash.edu	Hazel.Tan@monash.edu

Using an innovative recruitment tool, the social network site Facebook, survey data were gathered from samples of the Australian general public and from around the world. Views on the gendering of mathematics, science, and ICT were gathered. In this paper we report the findings from six of the 15 questions on the survey, and only from respondents in predominantly English-speaking countries. The findings reveal that the majority was not gender-stereotyped about mathematics and related careers. However, if a gendered view was held, it was overwhelming to endorse the male stereotype. Male respondents' views were more strongly gendered than were females'.

Prologue

The new focus on nature seems to be encouraging parents to indulge in sex differences even more avidly…. From girls' preschool ballet lessons and makeovers to boys' peewee football… the more we parents hear about hardwiring and biological programming, the less we bother tempering our pink and blue fantasies. (Freeman-Greene, 2009, p.11)

Providing a Context

Publication of student achievement data from large scale testings ensures that gender differences in mathematics learning continue to attract sustained attention from both the research and broader communities. Results from the Organisation for Economic Co-operation and Development's [OECD] Programme for International Student Assessment [PISA], for example, receive considerable media attention on their release. Such media reports on performance may include comments on gender differences. Often, however, simplified summaries of complex data are presented (Forgasz & Leder, 2011). This is not altogether surprising, given reporters' time and space constraints. That such media accounts often shape and sway public opinion, including views on gender issues, is well documented (e.g., Barnett, 2007; Jacobs & Eccles, 1985).

Possible Explanations for Gender Differences in Mathematics Achievements

Multiple explanations have been put forward for the persisting patterns of gender difference in mathematics achievement. After a detailed review of relevant literature, Halpern et al. (2007) concluded that the reasons for the overlap and differences in the performance of males and females were multifaceted, could not be explained by a single factor, and that "[e]arly experience, biological constraints, educational policy, and cultural context" (p. 41) could all play a part. Geist and King (2008) referred to pervasive societal beliefs about gender linked capabilities and their impact:

Many assumptions are made about differing abilities of girls and boys when it comes to mathematics. While on the 2005 NAEP girls lag only about 3 points behind boys, this is only a recent phenomenon. In the 1970's, girls actually outperformed boys in all but the 12th grade *test…. assumptions about differing levels of ability pervade not just the classroom, but home. (pp. 43-44)*

In their detailed model of achievement motivation, and implicitly of academic success, Wigfield and Eccles (2000) highlighted the influence on students' learning and behaviours not only of learner-related variables but also of the overall context in which learning occurs, that is the attitudes, actual and perceived, of critical "others" in the students' home, those at school, and societal expectations more generally.

Societal Expectations - Public Views about Mathematics: Gauging Public Opinion

Attempts to measure directly the general public's views about mathematics, science, or ICT, or the teaching of these subjects, or their impact on careers, are rare. With respect to mathematics, for example, more than two decades have passed since a genuine attempt was made by the Victorian (Australia) state government to gauge parents' attitudes towards their daughters' education and career (McAnalley, 1991). This exercise was linked to the state-wide media campaign, *Maths Multiplies Your Choices,* a program introduced to encourage parents to think more broadly about the likely influence of mathematics on their daughters' careers. Since that time, in Australia there has been no similar concerted, large scale, and appropriately funded, attempt to measure the general public's views about school mathematics, its link with technology, and possible career options.

A decade ago in the UK, Sam and Ernest (1998, p. 7) noted that "there are relatively few systematic studies conducted on the subject of myths and images of mathematics. We need an answer to the question: What are the general public's images and opinions of mathematics?" Lucas and Fugitt (2007) similarly argued that the public's views on mathematics and mathematics education were rarely sought. Yet, they found that Mid-West USA residents responding to a 10-item survey were generally interested in, and often well informed about, the way mathematics was taught in schools. The respondents generally believed that a good mathematics education offered young people a better and successful future; schools failed to offer effective mathematics education because too much emphasis was placed on technology and not enough on the basics; teachers often exerted too much pressure and criticism to the detriment of their students' attitudes to mathematics; and teachers should make learning mathematics more enjoyable. Issues such as these were also explored in the study reported in this paper. The general public's views about aspects of mathematics were explored. Also examined was whether or not the views expressed were gender stereotyped.

The Study

In the present study, data from respondents in countries in which English is the dominant language – Australia, Canada, Ireland, New Zealand, UK, and USA – were analysed. While data were also gathered from participants living in many other countries around the world, in this paper we focus predominantly on countries where English is the most commonly spoken language for the following reasons:

- In broad terms, cultural differences are small among citizens across these countries
- Almost without exception, the mathematics achievements of males in these countries are found to be superior to females'

All six countries participated in PISA 2009. The gender differences in the mean scores for these countries are shown in Figure 1 – the data were drawn from Thomson, De Bortoli, Nicholas, Hillman, and Buckley (2010).

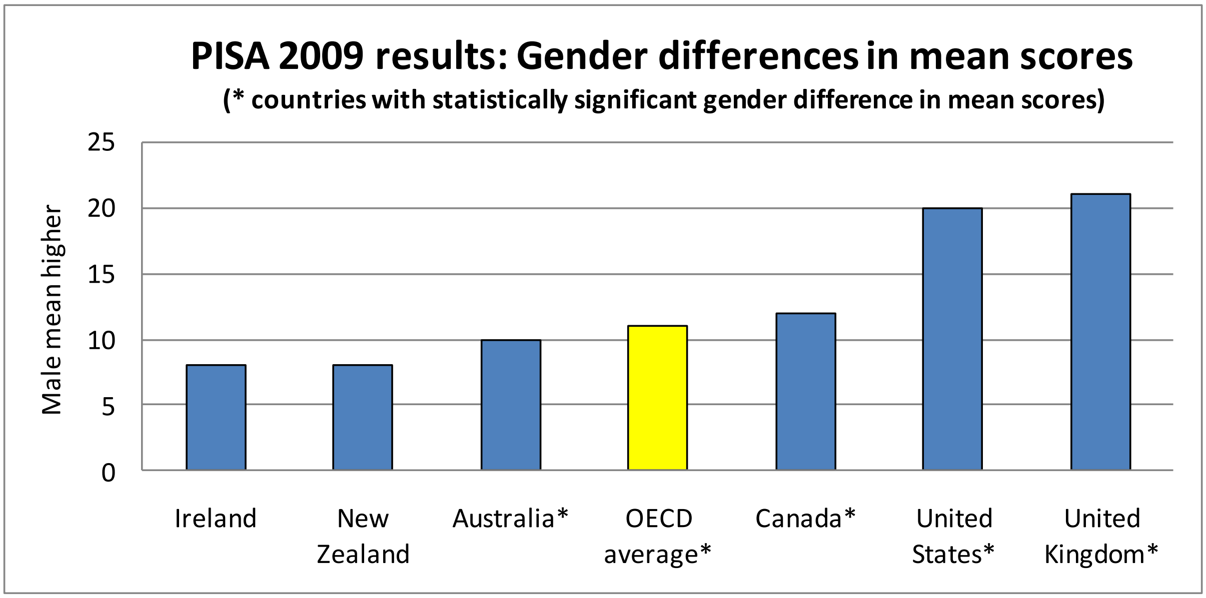

Figure 1. PISA 2009 results by country and gender difference in mean scores

From Figure 1 it can be inferred that there is much overlap in the performance of males and females. However, it is also apparent that males outperformed females in each country. As noted by Thomson et al. (2010), the differences in the mean scores were statistically significant for Australia, Canada, UK, and USA.

For many countries participating in the Trends in Mathematics and Science Study [TIMSS] in 2007, females' mean scores in mathematics were higher than males'. However, there were several countries, including all participating English-speaking countries, for which the reverse was true. Gender differences in favour of males were noted as follows at the Grade 4 and Grade 8 levels respectively: Australia (6 points, 16 points*), New Zealand (1 point, did not participate), England (1 point, 5 points*), Scotland (did not participate, 3 points) and USA (6 points*, 3 points) – see Thomson, Wernert, Underwood, and Nicholas (2008, pp. 59, 61). [NB. * indicates statistically significant gender differences.]

In this study, it was of particular interest to determine if members of the general public in English speaking countries held views that might support the hypothesis that performance differences are consistent with the perceptions of society at large with respect to the gendering of mathematics learning outcomes.

The data presented in this paper are a subset of a larger study which involved gathering data from 12 different heavy foot-traffic sites throughout Victoria (see Leder & Forgasz, 2010 for details) as well as from an 'advertisement' to recruit participants placed on the social network site, Facebook (http://www.facebook.com). Facebook was selected as the recruitment site to reach a more diverse international group of participants. The overall aim of the study is expressed concisely in an excerpt, provided below, of the "explanatory statement" made available to Victorian participants and required for obtaining ethics approval for the study.

We have stopped you in the street to invite you to be a participant in our research study. ...We are conducting this research, which has been funded by [our] University, to determine the views of the general public about girls and boys and the learning of mathematics. We believe that it is *as important to know the views of the public as well as knowing what government and educational authorities believe*.

A modified version of this statement was used in the online survey that was directly linked to the Facebook advertisement. That is, Facebook users who clicked on the advertisement were directed to the online survey.

The Instrument

To maximize cooperation and completion rates, the surveys used (in the street and on Facebook) were limited to the same 15 core items. These focused on personal background data; the learning of mathematics at school; perceived changes in the delivery of school mathematics; beliefs about boys and girls and mathematics, and their perceived facilities with calculators and computers; and careers. In this paper we focus on six questions related to the importance of mathematics and the gendering of mathematics. The six items analysed and discussed are:

- Should students study mathematics when it is no longer compulsory?
  Yes/No/Don’t know/Depends
- Who is better at mathematics, girls or boys?
  Girls/Boys/Don’t know/Depends
- Do you think studying mathematics is important for getting a job?
  Yes/No/Don’t know/Depends
- Is it more important for girls or boys to study mathematics?
  Girls/Boys/Don’t know/Depends
- Who are better at using calculators, girls or boys?
  Girls/Boys/Don’t know/Depends
- Who are better at using computers, girls or boys?
  Girls/Boys/Don’t know/Depends

Respondents had the option to explain their responses to each question. However, only quantitative data analysed are presented and discussed here. [Space constraints precluded the reporting of findings from the open-ended responses and from quantitative analyses by respondent gender.]

Participant Recruitment, Online Survey, and the Social Networking Site, Facebook

The social network site, Facebook (http://www.facebook.com), was the avenue adopted to recruit the participants from whom data are reported in this paper. With the rapid advancement of internet technology, online surveys have become a viable method for data-collection in research (e.g., Sue & Ritter, 2007). Social network sites (SNS) such as Facebook are rapidly gaining worldwide popularity. “As of March, 2010, Facebook is the second ranked site on the Internet traffic metrics on alexa.com, accounting for almost 5 percent of all global page views” (Hull, Lipford, & Latulipe, 2010, p.1).

Except for research in which SNS users’ profiles and SNS usage are investigated, studies using Social Network sites [SNS] as a method of recruiting participants are relatively rare. In one such study, Howell, Rodzon, Kurai & Sanchez (2010) administered a well-being and happiness survey to participants recruited from a college and from the SNS, Craigslist. Incentives were offered for both data gathering methods. Although the completion rate was lower for those recruited via SNS (68.5%) than from the college (93.6%), the quality of data obtained by the two methods was comparable.

The Sample

There were 314 participants who completed surveys via Facebook. The advertisement was designed through Facebook's commercial advertising campaign system. The system allows particular groups to be targeted. Countries targets were changed on a weekly basis, but at all times, only those over 18 were sought. The advertisement appeared randomly on individual Facebook users' homepages in the targeted countries. Clicking on the advertisement was voluntary, as was completion of the survey. Thus the respondents were considered to represent a random sample of Facebook users over the age of 18 from a range of countries. The respondents represented 57 different countries around the world. Six were countries in which English is the dominant language: Australia, Canada, Ireland, New Zealand, the United Kingdom, and the United States. The composition, by gender (M=male, F=female), of the sample from each of these six countries is summarised in Table 1.

Country	N (M, F)	Country	N
Australia	74 (39M, 35F)	New Zealand	1 (OM, 1F)
Canada	12 (5M, 7F)	United Kingdom	22 (12M, 10F)
Ireland	2 (0M, 2F)	United States	6 (4M, 2F)

Table 1. Sample size, by gender, for English speaking countries

Results and Discussion

Since the Australian sample was the largest, we decided to explore if the combined data from the five other countries differed significantly from the Australian data. Chi-square tests were conducted on the responses to the six questions and no statistically significant differences were found in the response distributions for any item. This allowed us to confidently combine the data from all six countries. The valid percentage frequency distributions of the 117 participants' responses to the six questions are illustrated in Figure 2.

The data in Figure 2 indicate that the respondents generally agreed that:

- Students should study mathematics when it is no longer compulsory (65%), and that
- Studying mathematics is important for getting a job (72.2%)

For each of the questions to which respondents were asked to indicate whether boys or girls were more proficient, the majority of respondents claimed that there was no difference. This indicates that the majority is not gender-stereotyped in their views on boys' and girls' mathematics capabilities or their proficiency with calculators and computers, and that mathematics is considered equally important for both boys and girls.

However, a less positive pattern is also discernible in the data. If respondents held a gendered view on mathematics capability, calculator or computer proficiency, or for whom mathematics was considered more important, they were much more likely to indicate that it was boys rather than girls:

- Better at mathematics: 31.1% said boys, 10% said girls
- Studying mathematics is more important: 2.2% said boys, none said girls
- Better at using calculators: 14% said boys, 1.2% said girls
- Better at using computers: 34.5% said boys, 3.4% said girls

The data re-inforce earlier reported research findings. That is, there appears to be little difference between the perceptions of the general public and those of stakeholders (e.g., students, teachers, or parents) that boys are more talented mathematically and more able with technology than are girls (see Leder, 1992 with respect to views on mathematical talent; see Forgasz, 2009 with respect to teachers' views on technology for mathematics learning). There is also no evidence of a change in these perceptions over time – disappointing and pessimistic outcomes.

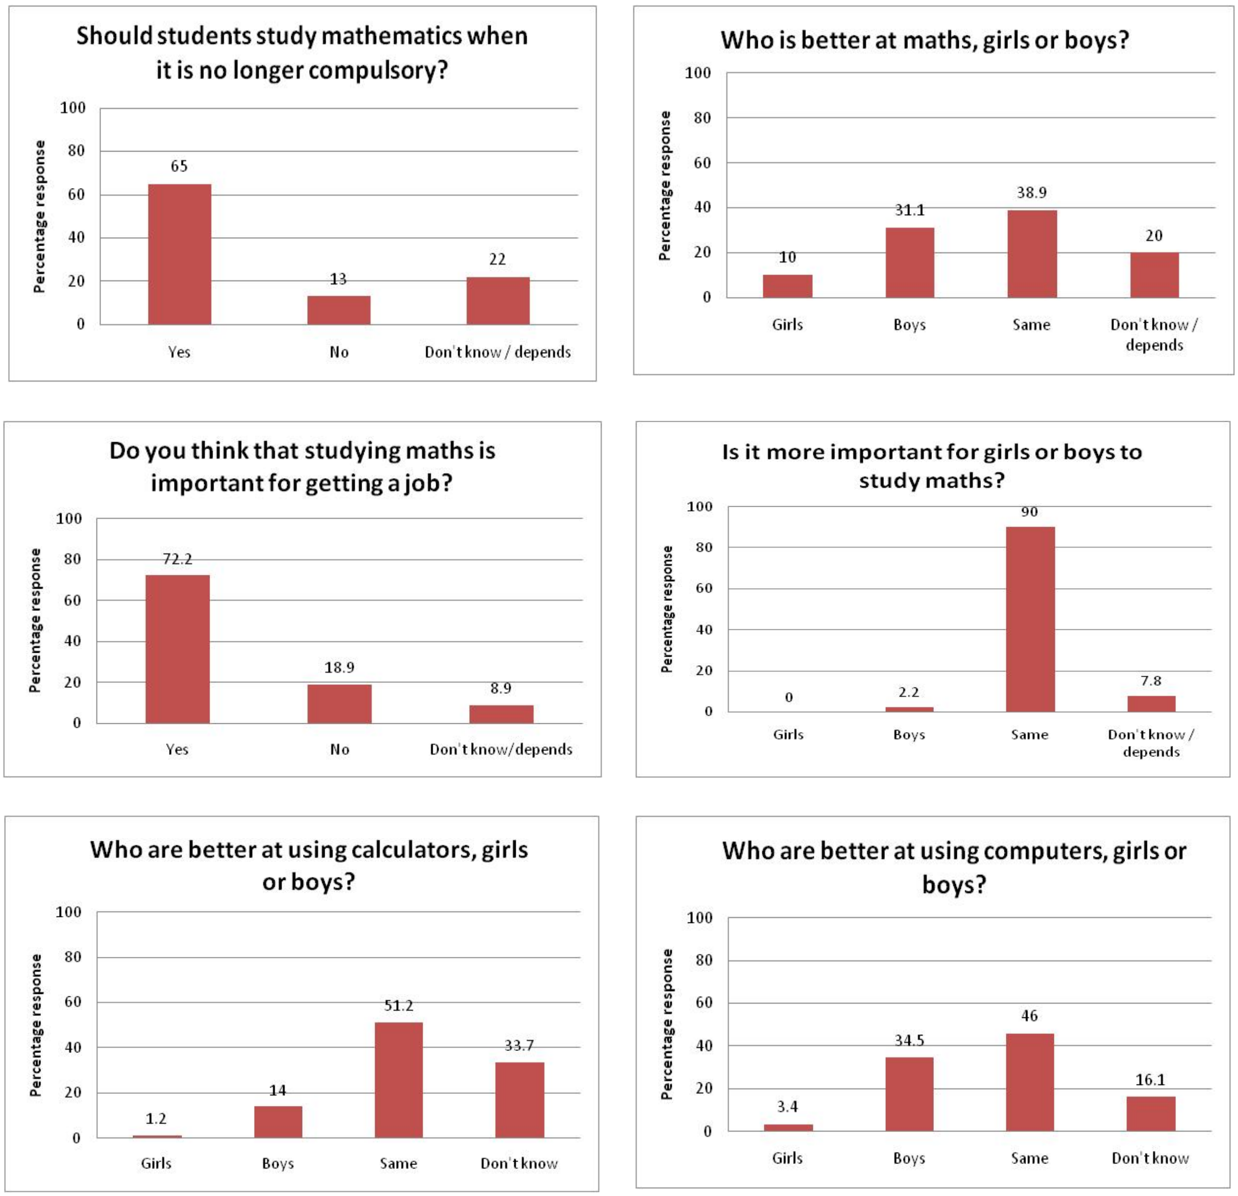

Figure 2. Valid percentage responses to the six survey items

Final Words

As noted above, gender differences favouring males in mathematics achievement are evident in large scale international testing results (PISA and TIMSS) in English speaking countries. In Australia, results from the National Assessment Program for Literacy and Numeracy [NAPLAN] reveal a similar pattern (see Leder & Forgasz, 2010). What is particularly alarming about the NAPLAN results is that the gender differences in favour of males are found at each grade level being tested: grades 3, 5, 7, and 9. This appears to be a retrograde trend since when Fennema was writing about gender differences in the 1970s (e.g., Fennema, 1974), there was little evidence of gender differences emerging prior to about grade 7. Gender differences in mathematics learning continue to attract media attention (see Forgasz & Leder, 2011). If the stories are not carefully crafted, the public will come away with views and beliefs shaped by the basic (simplistic) words they read (and interpret) and the images they see.

The data presented in this paper suggest that the general public from the targeted English speaking countries who engage with Facebook hold views that resonate with contemporary mathematics achievement data that they will have had thrust at them by way of the popular media and press. When the age profile of the respondent group is considered – no respondent was older than 60 and 85% was under 40 – the data become of even greater concern. It would appear that there is a critical mass of the younger generation who are reverting back to holding gender-stereotyped beliefs in favour of males with respect to mathematics and with the technology associated with mathematics learning. Their parent generation, mainly "Baby Boomers", lived through the era of feminist agitation that happened in the 1970s and 1980s. Their views were tapped by way of the street-based survey; many over 60s are in the streets during weekday hours. It was clear from the data that "[C]ompared to older respondents, the younger cohort was more likely to consider boys to be better than girls at mathematics and also better with calculators" (Leder & Forgasz, 2011).

The data presented here, although limited to a relatively small group of Facebook users in English speaking countries, lend weight to the contention that we may have come full circle and are now confronted with a young adult group holding traditionally gender-stereotyped beliefs about the domains of mathematics and the technology associated with mathematics.

AN ELEMENTARY 3D VISUALIZATION LEARNING TRAJECTORY

Jacqueline Sack
University of Houston Downtown
sackj@uhd.edu

Irma Vazquez
Houston Independent School District
irmavazquez@sbcglobal.net

This research team has developed a learning trajectory on 3D visualization for elementary children. This paper focuses on the interchange among the three Spatial Operational Capacity framework representations, namely, 3D models, 2D conventional diagrams, and semiotic abstract representations, and the critical role of a dynamic computer interface that simulates the representations. The trajectory is described through an actions-on-objects (Connell, 2001) lens and the project's strong problem-solving approaches that are critical to its successful enactment.

The National Research Council's report, *Learning to Think Spatially* (2006), identifies spatial thinking as a significant gap in the K-12 curriculum, which, they claim, is presumed throughout but is formally and systematically taught nowhere. They believe that spatial thinking *is* the start of successful thinking and problem solving, an integral part of mathematical and scientific literacy. The importance of visual processing has been documented by researchers who have examined students' performance in higher-level mathematics. For example, Tall et al (2001) found that to be successful in abstract axiomatic mathematics, students should be proficient in both symbolic and visual cognition; Dreyfus (1991) calls for integration across algebraic, visual and verbal abilities; and, Presmeg (1992) believes that imagistic processing is an essential component in one's development of abstraction and generalization.

The National Council of Teachers of Mathematics' *Principles and Standards for School Mathematics* (NCTM, 2000) recommends that in their early years of schooling, students should develop visualization skills through hands-on experiences with a variety of geometric objects and use technology to dynamically transform simulations of two- and three-dimensional objects. Later, they should analyze and draw perspective views, count component parts, and describe attributes that cannot be seen but can be inferred. Students need to learn to physically and mentally transform objects in systematic ways as they develop spatial knowledge.

Using design-research (Cobb, et al, 2003) principles this research team has developed a learning trajectory on spatial development for elementary children guided by the Spatial Operational Capacity (SOC) framework developed by van Niekerk (1997) based on Yakimanskaya's (1991) work. This paper focuses on the interchange among SOC representations and the critical role of a dynamic computer interface, through an actions-on-objects (Connell, 2001) lens. The project's strong problem-solving approaches make this possible. It is conducted in a dual-language urban elementary school within one of the largest public school districts in the mid-southwestern United States. More than 70% of its students are designated "At Risk" and at least 50% of its students are English Language Learners.

Theoretical Frameworks

The *spatial operation capacity* (SOC) framework (van Niekerk, 1997; Sack & van Niekerk, 2009) that guides this study exposes children to activities that require them to act on a variety of physical and mental objects and transformations, as prescribed by the National Council of Teachers of Mathematics (NCTM, 2000) to develop the skills necessary for solving spatial problems. The framework (see Figure 1) uses: full-scale figures, that, in this study, are created from loose cubes or Soma figures, made from 27 unit cubes glued together in different 3- or 4-

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

cube arrangements (see Figure 2); conventional 2D pictures that resemble the 3D figures; semiotic representations such as front, top and side views or numeric top-view codings that do not obviously resemble the 3D figures; and, verbal descriptions that may be accompanied by gestures using appropriate mathematical language (Sack & Vazquez, 2008).

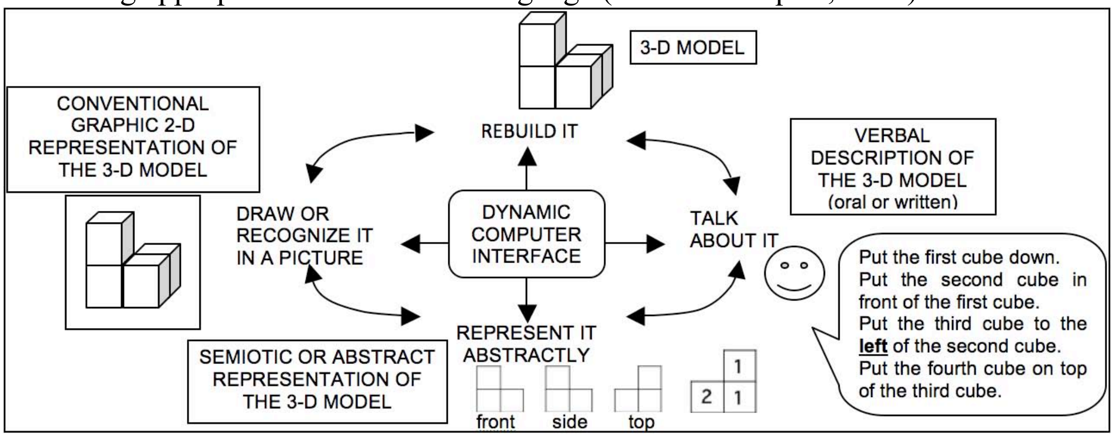

Figure 1. Multiple representations within 3-D visualization

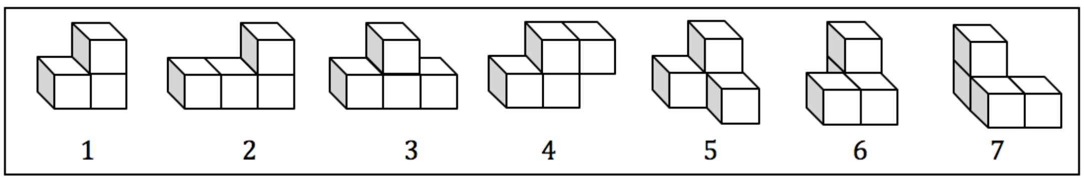

Figure 2. The Soma set can be made by gluing unit cubes together.

The project utilizes a dynamic computer interface, Geocadabra (Lecluse, 2005). Through its Construction Box module, complex, multi-cube structures can be viewed as 2-D conventional representations or as top, side and front views or numeric top-view grid codings (see Figure 3). These options can be (de)selected according to instructional goals. The Control-line-of-view option allows the user to move the figure dynamically using the mouse or by clicking on the arrows at the ends of the space's triaxial system.

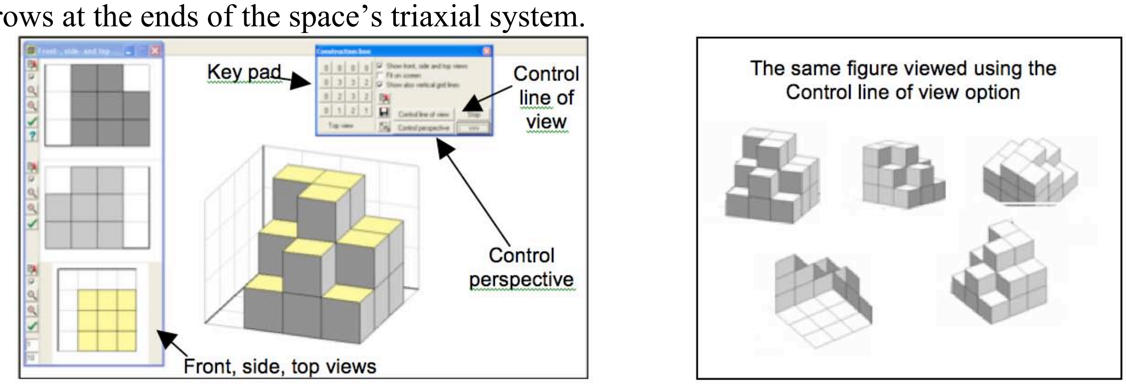

Figure 3. The Geocadabra Construction Box

Connell's (2001) *action on objects* metaphor guides the discussion section of this paper. Through carefully designed activities, children act strategically upon manipulative objects as they solve problems. Computer images that replicate the attributes of the physical objects then behave as real objects in the mind of the learner. The Geocadabra Construction Box interface integrates the SOC representations in the form of a dynamic image that can be moved to provide the same views as if moving about a 3-D object; a 2-D image when the figure remains static; and if selected, simultaneous semiotic top-view numeric, or face view representations. Follow up problems or questions require the child to relate to the newly instantiated and defined object of thought, which becomes the basis upon which later mathematical thinking occurs. This model extends as the child develops his or her own problems based upon the objects that were recently defined. "This ability, to pose one's own problems and to then successfully solve these problems, provides further opportunity for growth in mathematical thinking and problem solving" (p. 161).

Methodology and Context

Since the project's inception in 2007-2008, a university-based researcher and two teacher-researchers have formed the research team working with a group of children weekly for one hour in teacher-researcher, Vazquez' 3rd-grade classroom within the school's existing after-school program. English and Spanish parent/guardian and student consent-to-participate forms are sent home to parents of all 3rd grade children. All respondents are accepted into the program. The research team uses socially mediated instructional approaches to support a problem-solving environment that fosters students' creativity according to readiness and interest.

Design research methodology (Cobb, et al, 2003) guides this study's instructional decisions based on learning trajectories developed from an instrumentalist standpoint (Baroody, et al, 2004). This conceptual and problem-solving approach aims for "mastery of basic skills, conceptual learning, and mathematical thinking" using any "relatively efficient and effective procedure as opposed to a predetermined or standard one" (p. 228). Each lesson is part of a design experiment followed by a retrospective analysis in which the research team determines the actual outcomes and then plans the next lesson. This may be an iteration of the last lesson to improve the outcomes, a rejection of the last lesson if it failed to produce adequate progress toward the desired outcomes, or a change in direction if unexpected, but interesting, outcomes arose that are worthy of more attention. Data corpus consists of formal and informal interviews, video-recordings and transcriptions, field notes, student products and lesson notes.

Results and Discussion

During the learning trajectory's introductory lessons, children interact with loose cubes and the Soma figures initially solving problems with the 3D models and with 2D task cards (e.g., see Figure 4a). These illustrate a variety of assemblies of two Soma combinations in different orientations requiring figure identification and classification. Thus, learners become familiar with the SOC framework's 3D and 2D conventional graphic representations before they are introduced to the Geocadabra virtual interface. By the middle of the second month, children begin to digitally reproduce figures printed in a customized manual (e.g., see Figure 4b). These activities provide the children opportunities to coordinate numeric top-view codings with 2D pictures. In addition, there is a strong focus on enumeration of cubes in the manual's figures. Whereas beginning learners generally are able to determine the numbers of cubes in relatively simple figures (such as the left-most task card in Figure 4a), very few can do so with figures containing hidden cubes (as in Figure 4b). Battista (1999) has shown that many learners count visible faces when asked to find the number of unit cubes in 3D rectangular arrays, often double counting edge cubes and triple counting vertex cubes. This research team's pre-program interviews, September, 2010, using both 3D rectangular arrays and multi-level structures as in Figure 4b, yielded similar results. Some children recognize that cubes are hidden but lack the mental structuring capacity to determine precisely how many in a logical fashion.

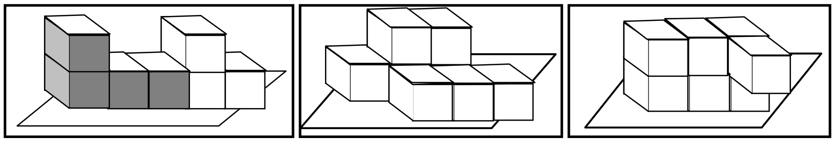

Figure 4a. Task cards increasing in level of difficulty

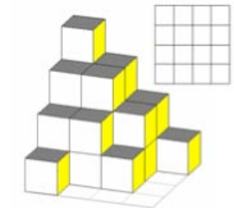

Figure 4b. Task 1*f*

By working systematically with increasingly more complex figures and by enabling the Geocadabra Construction Box's Control-line-of-view function has developed children's capacity to solve such enumeration problems. The learner's ability to see the digital figure in the same way as a 3D model enhances the digital experience. This way, since a stack of cubes grows by repetitive clicks on the corresponding position on the number grid, the children know that the computer figures can have no holes beneath any visible cubes. The ability to rotate the digital image allows them to see the sides, back and bottom views of the figure. Thus, movement from conventional 2D graphical images to virtual 3D models via the numeric top-view semiotic representation is realized.

After developing reasonable proficiency with the Geocadabra Construction Box through the manual's tasks, more open-ended problems are posed to further develop children's mental imaging capacity with respect to volume concepts. They are expected to correlate the numbers in the Geocadabra Construction Box grid with the height of each stack of cubes in each 2D picture; and, to verify that the number of cubes in the 2D picture is the same as the sum of the numbers in the Geocadabra Construction Box grid. Children create their own structures consisting of 24 unit cubes, using the Geocadabra Construction Box. Initially, they may choose to build the figure using 24 loose cubes, but most discard the loose cubes almost immediately. Conventional 2D images of these digital figures are converted by the researcher into new task cards essentially created by the children. The creator then draws the numeric top-view code and a peer decodes and re-creates it on the computer, first hiding the visual figure, and then showing it to check that it matches the task card figure. In addition, the peer checker ensures that the figure consists of exactly 24 cubes by adding the numbers in the top-view numeric grid on the computer. Examples of student-created task cards are shown in Figure 5. Enumeration of these figures using symmetry and slicing is encouraged and shared during whole class discussions when verbal language is developed. The research team has noted that children seem to have more difficulty enumerating 3D rectangular arrays than the types of figures shown in Figure 5. However, with practice, they are able to represent 3D rectangular arrays using numeric top-view coding grids. This is a critical step in their understanding of formula-based volume concepts (see Sack, & Vazquez, 2010).

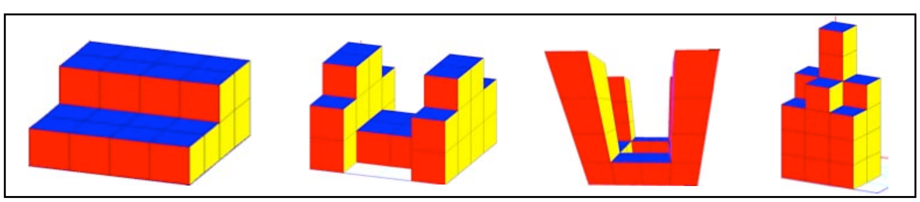

Figure 5. Students' 24-cube figures

Numeric top-view coding	Peer solutions	Original task figure
E 	E1 Soma #7 and Soma #4 E2 Soma #3 and Soma #5 OR Soma #6 and Soma #2	F 		
Table 1. Examples of student-made semiotic puzzles and peer solutions

The discussion now moves to Connell's (2001) notion of deepening mathematical understanding through self-developed problems that encompass all of the visual SOC representations. Using a complete set of seven Soma figures, children first select two to create a 3D assembly structure that can be reproduced on the Geocadabra Construction Box, unlike the rightmost structure in Figure 4a. The following week, without the aid of the computer interface, each child draws the numeric top-view coding from the picture of his or her own structure that the research team has formatted into a task card. Regardless of whether the children remember which Soma figures were used they know that the figures were assembled from two different ones since these pictures are their own creations. These semiotic codings become puzzles for their peers to decode using only the set of seven Soma figures. Examples are shown in Table 1. Some students drew 4-by-4 grids (as in C and D), which is a throwback to the grid provided by the Geocadabra Construction Box interface. Others (as in A, B and E) understood that rows or columns containing zeros were not needed. The child who created grid B enumerated the cubes in her structure, reflecting on work that had been done some weeks prior to this activity, to verify the volume of her structure.

To begin some puzzle solvers use enumeration strategies. A sum of 7 must mean that Soma #1, the only figure with 3 cubes, is used in combination with a 4-cube Soma figure, as in puzzles A and D. Some children are able to directly state which two Soma figures can be used to solve the puzzle. Others mentally visualize at least one Soma figure in the coding. The children quickly realize that selecting two random Soma figures is a time-consuming and ineffective strategy. A more effective scaffolding strategy discovered by some children is to use Soma #1 together with a loose cube. For example, in Puzzle B, the left side appears to be Soma #7 (see Figure 6). Then, the child places Soma #1 on the right side and holds a loose cube to its left as shown in Figure 6, to create Soma #6. Some children use one or two loose cubes in their interim solutions before they arrive at the assembly solution.

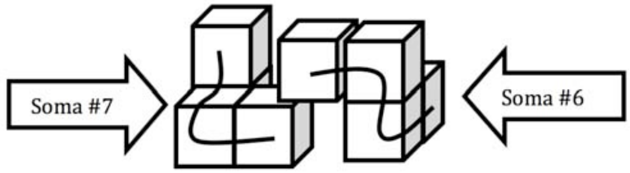

Figure 6. Using Soma #1 to solve puzzle B

While the 2D task cards were created with a 3D stimulus via the Geocadabra Construction Box computer interface, the reverse process, using the semiotic puzzle as a stimulus and the 3D model as a product, is performed without the aid of the computer interface. The capacity to visualize develops further when children are able to find more than one Soma figure combination to solve these particular problems as shown in puzzles A, C-E (Table 1). Two different children solved puzzle E using three different Soma figure combinations (solutions E1 and E2).

These examples are evidence of problem situations created and solved by the children based on the objects that were previously used as stimuli. Puzzle F is particularly interesting because this child created a unique extension of the original task using his two solutions, shown as E2. He realized that the two Soma figures were the same as the ones he had used for his own assembly shown in F to the far right. He stated that with "two movements" of the Soma figures he needed for puzzle E he could re-create his own assembly.

Following the puzzle posing activity, the teacher researcher displayed for the first time the formal SOC framework as shown in Figure 1 in order to elicit metacognitive interpretation of this graphic organizer from the children. She asked if anyone recognized any of the project's activities within the figure. One child pointed out that the puzzle creation activity (Table 1) started with the 3D model to create 2D pictures on the computer. Another recognized that the numeric top-view codings that they created from their 2D pictures belonged to the semiotic or abstract representation. She also stated that the class had moved from the semiotic to the 3D figures directly without the computer. When asked about the verbal description, one child said that they do it all the time when they think and share solutions together. The participating children have made sense of the SOC framework through the myriad of hands-on experiences over the past 5-6 months without prompting from more-knowledgeable adults. This is strong evidence that through carefully designed activities, using strategically chosen manipulatives, deep mathematical knowledge (Connell, 2001) and generalized abstraction (Presmeg, 1992) can develop in unprecedented ways. Furthermore, this occurrence demonstrates how the instructional team attends to and accommodates child-centered contributions to the development of the learning trajectory.

Conclusions

The capacity to move among the three SOC visual representations, namely, 3D models, 2D conventional pictures and semiotic representations, was developed through the Geocadabra computer interface. However, through extended problems created by the learners themselves, it is remarkable that they are able to move from the semiotic representation to the 3D model independently of the computer (Connell, M., personal communication, September, 2010). The research team considers this to be evidence of the children's growing ability to visualize as they move between semiotic and 3D assembly models. Through their different configurations the Soma figures provide a high degree of complexity to the instructional tasks and force the children to engage in mental transformations in ways that would not be possible if they used loose cubes.

The actions on objects (Connell, 2001) occur concretely with the 3D models, virtually through the Geocadabra interface and ultimately as mental imaging through the powerful problem-solving approaches developed by the research team. These evolve through the reflective practices enacted by the team immediately following each lesson (Sack, & Vazquez, 2011). The team has a very strong child-centered philosophy, coupled with the belief that children learn best when engaged in problems of their own creation (see also Connell, 2001).

DEVELOPING ELEMENTARY TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE OF RATE-OF-CHANGE IN ENGINEERING THERMODYNAMICS: A DESIGN STUDY

James A. Middleton
Arizona State University
jimbo@asu.edu

Eric Weber
Arizona State University

The developing pedagogical content knowledge of elementary-certified teachers was supported in a course on concepts in algebra and calculus. Engineering thermodynamics was used as a domain through which participants could model rate-of-change for a variety of functions. The design of the professional development course is examined, and teachers' struggles and triumphs with course content described. Results show teachers' backgrounds in elementary algebra proved a barrier to their ability to treat relationships among variables as mathematical objects. Once these barriers were overcome rate-of-change served as a powerful support to model complex thermal applications that utilized rate-of-change as an index of efficiency.

This paper describes a design-research project that focuses on developing the mathematical knowledge for teaching of elementary-certified teachers who are interested in becoming STEM specialists in the middle grades. The case described is of the design of a graduate-level course focusing on the mathematics of change and how it relates to engineering thermodynamics. We first describe our approach to teacher knowledge, and why pedagogical content knowledge is the key lever for practical change in the classroom. Then we address design-theory and why it is an appropriate paradigm for studying teachers' mathematical learning at the same time as we attempt to improve it. Next, we describe the course design, dwelling on modeling as the pedagogical approach to the course, the mathematical content and its sequencing, and engineering thermodynamics as an ideal context for the development of essential concepts of calculus. Lastly, we describe the ways in which teachers interacted with this content, and particularly how they grappled with their "fuzzy" prior knowledge of algebra, attempting to repair holes in their understanding, even while continuing to move forward on more advanced content.

Pedagogical Content Knowledge

Teachers' knowledge has long been promoted as a lynchpin variable, connecting standards and curricular innovation with classroom practice and student learning. Ostensibly, teachers' understanding of content, pedagogy, students, and curriculum enables them to better design instructional environments, tailor activities to the needs of their students, and to assess and improve their practice for the purpose of increasing student learning outcomes.

Lee Shulman and colleagues are generally credited with the initial promotion of teacher knowledge in this lynchpin role (e.g., Grossman et al., 1989; Shulman, 1986; Wilson, Shulman, & Richert, 1987). They generated a number of descriptions of teacher knowledge as an attempt to show teachers' knowledge as multi-faceted, drawing from a number of experiences in their early lives as well as university coursework, teacher education, and practice (Shulman, 1986, p. 9). In general, research has focused on three categories of teacher knowledge: (a) subject matter knowledge, (b) pedagogical content knowledge, and (c) curricular knowledge. Content knowledge refers to both subject matter knowledge and its organization or lack thereof, while pedagogical content knowledge involves content knowledge as it is directly related to the teaching of specific subject matter. Finally, curricular knowledge attunes to knowledge of the programs of study and instructional materials and technology used by teachers and students.

There is some evidence from certification studies as well as large-scale surveys and quasi-experimental studies that indicates that teachers' knowledge has a significant impact on student gains in achievement over time (Darling-Hammond, 2000; Hill, Rowan, & Ball, 2005). This information is mixed, showing mathematical content knowledge as only moderately correlated with student achievement gains. Pedagogical Content Knowledge also shows a significant moderate correlation with student gains separable from mathematical content knowledge. This separability supports Shulman and colleagues' initial assumptions that several funds of knowledge interact to impact instruction and subsequent learning.

More recently Hill, Ball, & Schilling (2008) argue that the knowledge required for teaching mathematics, Mathematical Knowledge for Teaching (MKT), is multifaceted, incorporating aspects of: 1) common content knowledge held by all mathematically sophisticated occupations, 2) content knowledge specialized to the teaching of mathematics, 3) knowledge of student learning of mathematical content, 4) knowledge of the practices of teaching mathematics, and 5) knowledge of mathematics-related curriculum. Each of these knowledge components has some effect on teachers' ability to develop, select, and deliver tasks at an appropriate developmental level at the appropriate time in mathematical sequence and student learning. Moreover, each of these components supports and updates the other components as teachers' learning of mathematics and mathematics-relevant pedagogy grows. It is likely that, unless each of these aspects of MKT is addressed, and their interdependence emphasized, that professional development for mathematics improvement will result in only modest student gains over only a short term (Ball & Bass, 2000).

Of these facets of MKT, pedagogical content knowledge is of primary concern because it lies at the confluence of the content and the curriculum; it is the knowledge base of mathematics education: PCK comprises the knowledge and skills required for one to transform the other facets of MKT (like mathematical content, knowledge of curriculum, knowledge of students) into a set of experiences, activities, and environments that optimize the likelihood of students learning. In our program, we attempted to improve elementary teachers' content knowledge related to fundamental concepts in algebra and calculus utilizing Modeling Instruction as the pedagogical theory for both teacher learning and for student learning. It was by integrating Modeling Instruction with teachers' own content learning experiences that we hoped to impact their ability to understand and apply this content in an appropriate pedagogical manner with their own classrooms—hypothetically connecting new content with new knowledge of curriculum and pedagogy—addressing three of the five aspects of MKT through PCK.

Modeling as an Integrative Construct

One of the key goals for professional development is for teachers to develop new models of content, teaching, and curriculum. Models are conceptual structures—mental (and oftimes physical or inscriptional) representations of real things, real phenomena. *Modeling* as it refers to content knowledge, involves building, testing and applying conceptual models of natural phenomena and is a practice that is central to learning and doing science and mathematics (Hestenes, 1992). In fact, it can be accurately stated that Mathematics, Science, and Engineering are all fundamentally modeling enterprises. Educationally, modeling has been touted as a unifying theme across science and mathematics education as recommended by both the National Science Education Standards (1996) and the Common Core Standards for Mathematics (2010).

In sum, we think with models, we think through models, and we think about models. Our approach to instruction attempted to embody this fact and exploit this facet of human cognition.

Modeling Instruction as an instructional theory aims to correct many weaknesses of the traditional lecture/demonstration method in science and mathematics education, including the fragmentation of knowledge, student passivity, and the persistence of naive beliefs about the physical world. Modeling Instruction objectives begin with the goal to engage students in understanding the physical world by ***constructing and using scientific models*** to describe, to explain, to predict and to control physical phenomena. To do this, students must gain proficiency with ***basic conceptual tools*** for modeling real objects and processes, especially mathematical, graphical and diagrammatic representations. This is the underlying curricular model we employ at all levels in the reported program: Build and use models of important scientific content, utilizing important mathematical and representational tools.

It has been shown in a variety of studies of student learning that context is critical for coming to understand mathematical concepts and skills. Moreover, the capacity to create models of scientific phenomena, and to test those models is dependent on the development of mathematical ways of thinking about the phenomena, including the ability to make sense of patterns in data. For this reason, modeling truly is an integrative construct, connecting mathematics and scientific content through meaningful activity.

Unfortunately, teachers are not exposed to mathematical modeling of scientific phenomena during their undergraduate careers to any great extent. This is especially true for middle school teachers. With typically one course in mathematics at the College level, and only one non-calculus-based science course, middle school teachers trained as generalist elementary education majors are just not equipped to handle the traditional mathematics curriculum let alone Algebra I and Geometry which are currently common offerings in US schools. The same can be said for middle school science, where teachers may teach life science, physical science and earth and space science in any given year. It is therefore imperative that the curriculum and instruction that takes place for teachers closely resembles that which they are expected to provide for their students—yet not be so prescriptive as to squelch personal style, initiative and inspiration. We structured our classroom tasks and pedagogy based on the past 20 years of research on modeling (citations from Lesh, Hestenes here).

Design Research and Curriculum Development

Lamberg & Middleton (2009) describe how design theory can provide a rigorous paradigm for disciplined inquiry in learning and instruction, and a pragmatic framework for defensible change in curriculum and instruction. Briefly, this theory outlines seven "phases" through which a research program progresses, beginning with more grounded methods, where the researcher attempts to understand a little-researched area of inquiry, consolidating evidence about learning and practice, until a local theory of change can be generated that seems to explain and predict positive movement along a trajectory of change. This *theory*, then is used to design curricular tasks, which serve as operational definitions of that theory. Through iterative testing and revision, tasks are made more effective, while at the same time, the theory is refined, refuted, and made more useful and explanatory (Author, 2008). Design research, thus has two primary outcomes: A theory of change that describes how learning progresses across a defined set of topics, and a mechanism for at least partly driving that change—curriculum materials or other supports that have been refined over time to be optimally (or at least *reasonably*) effective.

Design theory is a kind of modeling theory that focuses on the development of systematic knowledge about teaching and learning. As such, it is consistent with the theory of learning and instruction we employed in the reported research: Modeling Instruction. The study reported here is situated in Phases 2 and 3: Development of the Artifact (in this case, the course curriculum and activities), and Feasibility Study (initial trialing and iterative improvement of the course).

Description of Modeling Course

Participants

The focus teachers in this study were 11 elementary certified teachers. Two additional students (masters' degree graduate students in mathematics education with no prior teacher training) participated as well. Of the teachers, two had a calculus course early in their collegiate experiences, but the rest had no mathematics beyond basic College Mathematics and Mathematics Methods for Elementary Teachers. All were female, and all were teaching elementary grades subjects. On a pre-Calculus assessment, none scored higher than 50%, and the majority scored around the 20% or chance level.

Course Foci

The modeling course for teachers focused on developing key mathematical content related to modeling scientific and engineering concepts. We emphasized discussing the most common linear, polynomial, exponential, and inverse square functions and their representations, focusing especially on the analysis of change in the context of applied problems. We focused on these concepts in the context of modeling situations of thermodynamics, which is the study of energy transformation. We chose thermodynamics because we hypothesized that most of the teachers had everyday experience with heat and temperature, energy, pressure and work, whether formally in a classroom or informally solving problems in their daily lives. We emphasized convection and conductance as key ideas in thermodynamics because they were the most accessible concepts in thermodynamics while also providing convenient ways to talk deeply about rate of change: Newton's law of cooling for convection and thermal exchange in conductance both are examples of exponential functions, while radiation follows the classic inverse-square law. Our goal was to formalize the in-service teachers' knowledge while exploring applications of thermodynamics in engineering contexts, environmental science, and biology such as passive solar heating and cooling, properties of insulators, and heat capacity of materials.

Thermodynamics is an area of science where several key variables, such as entropy, cannot be measured directly; one can only measure them by examining related variables and doing the algebra. So in this case the mathematics is absolutely critical for understanding the science—thermodynamics cannot be understood at even a basic level without it. In general, we wanted to emphasize the deep connections between mathematics and science, and help the teachers understand how one can better understand science by knowing the mathematics.

Structure of Course

We attempted to structure the course so there was a common substrate of activities in each homework assignment and weekly meeting of the course. Each week, teachers were engaged in the following tasks:

Book club write-ups. Students read 1 to 3 chapters from *Calculus Made Easy* (Thompson, 1914) each week. To get them to reflect deeply on the content of that book, students were required to write a review of the chapter(s). In their review, we asked them to focus on what they know, what they wanted to know, and what they had learned: 1) What you know: A description of the reading, as if you were describing the concepts to an 8th grade algebra student; 2) What you want to know: Analysis and insights you have about the study of change, and especially those things you feel confused about; and 3) What you have learned: Students listed those ideas and ways of thinking they had that they didn't have prior to reading the text.

Weekly Modeling Problem. In each class session, we presented the students with a new thermodynamics problem to model. Following class, they were required to do a formal lab write-up of their model. Their analyses addressed the following points: 1) A description of the relationship they attempted to model; 2) A description of the methods they used to model the relationship; 3) The problem solution presented in a general form (e.g., a rule, procedure, or symbolization, which was often a combination of formulae, graphs, and data tables); and 4) An analysis of why the problem solution was correct.

Problems emphasized convection rates, conductance/insulative properties of materials and radiation rates, which mathematics paralleled the content being developed in the Book Review assignments, but required application in messy, data-rich situations.

Weekly Mathematics Problems. Finally, based on the modeling problem and ideas introduced in the book club, we presented students with a set of algebra and calculus problems to attempt. Their response to each problem included all their work, including mistakes, and their answer, if they arrived at one; and a reflective statement describing the core mathematical idea the problem was addressing.

For the reported course, we organized the mathematics content into 7 modules:

- Proportional Reasoning: Direct, Inverse, and Joint Variation
- Average Rate of Change: $\Delta y/\Delta x$, Analyzing Functions Qualitatively, Rational Expresssions
- Families of Functions: Linear, Polynomial, Exponential/Logarithmic/Power
- Comparing Functions within Families: Coefficients, Exponents, Bases, Local Maxima/Minima, Inflection Points
- Derivatives as local average rate of change
- Derivatives at a point; Derivatives as Functions; Limits
- Accumulations; Area under a curve

Structure of Daily Sessions

Each 4.5-hour class session was broken into three 1.5 hour activities. One activity focused on discussion of the week's readings and calculus concepts. The second activity focused on discussing any difficulties participants had with understanding and completing homework activities. The third activity engaged teachers in modeling thermodynamics problems and applying the readings and problems.

Each modeling session was organized into ***modeling cycles*** which move students through all phases of model development, evaluation and application in concrete situations — attempting to promote an integrated understanding of modeling processes and acquisition of coordinated modeling skills (Lesh & Yoon, 2007). Typically, the instructor set the stage for classroom activities, ordinarily with a demonstration and class discussion to establish common understanding of a question to be asked of nature. Then, in small groups, students ***collaborated*** in planning and conducting experiments, collecting and analyzing data to answer or clarify the question. Teachers were required to present and justify their conclusions in oral and/or written form, including a ***formulation*** of their own models for the phenomena in question and an ***evaluation*** of the set of models by comparison with data. Technical terms and concepts were introduced by the instructor only as they were needed to sharpen models, facilitate modeling activities and improve the quality of discourse.

Additionally, in 3 of the 8 sessions, we carved out an hour to examine the Common Core Standards for Science and Mathematics for middle grades, and map the key content they were learning in the course to the key mathematical ideas emphasized by the Standards. Teachers developed maps of the content to show how it fit together in an integrated fashion in science and mathematics classes.

Analysis of Sessions and Course Revision

The research team consisted of three mathematics educators with engineering backgrounds, and an expert in teacher professional development. The research/teaching team met each week following the daily sessions. In the manner of Cobb et al (1997), we reviewed student work, planned subsequent sessions, and revised tasks and assignments based on the discourse engendered in the daily sessions. In particular, we reviewed the difficulties students had in their conceptual understanding of the algebra, and their facility with its manipulative skills, and developed new tasks to help them bridge this knowledge, while still forging ahead thinking about derivatives and rate-of-change as a function.

Sources of data included their homework, book club reflections, modeling problems, and their posts to the class discussion group, which we developed to be able to handle ad-hoc questions just-in-time.

Results and Discussion

We set out to focus on a mathematically rich course focused on thermodynamics, and eventually we were able to talk about difficult mathematical concepts to explain and model scientific phenomena. However, the level of resistance and frustration the teachers exhibited in the first three weeks of the course was palpable. Their homework reflections and midterm course evaluations suggested that they were not thinking about modeling phenomena. Instead, they were highly frustrated or confused about concepts like algebraic field properties and representation of proportional quantities using fractions. We used their class discussions, homework assignments, and book reviews to gain insight into what sense they were making of modeling thermodynamics ideas using mathematics.

We found that the majority of students' ways of thinking about the mathematics was not at a level where discussions about rate of change could be interesting or productive to the teachers. Given our data and feedback from the teachers, we concluded there were two major obstacles to their understanding. First, a chief barriers we faced was the confluence of factors associated with teachers' knowledge and the nature of disciplinary knowledge and how these factors could be made compatible and even complementary. Second, there was a real disconnect between the community of mathematics and that of the sciences regarding what was being modeled and what its conceptual substrate is. With motion and mechanics the connections between the particular functions being modeled is pretty close, but when there is no macroscopic motion to serve as a grounding metaphor (i.e., in thermodynamics), students must rely on more abstract understanding of variable quantity, function, rate, direct and indirect proportions, and the combinations of these ideas as they are manifest in the typical power functions and exponential functions we see in science applications not derived from motion examples.

Teachers' Content Knowledge

Most of our students had not taken a course in mathematics, or had significant content professional development since their 1st or second year of college. Most teachers, because they are elementary certified, took required courses up through college mathematics, and therefore have little experience with algebraic methods, functions and functional reasoning, the mathematics of change, or geometry and its relationship to algebraic relations. As a result, teachers' knowledge of and understanding of variable, function, field properties and their tie to the manipulative skills of algebra, basic concepts of exponents, factors and multiples, and proportional reasoning was generally poor and uneven across the cohort.

Nearly all teachers possessed poor mathematical self-efficacy. Reasons for this include poor prior performance resulting from poor prior learning experiences, knowledge that their coursework was not sufficient for a developed conceptual understanding and procedural skill, and the fact that much time has passed in which they have not continued mathematical learning nor practiced mathematical skills previously learned. As a result, teachers' confidence in their conjectures and insight appeared to be tentative; their ability to judge their learning and understanding (meta-cognition) was under-developed.

Given the breath and depth of these problems, we took steps taken to deal with these issues. We immediately stepped back from a pre-Calculus level of instruction to a high school algebra II level, to an 8th-grade pre Algebra/Algebra I level with some high school ideas integrated. We focused on scaling back on the quantity of homework to allow for students to focus on ideas discussed in class, and developed homework activities based on class discussion the day following, so that teachers can do relevant work the following week. We used 3 of 8 to focus on the most basic ideas of quantities, algebraic manipulative skills and their conceptual basis in the field properties, recognizing the form of familiar functions (linear, polynomial, exponential). Once we helped the teachers construct a foundation of basic mathematical concepts, we used rate of change as an integrative concept to help students look at different regions within the same curve, and the same regions across different curves, to examine the behavior of these functions, and their similarities and differences.

Teachers' Disciplinary Knowledge

In science, the mathematical models developed can be derived from specific circumstances to assist the student to be able to describe their behavior. In mathematics, mathematical models must have a generality across applicable situations—this implies that, if an idea is developed within a context, there must be other application contexts where the student is expected to transfer their knowledge, and some opportunity to make the mathematical abstractions explicit and their transferable structure overt.

Much of school science is done without any mathematics or any significant mathematics. This make students not lazy per se, but the teachers were disinclined to mathematize or to frame scientific questions or conjectures in mathematical terms other than just basic correspondence relations. Functional reasoning was not a habit of mind. Overreliance on solving for a number detracted the teachers from the examination and description of relationships. We believed that the general practice of making science "conceptual" typically eliminates the critical mathematical structure of the concepts in favor of more qualitative or general depictions of phenomena

The use of software for scientific data analysis was tremendously helpful to both the teachers and us. However, the learning curve for students to learn the software takes a lot of time and focus away from the mathematical content itself. Graphing Calculators are excellent tools, but a distinct effort had to be made to develop some proficiency with these tools. Excel was also excellent, but the teachers had little to no experience with spreadsheets or other data systems, so this also took much of their time and energy. The important aspects of these programs are to allow students to see the form of relationships, to create an explicit algebraic relationship by manipulating cell formulae (excel) and lists (graphing calculators). As the semester progressed, the teachers moved from viewing technology as a barrier to understanding to using it as a tool for thinking about modeling complex thermodynamic situations.

An interview with a sixth-grade student illustrates how her number sense and understanding of variability relate to her ability and proclivity to apply a frequentist (statistical) approach to probability tasks. A general suggestion for teaching about mathematics of uncertainty through the gradual strengthening of estimation, as per the historical development, is also discussed.

Theoretical Background

The Three Views of Probability

There are three main views of probability: classical, frequentist, and subjective (Shaughnessy, 1992). Using the classical view, one first partitions a sample space into equally likely outcomes. The probability of an event is simply the ratio of the number of outcomes in which that event occurs to the total number of outcomes. In contrast, the frequentist approach to probability involves repeated trials. A person using a frequentist approach might conduct a simulation with a large number of trials, examine the data, and assert probabilities based on the observations. If the number of trials is large enough, and if the results are repeated in other contexts, then the probability is judged reliable. A classical approach examines *a priori* how different arrangements of events could happen in order to develop a uniform distribution model. The frequentist approach is mathematically more related to statistics, since it involves the search for a distribution and subsequent application of the distribution's properties. Thus the mathematics behind the frequentist approach tend more to the notions of limits and convergence, as relating to the law of large numbers (Shaughnessy, 1992). The third view of probability, the subjective view, also takes into account an individual's own knowledge, opinions, or feelings. Reliance upon subjective reasoning may signal misconception, lack of confidence, or uncertainty of the relevant mathematics, but its use is not necessarily irrational. A child might always express a favorite color to be most probable on a spinner, while some situations, such as the probability of a Mars landing in the next century, can only be estimated by a subjective approach (Jones, Langrall, & Mooney, 2007).

Development of the Mathematization of Statistics and Probability

The oldest examples of statistical thought each related to the concept of estimation (Bakker, 2003). Examples from Indian, Egyptian, and Greek stories contained phenomena similar to the *mode*, *mean*, and a measure called the *midrange.* For data that has a symmetric distribution, the mean, median, mode, and midrange all coincide, so there is no need for their distinction. Bakker (2003) found, using classroom teaching experiments, that modern-day students also benefited from beginning with estimation while learning measures of center. It was not until students were faced with the task of computing an average with non-symmetric data that they felt the need to develop and formalize other methods of average.

The parallel between the historical development of average and the historical development of probability is the original expectation of symmetry (or uniformity), the subsequent adjustment to increase the accuracy (or number of successes), and the reliance upon estimation. The oldest manuscript describing observed frequencies and non-uniform distribution was written in the 13th

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

century, while the first known and solved probability problem (by Galileo) took place about 1620 (Batanero, Henry & Parzyz, 2005). The conflict between theoretical calculation and observed frequencies is what led to the development of more rigorous combinatorics methods (Batanero et.al., 2005). A teaching experiment using non-uniform dice by Nilsson (2009) showed that students went through a similar process when their previous conception of uniformity was challenged by observation. When the amount of variation was too great, the students reexamined their assumptions based on empirical data and modified their theoretical model.

Probability and Statistics Frameworks

Jones, Langrall, Thornton, and Mogill (1999) developed a framework for the development of probabilistic thinking through the middle grades by observing students' responses to tasks that could be solved using classical probability. The framework consists of four levels: subjective, transitional, informal quantitative, and numerical. At level one, a student might only be able to recognize certain or impossible events; at level two, most or least likely events. By level three, students' quantitative reasoning and measures are used to describe likelihood. By level four, students are able to assign numerical probabilities (Jones et al., 1999). As a student's level increases, the tendency to use subjective judgments decreases. Polaki (2002) validated this framework in a study in South Africa, and found that the highest levels of probability thinking require part-whole reasoning, while students without even part-part reasoning generally operate in the subjective level.

Watson, Collis, and Moritz (1997) describe a complementary framework of probabilistic thought. There is a hierarchy of four levels: prestructural, unistructural, multistructural, and relational, and students must pass through two cycles within the levels to achieve the highest realm of probabilistic thinking. The first cycle involves the development of probability as a measure, while the second cycle involves the development of that measure. Considering that the second cycle requires part-part reasoning for the multistructural level and part-whole for the relational level (Watson et al., 1997), this view is compatible with that of Jones et al. (1999). The additional levels of the framework more clearly describe the phenomena of students' demonstrating a relational level of reasoning for a single task, while a subjective level for a multiple-part task.

Both of these frameworks support the view that probabilistic instruction should begin with part-part comparisons instead of part-whole relationships. However, the classical view of probability necessitates part-whole comparisons in order to declare a uniform distribution (at least implicitly). Since comparing frequencies of outcomes is essentially performing a statistical task, perhaps further insight into the requisite knowledge for learning probability can be obtained by studying existing frameworks for the learning of statistics. According to Shaughnessy, "there are important connections between probability and statistics, particularly when repeated trials of probability experiments generate a distribution of possible outcomes" (2007, p. 981).

A relevant connection is the interaction between students' understanding of expectation and variability. Watson, Callingham, and Kelly (2007) developed a framework for the understanding of expectation and variation with six levels ranging from idiosyncratic, with little or no appreciation of either variation or expectation, to comparative distributional, in which links between variation and expectation are established in comparative settings with proportional reasoning. To compute simple probabilities with the frequentist approach, only the fifth level of statistical reasoning is needed: understanding of the relationship between variation and expectation within a single context. It is at this level that students can articulate an expectation; at levels four and below, they are able to articulate only comparative aspects such as more or less likely. Thus the higher levels of this framework are distinguished by the use of part-whole reasoning, as was the case with the probability frameworks. In order to use the frequentist approach to *develop* a theoretical distribution, one must determine a permissible amount of variance between observed frequencies and a theoretical distribution, i.e., a search for a signal of variability (Shaughnessy 2007). This requires the highest level of statistical reasoning, for it necessitates the comparison of distributions across two groups: the observed frequency and the expected frequency (Watson et al., 2007).

Purpose

The purpose of this study was to examine the relationships between students' understanding of probability and statistics. The frequentist approach to computing probabilities relies on an understanding of what constitutes an acceptable level of variance. On the other hand, students' expectations for variance may be influenced by an assumption of uniform probability. Thus we sought to ascertain whether the students' level of statistical understanding could help explain their level of probabilistic understanding, and consequently further understand the role of the teaching of statistics and variability in teaching probability.

Methods

An extended clinical interview was conducted with one sixth-grade female from Virginia. The interview was divided into two sessions, each lasting approximately thirty minutes, involving a total of nine tasks. The first session, consisting of the first seven tasks, was designed to gauge the student's level of probabilistic thinking as per the frameworks of Jones et al. (1999) and Watson et al. (1997); questions and activities similar to their released items were used to assess the student's probability thinking. In order to ascertain the student's level of statistical thinking, tasks similar to those described by Watson et al. (2007) and Bakker (2003) were used. Each task was presented orally by the first author who served as the teacher researcher throughout the study. Manipulatives available to the student included physical dice, pencil and paper, and virtual spinners. Following are the tasks presented to the student in the first session.

1. If you were to roll this die (student is presented with a six-sided die), do you think it's easier to roll a one or a six?
2. In mathematics class, there are 13 boys and 16 girls. If a teacher were to write the names of the students on slips of paper and draw one out of a hat, would it be more likely that the name would be that of a boy, that of a girl, or is it equally likely?
3. There are two boxes, Box A and Box B. Box A has six red marbles in it. Box B has 60 red marbles. Box A has four blue marbles, while Box B has 40 blue marbles. If you want to pick a blue marble, from which box should you choose?
4. Create a possible graph depicting the monthly high temperatures in your hometown, given that the average yearly high temperature was 69 degrees.
5. A game is played where two spinners, each 50% black and 50% white, are spun. If they are both black, then person A wins; if they are different colors, person B wins. Which person would be more likely to win?
6. Estimate the number of penguins in a photograph in which the penguins are not of uniform size.
7. Ten Twizzlers of different colors are placed in a bag, and the student is asked to guess which color is most likely to be drawn out.

Each session was videotaped, and the authors planned additional tasks after discussing their individual interpretations of the video. The second session consisted of an extension of Task 4 and a new task that merged two dice throwing tasks, the first by Watson and Kelly (2007) and the second by Nilsson (2009). These were designed to explore the role of variance in the student's perception of the likelihood of outcomes.

The focus of the first session was that of a clinical interview: both the questions and the sequence of tasks were chosen in advance, and no attempt to teach the student was made. The second session was more of a teaching experiment (Steffe, 1991), as the student was encouraged to examine her notions of variance and expectation in the following tasks.

8. Create and critique possible graphs depicting the average yearly temperature.
9. Predict the results of rolling a six-sided die 60 times. The dice in question were (a) fair, (b) had two ones and no sixes, (c) were "loaded" in favor of ones.

Results

Probability Tasks Results

The student response to the first task was that it was equally likely to roll a one or a six: "because there are the same number of sides, so I don't think it really matters the number."

The second task response was "a girl, because there's more girls than boys." This correct response using part-part reasoning indicates achievement of the multi-structural level of Watson's framework (Watson et al., 1997) and the transitional level of Jones' framework (Jones et al., 1999).

According to Watson et al. (1997), a correct response to the third task is associated with the relational level of reasoning. The conversation associated with this task proceeded as follows:

Student: I would think they would be the same, but, ... maybe Box B just because it has a bigger number?

Interviewer: What makes you think they might be the same?

Student: Because that has 10 and that has 100, so out of, like, 100 percent would be 60 percent for both of them, to 40 percent.

Interviewer: What made you think that maybe Box B would be the one to pick?

Student: Ummm...maybe because it has the bigger number. I don't know.

The student's initial correct response to the task was based on proportional reasoning, which is requisite for the higher levels of probabilistic thinking in both Jones' and Watson's frameworks. The fact that she thought that Box B having a bigger number might make it the one to pick suggested that there might be some confusion over the law of large numbers. It was suspected that the student might believe that having "large numbers" is desirable when computing probabilities, but that she had not yet conceptualized a justification.

The teacher researcher then presented her with the option of simulating the task using Probability Explorer (Lee, 2005) because he wanted her to become familiar with the program for a future task and also wanted to see her reaction to the result of an experiment. Specifically, he wanted to see if the result of the experiment would help her make a decision. The conversation continued:

Interviewer: Which do you think is more likely to come up, red or blue?

Student: Red.

Interviewer: Why?

Student: Because there are more reds than blues.

Interviewer: [Clicking the button to simulate a grab, which was blue.] Why do you think it came up blue instead of red?

Student: I don't know, I'm not sure.

Interviewer: What if I click it again, do you think it will come up blue again, or do you think it will come up red?

Student: I'm gonna guess red. I guess it's a fifty-fifty chance because there's two colors. I don't know.

The inconsistency in the responses here is indicative of the transitional level in Jones' framework. The simulation didn't help her decide an answer - in fact, it encouraged her to even question the part-whole reasoning with which she earlier seemed comfortable. Here the term “fifty-fifty” seemed to mean that it could be either of two outcomes rather than a rejection of the part-part reasoning earlier displayed. This language pattern has often been noted by researchers (e.g., Jones et al, 1999; Shaugnessy & Ciancetta, 2002). The uncertainty of her response seems to indicate a lack of knowledge or confidence in the relationship between her theoretical model and empirical trials.

The student again said that there was a “fifty-fifty” chance that each person would win when faced with the fifth task on spinners. This was not surprising, since it involves a compound event and hence would require the higher levels of probabilistic thinking (Jones et al., 1999). When presented with a simulation in which the spinners came up differently seven times out of ten, the student decided that choosing different colors probably had an advantage. This aligns with Shaughnessy and Ciancetta’s (2002) results which indicated that playing this game and seeing variation could help students reject their equiprobable hypothesis.

The seventh task was also aimed at understanding the student’s level of probabilistic thinking. She estimated that blue would be most likely to be drawn out since there were more blues than any other color. A blue was drawn and not replaced, leaving 2 green, 2 blue, and 2 yellow. She was asked again what color was most likely to be drawn, and she said "blue, green, or yellow" because they had the highest number. When the blues were replaced, she said that the chance of a blue would increase because the number of blues increased. This is evident of a relational understanding (comparing the possibility across two sample spaces).

Overall, the student's level of probabilistic reasoning appeared to be “informal quantitative” in the framework of Jones et al. (1999). She displayed use of part-part reasoning throughout and at times exhibited part-whole reasoning such as percentages. She was able to compare sample spaces and make relational judgments such as “more or less likely,” while at the same time used subjective judgments for compound events. This indicated that she was in the first-cycle relational stage or second-cycle idiosyncratic stage in the framework of Watson et. al. (1997).

Statistics Tasks Results

When creating a scale for her graph in Task 4, the student made the lowest value 30 degrees and the highest 80 degrees “because I think the coldest it would get is around thirty” and “eighty is probably about the highest it gets around here.” Bakker (2003) observed similar behavior when asking students to explain their understanding of “average,” in which several students gave a response indicative of a mid-range concept.

The student seemed to display an expectation for variation in temperatures, as the temperature trends cooler in the winter months and warmer in the summer, but the overall mean of the temperatures she displayed was much lower than 69 degrees. It appeared that she was focused on the variation and the range but not the mean. Based on these initial findings, it was decided to follow up in the next session with other graphs to compare to hers in order to determine her level of understanding of variability and expectation via the framework of Watson et al (2007).

When judging the number of penguins in the sixth task, she originally did not want to guess, but said "two million" upon encouragement. I believe that the hesitation toward calculation was due to the fact that the penguins were not uniform in size and were in rows of non-uniform width. She was offered a ruler, and encouraged to create a way to estimate using proportional reasoning. She counted the number of penguins in the bottom row, estimated visually the number of rows, and multiplied to get an estimate of 1,200 penguins. This was similar to the method that Bakker (2003) found children using to estimate the number of elephants in a picture, although the students in his study first found an "average" block. She made no mention of the fact that the penguins in the row she chose were larger than the penguins in the other rows, even after that error led her to a much smaller estimate than she had originally guessed. Her behavior in this task was opposite of her behavior in the temperature-graphing in which she initially focused on the mean and subsequently on the variation. In the penguin counting she was initially focused on the variation (causing the difficulty in counting) and subsequently ignored the variation when performing the calculation.

In preparation for Task 8, the student was introduced to four graphs of supposed student work and asked to critique them as possible graphs for the average high temperature. The first graph depicted a uniform temperature of 69 degrees, which she decreed unlikely since "February was too warm…and August is too cold." The second graph was also unlikely, for although the temperatures varied, they did so linearly, which was "too perfect." However, she did express that the first two graphs were possibilities. The third and fourth graphs both had varying temperatures, and neither graph increased or decreased linearly. However, by putting a pencil across the graph at 69 degrees, the researcher showed her that graph 3 had substantially more data below the line than above the line (this would technically be comparing to the median, but the data is nearly symmetric and hence the mean and median are close). It was thought that this would have led her to believe that it was not a possible graph of the data with mean 69 degrees, and she did make the observation that "it was too low." She drew a similar line using the fourth graph, and found about the same number of temperatures above and below the line. But when asked whether the third or fourth graphs were more likely, she chose the third because in the fourth graph the change in temperatures was closer to linear. She seemed to value the observed variance and high probability of "randomness" from month to month more than the presence or absence of the desired overall mean.

When faced with the die rolling tasks, the student was first asked to write down her prediction of how many of each number would come up. She said that she expected an equal number, 10, of each of the six values on the dice, which is indicative of level 2 on the scale of variation used by Watson and Kelly (2007), a "strict probabilistic prediction"(p. 3). When she rolled a standard die, six came up 17 times, which she attributed to chance. When asked if she would like to revise her prediction, she declined and indicated that she still thought each number would come up ten times if she rolled again.

The results of sixty throws of the second die (biased in favor of one) included a total of 21 ones and zero sixes. It was expected that the student would think that having no sixes was very unusual, and that she might wonder about the fairness of the die. She said that she thought it was "weird," but once again attributed the outcome to "chance" and declined to revise her prediction.

The roll of the third die (weighted) resulted in 29 ones, this time with two sixes. Once again, the student was not surprised by the result, attributing it to chance. It was expected that she would immediately question the die, for Nilsson (2009) found that students noticed unexpected frequencies with non-uniform dice and resolved the conflict between theoretical and empirical probability by developing an empirical model.

The teacher researcher felt that it might not occur to the student that some of the dice might be unfair, so she was encouraged to examine the second die more closely. After she noticed that there were two ones and zero sixes, she explained that she was no longer surprised about the presence of 21 ones. “The ten from the sixes went to the ones and 21 is near 20.” She was then asked what might explain the 29 ones in the third trial. She ruled out the possibility that there were any numbers missing with the third die, because she had rolled at least one of each number. The teacher researcher encouraged her to watch the die as it spun, and she noticed that it was “loaded” by the way it landed. When asked to predict the way it was loaded and determine how many ones would be expected, she first suggested that we should expect to get 20 ones, just as in the second problem, but was unable to articulate a reason for this prediction. She was then asked, “If I were to roll this die a million times, how could you predict how many ones would come up?” She suggested that we had rolled “almost 50 percent ones,” in the first 60 rolls, so we could “roll it another 100 times, and see if it came up about half ones.” When asked why she chose 100 times instead of more or less than 100, she said “maybe do more, like 300.” She had suggested the use of a frequentist approach to compute probability.

Discussion

The student's performance on the probability tasks showed initial understanding and preference for part-part comparisons and the occasional use of part-whole reasoning when faced with classical probability tasks. However, when engaged with actual events, she showed a lack of confidence in the application of such comparisons to make predictions by rejecting the results of her comparisons and relying instead on subjective judgments. While her performance fell into the “informal quantitative” stage (Jones et al. 1999), the reliance on subjective probability in simulation showed the value of also considering the student's statistical understanding. Her initial demonstration of a “purely probabilistic” approach to variance shows her view of the calculation of probability as a deterministic exercise. Without further statistical understanding of variance, average, and the law of large numbers, she was inconsistent with both the application of probabilities to make predictions beyond a single event and the reconciliation of her prediction with a contrary outcome.

The interactions with this student led us to believe that after the second session, she became more likely to consider a frequentist approach to calculating probabilities of events that can be simulated. This mirrors the historical development of probability, in which theoretical notions of expectation are strengthened or rejected based on the observation of the frequency of outcomes. Because the student had been exposed to classical probability, she originally focused on the mathematical task of comparing outcomes in a uniform sample space. The performance on the tasks showed consistently that her probabilistic reasoning was in transition between focusing on part-part relationships and focusing on part-whole relationships. The statistical tasks also showed that she had difficulty gauging what was a reasonable level of variation, resulting in her subjectivity in and hesitation toward the rejection of a theoretical model based on trial outcomes. When tasks involved calculations, she ignored variation, and when tasks did not involve calculations, she focused on the variation.

Conclusions

Statistics and probability understanding are connected, for the evaluation of probabilistic claims with the frequentist approach requires one to both understand and expect variance in situations of uncertainty. Students who are taught to calculate probabilities using the classical approach may have difficulty reconciling empirical evidence that differs from their calculations. By exposing children to probabilistic situations in which their intuitions and theories are challenged, teachers can encourage them to evaluate their own and then others' claims. Future research may explore in more detail the relationship between the transitions that students make between levels of probabilistic understanding and understanding of variation and expectation.

AN INFORMAL FALLACY IN TEACHERS' REASONING ABOUT PROBABILITY

Egan J. Chernoff

gale.russell@.usask.ca

The main objective of this article is to contribute to the limited research on teachers' knowledge of probability. In order to meet this objective, we presented prospective mathematics teachers with a variation of a well known task and asked them to determine which of five possible coin flip sequences was least likely to occur. To analyze particular normatively incorrect responses we utilized a brand new lens – the composition fallacy – instead of the traditional lenses and models associated with heuristic and informal reasoning about probability. In our application of the new lens we were able to determine that fallacious reasoning, not just heuristic reasoning, can account for normatively incorrect responses to the task. Given the success of the new lens, we contend that logical fallacies are a potential avenue for future investigations in comparisons of relative likelihood and research in probability in general.

The general purpose of this article is to contribute to the paucity of research on (prospective) teachers' knowledge of probability (Jones, Langrall & Mooney, 2007; Stohl, 2005). More specifically, the purpose of this article is to merge the established thread of investigations into comparisons of relative likelihood (e.g., Borovcnik & Bentz, 1991; Cox & Mouw, 1992; Hirsch & O'Donnell, 2001; Kahneman & Tversky, 1972; Konold, Pollatsek, Well, & Lohmeier, & Lipson, 1993; Rubel, 2006; Shaughnessy, 1977; Tversky & Kahneman, 1974; Watson, Collis, & Moritz, 1997) with a developing thread of investigations into prospective teachers' comparisons of relative likelihood (e.g., Chernoff, 2009, 2009a, 2009b).

In order to achieve the general and specific goals detailed above, prospective teachers, as has been the case in past research, were presented with five different sequence of heads and tails – derived from flipping a fair coin five times – and were asked to declare which sequence was least likely to occur. However, unlike previous research, we utilize a brand new lens to account for certain responses; we demonstrate that certain responses fall prey to the fallacy of composition (i.e., because parts of a whole have a certain property, it is argued that the whole has that property). Further, we contend that informal fallacies, in general, create a new research opportunity for those investigating comparisons of relative likelihood.

A Review of the Literature

In mathematics education (and psychology) research, comparative likelihood responses are categorized, in a broad sense, into two particular categories: correct responses and incorrect responses. While correct responses are, for the most part, associated with normative reasoning, different individuals account for incorrect responses differently. In particular, two types of reasoning – heuristic (Tversky & Kahneman, 1974, LeCoutre, 1992) and informal (Konold, 1989) – have dominated the research literature.

Heuristic reasoning

Psychologists Daniel Kahneman and Amos Tversky (1972) asked a group of individuals whether there would be more families with a birth order sequence (using B for boys and G for girls) of BGBBBB or GBGBBG. Further, the same individuals were asked whether there would be more families with a birth order sequence of BBBGGG or GBGBBG. Kahneman and Tversky argued that individuals who declared one sequence as less likely were reasoning according to the *representativeness heuristic*, where one "evaluates the probability of an uncertain event, or a sample, by the degree to which it is: (i) similar in essential properties to its parent population; and (ii) reflects the salient features of the process by which it is generated" (p. 431). In other words, the BGBBBB sequence of births was seen as less likely than the sequence GBGBBG because the ratio of boys to girls (in the parent population) is one to one and the BBBGGG sequence of births was seen as less likely than the sequence GBGBBG because BBBGGG did not appear random. The representativeness heuristic, in essence, provided a new interpretation of normatively incorrect responses to comparisons of relative likelihood.

Informal reasoning

Building upon certain task developments introduced by Shaughnessy (1977) (i.e., including the equally likely option and providing a response justification), Konold et al. (1993) introduced a different version of the relative likelihood task than had been seen in the past. For example, Konold et al. asked individuals "which of the following is the most likely result of five flips of a fair coin?" and provided them with the following options, "a) HHHTT b) THHTH c) THTTT d) HTHTH e) all four sequences are equally likely" (p. 395). Further, the researchers gave students a most likely version of the task followed by a least likely version. They found, for the most likely version, certain participants answered using *the outcome approach* – "a model of informal reasoning under conditions of uncertainty" (Konold, 1989, p. 59) – and for the least likely version subjects answered using the representativeness heuristic. The outcome approach represented, as had the representativeness heuristic earlier, a new interpretation of normatively incorrect responses to comparisons of relative likelihood.

Theoretical Framework

With a few exceptions (e.g., Abrahamson, 2009), there has been a lull in the past number of years in the creation and development of fresh perspectives and interpretations of normatively incorrect responses to comparisons of relative likelihood. Inspired by the notion that novel perspectives and interpretations to normatively incorrect responses to comparisons of relative likelihood have, in the past, established new domains of research (e.g., Konold's most likely version leading to the outcome approach), we introduce the fallacy of composition to account for certain responses to comparisons of relative likelihood. In doing so, contend that informal fallacies, in general, may provide a original research domain; however, given pagination limitations associated with the present article, we decided to limit our scope and, further, our theoretical framework. As such, our impending analysis of results will consist of one particular fallacy: the fallacy of composition.

Put simply, *the fallacy of composition* occurs when an individual infers something to be true about the *whole* based upon truths associated with *parts* of the *whole*. For example: Bricks (i.e., the parts) are sturdy; buildings (i.e., the whole) are made of bricks; therefore, buildings are sturdy (which is not necessarily true). Applying the fallacy of composition framework to existing research (for example, and more specifically, Kahneman and Tversky's (1972) research involving the birth of boys and girls where participants deemed the sequence BGBBBB less likely than the sequence GBGBBG): the birth of a boy or a girl (i.e., the parts) occurs at a ratio of 1 to 1; birth order sequences (i.e., the whole) are made of births of boys and girls; therefore, birth order sequences should have a 1 to 1 ratio of boys to girls, which is not necessarily true. Beyond the application of the fallacy of composition framework to existing research, as presented, we will also demonstrate, in the analysis of results, certain participants in our research associated certain properties of individual coin flips (e.g., the ratio of heads to tails) to be true for sequences derived from individual coin flips – demonstrating our new perspective for normatively incorrect responses to relative likelihood comparisons.

The Task

As presented in Figure 1 below, the task given to participants was both similar and different to the task utilized by Konold et al. (1993), which we will comment on, in turn.

Which of the following sequences is the *least likely* to occur from flipping a fair coin five times:

a) HHTTH
b) HHHHT
c) THHHT
d) HTHTH
e) THHTH
f) all five sequences are equally likely to occur

Justify your response...

Figure 1. The relative likelihood task

Fundamentally, and is the case with all subsequent research since Konold et al.'s version of the task (e.g., Cox & Mouw, 1992; Chernoff, 2009; Hirsch & O'Donnell, 2001; Rubel, 2006), the structure of our task is similar Konold et al.'s. For example, participants are asked to pick out a particular sequence as more or less likely or to declare that all sequences are equally likely to occur and, subsequently, are asked to justify their response. The minor differences, however, between our current version of the task and Konold et al.'s version lie in the number of sequences available to choose from and certain sequences have been replaced with others.

Participants

Participants in our research were (n =) 147 prospective mathematics teachers enrolled in a methods course designed for teaching elementary school mathematics. More specifically, the 147 participants were comprised of five classes, each containing approximately 30 students, which were all taught by the same instructor. Of note, the topic of probability had not been covered in the course they were taking part in at the time of the research and, further, it was determined, afterwards, that none of the individuals involved in the research had ever answered an alternative version of the relative likelihood task. Individuals were given as much time as necessary to complete the task.

Results and Analysis

As presented in Figure 2 below, the majority of participants' responses fell into three different categories.

Students	***HHTTH***	***HHHHT***	***THHHT***	***HTHTH***	***THHTH***	***equally likely***
Total (147)	***1***	***38 (26%)***	***1***	***15 (10%)***	***1***	***91 (62%)***

Figure 2. Breakdown of responses from the 147 participants

Most participants, that is, 91 of the 147 (or 62%), responded correctly, that each of the five sequences were equally likely to occur. (However, not all 91 participants who answered correctly provided proper or, for that matter, normatively correct response justifications.) Fifteen (or 10% of the) participants responded incorrectly that the sequence HTHTH was least likely to occur and 38 (or 26% of the) participants declared that HHHHT was least likely to occur. For the analysis of results and in order to bolster the claim that the fallacy of composition can be used to account for particular responses to comparisons of relative likelihood, certain response justifications from the 38 individuals that responded HHHHT as least likely to occur are analyzed in detail.

The Ratio of Heads to Tails

As seen in the responses of Dave and Jerry, presented below, they both reference the ratio of heads to tails in the sequences they are presented and, further, declare that the sequence B (i.e., HHHHT) is least likely to occur because it has a heads to tails ratio of 4 to 1, whereas all other sequences have a ratio of 3 to 2.

Dave: I think B is least likely to occur because the others are all 2 only B is 1.

Jerry: B, it's the only one with one T and four Hs, the rest have 3Hs and 2Ts.

However, neither Dave nor Jerry elaborate beyond "that" one sequence has a different ratio of heads to tails, which leaves one to infer as to "why" they would think a 4 to 1 ratio of heads to tails is less likely. Based upon previous research (e.g., Tversky & Kahneman, 1974), one may argue that Dave and Jerry find the equally likely sequences to not be equally representative and, further, that the sequence with a heads to tails ratio of 4 to 1 is less representative, because the parent population of coin flips would have a ratio of 1 to 1, and, thus, less likely. However, the eight responses presented below tell a slightly different story.

Emboldened in the response justifications below, three individuals mention, in one form or another, that the 4 to 1 ratio is less likely because of the notion of equiprobability.

Gustav: It's more unlikely to have 4 heads and one tail **because there is a 50% chance**.

Igor: **Because the likeliness of both is the same**. It's unlikely that out of 5 the ratio would be 4:1 instead of something like 2:3.

Farhan: **because it's 50/50** so it will probably be 3H2T or 3T2H so B has the least likelihood of happening (4H1T).

However, none of the three individuals explicitly reference where the equiprobability they are using is coming from, which is not the case with the justifications of Hermine, Keanu, and Ferdinand.

Hermine: **Because the chance for H and T are both ½**. So it will be least likely to have H, H, H, H, T.

Keanu: **Both heads and tails have an equal chance for getting flipped**. I think B as in B H had more chance.

Ferdinand: I think that HHHHT is the least sequence that is more likely to occur, **because the chances are when you flip a coin once, the possibility of getting a tail is ½ because there are 2 sides on a coin.**

From the responses above, the notion of 50-50, 1/2, 1 to 1 ratio or equiprobability used in their justifications is derived from an individual coin, which, as Keanu declares, "ha[s] an equal chance of getting flipped."

Taking their justifications one step further, Duncan and Andrew make reference to individual coin flips, which each have a 50-50 chance of landing heads and tails.

> *Duncan:* I chose B because there are more H's than T's and they are not spread out. **A likely guess would be a 50/50 chance for each, eg: H, T, H, T,...**
>
> *Andrew:* b is least likely because **if each flip gives a 50/50 chance of resulting in heads/tails**, it is more likely that in five flips more tails would result than one. I mean it is not as likely that one result would dominate over the other (but possible).

For both individuals, since each individual coin flip has a 50-50 chance of heads or tails, the sequence with a 4 to 1 ratio of heads to tails is least likely to occur because the ratio is furthest away from 50-50 or 1 to 1.

As found in past research, responses reference the ratio of heads to tails as the reason why the coin flip sequence with a 4 to 1 ratio (i.e., HHHHT) is least likely to occur; however, we break tradition from previous research and demonstrate that the fallacy of composition – not just Tversky and Kahneman's (1974) sample to parent population determinant of representativeness – can account for the above ten responses. For example, all responses declare that the ratio of heads to tails for flips of a fair coin is 1:1 (i.e., the bricks); further, they note that the sequence (i.e., the building) is comprised of five flips of a fair coin; therefore, the sequence (i.e., the building) should also have a heads to tails ratio of 1:1 (i.e., the bricks), which, simply, is not true. As such, the expectation of a 1:1 ratio of heads to tails for individual flips of a fair coin (not the sample to parent population) leads the individuals to declare that the sequence with a head to tails ratio of 4:1 (the furthest "away" from 1 to 1) is least likely. A similar situation is revealed when looking at those responses, which traditionally would have been analyzed according to Tversky and Kahneman's reflection of randomness determinant.

The Appearance of Randomness

Aaron, Candy, Zoni, and Geena, declare that the sequence HHHHT is least likely to occur because of the "long" run of heads. However, the responses do not get into detail as to why the run of 4 heads in a row make the sequence less likely.

> *Aaron:* The chances of getting the same one four times is least.
>
> *Candy:* because the chances of getting 4 same sides are small.
>
> *Zoni:* B. It's more unlikely to flip four of the same sides 4 times in a row.
>
> *Geena:* B. Because that has the most of one side of the coin, which makes it less likely.

Peter, on the other hand, provides some insight, in his response below, as to why the sequence with a run of 4 heads is less likely.

> *Peter:* There is less of a chance of getting the same answer four times in a row. It's more likely to get a variety of answers.

Peter, and perhaps Aaron, Candy, Zoni, and Geena are expecting some mixture of heads and tails and not a run of 4 heads in a row. Presented in terms of previous research, Peter and the other individuals are focusing on the sequences appearance of randomness (Tverksy & Kahneman, 1974). More specifically, the run of 4 heads in a row is not locally representative, which demotes the sequences appearance of randomness and, further, demotes its likelihood.

A large number of responses, however, provide a very particular reason for the why the run of 4 heads in a row in less likely to occur than the other sequences. Chiefly, the sequence HHHHT is not likely to occur because the fair coin, which is used for individual flips that make up each of the sequences, is equally likely to result in heads or tails. References to the equiprobability (i.e., the 1 to 1 ratio of heads to tails) associated with the coin (and the flip of the coin) are emboldened in the response justifications below. Further, the response justifications are categorized in two different (sub) groups.

The first group, made up of the responses from Velma, Wally, Nina, and Carol, all reference that the four heads appear in the sequence. Further, they argue that it would be less likely to have four heads in the sequence because, as Wally mentions, "each side has an equal chance."

> *Velma:* **Because there are 2 sides the percentage is 50-50** so that means it is more likely to have 3 tails or 3 heads. 4 heads is possible, but if you flip a coin, I think 4 heads isn't going to happen a lot.
>
> *Wally:* B **because each side has an equal chance**. Therefore, it's very hard to flip a coin and get the same side 4 times.
>
> *Nina:* I first thought the answer was F, but my gut feeling was telling me the correct answer was B. **To consistently flip heads when you have equal opportunity to flip tails** has made me chose B.
>
> *Carol:* B is least likely because it would be hard to flip a coin 5 times in a row and have it land on heads **because coins are pretty much equally weighted throughout and there is just as much chance of it landing on tails as heads** and heads is probably heavier since the design has got more metal on it. 50/50 chance.

The above four responses, we contend, fall prey to the fallacy composition. For example, all four responses declare that the coin, which has two equally likely sides, has a 50-50 chance of landing on heads or tails (i.e., the bricks); further, all participants note that the sequence (i.e., the building) is made of flips of that fair coin; therefore, the sequence (i.e., the building) should also have a heads to tails ratio of 1 to 1. As was also seen in the ratio of heads to tails responses earlier, the equiprobability of the coin and coin flips (i.e., the bricks) correlates with an expectation of "heads to tails equiprobability" for the sequence, which is not found in the sequence with four heads and, as such, is deemed less likely.

The second group, made up of the response justifications from Quinn, Reno, Susan, Terry, and Uma, also reference the number of heads, that is, four, found in the sequence. They do, however, also reference that the four heads occur in a row. Further, all five individuals declare that the sequence with four heads in a row is less likely to occur because, as Quinn declares, "there is a fifty-fifty chance it will land on heads or tails."

> *Quinn:* **Because there is a fifty-fifty chance it will land on heads or tails**. So for it to land on head four times straight is possible, but the least likely to happen.
>
> *Reno:* I think HHHHT is least likely to occur **because there is a 50% chance to land on H or T** so you probably wouldn't get H 4 times in a row.
>
> *Susan:* B is least likely to occur because there is a very low chance to get 4 head in a row. **It is a 50% chance to get H or T** so it is the most unlikely sequence.
>
> *Terry:* The reason why is **because a coin has 2 sides, so there is a 50/50 chance of one or the other**, so it is unlikely for so many heads to appear in a row. It would be more likely to have 3 or 2 heads (or tails).
>
> *Uma:* I believe this is **because there is a fifty-fifty percent chance that it will land heads or tails** and 4 head in a row is very unlikely to happen.

All five responses above – which, in the past, would have been accounted for with the reflection of randomness determinant of the representativeness heuristic – we contend, are also falling prey to the fallacy composition. All responses declare that the coin, which has two equally likely sides, has a 50-50 chance of landing on heads or tails or has a heads to tails ratio of 1 to 1 (i.e., the bricks); further, the sequence (i.e., the building) is derived from flips of a fair coin (i.e., with a heads to tails ratio of 1 to 1); therefore, the sequence (i.e., the building) should also have a heads to tails ratio of 1 to 1 and, as such, the sequence with too many heads is deemed least likely to occur. As was seen in the ratio of heads to tails and in the "four of one side responses," the heads to tails ratio of the coin (i.e., the bricks) correlates with an expectation of the same heads to tails ratio for the sequence, which is not found in the sequence with four heads (in a row).

Concluding Remarks

Demonstrated in the analysis of results, the fallacy of composition accounts for certain responses (i.e., certain normatively incorrect responses) to the relative likelihood task (which we have introduced in this article). Also as demonstrated in the analysis of results above, all responses presented can be framed within the fallacy of composition. In particular, participants: make note of the 1 to 1 ratio of heads to tails of the coin (alternatively expressed throughout as: "fifty-fifty," "equiprobable," "the possibility of getting a tail is 1/2"); note that sequence is made up of flips of said fair coin; and, as such, determine (fallaciously) that the sequence of coin flips should also have a heads to tails ratio of 1 to 1. In other words, the properties associated with the fair coin (i.e., the brick), which make up the sequence (i.e., the building), are expected in the sequence. Subsequently, when looking at potential responses, the one sequence with a heads to tails ratio furthest away from 1 to 1 (i.e., the only sequence with a heads to tails ratio of 4 to 1 when compared to all others sequences with a heads to tails ratio of 3 to 2) is deemed the least likely to occur. The respondents are taking their knowledge of equiprobability in one context and transferring it to another without validation of equiprobability in the new and expanded context. It is in this reasoning that the fallacy of composition lays.

Discussion

Research involving comparisons of relative likelihood has, historically, been focused on accounting for individuals' responses – both correct and incorrect. Through investigating normatively incorrect responses, research has developed a variety of theoretical models (e.g., the representativeness heuristic, the outcome approach, and the equiprobability bias) to account for incorrect, sometimes incomprehensible, responses. In a more general sense, the incorrect responses have, in the past, been accounted for by contending that individuals were employing heuristic or informal reasoning in their justifications. In more recent years, there has been a lack of developments and new perspectives to response justifications associated with comparisons of relative likelihood. We have, however, in this article, presented a fresh perspective, the composition fallacy, to account for certain response justifications. This novel perspective, we contend, opens a new area of investigation for future research on comparisons of relative likelihood: the use of logical fallacies. While, in this article, we have demonstrated the descriptive power of the fallacy of composition, more research in the new domain will lead researchers to determine to what extent informal logical fallacies can describe response justifications to comparisons of relative likelihood and, in doing so, determine to what extent logical fallacies are a part of teachers' knowledge of probability. Through the identification of these logical fallacies within teachers' probabilistic knowledge, teacher educators can assess the origins of teachers' non-normative (e.g., heuristic, informal, fallacious) probabilistic reasoning. Once assessed, educators can then address the teachers' knowledge and model effective strategies for assessing and responding to their future students' non-normative probabilistic reasoning.

DATA MODELING IN ELEMENTARY AND MIDDLE SCHOOL CLASSES: A SHARED EXPERIENCE

Lyn D. English
Queensland University of Technology
Australia
l.english@qut.edu.au

This paper argues for a renewed focus on statistical reasoning in the elementary school years, with opportunities for children to engage in data modeling. Data modeling involves investigations of meaningful phenomena, deciding what is worthy of attention, and then progressing to organizing, structuring, visualizing, and representing data. Reported here are some findings from a two-part activity (Baxter Brown's Picnic and Planning a Picnic) implemented at the end of the second year of a current three-year longitudinal study (grade levels 1-3). Planning a Picnic was also implemented in a grade 7 class to provide an opportunity for the different age groups to share their products. Addressed here are the grade 2 children's predictions for missing data in Baxter Brown's Picnic, the questions posed and representations created by both grade levels in Planning a Picnic, and the metarepresentational competence displayed in the grade levels' sharing of their products for Planning a Picnic.

Introduction

The need to understand and apply statistical reasoning is paramount across all walks of life, evident in the variety of graphs, tables, diagrams, and other data representations that need to be interpreted. Elementary school children are immersed in our data-driven society, with early access to computer technology and daily exposure to the mass media. With the rate of data proliferation has come increased calls for advancing children's statistical reasoning abilities, commencing with the earliest years of schooling (e.g., Franklin & Garfield, 2006; Langrall, Mooney, Nisbet, & Jones, 2008; Lehrer & Schauble, 2005; National Council of Teachers of Mathematics [NCTM], 2006; Shaughnessy, 2010). We need to rethink the nature of young children's statistical experiences and consider how we can best develop the important mathematical and scientific ideas and processes that underlie statistical reasoning (Franklin & Garfield, 2006; Langrall et al., 2008; Watson, 2006). One approach in the beginning school years is through data modeling (English, 2010; Lehrer & Romberg, 1996; Lehrer & Schauble, 2007; Lehrer & Schauble, 2000).

Data modeling is a developmental process, beginning with young children's inquiries and investigations of meaningful phenomena, progressing to identifying various attributes of the phenomena, and then moving towards organising, structuring, visualising, and representing data (Lehrer & Lesh, 2003). As one of the major thematic "big ideas" in mathematics and science (Lehrer & Schauble, 2000, 2005), data modeling should be a fundamental component of early childhood curricula. Limited research exists, however, on such modeling and how it can be fostered in the early school years. Indeed, the majority of the research on mathematical modeling has been confined to the secondary and tertiary levels, with the assumption that elementary school children are not able to develop their own models and sense-making systems for dealing with complex situations (Greer, Verschaffel, & Mukhopadhyay, 2007).

In this paper, I first consider briefly the core components of data modeling relevant to the present activity, namely, structuring and representing data, and informal inference (specifically, making predictions). I also consider the role of task context in data modeling. Specifically, I address the following questions:

- What was the nature of the three grade 2 classes' predictions for the missing values in a table of data for *Baxter Brown's Picnic*?
- What questions were posed and representations created by one second-grade and one seventh-grade class in *Planning a Picnic*?
- How was metarepresentational competence displayed in the sharing of products between the second-grade class and the seventh-grade class?

Structuring and Representing Data

Models are typically conveyed as systems of representation, where structuring and displaying data are fundamental—"Structure is constructed, not inherent" (Lehrer & Schauble, 2007, p. 157). However, as Lehrer and Schauble indicated, children frequently have difficulties in imposing structure consistently and often overlook important information that needs to be included in their displays or alternatively, they include redundant information. Providing opportunities for young children to structure and display data in ways they choose, and to analyze and assess their representations is important in addressing these early difficulties.

Constructing and displaying data models involves children in creating their own forms of inscription. By the first grade, children already have developed a wide repertoire of inscriptions, including common drawings, letters, numerical symbols, and other referents. As children invent and use their own inscriptions they also develop an "emerging meta-knowledge about inscriptions" (Lehrer & Lesh, 2003). Children's developing inscriptional capacities provide a basis for their mathematical activity. Indeed, inscriptions are mediators of mathematical learning and reasoning; they not only communicate children's mathematical thinking but they also shape it (Lehrer & Lesh, 2003; Olson, 1994). As Lehrer and Schauble (2006) emphasized, developing a repertoire of inscriptions, appreciating their qualities and use, revising and manipulating invented inscriptions and representations, and using these to explain or persuade others, are essential for data modeling. In a similar vein, diSessa has argued for the development of students' metarepresentational competence, which includes students' abilities to invent or design new representations, explain their creations, and understand the role they play (e.g., diSessa, Hammer, Sherin, & Kolpakowski, 1991).

Informal Inference: Making Predictions

There has been limited research on young children's abilities to make predictions based on data, an important component of beginning, informal inference. Although young children obviously do not have the mathematical background to undertake formal statistical tests, they nevertheless are able to draw informal inferences based on various types of data (Watson, 2007). Predictions can be based on aspects of the problem scenario and context, and children's understanding of the data presented. As pointed out by Watson (2006), one of the aims of statistics education is to help students make predictions that have a high probability of being correct. Yet in the real world, decisions are required where there is uncertainty and where several alternatives might be reasonable. Hence, young children's exposure to informal inference involving uncertainty is an important learning foundation if a meaningful introduction to formal statistical tests is to take place in secondary school.

The Role of Context

The nature of task design, including the task context, is a key feature of data modeling activities. Children need to appreciate that data are numbers in context (Langrall, Nisbet, Mooney, & Jansem, 2011; Moore, 1990), while at the same time abstract the data from the context (Konold & Higgins, 2003). Moore emphasised that a data problem should engage students' knowledge of context so that they can understand and interpret the data rather than just perform arithmetical procedures to solve the problem.

The need to carefully consider task design is further highlighted in research showing that the data presentation and context of a task itself have a bearing on the ways students approach problem solution; presentation and context can create both obstacles and supports in developing students' statistical reasoning (Cooper & Dunne, 2000; Pfannkuch, 2011). In designing the present activities, literature was used as a basis for the problem context. It is well documented that storytelling provides an effective context for mathematical learning, with children being more motivated to engage in mathematical activities and displaying gains in achievement (van den Heuvel-Panhuizen & van den Boogaard, 2008).

Methodology

Participants

The participants were from an inner-city Australian school, situated in a middle socio-economic area, with an enrolment of approximately 500 students from Prep (K) -7. The three first-grade classes (2009, mean age of 6 years 8 months) continued into the second year of the study, the focus of this paper (2010, mean age of 7 years 10 months, n=68). The grade 7 class (n=24), who participated in the *Planning a Picnic* activity, described below, had an age range from 12 to 13 years.

Research Design

A teaching experiment involving multilevel collaboration (English, 2003; Lesh & Kelly, 2000) was adopted here. This approach focuses on the developing knowledge of participants at different levels of learning (student, teacher, researcher) and is concerned with the design and implementation of experiences that maximise learning at each level. The teachers' involvement in the research was vital; hence regular professional development meetings were conducted. This paper addresses aspects of the student level.

Activities and Procedures

The final activity implemented in the second year of the study continued the story context (purposely created) from the first year of activities. The context involved the adventures of Baxter Brown (a "westipoo"—West Highlander X toy poodle). The children requested more stories about Baxter Brown in the second year of the study; hence a story about Baxter Brown's picnic was created as the context for the first part of the activity (*Baxter Brown's Picnic*). For the *Planning a Picnic Activity*, two story picture books about foods and picnics were read to the grade 2 classes prior to their planning their own picnic.

For the *Baxter Brown's Picnic Activity*, the children (as a whole class) were presented with a table of six different items that he and each of his five canine friends chose to take on their picnic. The final column of the table was left blank, as indicated in Table 1 below. After discussing what they noticed about the values and variation in values across the table, the children were invited to predict the number of Oinkers that Baxter Brown and each of his friends might take on the picnic.

Table 1. Items Taken to Baxter Brown's Picnic

	Liver Straps	Beef Discz	Dentastix	My Dog Gourmet Beef	Bones	Oinkers
Baxter B.	3	5	2	1	3	
Monty	2	7	1	2	1	
Fleur	4	0	3	4	5	
Daisy	3	1	4	3	2	
Lilly	5	3	0	2	4	
Pierre	7	5	2	6	10	

For *Planning a Picnic* (grades 2 and 7), an initial whole-class discussion focused on questions the children might ask about planning a class picnic. In their groups, the children then listed five items they would like to take on the picnic, which were recorded by the teacher in a table on an interactive whiteboard. The children were subsequently asked what might be done with the data and what questions they might ask about the data. Each group's question was recorded on the board, with brief discussion on how some of the questions might be refined. In their groups, the children proceeded to answer their question and were to display their findings using whatever representation they liked. They were provided with a range of recording material including blank chart paper, grid paper, and chart paper displaying a circle shape. The children could use whatever of these materials they liked; no encouragement was given to use any specific recording material. On completion of the activity, the groups reported back to their class peers on how they answered their question. The grade 2 children were subsequently asked how their responses might compare with those of the other grade two classes, and were then asked to consider how the grade 7 classes in their school might respond to the activity. On the suggestion of one of the second-grade teachers, we administered the *Planning a Picnic* activity in one seventh-grade class. We then brought together the teachers and students from the second-grade class and the seventh-grade class for a sharing of how they worked the activity.

Data Collection and Analysis

In each of the second-grade classrooms, all whole-class discussions were videotaped and audiotaped; likewise, in each class, two focus groups (of mixed achievement levels and chosen by the teachers), were videotaped and audiotaped, with all tapes subsequently transcribed. There were 17 groups of second-grade children (3-4 per group), five in one class and six in each of the remaining two classes. For the seventh-grade class, the teacher chose mostly two-member groups, making 11 groups in total. The sharing of products between the two grade levels was videotaped and transcribed. All artifacts were collected and analyzed along with the transcripts. Where appropriate, iterative refinement cycles for analysis of children's learning (Lesh & Lehrer, 2000) were used, together with constant comparative strategies (Strauss & Corbin, 1990) in which data were coded and examined for patterns and trends.

Selection of Findings

Grade Two Children's Predictions for Baxter Brown's Picnic

In contrast to the children's use of informal inference in the first year of the study (English, in press), where they used the variation and range of values in a table of data to predict unknown values, the context of the present activity appeared to inhibit the children's ability to abstract the data from the context (Konold & Higgins, 2003). Each class initially identified the blank column as the first feature they noticed, with one child explaining, "Nobody wants Oinkers." In predicting how many Oinkers each of the dogs might take to the picnic, the children predicted small values less than 10, with their reasoning mainly based on the total number of other items each dog was bringing and the fact that if a larger number of Oinkers were brought to the picnic, the dogs "might get sick," "get a tummy ache," or "get fat." One child suggested zero, "because there has to be something that he doesn't like." There were some responses however, indicating an awareness of the need to consider the nature of the existing values, such as, "Because he (Monty) doesn't eat that much of anything else so he mustn't eat that much." In response to a child who predicted that Baxter Brown would take zero Oinkers, because he already has many other items, the teacher accepted the response as a reasonable prediction. Another student, however, disagreed, stating, "I don't think it's reasonable because he's pretty of a greedy guts so I think he would have more" (basing her decision on the existing item values for Baxter Brown).

On asking each class to consider the scenario of Baxter Brown taking 26 Oinkers, Monty 33, Fleur 50 etc., the majority of children used the task context to decide that these values were inappropriate. Comments such as, "They're um too big, the dogs would probably get a tummy ache and get sick" and "It's too heavy for them to carry to the picnic," were common. On the other hand, other responses suggested that some children were aware of the need to focus on the data itself, for example, "They would be bigger than all the numbers," "Ten is the highest number you can go up to," There's only one two-digit number," and "Because there would be too much."

Children's Questions and Representations for Planning a Picnic

The findings reported in this section focus on the responses of the selected second-grade class and the seventh-grade class. The table created by the grade 2 class appears below; a comparable table was developed by the grade 7 students.

<u>Table 2</u>. Picnic Items Chosen by the Grade 2 Class

Group1	Group 2	Group 3	Group 4	Group 5
choc chip cookies	sandwiches	blanket	food	cup cakes
fruit	fizzy drinks	fruit	picnic basket	cake
sausage rolls	cookies	cake	sunscreen	juice
cordial	fruit	esky	drinks	fruit soft drink
sandwiches	fruit pudding	soft drinks	chairs	carrots

The questions posed by each class are listed below. These questions addressed the table of data displaying the items each group would take on their picnic.

<u>Grade 2</u>

- Did everybody choose healthy items?
- Is there a most popular food?
- What are the different types of items?
- Did everybody choose the same items?
- Is there a most popular item?

<u>Grade 7</u>

- What percentage of foods are in each food group?
- How many different picnics brought 2 or more healthy foods?
- What percentage of foods are unhealthy?
- What is the most popular item on the list, soft drink or sandwich?
- How many items are processed foods in each picnic?
- What percentage of groups brought fruit on their picnic?

- What was the most popular food?
- What percentage of groups chose sandwiches compared to groups who chose fruit to bring on their picnic?
- Is there more healthy than unhealthy food?
- What food group does the majority of food from all of the picnics come from?

Not surprisingly, the grade 2 students' questions were less sophisticated than their older counterparts, resulting in a few difficulties in answering their question and representing their findings. Nevertheless, the younger children displayed a wider range of representations, albeit less sophisticated than their older counterparts. Each grade 2 group made use of the table of chosen items given to them (Table 1) and displayed a range of inscriptions in analyzing their data. For example, one group who addressed their question, "Did everybody choose healthy items?" placed a X on what they considered to be unhealthy items, a * on healthy items, a 0 on "things that aren't food," and a created symbol of mixed shapes for "fruit/sugar." This group also drew a food pyramid, with a focus on healthy and unhealthy items, and followed this with a third representation, a circle divided into halves displaying drawings and labels of "junk food" and "healthy foods." Four of the grade 2 groups made a list of selected items, before constructing a bar graph (3 groups) or a pie graph (cut into thirds; 1 group). One of the groups explained how their construction of a bar graph made them change their initial answer to their question:

> *Our question is, "Is there a most popular food?" There is, there is, the answer was, there is not any popular food because there were, there's 3. We, um, our finding things out was that all the things, we've made all the things that go together on the graph here and then we found out, we recorded how many different stuff there was and on one square it means that um, it means that there was one thing, on two squares it means that's there's two things and it keeps on going up to 6. And then we found out that there was no most popular food. There were 3 tying, drinks, cakes and picnic stuff…We wrote first that there was a popular thing but then when we ended up doing the graph, it ended up that there was, um, three populars.*

In contrast to the grade 2 children, all but one of the 11 grade 7 groups chose only one representation, with vertical bar graphs and pie graphs being equally popular (each chosen by 5 groups, with the display of percentages prominent). One group who created a pie graph also made a tally chart first. The remaining group created a line graph. When asked why they selected a line graph in preference to a bar graph, this group explained, "Well we thought because there are so many foods, drawing bars to make them seeable would be quite squishy; we just thought it would be easier to read if it was a line graph."

The children's foregoing explanations indicate a metarepresentational competence where they were able to explain and justify the representations they generated and also understand the role these played. Further evidence of such competence was evident in the sharing of products between the two grade levels.

Children's Metarepresentational Competence in Sharing Products for Planning a Picnic

As indicated in the methodology section, one grade 2 class and one grade 7 class came together to share their products for the *Planning a Picnic* activity. The grade 2 teacher initially asked her class to recall how they predicted the grade 7 students might work the activity. The children responded that "They won't have the same ideas," and "We said that they might be better because they'd had more years."

As the grade 7 class presented their products to their younger counterparts, there were several displays of metarepresentational competence at both grade levels. One grade 7 group reported that they solved their question using a bar graph that showed percentages of the particular items targeted in their question. When asked why they chose this representation, the group explained, "We tried a pie graph but we couldn't like split it into the right amount of groups." When invited to define a pie graph for the grade 2 children, one group member explained, "A pie graph is a circle that you put lines into and then color sections which is what, yeah, is what you chose." When the grade 2 children were asked to compare their bar graph representations with the grade 7 group, they responded that theirs was easier to read as "They (grade 7) used percentages and we don't know about percentages yet." However, the younger children were able to interpret the grade 7 representation when asked what the most popular and least popular item was:"Cause it's got the names at the bottom (labels under X axis). I was looking at the fruit one and I knew that it was the most…cause it's got the highest thing (bar) that goes up." In answering their question, "How many different picnics brought two or more healthy foods?" another grade 7 group justified their selection of a bar graph in preference to a pie graph by explaining, "Cause if you did like a pie graph… you wouldn't really show each group and how many items each individual group brought."

A follow-up grade 2 class discussion on how their working of the activity compared with the grade 7 students included comments such as: "We took more healthy food than they did;" "They were really bad choices;" "They did pie graphs and we didn't know like how to;" and (they did) "The line graph." In a follow-up question, the grade 2 children commented that 100% means "all of it" (circle) and "to understand the pie, we can look at it and see if it adds up to 100%."

Discussion and Concluding Points

Three main issues arising from the children's responses are worth highlighting here—the role of task context in the grade 2 children's predictions, the nature of the questions and representations created by the grade 2 and 7 classes, and the metarepresentational competence displayed in their sharing of products.

As previously noted, children need to appreciate that data are numbers in context, while at the same time abstract the data from the task context. Although context provides meaning in statistics (Garfield & Ben-Zvi, 2008), it can create both obstacles and supports in student's statistical reasoning (Pfannkuch, 2011). The purposefully created context of Baxter Brown and his canine friends organizing a picnic appeared to hinder the children's analysis of the table of data (Table 1). Only a few children justified their predictions by considering the nature (range and/or variation) of the values displayed, with the majority making contextual inferences such as the need to consider the dogs' health. The role and impact of task context require careful consideration in designing statistical activities; clearly a good deal more research is needed here to guide the development of data modeling in the early years.

Posing questions about the class selection of picnic items was a comparatively new learning experience for the second-grade children and did present some difficulties, resulting in discussion on how some of the questions might be refined. Such difficulties can be expected—transforming initial questions into more specific statistical questions is not an easy step, especially for young children (Konold & Higgins, 2003). Not surprisingly, the grade 7 students generated more sophisticated questions, applying mathematical understandings they had developed during their additional years of schooling. Nevertheless, both grade levels displayed metarepresentational competence in generating, describing, explaining, and justifying their representations. Interestingly, most of the grade 2 children, in contrast to their grade 7 counterparts, created more than one representation and could identify the links between their representations. The sharing of products was a rich learning experience for both grade levels, providing opportunities for appreciating different approaches to dealing with data and for questioning, explaining, and interpreting the data models of others. Consideration should be given to creating such sharing opportunities across grade levels.

PROBABILISTIC MISCONCEPTIONS OF PRESERVICE TEACHERS

Alexis Johnston
Virginia Tech
alexis05@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

Probabilistic misconceptions are common among students and teachers alike. This study involved 18 preservice secondary mathematics teachers and documents some of the common probabilistic misconceptions held by these preservice teachers. Data was collected through a survey involving eight probability problems and two semi-structured interviews. Findings indicate that the most common misconception held by these preservice teachers related to time axis, compound events, and availability.

Many people struggle with probabilistic misconceptions in situations of uncertainty. A misconception is more than just a mistake. Mistakes are easy to make and can be made for a number of different reasons: e.g., carelessness or distractions from another classmate. A misconception, however, is an incorrect concept held by a person that leads to a systematic pattern of errors (Khazanov, 2008). Teachers' practices and beliefs play an extremely important role in student learning (Beswick, 2006, 2008; Thompson, 1984), therefore identifying and addressing probabilistic misconceptions held by preservice teachers is important because they may pass those misconceptions on to their future students. This study examines and documents some of the probabilistic misconceptions held by preservice teachers.

Theoretical Framework

Shaughnessy (1992) argued that people need to "learn about probability and statistics just to be able to make reasonable decisions (as consumers or voters or even in choosing a career) on the basis of the mounds of data and probabilistic statements that confront them" (p. 95). Any well-informed citizen or consumer should have a good understanding of probabilistic statements – free from misconceptions. However, probabilistic misconceptions are common among students of all ages – elementary students, secondary students, college students, and even adults (Shaughnessy, 1992; Fischbein & Schnarch, 1997).

Fischbein and Schnarch (1997) explored common probabilistic misconceptions of students at various ages. A seven-item questionnaire was developed and administered to five groups of students: 20 students in fifth-grade, 20 students in seventh-grade, 20 students in ninth-grade, 20 students in eleventh-grade, and 18 preservice mathematics teachers. The seven items on the questionnaire were each related to seven common probabilistic misconceptions. Each of these is briefly discussed below (for further discussion see Fischbein & Schnarch, 1997; Kahneman, Slovic, & Tversky, 1982). Misconceptions related to the use of the representativeness heuristic involve an individual estimating the likelihood of an event based on how similar that event is to the population that it comes from. Misconceptions associated with negative and positive recency effects involve a person relating the probability of an event to the most recent similar events (e.g., flipping a coin a certain number of times). Misconceptions related to compound and simple events involve a misunderstanding of all possible outcomes for two events occurring simultaneously (e.g., rolling two dice). Misconceptions related to the conjunction fallacy involve a person believing that, under certain conditions, the probability of an event appears to be higher than the probability of the intersection of the same event with another. Misconceptions related to sample size involve individuals neglecting the importance of the size of a sample when estimating probabilities. Misconceptions related to the availability heuristic involve a person estimating the likelihood of an event based on how easy it is to think of an example or recall a particular instance of the event. Finally, the time-axis fallacy involves a person inverting the time axis of cause implying effect.

Fischbein and Schnarch (1997) hypothesized that all of the probabilistic misconceptions would decrease with age, and specifically, that they would stabilize during what Piaget labeled as the formal operational period (ages 12 and above). However, the actual findings of the study were extremely varied. Some of the misconceptions decreased with age, some remained constant, some increased with age, and some were absent altogether. Misconceptions dealing with the representativeness heuristic, negative recency, and the conjunction fallacy all decreased with age. Misconceptions dealing with compound and simple events were frequent among the students in the study and stable across all ages. Misconceptions dealing with the effect of sample size, the availability heuristic, and the effect of the time axis all increased with age. Only one of the misconceptions, positive recency, seemed to be absent from the students.

In summary, probabilistic misconceptions are common among students, teachers, and citizens (Fischbein & Schnarch, 1997; Wilkins, 2007; Shaughnessy, 1992). The purpose of this study is to identify and discuss probabilistic misconceptions of secondary mathematics preservice teachers.

Methods

Participants

Eighteen preservice secondary mathematics teachers participated in the study. All of the preservice teachers were graduating seniors in a five-year teacher preparation program. The preservice teachers graduate with an undergraduate degree in mathematics after four years and a master's degree in education after one additional year. The preservice teachers' undergraduate degree in mathematics included at least one course in probability or statistics, which they had all already taken. At the time of the study all of the preservice teachers were enrolled in a senior capstone course in which one of the researchers was the instructor.

One limitation of the study is the dual relationship that one of the researchers had with the participants in the study. The researcher personally knew all of the participants because they were students in her class. However, the researcher and the participants had never before discussed probabilistic misconceptions. Participation in the study was voluntary and was in no way linked to course credit.

Data Collection

The study consisted of an initial survey and two follow-up semi-structured interviews. The initial survey was designed to identify probabilistic misconceptions held by the preservice teachers. All eighteen of the preservice teachers in the study completed the initial survey. The initial survey included eight problems, each of which focused on one of the seven common misconceptions outlined previously by Fischbein & Schnarch (1997) with two of the problems focused on the effect of sample size.

Preservice teachers completed the eight problems by selecting the correct answer from three or four answer choices. In addition, preservice teachers were asked to explain their thinking for each of the eight problems. It was extremely important to have the preservice teachers explain their problem solving process for each of the eight problems. In this way the researchers were able to more accurately determine whether or not the preservice teachers actually held a particular probabilistic misconception.

From the results of the initial survey, six preservice teachers who demonstrated probabilistic misconceptions were selected. Of these six preservice teachers, only two of them participated in the follow-up interview sessions. The semi-structured interviews were especially beneficial because they allowed the researcher to "experience, firsthand, students' mathematical learning and reasoning" (Steffe & Thompson, 2000, p. 267). Both of the follow-up interview sessions were video recorded for future analysis.

This first semi-structured interview consisted of a short background interview and a time for the preservice teacher to work on two probability problems. The background interview focused on the preservice teachers' prior experiences with mathematics in general and with probability and statistics in particular. The background interview also focused on the preservice teachers' attitudes about teaching probability and statistics in the future. The preservice teacher then engaged with two probability problems that related directly with two common probabilistic misconceptions, the availability heuristic and compound and simple events.

The second semi-structured interview consisted of a probability activity that dealt specifically with the representativeness heuristic. The activity combined a hands-on experiment in which the preservice teacher flipped six fair coins 50 times in order to find experimental probabilities and also created a theoretical model for the same situation. While completing the probability activity, the interviewer probed the mathematical and probabilistic understanding of the preservice teacher by asking questions such as: "What is your reasoning for this?" and "Why did you choose this approach?"

Data Analysis

The analysis of the data included both quantitative and qualitative methods. From the initial screening survey, the percentage of preservice teachers who demonstrated the various probabilistic misconceptions was calculated. The video recording from the two semi-structured interviews was transcribed and analyzed for rich evidence of probabilistic misconceptions held by the preservice teachers.

Results

The percentage of teachers who held the various probabilistic misconceptions is presented in Table 1. The most common misconception held among these preservice teachers is related to the effect of the time axis (72.2%). Interestingly, after all eighteen participants completed the initial survey they animatedly debated their answers to this particular problem. The second most common misconception held among these preservice teachers is related to compound and simple events (44.4%). The third most common misconception held among preservice teachers is related to the availability heuristic (33%). The specific problems dealing with these three probabilistic misconceptions from the initial survey can be found in Table 2 below.

Effect of time axis	72.2%
Compound and simple events	44.4%
Availability	33.3%
Effect of sample size	27.7%
Effect of sample size	22.2%
Conjunction fallacy	11.1%
Negative recency	5.5%
Positive recency	0%
Representativeness	0%

Table 1. Percent of preservice teachers who demonstrated misconceptions (N = 18)

Effect of the time axis
Jack and Jill each receive a box containing two white marbles and two black marbles. a) Jack extracts a marble from his box and finds out that it is a white one. Without replacing the first marble, he extracts a second marble. Is the likelihood that his second marble is also white smaller than, equal to, or greater than the likelihood that it is a black marble? b) Jill extracts a marble from her box and puts it aside without looking at it. She then extracts a second marble and sees that it is white. Is the likelihood that the first marble she extracted is white smaller than, equal to, or greater than the likelihood that it is black? Explain your thinking.
Compound and simple events
Suppose Cathy rolls two dice simultaneously. What of the following has a greater chance of happening? a) Obtaining two sixes. b) Obtaining a five and a six. c) Both have the same chance. Explain your thinking.
Availability
When choosing a committee comprised of 2 members from among 10 candidates, the number of possibilities is: a) Smaller than… b) Equal to… c) Greater than… the number of possibilities when choosing a committee of 8 members from among 10 candidates. Explain your thinking.

Table 2. Initial survey problems

Semi-Structured Interviews

For the purposes of this paper, the results from the semi-structured interviews will focus primarily on Amanda, one of the two preservice teachers who participated in the follow-up interviews. During the first interview, Amanda was given two tasks. These tasks were related to availability and compound and simple events. The misconceptions associated with these two types of problems were among the most common in the initial survey. On the initial survey, Amanda did not seem to hold a misconception related to availability, but she did seem to hold a misconception related to compound and simple events.

The first task related to availability (see Figure 1). Amanda's initial approach was to draw all the possible paths in each of the grids. This turned out to be a daunting task and led Amanda to some confusion. She eventually took a step back and tried to relate the paths in each of the grids to a more concrete example. She exclaimed,

> Trying to figure out the number of paths in the grid is like trying to pick out a pizza. If you have to choose a certain kind of crust, a certain kind of cheese, a certain kind of

> meat, and a certain kind of vegetable to put on the pizza, then you would just multiply the number of each to get the total number of possible pizzas.

Amanda related this back to the number of possible grids by saying,

> For the first *x*, you've got one, two, three, four, five, six, seven, eight possibilities to go to the next row. And then from whatever *x* you pick there, you've got eight more ways to go to the next row… yeah, that would give you all the paths because it would be just like making a tree.

This reasoning convinced Amanda that she had developed a correct method to find the possible paths in each grid by multiplying the number of rows in the grid by the number of symbols in each row. Based on Amanda's final answer to the problem and her reasoning supporting that answer, Amanda did not seem to demonstrate a misconception related to the availability heuristic.

Consider the grid below. A path is a polygonal chain of line segments, starting at the top row and proceeding to the bottom row and meeting one and only one symbol in each row.

Grid A	Grid B
xxxxxxxx	xx
xxxxxxxx	xx
xxxxxxxx	xx
	xx
	xx
	xx
	xx
	xx
	xx

a) Are there more paths possible in Grid A?
b) Are there more paths possible in Grid B?
c) Are there about the same number of possible paths in each grid?

Figure 1. Availability task

The second task related to compound and simple events (see Figure 2). For the first question in this task, Amanda's response was,

> It's one-half…it doesn't matter…this reminds me of genetics…and it doesn't matter what your first child is, I mean, we know that his first child is a son, but that has no bearing on what the [other child is]. Every time you have a child, you have a one-half probability of it being a boy or a girl. So it's one-half because they are completely independent events.

Amanda's response was especially interesting because she is a double major in both mathematics and biology. Because of her focus on biology and her past experience in genetics classes, Amanda was very passionate to say that no matter what we know about a situation (such as the gender of one child) the probability of the other child being a boy will *always* be one-half. Amanda was confident that the probability of the second child being a boy was one-half. In response to the second question in this task, she said that it still did not matter what the gender of the eldest child was. She said, "even if you ask the probability that…the other child is a girl, it's still one-half." Based on her response to this task and her reasoning for her response, it seems as though Amanda does hold a probabilistic misconception related to compound and simple events. More specifically, Amanda's misconception hinges on the idea that the events are "independent" of each other. Amanda's misconception also suggests that she does not take into consideration the fact that there are four different possibilities for Mr. Smith's two children; the two children could either be a boy and a boy, a boy and a girl, a girl and a boy, or a girl and a girl.

1) Mr. Smith is the father of two. We meet him walking along the street with a young boy whom he proudly introduces as his son. What is the probability that Mr. Smith's other child is also a boy?
2) We meet Mr. Smith (who we know to be the father of two) in the street with a boy. He is very elaborate with his introduction, presenting the boy as his eldest child. What is the probability that Mr. Smith's other child is also a boy?

Figure 2. Effect of time axis task

During the second interview, Amanda engaged with a task that had both an experimental and a theoretical component (see Figure 3). The hands-on experiment required that she flip six coins 50 times and record the number of heads (out of six) for each of the 50 flips. Before starting the experiment, Amanda hypothesized that "three heads would come up the most…there's just more ways to get three heads than six heads." This shows that Amanda had a notion of which combinations of heads and tails would be the most common. Also, when flipping the coins, Amanda observed, "one head is coming up more than one tail." This surprised her. She thought that she should have about the same number of flips when there was only one head showing as when there was only one tail showing. This observation shows that Amanda also understood the notion of symmetry in the distribution of the number of heads out of six.

Based on the experiment, Amanda developed an experimental probability model. This model described the probability of getting x number of heads when six coins were flipped at one time. These beginning observations seem to indicate that Amanda has a good understanding of the distribution and sample space she is dealing with and that she does not hold a misconceptions related to the representativeness heuristic.

<table>
<tr><td colspan="9">1) Flip 6 coins 50 times and record the number of heads in the chart below.</td></tr>
<tr><td rowspan="2"></td><td>6 H</td><td>5 H</td><td>4 H</td><td>3 H</td><td>2 H</td><td>1 H</td><td>0 H</td><td rowspan="2"></td></tr>
<tr><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr>
<tr><td colspan="9">2) Based on your data, what is the probability of getting 6 heads? 5 heads? 4 heads? 3 heads? 2 heads? 1 head? 0 heads?</td></tr>
<tr><td colspan="9">3) Make a list of all possible outcomes for flipping 6 coins.</td></tr>
<tr><td colspan="9">3) Based on your list, develop a mathematical model to find the theoretical probability for the outcomes of flipping 6 coins.</td></tr>
</table>

Figure 3. Experimental and theoretical probability task

The theoretical component of the task required that Amanda develop a theoretical probability model, again describing the probability of getting *x* number of heads when six coins were flipped at once. Amanda initially used a tree diagram to list out all the possible outcomes for flipping six coins. From her tree diagram, Amanda quickly articulated that a flip of TTTTTH is very different from a flip of HTTTTT. She then explained that you could "move around" the one head to get all the possible ways that the flip of six coins could have one head. Because Amanda had an intuitive notion of symmetry, she knew that this was similar to one tail (which she also explained was the same thing as looking at five heads). Amanda also explained that there would be a lot more ways to "move around" three heads than just one head. Because it would have been difficult to count all the theoretical ways of getting *x* number of heads on a flip of six coins based on her tree diagram, Amanda switched to using her understanding of combinations to develop the theoretical model.

Throughout this activity, Amanda did not seem to demonstrate that she held any probabilistic misconceptions associated with the representativeness heuristic. She did demonstrate that she held intuitive notions of symmetry and combinations related to the activity based on her observations during the experiment and the ease in which she calculated her theoretical model.

Discussion and Conclusions

The purpose of this study was to explore and document some of the common probabilistic misconceptions of preservice teachers. Although all of the preservice teachers in this study are undergraduate mathematics majors who have taken at least one course in probability and statistics, these preservice teachers still demonstrate probabilistic misconceptions. The most common probabilistic misconceptions of the eighteen preservice teachers were related to the effect of the time axis, compound and simple events, and availability.

Most secondary mathematics preservice teachers are required to take at least one probability and statistics course, similar to the preservice teachers in this study. However, because data analysis and probability is one of the National Council of Teachers of Mathematics' five content standards for pre-kindergarten through grade 12 mathematics education (NCTM, 2000), it might be necessary to examine both the probability and statistics courses and methods courses of secondary mathematics preservice teachers in order to discuss any potential probabilistic misconceptions of preservice teachers.

Based on Amanda's responses during the second interview, it was clear that she valued the theoretical model over the experimental model. Amanda developed both an experimental and a theoretical model for finding the probability of *x* number of heads when flipping six coins. Both models accurately described the probabilities. However, Amanda trusted her theoretical model over her experimental model. She compared the experimental model to the theoretical model and found that the experimental model was not "off by that much." This is most likely due to the fact that Amanda had little experience with experimental probabilities; she was much more familiar with theoretical probabilities. This is typical for many preservice teachers like Amanda; they do not often have meaningful experiences with activities in which they find both the experimental and the theoretical probabilities and compare the two models.

One benefit of a task like this – developing both an experimental and theoretical model for finding probabilities and then comparing the two models – is to show preservice teachers that *both* models are valuable. It is important to explicitly explore the connections between both models to enforce the validity, usefulness, and power of the experimental model.

Identifying and discussing probabilistic misconceptions of preservice teachers should be an important part of the teachers' methods courses as preservice teachers will have an influence on their future students' understanding of probability. Further, having preservice teachers engage in hands-on experiments involving well-designed tasks may be one way to help them address their own misconceptions (Shaughnessy, 1982; Wilkins, 2007, Khazanov, 2008) and better prepare them to help their future students develop sound probabilistic conceptions.

This study examined a random stratified sample (n=62) of prospective teachers' work across eight institutions on three tasks that utilized dynamic statistical software. Our work was guided by considering how teachers may utilize their statistical knowledge and technological statistical knowledge to engage in cycles of investigation. Although teachers did not tend to take full advantage of dynamic linking capabilities, they utilized a large variety of graphical representations and often added statistical measures or other augmentations to graphs as part of their analysis.

Purpose of Study

Dynamic statistical software tools have become more common in schools in the past decade, and mathematics teacher educators are beginning to use these tools in courses for prospective mathematics teachers. Although the tools are available, teachers' effective use of these tools in classrooms is influenced by their own understanding of how to use the tools to explore statistical ideas. In this paper we examine how prospective teachers use representations of data when solving statistical tasks using Fathom (Finzer, 2002) or TinkerPlots (Konold & Miller, 2005).

Theoretical Framework and Background

Lee and Hollebrands (2008, in press) proposed a framework that characterizes the important aspects of knowledge needed to teach statistics with technology (see Figure 1). In this framework, three components consisting of Statistical Knowledge (SK), Technological Statistical Knowledge (TSK), and Technological Pedagogical Statistical Knowledge (TPSK) are envisioned as layered circles with the inner most layer representing TPSK, a subset of SK and TSK. Thus, Lee and Hollebrands propose that one's TPSK is founded on and developed with teachers' technological statistical knowledge (TSK) and statistical knowledge (SK).

Within Statistical Knowledge is prospective teachers' ability to engage in transnumeration (Wild & Pfannkuch, 1999) as a process of transforming a representation between a real system (real-world phenomena) and a statistical system (ways of modeling the phenomena statistically) with an intention of engendering understanding (Pfannkuch & Wild, 2004). Thus, teachers should be able to collect data, represent them meaningfully with graphs and computed statistical measures, and translate their understandings of the data back to the context. Often times, transnumeration occurs when data is represented in some way that highlights a certain aspect related to the context that can afford new insights into the data.

Within TSK, our focus is on how prospective teachers can take advantage of technology's capabilities to automate calculations of measures and generate graphical displays, and the ways they use these graphs and measures to explore data and visualize abstract ideas (Chance, Ben-Zvi, Garfield, & Medina, 2007). For example, how do prospective teachers visualize measures (e.g., mean) and graphical augmentations (e.g., shade a region of data, showing squares on a least squares line), and how do they take advantage of ways to link multiple representations?

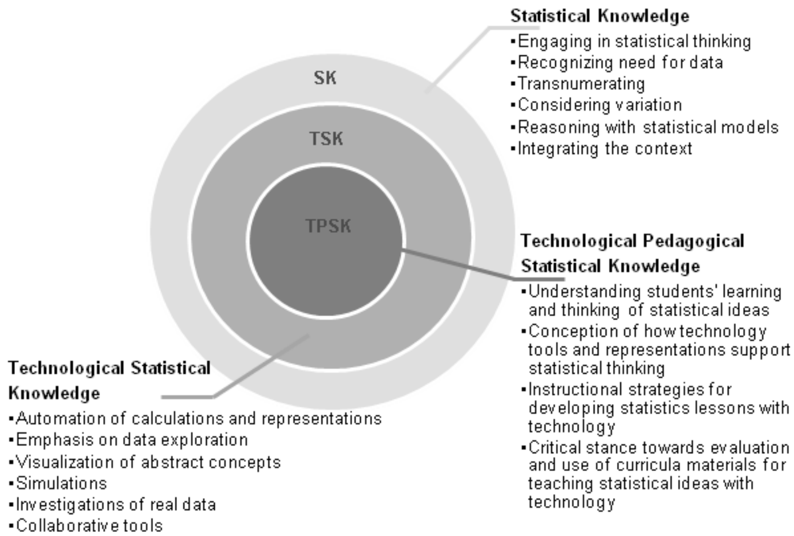

Figure 1. Components of Technological Pedagogical Statistical Knowledge (adapted from Lee & Hollebrands, in press).

Several researchers have studied teachers' use of dynamic statistical tools, usually focused within a single professional development experience or course at a specific university (e.g., Doerr & Jacob, 2011; Hammerman & Rubin, 2004; Makar & Confrey, 2008; Meletiou-Mavrotheris, Paparistodemou, & Stylianou, 2009). Overall these studies have shown that dynamic tools can provide opportunities for teachers to increase their approaches to statistical problem solving, moving beyond traditional computational based techniques and utilizing more graphical based analysis. Teachers using TinkerPlots and Fathom in these studies often combined graphical and statistical measures by either adding a measure to a graph or using a graph to make sense of a statistical measure computed separately. Such analysis by teachers often affords opportunities to consider an aggregate view of a distribution that incorporates reasoning about centers and spreads (Konold & Higgins, 2003). Although prior research discussed how teachers analyzed data where a link among representations can be inferred, researchers often did not focus their analysis on how teachers utilized linked representations.

Method

The overarching research question for the study was: *When teachers use technology tools to solve data analysis tasks, in what ways do they use representations (dynamic and static) to investigate these problems?* To further research teachers' use of dynamic statistical tools beyond small samples and limited contexts, data were collected from eight different institutions in which faculty were using materials (Lee, Hollebrands, & Wilson, 2010) developed by the PTMT project[1]. What is reported here is based on analysis of teachers' work on three tasks that use similar statistical concepts and tools in either TinkerPlots or Fathom (see Table 1).

The faculty implementing the materials attended a week-long summer institute to become familiar with technologies, specific tasks and data sets, and pedagogical issues. Across institutions, materials were implemented in a variety of courses, some focused on using technology to teach middle or secondary mathematics, and others on statistics for elementary or middle school teachers. The courses predominately enrolled prospective teachers, with a few practicing teachers or graduate students. Each teacher worked individually and created a document that described his or her work, including illustrative screenshots of ways they used technology in solving the task. A total of 247 documents were collected across institutions and blinded to protect teacher, faculty, and institutional identity.

Table 1. Research tasks

	Task as Posed in Materials
Ch 1 Task TinkerPlots	[Note: Faculty had a choice of two similar data sets to use of state level school data from two regions of the US. Data included attributes such as average teacher salary, student per teacher ratios, expenditures per student] Explore the attributes in this data set and compare the distributions for the South and West [Northeast and Midwest]. Based on the data you have examined, in which region would you prefer to teach and why? Provide a detailed description of your comparisons. Include copies of plots and calculations as necessary.
Ch 3 Task Fathom	Explore several of the attributes in the 2006Vehicle data set. a) Generate a question that involves a comparison of distributions that you would like your future students to investigate. b) Use Fathom to investigate your question. Provide a detailed description of your comparisons and your response to the question posed. Include copies of plots and calculations as necessary.
Ch 4 Task Fathom	Explore several of the attributes in the 2006Vehicle data set. a) Generate a question that involves examining relationships among attributes that you would like your future students to investigate. b) Use Fathom to investigate your question. Provide a detailed description of your work and your response to the question posed in part a. Include copies of plots and calculations as necessary.

To begin analysis, four documents were randomly selected from each chapter. Through iterative discussions by the research team[2], examining documents and making sense of prospective teachers' work, both top-down methods of Miles and Huberman (1994), and grounded theory (Strauss & Corbin, 1990) were used to develop and apply a coding instrument. The coding instrument that emerged was based on theory from research on statistical problem solving, particularly cycles of exploratory data analysis and typical phases (ask a question, represent data, analyze/interpret, and make a decision, e.g., Wild & Pfannkuch, 1999) and use of static and dynamic representations in statistics and other domains of mathematics; and on categories and codes that emerged from analyzing an initial random sample of teachers' work. In the coding procedures, each teacher's work was chunked into smaller cycles of investigation that included four phases (Choose Focus, Represent Data, Analyze/Interpret, and Make Decision). Within each phase, several categories were used to characterize the work (e.g., number of attributes, type of representations, what was noticed, interpretations, type of claim).

In the second phase of analysis, we examined a larger randomly chosen subset of documents. From an initial review of the 247 documents it was obvious that some responses were more detailed than others, contained more statistical investigation cycles, and used more representations. Thus, each document was classified as either short or long. Short responses were typically 1 page and included 1-2 screenshots with minimal explanation. Others were classified as a long response. We then conducted a stratified random sample to have proportional representation of short and long responses, and to select about 25% of our documents (Table 2).

Table 2. Design of stratified random sample

	Chapter 1			Chapter 3			Chapter 4		
	Short	**Long**	**Total**	**Short**	**Long**	**Total**	**Short**	**Long**	**Total**
Total Documents Collected	52	50	102	12	29	41	38	66	104
Stratified Random Sample	13	12	25	4	8	12	9	16	25

Pairs of coders were assigned 8-12 documents to code. All documents were initially coded individually, then the pair met to discuss, compare, record inter-rater reliability, and come to consensus for each document. During early stages, several coding categories were clarified and new categories emerged that were then adopted into the coding procedures by all coders. For several categories of codes discussed in this paper, the overall IRR across documents was 0.923 for coding representations used, and 0.94 for coding measures added to representations. There was low initial agreement about coding an augmentation to a graph (0.523), which led to discussions to establish agreed upon coding and a better definition of a graphical augmentation.

Results

A major advantage of dynamic statistical software is the ability to link representations and view different representations and statistical measures or graphical augmentations that can perhaps lead to interpretive insights. Thus, to organize our cross-document and cross-chapter analysis, we first focused on whether or not a teacher provided evidence of linking representations (see Table 3). We considered a teacher was dynamically linking two or more representations if there was evidence they had to interact (e.g., click on or drag a data point, select a region of data) with data in one representation and use information linked (often highlighted) about data in another representation. A teacher was coded as using static representations if he coordinated two or more representations without direct interactions. With differences noted across chapters, we carefully examined use of representations within chapters.

Table 3. Number of responses providing evidence of linking representations

	No Evidence of Linking	Dynamic Linking	Static Coordination
*Chapter 1 (TinkerPlots) n= 25	13 (52%)	11 (42%)	3 (12%)
Chapter 3 (Fathom) n=12	8 (66.67%)	2 (16.67%)	2 (16.67%)
*Chapter 4 (Fathom) n=25	14 (56%)	7(28%)	6 (24%)
*Totals (n=62)	35 (56.5%)	20 (32.3%)	11 (17.7%)

*Percents do not sum to 100 since 2 cases in Ch1 and 2 cases in Ch4 were coded as both static and dynamic.

Representation Use in Chapter 1 Task

In coding Chapter 1 documents, we did not specifically list a data card of a collection as a representation of that data, as it was automatically available in TinkerPlots. Data cards look like a stack of index cards, with each card representing a case (e.g., the state of Virginia) and containing the values for that case for each attribute (e.g., Average salary, Census region) in the dataset. Thus, we considered this as a representation of data readily available. Data Tables and Plots, however, were considered representations as teachers needed to drag down a Data Table to view a different numerical representation, or use a Plot and construct a visual representation. The most common Plots created were dotplots and box plots. When teachers engaged in dynamically linking or statically coordinating information in more than one representation, they could have been explicitly using or attending to a data card as a representation in that process. This focus was typically evident with those who used dynamic linking. The most common purpose for dynamic linking was to identify a particular value for a specific case of interest (e.g., clicking on a particular case icon in the graph and using the data card to determine the value of an attribute) or to click on a different attribute in the data card that would augment the graph by recoloring the data icons for a new attribute of interest. In the first type of linking, teachers were often focused on special cases such as those that appeared to be outliers and often situated these cases in comparison to the aggregate (see Figure 2 as an example of this type of linking). It was also inferred that teachers linked the data card and graphical displays in order to report specific values (e.g., data point at Q1) or compute measures such as the range. In the latter type of dynamic linking, the addition of a second or third attribute in the plot often increased the complexity of analysis as teachers considered relationships among attributes.

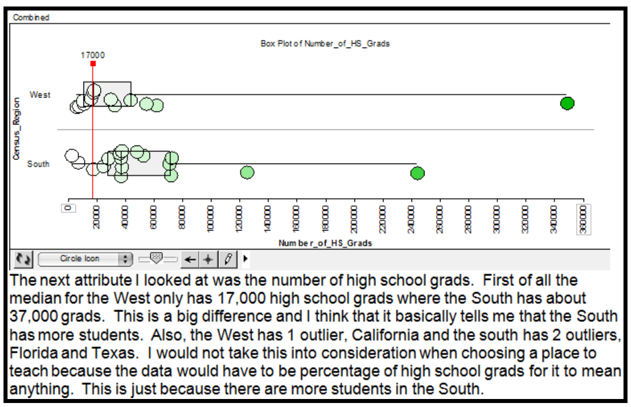

Figure 2. Using dynamic linking to identify state names of data points considered outliers.

In considering ways teachers may have used their TSK, we further examined relationships among their actions of augmenting graphs, adding statistical measures to graphs, and whether they linked representations. All teachers who dynamically or statically linked representations also augmented their graph. Teachers who interacted more with a graph through augmenting tended to also engage in linking representations (66.6% of teachers who augmented also linked). This pattern was not as strong when considering a relationship between adding a statistical measure to a graph and linking representations. Only 50% of teachers who added statistical measures to a graph also linked representations, and 3 of the 7 teachers who did not add any statistical measures to a graph still engaged in linking representations.

Representation Use in Chapter 3 Task

In Chapter 3, teachers were asked to explore several attributes in the data and to determine questions for their future students to compare distributions. More than half of the examined documents were done and submitted within Fathom, rather than in a Word document, so they could leave many of their representations viewable in Fathom and write their responses in a text box. Those that did their response in a Word document interspersed their text responses with purposeful screenshots of their work in Fathom. The data table was not specifically listed as a representation in Chapter 3 documents as teachers used this as a primary view of the data in Fathom and for grabbing the label for attributes to graph, similar to how teachers used the TinkerPlots data cards in Chapter 1. In one case a teacher used the data table as a dynamically linked representation; it was thus coded as a representation. Chapter 3 documents tended to be long (71%) yet had the smallest percentage of teachers across all chapters who showed evidence of linking representations. The two teachers that linked dynamically did so to examine particular cases and clicked on data points in a graph to locate specific values for attributes in a data table. The two teachers that demonstrated evidence of static linking did so near the end of their problem solving to examine trends across cycles. Both purposes are the same as in Chapter 1.

Teachers working on the Chapter 3 task used a wide variety of representations, and often 2-3 representations per cycle of investigation. They seemed to take advantage of the ability to generate multiple graph types (box plots, dot plots, scatterplots), and used Summary Tables extensively (many had more than one). Several teachers also added statistical measures (e.g., mean, median) to the graphs in Fathom; however in two cases, it seemed they were mainly using a graph window as a place to compute a statistical measure (e.g., IQR, StDev) whose location in the distribution did not add a way to reason about the measure in relationship to the aggregate.

Representation Use in Chapter 4 Task

In coding representations in Chapter 4 documents, again we did not specifically list the data table as a representation, as it was used as a primary view of data in Fathom. Six of the 25 documents sampled from Chapter 4 were completed entirely within Fathom rather than as a Word document. Of the 25 teachers, only 44% (n=11) linked their representations statically or dynamically. Overall, the most common purpose for linking was to compare the position of groups of cases across graphical representations and to make statements about their relationships. Of the four teachers that statically linked representations, three linked between two or more graphs. This linking typically occurred as a teacher noted the shape of a graph and commented whether or not a second graph using a different attribute was similarly shaped. Furthermore, of the four teachers that statically linked representations, two linked numerical measures with a graphical representation. One of these teachers linked the standard deviation to a histogram in an attempt to make sense of magnitude of the standard deviation. There was no evidence that the other teacher attempted to make sense of, or interpret the slope of the least squares line that was explicitly linked. Five teachers either implicitly or explicitly linked their representations dynamically. Three of these teachers linked two graphs, one linked a graph with the data table, and another linked the numerical values of sliders (controlling values of coefficients in a model) to characteristics of a graph of the model. Two teachers that linked dynamically and statically did so by linking several univariate graphs, and one teacher also linked a boxplot to a scatterplot.

In considering the ways teachers may have used their TSK, we further examined relationships among their actions of augmenting graphs, adding statistical measures to graphs, and the ways in which they did or did not link representations. Six out of 11 teachers who dynamically or statically linked representations also augmented their graph; whereas, 40% of teachers neither augmented their graph, nor engaged in any type of linking among representations, and 66% of teachers who did not augment their graph also did not link representations. Five of the 11 teachers who linked representations also added statistical measures to their graphs. Out of 16 teachers who only displayed data graphically, two-thirds (11 of 16) did not link their graphs. In contrast, all teachers who either statically or dynamically linked representations (n=11) used graphical displays.

Cross-chapter Representation Use

Teachers in Chapter 3 tended to use several more and unique types of representations of data in their response than those in Chapter 1 or 4. This may be an artifact of more than 50% of teachers in the Chapter 3 sample submitting their work in a Fathom document. Using Fathom as an analysis and reporting environment may give better insight into all the representations teachers used. When reporting work in a separate document and asked to supply screenshots of their work, teachers may not report all their representations used. The lack of evidence of linking representations may be an artifact of the task posed for Chapter 3 or may be due to the difficulty of illustrating linking when many representations are in a single Fathom document.

The graphs teachers created in Chapter 1 and 3 (tasks about comparing distributions) were typically double box plots or dot plots, with a few bar charts and scatterplots in Chapter 3. While Chapter 1 teachers most often used one graph per investigation cycle, teachers in Chapters 3 and 4 typically used more than one graph per cycle. A much wider variety of representations (simple box plots and dot plots, double box plots and dot plots, histograms, and scatterplots) were used in Chapter 4 (questions about relationships among attributes), and almost always there was more than one representation per cycle. In Chapters 1 and 3, the most common use of dynamic linking was to coordinate a single graph with either a data card or data table to find out details about a specific case of interest. Only occasionally in solving the Chapters 1 and 3 tasks did teachers use dynamic linking to look at an interval of data. However, teachers who linked representations in a dynamic way in Chapter 4 often were comparing the position of groups of cases across graphical representations and using such noticing to make statements about relationships. Static linking was done across chapters to compare trends in graphs of different attributes across cycles. This was often done towards the end as teachers reflected on their work and made a final decision.

Teachers who dynamically linked representations tended to also augment a graph (75% across all chapters). Most of the teachers (71%) who either did not link representations or only statically linked representations did not augment a graph. Chapter 3 teachers added more summary statistics to provide detail to fully answer the questions they explored. In Chapter 3, 75% of teachers added statistical measures to summary tables as compared to 28% in Chapter 4. A similar percentage of teachers from Chapter 3 and 4 (58% and 56% respectively) added statistical measures to graphical representations as compared to 72% of the teachers in Chapter 1. This may be attributed to features of TinkerPlots and Fathom. Whereas, Fathom offers the ability to summarize statistical measures in a summary table, TinkerPlots affords being able to easily incorporate summary statistics, such as measures of center, on graphical representations.

Discussion

Given the dynamic nature of Fathom and TinkerPlots, and emphasis in the materials on using dynamic linked representations, it was somewhat surprising how few teachers' responses provided evidence of either dynamic or static linking among representations. We recognize, however, that lack of evidence of linking does not mean that teachers did not engage in this activity, just that they did not report their work or findings in a way that we could infer that linking had occurred. In addition, it was apparent that those who linked in the Chapter 1 and 3 tasks did so for similar purposes, often focused on specific individual cases, whereas the Chapter 4 teachers who linked often did so to examine group propensities. We wonder if this difference is related to the nature of the tasks (comparing distributions versus relationships among attributes). In the next phase of analysis, it will be important to have a better way of capturing how a teachers' use of representations is connected with the complexity of their statistical problem solving (i.e., what is a relationship between their SK and TSK). Based on our cross-institutional sample, teachers educators may need to provide many opportunities to engage teachers in tasks that explicitly encourage dynamic linking. This may facilitate teachers understanding and using dynamic capabilities in their statistical work, and hopefully their work with students.

THE TEMPORAL CONCEPTION: STUDENT DIFFICULTIES DEFINING PROBABILISTIC INDEPENDENCE

David Plaxco
Virginia Polytechnic Institute and State University
dplaxco@vt.edu

This article discusses results from interviews investigating students' understanding of probabilistic independence and mutual exclusivity. Three students compared several sets of events in various sample spaces. Data collected from these interviews gives evidence of a temporal conception wherein students think of independence as reliant on a chronological sequence of events and conditioning. With this approach, students may see some sample spaces (e.g. spinners) as having pair-wise independence for all events. In other sample spaces, (e.g. decks of cards) students see pairs of events as both independent and not independent, this being determined by whether replacement occurs.

Introduction

Probability and Statistics have been increasingly emphasized in elementary and high school education over the past two decades (National Council of Teachers of Mathematics [NCTM], 1989; NCTM, 2000). This emphasis has also extended into post-secondary education. Mutual exclusivity and independence have gained such emphasis, making it important to accurately gauge students' conceptualizations of these two ideas. This article discusses results from interviews aimed to better understand how students think about independence and mutual exclusivity in turn contributing to the theoretical framework of how we approach learning in this area.

Manage and Scariano (2010) found that an alarmingly high percentage of undergraduate students who were enrolled in a course in probability and statistics had fundamental misunderstandings about the relationship between the ideas of independent events and mutually exclusive events. They found this by directly assessing students' understanding of this relationship through a non-scientific, multiple-choice survey of 217 students.

The researchers explored student responses to two questions. In each question, two events, A and B, are assumed to have nonzero probabilities in the same sample space. The first question presented a Venn diagram of the sample space with non-intersecting areas, labeled "*A*" and "*B*," within a rectangular sample space. The question stated that *A* and *B* are mutually exclusive and gave four responses: "*A* and *B* are independent events," "*A* and *B* are not independent events," "*A* and *B* may or may not be independent events," and "I really don't know how to do this problem" (Manage & Scariano, 2010, p. 18). The second question presented the fact that *A* and *B* are independent, have nonzero probabilities, included no diagram, and gave four responses: "*A* and *B* are mutually exclusive events," "*A* and *B* are not mutually exclusive events," "*A* and *B* may or may not be mutually exclusive events," and "I really don't know how to do this problem" (Manage & Scariano, 2010, p. 19).

In the first question, 68.3% of students incorrectly chose the first answer choice, namely "*A* and *B* are independent events." In total, 88% of students incorrectly answered this question. With respect to the second question, 36% of students gave the incorrect first response, "*A* and *B* are mutually exclusive events" whereas 23.3% of students responded correctly. By the results of the first question, students seem to think that these two ideas have a direct relationship, that mutual exclusivity implies independence. This misconception seems less prevalent in the second question, since the responses were more evenly distributed than they were in the first (Manage & Scariano, 2010).

D'Amelio (2009) found that most participants could not correctly identify a method for calculating the probability of the union of mutually exclusive events. Most students mistook the product, rather than the sum, of the two events' respective probabilities for the proper calculation. These results suggest students' confusion about the use of such a product when calculating certain probabilities. They also point to a similar misconception to that found in Manage and Scariano (2010), particularly a misunderstanding of the distinction between independent and mutually exclusive events. Confusion between calculating the probability of the intersection of two events rather than their union provides an alternative explanation for this mistake.

Shaughnessey (1992) identifies two equivalent definitions of independent events given that the two events *A* and *B* are in the same sample space and have nonzero probabilities:

Definition 1- $P(A\|B) = P(A)$	**Definition 2-** $P(A \cap B) = P(A) \times P(B)$.

Table 1. Definitions of Independence

Both D'Amelio (2009) and Manage and Scariano (2010) use Definition 2 in their research. Each of these researchers also define two events *A* and *B* as "*mutually exclusive* if and only if (A and B) = $A \cap B = \varnothing$" (p. 15). From this definition, if *A* and *B* are mutually exclusive then $P(A \cap B) = 0$. So, by the zero product property, it cannot be the case that $P(A \cap B) = P(A) \times P(B)$ and $P(A \cap B) = 0$ when *A* and *B* have nonzero probabilities.

Of the research deliberated, the explicit relationship between independence and mutual exclusivity was found in only three articles (Keeler & Steinhorst, 2001; Kelly & Zwiers, 1988; Manage & Scariano, 2010). Manage and Scariano use the reasoning discussed above whereas Kelly and Zwiers address this relationship in the context of student misunderstanding. They provide several examples of how each of these ideas can be explored separately in a classroom. Kelly and Zwiers contend that, "most of the confusion arises because we, as instructors, do not take the time to relate the two concepts." They then blatantly state the relationship between the two ideas- "mutually exclusive events are (almost) never independent." They attribute the "almost" in this last quote to the "pathological cases" when one or both events considered have zero probability (Kelly & Zwiers, 1988). Keeler et al., however, acknowledge the relationship as a common misunderstanding among students.

In considering pedagogical implications for this research, we find that students have many difficulties with both conditional probability and independence (Shaughnessey, 1992). This research goes on to say that students' "misconceptions of conditional probability may be closely related to students' understanding of independent events and of randomness in general" (Shaughnessey, 1992, p. 475). He points out that many researchers "advocate introducing the concept of independence via the conditional probability definition (Definition 1), as they believe this is more intuitive for students" (1992, p. 475). This intuition comes in the context of without-replacement problems. If the sample space remains unchanged, then the first experiment bears no affect on the second experiment.

Other pedagogical research in this area discusses students' misconceptions related to independence almost exclusively with respect to conditional probability (Tarr & Lannin, 2005). Tarr and Lannin (2005) justify their concentration on these types of misconceptions, citing Shaughnessey (1992), and focus on replacement and non-replacement situations because of the prevalence of these types of problems in the typical curriculum. Tarr and Lannin state that "within this context [that of *with-replacement* situations], an 'understanding of independence' is demonstrated by students' ability to recognize and correctly explain when the occurrence of one event does not influence the probability of another event" (2005, p. 216). There is also an emphasis that students understand the change of an event's probability in non-replacement conditional probability problems is due to the change of the sample space.

While Shaughnessey (1992), Tarr and Lannin (2005), and Keeler and Steinhorst (2001) suggest conditional probability as a context for independence D'Amelio (2009), Kelly and Zwiers (1988), and Manage and Scariano (2010) each explore student misconceptions outside of the conditional probability setting. This could provide some reasoning into why D'Amelio (2009) and Manage and Scariano (2010) had such disturbingly low numbers of correct responses. Supposing that the students' previous curricula addressed independence in the context of conditional probability, the students may not have been able to correctly reason about the relationship between independence and mutual exclusivity without such a context. Perhaps this is what Kelly and Zwiers are arguing when they say that, "we, as instructors, do not take the time to relate the two concepts," referring to mutual exclusivity and independence (1988, p. 100).

Since independence can be defined outside of a conditional probability setting, it is not limited to an order of experiments. This can be seen in a standard deck of cards. The event of drawing a spade is independent of the event of drawing an ace. We can see this since P(spade) = ¼, P(ace) = 1/13, and P(ace ∩ spade) = 1/52 = 1/4 × 1/13. This example demonstrates that independence can be accessibly thought of outside the context of conditional probability. This can prove useful since mutual exclusivity is also defined without respect to time. For instance, in the above case, it can quickly be demonstrated that P(heart∩spade) = 0 since this intersection is empty; so these two events are mutually exclusive.

Altogether, we see that different researchers emphasize two different contexts for the independence of two events. Some focus on conditional probability for the definition of independence (Definition 1), while others focus on the product definition (Definition 2). Shaughnessey (1992) provides an explanation of why educators and some researchers focus on conditional probability when dealing with independence in that it is more intuitive for students to explore independence in the context of conditional probability. Regardless, students' misconceptions about the relationship between independence and mutual exclusivity prevail.

Methods

Interviews were conducted with three undergraduate students who were enrolled in a Junior-level Proofs course (Alex, Betty, and Caroline). Betty had recently taken an undergraduate course in probability and statistics, whereas Alex and Caroline had not. In these interviews, the students were asked to give definitions of independent events and mutually exclusive events as well as provide examples of each. The students were then given various sample spaces and events within those sample spaces and asked to determine whether pairs of events were independent. The purpose of these interviews as part of broader research was to gauge the students' understanding of these concepts and the relationship between the two. Two initial sample spaces were discussed and then others were explored as students and the interviewer responded to situations throughout the interviews.

The first sample space consisted of a standard deck of cards and a fair six-sided die. The events discussed were the simultaneous drawing of a card and rolling of the die. For example, event A was "drawing a spade and rolling any number on the die." Event B was "drawing any card and rolling a three on the die." This sample space is made up of two smaller sample spaces (let's call them "subsample spaces") that are often considered individually. Each of these subsample spaces is independent of the other, as the card drawn would have no effect on the die and vice versa. The second sample space was similar to the first in that it consisted of two subsample spaces. In this sample space, an event consisted of tossing a fair coin (heads and tails) and spinning a spinner with five colors (blue, red, green, orange, and yellow) with given probabilities (.3, .2, .2, .2, and .1, respectively). So, for example, event A was tossing a head and spinning blue.

These sample spaces were chosen to observe how readily students identified the subsample spaces as independent and how they thought of the events in these sample spaces with respect to independence and mutual exclusivity. The complexity of each sample space also provided somewhat familiar situations, the combination of which prevented the participants from simply remembering probabilities from previous experience. After several pairs of events in each sample space were discussed, the interviewer and participant each introduced different sample spaces in discussion. For instance, Betty discussed a deck of cards without a die and the interviewer brought up the sample space of a die without the deck of cards when interviewing Caroline. This allowed the interviewer and participant to discuss caveats and nuances of the concepts of independence and mutual exclusivity in their own terms.

Results

Alex defined independence as, "[when] the outcome of one event does not affect the outcome of a subsequent event." This definition implies an emphasis on a sequence of events, where one of the events being considered must occur prior to the other. With regard to mutual exclusivity, however, Alex was less certain of a formal definition- changing his phrasing twice throughout the interview and eventually declaring, "Performing an event or series of events causes a subsequent event to have zero probability of happening." Again, Alex implies that this relationship is defined over a period of time. When prompted for an example of independent events, Alex gave the example of a die. He stated that rolling a six on the first roll of a die does not affect rolling a six on the second roll of a die. This example is consistent with his definition, implying that the two events in consideration take place at separate times.

Betty stated that, "Two events are independent if the probability of A occurring does not affect the probability of B occurring." Betty also described the independence of events A and B using the equation $P(A) = P(A|B)$. In comparison to Alex, this definition of independence does not necessarily imply that one event must occur before the other. But, when prompted for an example of independent events, Betty described the act of picking a card from a deck of fifty-two cards, and putting it back so that the probability of picking a second card is not affected. Similarly, when asked for an example of events *not* being independent, Betty provided the case of picking a card and not replacing it. These examples are consistent with the notion of independence in the context of a "with replacement" and "without replacement" conditioning event. In contrast, Betty defined mutually exclusive events with the statement, "you can't have both at the same time." This definition explicitly states that the events can be compared instantaneously. Here, Betty gave the example that the queen of hearts and jack of diamonds are mutually exclusive, since they cannot both occur when one card is drawn.

Caroline's definition for independence was similar to the other two participants, stating, "Two events are independent if they do not affect each other." Caroline's example of independent events was different from both Alex's and Betty's in that Caroline described "everyday events" rather than "artificial" events (such as dice or cards) that are typically investigated in the classroom setting. Caroline described how "the probability of someone wearing a red shirt is independent of their age." Similarly, when prompted for an example of events that are not independent, Caroline provided the example of someone who is forgetful is less likely to win a student lottery for a football ticket, since they are less likely to enter the lottery. This example implies a directly causal relationship, where the lower probability of the first event (entering the lottery) decreases the probability of a later event (being selected in said lottery).

It should be noted that all three participants showed initial difficulty in differentiating between the concepts of independence and mutual exclusivity, although each did eventually distinguish between the concepts. Alex, for instance, initially stated that the two concepts are "more or less the same thing" and "pretty much synonymous." Betty's first definition for mutually exclusive events, which she quickly changed, was $P(A \cap B) = P(A)*P(B)$, the mathematical definition of independence. Caroline had greater difficulty defining mutual exclusivity, stating, "It sounds like they would be independent of one another." From this, we see at least initial difficulty distinguishing between these two concepts among all the participants, consistent with the literature (Manage & Scariano, 2010).

Independence in the Sample Spaces

In the first sample space, the participants explored two pairs of events (Table 2). All three participants reacted in similar ways to the question, "Are these events independent?" In each case, all three students established various cases, beginning with some form of the question, "Do you put the card back?" In the first case, the participant described successfully performing one event, putting the card back, reshuffling (or resetting) the deck, and then successfully performing the other event in question. In each interview, the participant claimed that the events would be independent in this case. In the second case, the sequence of events was identical, except that the card was not replaced and the deck was not reshuffled.

Answers were slightly more varied in this second case. For instance, Alex thought that neither pair of events was independent, since you "change the context," but only considered event A before event B and event C before event D. Betty considered whether A came before B or vice versa and similarly for events C and D. In the first pair, Betty responded that A before B gave independence, but B before A did not. With the second pair, each event would change the probability of the other, causing C to always be not independent of D. Caroline generalized all pairs of events under this case, explaining that without replacement you affect the probability of the second event, so that no two events will be independent without replacement.

		Card	Die
Pair 1	Event A	Spade	"Any Number"
	Event B	"Any Card"	3
Pair 2	Event C	Spade	3
	Event D	Heart	4

Table 2. Events in Sample Space 1

Event B produced the most diverse explanations. Alex seemed to think of event B as impossible after drawing any card without replacing it. He attributed this to the fact that the first card would be a member of "any card," so that drawing any card would not be possible, since you will have removed one of them. Betty thought of Event B as always successful and independent. Caroline thought of event B as always successful as long as a card was remaining, but independent only when the first card was replaced. It should be noted also, that explanations of whether events on the die were independent were almost nonexistent. All three participants focused on whether the card was replaced. Alex even said, "With the die, it really doesn't matter what you do… If you're just rolling dice over and over, those are always independent."

The second sample space provided much more homogeneous responses among the participants. Most of the events discussed were single outcomes from each subsample space (i.e. one color from the spinner and one side of the coin). A few events discussed were similar to events A and B from the first sample space, where a compound event from one of the subsample spaces was considered. When asked to compare any two events in the sample space, all three participants thought of every pair of events as independent from each other. This reflects the lack of emphasis on the die in the first sample space. Successfully completing an event on both a coin and a spinner does not physically remove an object from the sample space. This fact has strong implications about the students' understanding of the relationship between independence and mutual exclusivity.

Mutual Exclusivity in the Sample Spaces

The participants seemed to struggle much more with determining two events' mutual exclusivity than with their independence. Alex changed his definition of mutually exclusive events twice, each time after encountering examples that challenged his definition. Initially, Alex's definition seemed consistent with the mathematical definition. He explained a scenario of it raining or not raining, saying, "It couldn't be raining and not raining at the same time." This phrasing alludes to an empty intersection. Throughout the interview, Alex changed his definition to more closely align with how he discussed independence, so that one event would cause a subsequent event to be impossible. Interestingly, as a corollary to his last definition of mutual exclusivity, Alex pointed out that two mutually exclusive events couldn't be independent. He made this connection before the interviewer discussed any relationship between the two terms.

Because he changed his definition, Alex's responses in the beginning of the interview convey a different conceptualization of mutual exclusivity than do his later responses. When comparing events C and D he determined that these two events are not mutually exclusive since drawing a spade does not cause drawing a heart to have zero probability. In his exploration of the second sample space, Alex concludes that no two events are mutually exclusive. This relies on his responses regarding independence, since no event in the second sample space changed the probability of a subsequent event, no event could cause a subsequent event to have zero probability.

Betty's responses to questions of mutual exclusivity were consistent with the correct mathematical definition in both sample spaces. This is because her definition of the concept was a typical translation into "everyday" language, "You can't have them both at the same time." This is not too surprising since Betty was the only participant to have had recent instruction in probability, even though Betty showed early confusion about the distinction between independence and mutual exclusivity.

Caroline also had difficulty establishing a definition for mutual exclusivity. Her final definition, "Two events that do not include parts of each other," is very similar to the mathematical definition. Most of Caroline's responses in each sample space were consistent with correct responses, except two responses in the second sample space. Event A in this sample space was "spinning blue on the spinner and tossing heads on the coin" and event E was "spinning blue or yellow and tossing heads." Caroline concluded that event A is not mutually exclusive of event E, since it was a subset of event E. But Caroline claimed that event E is mutually exclusive of event A, since you could successfully perform event E and not event A by spinning a yellow and tossing heads.

The Temporal Conception

We see from these results that students think about independence of two events by assuming the occurrence of one event and then considering whether this changes the probability of a second event that occurs chronologically after the first. The tendency for students to think of independence in this way causes a temporal conception. With all three participants, questions of events' independence were answered with students considering sequences of events. With Alex, though not in the case of Betty or Caroline, this temporal conception was also evident in his definition of mutually exclusive events.

It should be noted that, had the interviewer asked the participants to determine if the first event in a sequence of trials had changed the probability of a second event, the responses that the participants gave would have been generally correct. The misconception is that examples of chronological dependence and independence generalize to the standard definition of probabilistic independence. For instance, in the second sample space, Alex viewed all events as independent and not mutually exclusive. Meanwhile, Betty and Caroline viewed all events in the second sample space as independent, with some pairs being mutually exclusive and some not. In reality, the majority of the events discussed were mutually exclusive of each other (e.g. blue/heads, red/tails, orange/heads, etc.) and therefore not independent since most had nonzero probabilities. Furthermore, in the first sample space all participants found at least some pairs of events to be both independent (with replacement) and not independent (without replacement). This allows students to think of independence as a consequence of time and therefore allows the misconception that the same two events can be both independent and not independent.

Discussion

Understanding this temporal conception could provide insight into how students confuse the concepts of independence and mutual exclusivity. For instance, under this conception, a student could conclude that mutually exclusive events can be both independent and not independent, as was seen in the first sample space with events C and D. One may suggest that the phrase "mutually exclusive" and the word "independent" are somewhat synonymous in their everyday context, as hinted in the literature (Manage & Scariano, 2010). This was evident in the initial responses by each participant. This explanation, however, only helps to explain the responses of those students who mistakenly thought that one term implied the other. The temporal conception could potentially help explain how students thought events could be "mutually exclusive and maybe or maybe not independent" or "independent and maybe or maybe not mutually exclusive."

Kelly and Zwiers (1988) touched on the notion that students had temporal conceptions about independence. The authors discuss statement, "events A and B are independent if knowledge about whether A has occurred provides us with no knowledge about whether has occurred," (1988, p. 98) noting that, "In a very subtle way an element of time is hinted at in such a statement and it often confuses students." (1988, p. 98) They then emphasize the importance that students understand that independent events are independent regardless of time. While I agree with the importance of such a concept, it is not entirely obvious that understanding this will help students avoid the temporal conception. It is equally important that students understand that knowledge of whether events are independent is calculable without any element of time, assuming that one knows the theoretical probability of each event and of their intersection.

It can be argued that this subtle element of time is also present when discussing conditional probability. This is important since much of the research suggests that independence be taught in the context of conditional probability (Shaughnessey, 1992; Tarr & Lannin, 2005; Keeler & Steinhorst, 2001). For instance, the phrase "given that the other event has occurred" implies that perhaps the first event's occurrence was chronologically prior to the second. Further research could investigate what relationships exist between these concepts with respect to this element of time. It is also important to understand how we as educators can overcome this temporal conception. Analysis of current school mathematics curricula could allow insight into how students build notions of independence. For instance, repeatedly seeing without replacement scenarios of conditional probability as a context for how two events can be "not independent" could enable students to develop the temporal conception with independence.

The likelihood-to-act (LtA) survey measures impulsive and analytic dispositions in solving mathematics problems. The current version has 16 impulsive and 16 analytic items. Its validity was assessed using a sample of 27 in-service and 92 pre-service teachers. Both the impulsive and analytic subscales were found to have internal consistency reliability, but they were not correlated with one another. The impulsive subscale was predictive of correctness in classifying the LtA items. The analytic subscale was predictive of how well a participant would perform in Part 2 of a math test after taking Part 1 and being warned that some items could be tricky.

Many pre-service teachers for elementary and middle grades appear to have an *impulsive disposition*—a proclivity to spontaneously proceed with an action that comes to mind without analyzing the problem situation and without considering the relevance of the anticipated action to the problem situation (Lim, 2006). For example, Lim (2009) found that 22 out of 28 pre-service middle-school teachers used the same strategy to solve two superficially-similar but structurally-different problems.

As mathematics educators, we want to help students advance from impulsive disposition to *analytic disposition*—where one analyzes the problem situation (Lim, 2006). An instrument that can identify problem-solving disposition will be valuable to both students and teachers. With this purpose in mind, we developed the likelihood-to-act survey (LtA). Based on our analyses of the data collected using the original 18-item version (Lim, Morera, & Tchoshanov, 2009), we increased the number of items from 18 to 32 and revised some of them. To establish the validity of this enhanced version, we developed and administered an open-ended questionnaire, a classification exercise, and a multiple-choice mathematics test.

Constructs Related to Impulsive-Analytic Disposition

Impulsive disposition can be viewed from various perspectives. From a cognitive perspective, impulsive disposition is related to the *Einstellung effect*—the phenomenon of solving a given problem in a fixated manner even when a better approach exists (Luchins, 1942). Ben-Zeev and Star (2001) used the term *spurious correlation* to account for students' association-based behavior: "when a student perceives a correlation between an irrelevant feature in a problem and the algorithm used for solving that problem and then proceeds to execute the algorithm when detecting the feature in a different problem" (p. 253). Einstellung effect, spurious correlation, and impulsive disposition emphasize different aspects of the same phenomenon: (a) Einstellung effect refers to a mental fixation, (b) spurious correlation refers to a feature-algorithm association, and (c) impulsive disposition refers to a cognitive tendency.

From a problem-solving perspective, problem-solving disposition is related to metacognition. Actively monitoring one's progress in relation to a goal is an indicator of analytic disposition. Impulsive disposition, on the other hand, is inferred when students "read, make a decision quickly, and pursue that direction come hell or high water" (Schoenfeld, 1992, p. 356). We consider impulsive disposition to be an externalization of certain beliefs such as "there is only one correct way to solve any mathematics problem—usually the rule the teacher has most recently demonstrated to the class" (p. 359).

From a psychological perspective, impulsive disposition can be viewed as a personality trait. Kagan et al. (1964) regard a child as (a) *impulsive* if the child responds to a question with an inaccurate answer but in a short response time, and (b) *reflective* if the child has an accurate answer but long response time. Nietfeld and Bosma (2003) found that college students' impulsive-reflective style is consistent across three types of tasks: verbal, mathematical, and spatial.

From a teaching-learning perspective, impulsive-analytic disposition can be viewed as *ways of thinking* (Harel, 2008) or *habits of mind* (Cuoco, Goldenberg, & Mark, 1996). In addition to helping students develop mathematical understanding, teachers can help students to develop desirable habits of mind such as being analytic in solving a problem instead of being impulsive by applying the first idea that comes to mind. Self-awareness is a crucial first step towards transforming habits of mind from undesirable to desirable. A way to create awareness is to have an instrument that can accurately assess one's own impulsive-analytic disposition.

Means to Assess Impulsive-Analytic Disposition

A reliable way to investigate students' problem solving behaviors is through task-based interviews (Clement, 2000; Goldin, 1998) and think-aloud protocols (Ericsson & Simon, 1993). Ways of thinking such as impulsive anticipation and analytic anticipation can be identified from the analysis of students' responses to interview tasks (see Lim, 2006). Although well-suited for uncovering problem-solving disposition in individual students, this mode of data collection is not practical for large-scale assessment of students' problem-solving disposition.

Well-designed mathematical problems can be an effective and efficient means to assess impulsive-analytic disposition. Frederick (2005) designed a three-item test for assessing cognitive reflection. One of the items is: "A bat and a ball cost $1.10 in total. The bat costs $1.00 more than the ball. How much does the ball cost?" (p. 27). The most common wrong answer, 10 cents, is considered impulsive. A reflective person, on the other hand, is likely to realize that the difference between $1.00 and 10 cents is not $1.00 but 90 cents. Other problems, such as missing-value problems involving non-proportional situations, can also be used to elicit impulsive behaviors.

An efficient way to measure cognitive and psychological constructs is through the use of questionnaire. For example, the *Need for Cognition Scale* (NfCS; Cacioppo & Petty, 1982) measures one's desire to engage in a complex thought. In the context of mathematics problem solving, Lim et al. (2009) developed the LtA survey to measure problem-solving disposition along the impulsive-analytic dimension. The LtA survey consists of six-point Likert items where participants are asked to indicate how likely they are to respond to a given mathematical problem in the described manner. The LtA survey, like most Likert-scale questionnaires, can be used for self-assessment.

The purpose of our study was two-fold. First, we sought to improve internal consistency reliability by lengthening the LtA survey to a 32-item measure. We then examined the validity of the LtA survey by determining whether the LtA scores were related to accuracy in classifying the LtA items and performance on a two-part mathematics test.

Method

Participants

There were three groups of participants: (a) 27 in-service teachers and 10 pre-service teachers in a program for improving mathematics and science education in El Paso; (b) two mathematics classes for pre-service EC-8 (Early Childhood to Grade 8) teachers with 33 and 22 students respectively; and (c) one class of 27 pre-service EC-8 teachers. Because this round of data collection was designed for testing and piloting the instruments, a convenience sample of in-service teachers was used. Data collection involving the first group was integrated into a 2.5-hour lesson on problem-solving disposition. The participants first took the LtA survey and an open-ended questionnaire. They then experienced their own problem-solving disposition via a three-problem activity involving clickers which are remote units for a personal response system that records student responses. They were introduced to impulsive and analytic dispositions via a PowerPoint Presentation and were then asked to classify each of the 32 LtA items based on whether they considered the act described in the item analytic or impulsive. The activities for the second group of participants differed slightly from that for the first group in that the three-problem clicker activity was excluded because of shorter class time. The third group of participants took the LtA survey and the two-part math test.

Instruments

Likelihood-to-Act survey. The current version of the LtA survey has four categories: algebra, fraction, word problem, and non-mathematically-specific description. In each category there are four impulsive items and four analytic items. A pair of items for each category is presented below.

aA3 $(x-7)(x-4)=0$. When asked to solve for x, how likely are you to study the equation and predict the solution? [*analytic, algebra*]

iA3 $(x-5)(x-8)=0$. When asked to solve for x, how likely are you to multiply out the terms (i.e., FOIL) and then solve $x^2-13x+40=0$ using the quadratic formula? [*impulsive, algebra*]

aF1 $\frac{3}{5}+\frac{11}{12}+\frac{1}{12}\frac{3}{5}+\frac{11}{12}+\frac{1}{12}$. When asked to find the answer for the above arithmetic expression without using a calculator, how likely are you to begin by studying the fractions to see if you can predict the answer? [*analytic, fraction*]

iF1 $\frac{3}{4}+\frac{1}{10}+\frac{9}{10}\frac{3}{4}+\frac{1}{10}+\frac{9}{10}$. When asked to find the answer for the above arithmetic expression without using a calculator, how likely are you to begin by finding the common denominator? [*impulsive, fraction*]

aW3 Paula is cycling from home to school. At 8 o'clock she has already cycled 2.4 miles. When asked to find her rate of cycling, how likely are you to analyze the problem situation instead of dividing 2.4 by 8? [*analytic, word problem*]

iW3 Jimmy is walking from home to school. At 7 o'clock he has already walked 1.4 km. When asked to find his rate of walking, how likely are you to use the $d = rt$ or $r = d/t$ relationship and obtain 0.2 km/hour? [*impulsive, word problem*]

aG1 In solving a problem in mathematics, how likely are you to interpret and understand the problem thoroughly before deciding what to do? [*analytic, general*]

iG1 In solving a problem in mathematics, how likely are you to use the first idea that comes to mind? [*impulsive, general*]

Three measures can be derived from the LtA survey: (a) the analytic subscale is based on the 16 analytic LtA items, (b) the impulsive subscale is based on the 16 impulsive items, and (c) the analytic-impulsive difference is computed based on the difference between the analytic score and the impulsive score for each pair of items.

Open-ended Questionnaire. In this questionnaire, six open-ended questions were posed to uncover participants' initial approaches for solving selected impulsive items in the LtA survey.

The following question, for example, is associated with Item iA3: “What are the first few actions that you would take when asked to solve $(x - 5)(x - 8) = 0$ for x?” Two versions were created to cover the 12 non-general impulsive items (i.e., iA1-iA4, iF1-iF4, and iW1-iW4). The first author and two first-year graduate students coded all the responses in one version. Another team of a full-time research assistant and a final-year doctoral student coded all the responses in the second version. Members from both teams met to analyze the responses in a training set and to discuss general principles for analyzing. The inter-rater reliabilities for the two teams were 0.91 and 0.97 respectively. For each written response, two codes were assigned: (a) disposition code using a five-point scale to indicate whether the response has a strong or weak indication of analytic (A+ or A-) or impulsive (I+, I-) or is inconclusive (U); and (b) correctness code (1 = correct or no indication of misunderstanding, and 0 = presence of misconceptions or non-trivial errors). The analysis of students’ written responses was reported in the 2010 PMENA conference (Lim & Mendoza, 2010).

Classification test. The classification test was designed to assess the accuracy in determining whether the act described in each LtA item is analytic or impulsive. For each of the 32 LtA items, participants were asked to label the item as analytic or impulsive, and then to rate whether they were confident or not confident in their answer.

Belief survey. On a 10-point scale (1 = Impulsive; 10 = Analytic), participants were asked which point on the scale best describes their own problem-solving and that of their peers, high-school (HS) math students, HS science students, HS math teachers, and HS science teachers. On a five-point scale (1 = strongly disagree; 5 = strongly agree), participants were asked whether they agree with statements about their problem-solving disposition, the lesson/presentation on impulsive-analytic disposition, and the U.S. mathematics education with regards to impulsive disposition. Listed below are representatives of the statements in the survey.

- I consider myself more impulsive than analytic.
- Today’s lesson has helped me appreciate the importance of differentiating between impulsive disposition and analytic disposition.
- U.S. high school mathematics curricula promote impulsive disposition.

Two-part mathematics test. The test was divided into two parts to test the effect of warning about trickiness of problems on performance. The test items in both parts are structurally equivalent. Each part has 12 problems: 6 involving non-proportional situations and 6 involving fractions, ratios, or percents. The problems were designed such that students with an impulsive disposition would be more likely to choose a wrong answer choice. Below are two test items:

- When a candle has burned 23 mm of its original length, its height is 82 mm.
  What is the candle’s height when it has burned 46 mm of its original length?
  (a) 41 mm (b) 59 mm (c) 164 mm (d) None of the above
- Benito needs to increase the money he has now by 20% so that he can buy a $540 laptop. How much more money does he need?
  (a) $90 (b) $108 (c) $432 (d) $2700.

After completing the first part and before beginning the second part, an example (see Figure 1) was presented to caution participants that “some of the items in this test may be considered ‘tricky’ for some students.”

Consider the following problem:

> John bought a new car this year. If the car depreciates by 20% each year, the car will have depreciated by _______ in two years.
> (a) 30% (b) 36% (c) 40% (d) 64%

Many students choose "c" because 20% plus 20% is 40%, but the correct answer is "b".
The actual depreciation in dollar amount in the second year is less than that in the first year because the cost of the car after 1 year is less. For example, suppose the new car costs $10,000.
After 1 year, the car's value drops by $2000 (20% of $10000), and it is now worth $8000.
In the second year, its value drops by $1600 (20% of $8000). So after 2 years, its value drops by $3600, which is 36% of $10000.

Figure 1: An example to warn students to be cautious prior to working on Part 2

Results and Discussion

Reliability of the Various Measures

The internal consistency reliability estimates for the various measures in each instrument were calculated using Cronbach's alpha. Table 1 presents for each measure the number of items in the measure, the mean value, the standard deviation, the α-value, and the 95% confidence interval. The reliability values for most of the measures are relatively high, except for the Coded-correctness score from the open-ended questionnaire and Part 1 of the mathematics test. The reliabilities for the analytic and impulsive subscales, 0.81 and 0.74 respectively, were greater for this version of the LtA survey than those in the previous version, 0.63 for the 7-item analytic subscale and 0.64 for the 7-item impulsive subscale (Lim et al., 2009).

Table 1: Descriptive and Reliability Measures for the Various Instruments

	No. of Items	Mean	Standard Deviation	Cronbach α	95% Conf. Interval for α
LtA Survey (N = 119)					
Analytic Subscale	16	3.96	0.71	0.81	0.76 , 0.86
Impulsive Subscale	16	4.45	0.63	0.74	0.67 , 0.81
Analytic-Impulsive Difference	16	-0.49	0.83	0.77	0.71 , 0.83
Open-ended Questionnaire (N = 92)					
Coded-disposition Score	6	1.86	0.31	0.71	0.61 , 0.79
Coded-correctness Score	6	0.77	0.26	0.29	0.38 , 0.49
LtA Classification Test (N = 92)					
Classification-accuracy Score	32	0.59	0.12	0.76	0.69 , 0.83
Classification-confidence Score	32	0.75	0.09	0.86	0.81 , 0.90
Belief Questionnaire (N = 92)					
Self-disposition Belief[a]	2	2.88	0.38	0.84	0.75 , 0.89
Lesson-on-disposition Opinion[b]	4	4.43	0.05	0.93	0.90 , 0.95
Two-part Math Test (N = 27)					
Math-Part1 Score[c]	10	0.28	0.22	0.57	0.28 , 0.76
Math-Part2 Score	12	0.32	0.22	0.67	0.46 , 0.83

[a]The 10-point scale item was transformed into a 5-point scale. The 5-point item was reverse coded.
[b]All the four items about the lesson used a 5-point scale.
[c]Two items had zero variance (all 27 students got them wrong) and were removed from the scale.

A mean value of -0.49 for analytic-impulsive difference indicates that the participants in this study chose lower values for analytic items than for impulsive items in the LtA survey. A mean value of 1.86 for the coded-disposition score on a 5-point scale (1 = impulsive; 5 = analytic) also indicates that the 92 participants were generally more impulsive than analytic in their open-ended responses. A mean value of 2.88 for the Self-disposition Belief score on a five-point scale, on the other hand, indicates that the participants view themselves as more analytic than impulsive. Mean values of 0.23 (12 items; 0.28 is Table 1 was based on 10 items) and 0.32 (12 items) for the two parts of the math test indicate that the 27 pre-service teachers on average responded correctly to 23% and 32% of the 12 items. These findings suggest that participants are generally more impulsive than analytic although they might view themselves as more analytic than impulsive.

A mean value of 4.43 on a 5-point scale indicates that the participants have a favorable opinion about the lesson on impulsive and analytic dispositions. A mean value of 0.59 for the classification-accuracy score indicates that the 92 participants (Groups 1 and 2) have a 59% accuracy in classifying the 32 LtA items. The 27 participants (Group 3) showed a 9% gain from Part 1 to Part 2, suggesting that students performed better when they were warned to be cautious.

Correlations among the Various Measures

The correlation between the analytic subscale and impulsive subscale was -0.014, not statistically different from zero. In other words, the analytic and impulsive subscales were independent of one another. Interestingly, the difference score between the two subscale scores for each pair of items had a relatively high reliability of 0.77 (see Table 1).

Table 2 presents the correlation between the measures from the LtA survey and other measures that might be related to impulsive-analytic disposition. The disposition scores derived from coding of the six open-ended responses were positively correlated ($r = 0.373$) to the analytic subscale and negatively correlated ($r = -.0488$) to the impulsive subscale. These significant correlations were probably due to the similarity between the items in the open-ended questionnaire and the LtA items. In addition, their initial exposure to the LtA survey first might have influenced their subsequent written responses.

Table 2: Correlations between LtA Subscales and Other Measures

	Analytic Subscale	Impulsive Subscale
Analytic Subscale	1	
Impulsive Subscale	-0.014	1
Analytic-Impulsive Difference	0.745**	-0.678**
Coded-disposition Score	0.373**	-0.488**
Coded-correctness Score	0.256*	-0.205*
Classification-accuracy Score	0.107	-0.286**
Classification-confidence Score	0.183	-0.048
Self-disposition Belief Score	0.418**	-0.275*
Lesson-on-disposition Score	0.011	-0.041
Math-Part1 Score[a]	0.075	-0.205
Math-Part2 Score	0.595**	-0.140

$^{*}p < .05$, $^{**}p < .01$.

Participant accuracy in classifying items was negatively correlated to impulsive subscale ($r = -0.286$) but not correlated to analytic subscale. This finding suggests that students who have an impulsive disposition tended to make more mistakes in classifying items. Participant confidence in their classification was not correlated to either of the LtA subscales.

Participant self-reported disposition score was correlated to both the LtA subscales. The lesson-on-disposition score was not correlated to either of the LtA subscales.

Participant performance in Part 1 of the mathematics test, prior to the warning, was not correlated to the LtA subscales. On the other hand, student performance in Part 2 was correlated significantly to the analytic subscale but not to the impulsive subscale. This suggests that the warning about problems being tricky had an impact on students with an analytic disposition but not those with an impulsive disposition.

In summary, the two LtA subscales were reliable and uncorrelated. Other measures in the study were reliable and were appropriately associated with the LtA constructs.

Concurrent Validity

In addition to the above analyses, we were also interested in determining whether the LtA subscales could be used to predict the following variables: (a) self-reported GPA, (b) classification-accuracy score, (c) lesson-on-disposition score, (d) Math-Part1 score, and (e) Math-Part2 score. To perform these analyses, a hierarchical multiple regression was performed. In the first step of the multiple regression, variables representing participant characteristics (years of teaching experience, sex, grade band and subject area currently teaching or planning to teach) were entered into the regression model. In the second step, we typically entered the two LtA subscales (except for predicting Math-Part2 score). None of the variables mentioned above could statistically explain variability in self-reported GPA, the lesson-on-disposition score, and the Math-Part1 score. In other words, the LtA scores could not predict these three variables, but the LtA scores did predict classification-accuracy score and the Math-Part2 score.

Predicting Classification-accuracy Score. The variables entered in the first step of the regression model explained 3.3% of variability in the classification-accuracy score. None of these predictors was statistically significant. When the LtA subscales were added, the fraction of variance explained, R^2, increased by 10.3% to 13.6%. The impulsive subscale ($\beta = -.316$, $p = 0.011$) accounted for a significant portion of the variance. In other words, increased impulsivity was associated with worse item classification.

Predicting Math-Part2 score. This regression consisted of four steps instead of two. In the first step, participant sex and indicator variables representing grade band were entered and accounted for 3.5% of variability in the Math-Part2 scores. None of these predictors was statistically significant. In the second step, Math-Part1 score was entered and accounted for an additional 27.8% of variability. Increased Math-Part1 scores were associated with increased Math-Part2 scores ($\beta = .556$, $p = .010$). In the third step, the LtA subscale scores were entered and accounted for an additional 37.8% of variability. Increased analytic disposition ($\beta = .652$, $p = .000$) was associated with increased Math-Part2 scores. In the final step, values representing the interaction between Math-Part1 and the LtA subscales were entered into the regression model. These interactions explained an additional 13.1% of variability. The interaction between Math-Part1 and analytic disposition was statistically significant ($\beta = 1.75$, $p = .004$) in that individuals who had both high Math-Part1 scores and high analytic scores had higher Math-Part2 scores.

Concluding Remarks

The results obtained in this research phase indicate that a measure of problem-solving disposition along the analytic-impulsive dimension could be created using the LtA survey. The LtA scales demonstrated adequate internal consistency reliability. In addition, we found that the analytic and impulsive subscales were independent of one another, replicating the result of an earlier study in the behavioral decision theory on types of decision making styles (Morera et al., 2006).

In this round of data collection, participants were also asked to complete a series of other measures. The analytic and impulsive LtA scores were found to be correlated to certain scores derived from the open-ended questionnaire, the belief survey, and the two-part mathematics test. In particular, the impulsive score was found to be predictive of correctness in classifying the LtA items, and the analytic score was predictive of how well a participant would perform in Part 2 of the math test after the warning, while controlling for the effects of Math-Part 1 scores. In summary, these findings represent a first step in demonstrating the utility of the LtA measures.

The data we obtained were used to refine the LtA survey (see Lim & Mendoza, 2010) and the two-part mathematics test. The revised versions of the two instruments have been administered to more than 450 pre-service teachers. The Barratt Impulsiveness Scale Version 11 questionnaire (Patton et al., 1995), the NfCS questionnaire (Cacioppo & Petty, 1992), and the Cognitive Reflection Test (Frederick, 2005) were administered concurrently to determine how well the LtA survey correlates with these three instruments and how well the LtA scores predict students' performance in the two-part mathematics test.

MATHEMATICAL PROBLEM SOLVING PRACTICES OF HIGH SCHOOL CHILDREN: FACTORS INFLUENCING CHOICES OF STRATEGIES

In this work we investigated the problem solving behaviors of 3 highschool students as each solved four common non-routine problems with the goal to trace performance constancy across different subject areas and problem types. Additionally, we aimed to identify possible factors that influenced children's choices of heuristics in different problem contexts. The results suggested the individual's confidence and preference for the use of certain strategies. Inconsistency in the same individual's mathematics problem solving behaviors across different subject areas was revealed.

Introduction

The development of problem-solving ability among school children has been a persistent goal of mathematics education community for over a century; however, the issue of how to develop problem solving skills among learners continues to be a major dilemma. This is, in part, due to lack of specific knowledge about mathematical problem solving practices of children and factors that influence their choices and actions (English, 2010). Indeed, previous research studies on problem solving have primarily focused on effective implementation of problem solving instruction by examining students' problem solving performance on tasks (Anderson & White, 2004). These studies have identified some key factors for the success or failure of implementation of problem solving approaches in mathematics teaching; however they do not provide detailed accounts of individuals' problem solving behaviors. Muir, Beswick, and Willamson (2008) suggested that researchers must focus on understanding what successful problem solvers do and use that knowledge to help individuals develop their problem solving skills. They further argued that instead of focusing on whether particular strategies should be taught or not and how, greater attention must be devoted to understanding processes that individuals use when engaged in problem solving. In support of this suggestion we argue that knowledge about children's problem solving behaviors and factors that influence their mathematical practices while solving problems can better assist teachers in helping nurture mature problem solvers. Such knowledge is currently not well developed. The goal of the research we report here was to address this need.

The purpose of this study was to examine mathematical problems solving practices of three students in an attempt to determine whether the individuals' performances were consistent across different subject areas and problem types. Moreover, we were interested in identifying those factors that influenced children's choices of heuristics used in different problem contexts. Lastly, we intended to isolate common and unique patterns of behaviors that children exhibited as well as those factors that seemingly contributed to the institution of those patterns.

Context and Background Literature

Nearly two decades ago Lester (1994) summarized the research community's perspectives on qualities that distinguish successful problem solvers from those characterized as poor problem solvers, and concluded that good problem solvers: know more and their knowledge is well connected and composed of rich schemata, focus more on structural features instead of literal features of problems, are more aware of their own strengths and weakness in terms of problem solving, monitor and regulate their problem-solving efforts more routinely and, are more concerned about obtaining best solutions to problems. More recently however, English and Sriraman (2010) argued for a reconsideration of this list, indicating that since previous research had focused mainly on solving word problems emphasized in school textbooks, primarily routine and procedural then results concerning quality of problem solving and nature of problem solving performance of children should be more critically examined. The authors attributed the lack of success of school based practices for fostering problem solving skills among children to community's inadequate knowledge about *how* individuals come to make decisions about when, where, why, and how to use heuristics and strategies when faced with novel problem contexts. Naturally, focusing on applying these strategies, without understanding how and why individuals make decisions about pathways for solving problems is non-productive (English, Lesh, & Fennewald, 2008). Despite these criticisms several fundamental factors regarding effective mathematical problem solving have been identified. First, knowledge of heuristics and their appropriate use are recognized as fundamental to mathematical problem solving (Schoenfeld, 1992). There is evidence indicating that students' use of heuristic strategies is positively related to success in problem solving, although the effect may not always be significant (Kantowski, 1977). Yet a number of studies have shown the deficiencies that students exhibit when applying heuristics and metacognitive strategies to their problem solving processes (Schoenfeld, 1992).

Flexibility in strategy use has also been referenced as a key aspect of successful problem solving. Flexibility refers to the quantity of variations that can be introduced by an individual in the concepts and mental operations one already possess (Demetriou, 2004). Elia, Heuvel-Panhuizen, and Kolovou (2009) discussed two methods for studying strategy flexibility usage: inter-task flexibility (changing strategies across problems) and intra-task flexibility (changing strategies within problems). They used three non-routine problems to study the strategy use and strategy flexibility by 4th grade high achievers. An implicative statistical method was performed to determine whether the strategies used by students to solve the three problems were successful or not. Guess-and-check strategy was found to be the most crucial strategy that led to the success of the three pattern/algebra problems. An important finding was that higher inter-task strategy flexibility was displayed by more successful problem solvers, while intra-task strategy flexibility did not support the problem solvers in reaching a correct answer. An intra-task strategy flexibility study showed that the understanding to the problem influenced the correctness of the answer, instead of the flexibility of the strategies.

A study of four 6th grade students' problem solving behaviors was conducted by Muir, Beswick, and Williamson (2008). The strategies students used in solving 6 problems were analyzed and three categories of performance were proposed to associate with the levels of problem solving behaviors students exhibited including, naive, routine and sophisticated. The consistency of approaches across problems for each individual was also studied, and the conclusion was that most individuals consistently exhibited behaviors characteristic in one category. Since all 6 problems used in this research concerned number and number sense, the consistency in performance across different content areas was not revealed. Our goal in the current study was to contribute to the existing literature on mathematical problem solving by examining the mathematical problem solving practices of 3 children on 4 tasks selected from different content areas in order to identify ways in which children's choices of heuristics and orientation may have influenced their mathematical problem solving performance.

Methodology

A task-based interview methodology was used to closely observe and study three students as they worked on non-routine mathematical tasks. A case study report was developed for each student, describing, in detail, their actions during interview sessions. These case study reports were used, first, to identify and analyze the processes students used and patterns of problem solving behaviors they exhibited while solving problems; second, to describe and analyze the problem solving strategies children utilized, their choice of representations and metacognitive behaviors they accessed and used.

Although the major research project from which the data for the study was selected involved interviews with nearly 60 children, only three participants, Jazzy in 8^{th} grade, Liza and Yoni in 9^{th} grade (all pseudo names), were selected to serve as case subjects for the current study. This selection was due to several important considerations as described below.

First, all three participants had signed consent forms to participate in the longitudinal research project. Second, all three had worked on the same four tasks used as data collection sources. This would allow us to draw inferences regarding comparisons among their thinking and orientations, processes they used during problem solving episodes and metacognitive behaviors they exhibited. Additionally, the three participants offered a wide range of backgrounds and habits that would strengthen the potential for generalizability of the results. Despite their differences, the participants shared similar attributes; they were characterized as "successful" students of mathematics as measured by grades they had secured in their mathematics courses and results of the State mandated standardized exams. Lastly, each of the subjects displayed distinct behaviors when interacting with problems during the enrichment sessions: Liza exhibited flexible explorations when tackling problems, Jazzy showed strong reliance on calculator and numbers, and Yoni possessed the most sophisticated mathematics technique learned in school curriculum. Diverse performances were expected among the three participants.

Data Sources

The data sources consisted of two interviews with each of the participants. Each interview consisted of approximately 35-40 minutes. Each interview was tape–recorded and used in analysis. The first interview consisted of two parts: the first part was assessing participants' mathematics background information, their beliefs about mathematics, and their views on value of mathematics for their lives. The second part of the first interview the children contained problem solving episodes. During the second interview it was reassured that the participants solved the remaining problem selected for data analysis.

The participants were interviewed individually. The protocol for problem solving interviews suggested the least interruption from interviewers during students' problem solving work. The protocol also suggested that interventions be made only when a clear understanding what children were doing was not evident or if reasoning and justification was not shared by them. The children were not restricted by a specific amount of time or their representational systems they could use.

Four non-routine problems were selected to access participants' problem solving performances in patterns, functions, and geometry (Table 1 illustrates two of the interview questions). The problems were selected so to elicit different heuristics. The diversity of subject areas and heuristics served the aim of studying the consistency of individual problem solving behaviors/performances across problem types and subject matter contexts.

1. Joe gives Nick and Tom as much money as each already has. Then Nick gives Joe and Tom as much money as each of them then has. If at the end each has 8 dollars, how much money did each have at the beginning?
4. What relationships exist among the areas of triangles and rectangle?

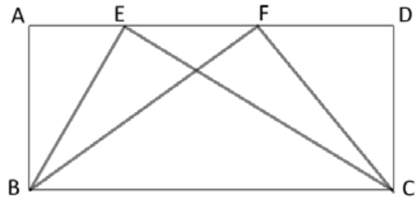

Table 1. Description of problems

Data Analysis

Using Mason's mathematical problem solving model, mathematical practices of each child were analyzed and modeled. Mason (1985) divided the process of problem solving into three phases: entry, attack, and review. The entry phase includes thinking about "what do I know," "what do I want," and "what can I introduce." The review phase further contains "checking," "reflecting," and "extending." However, a typical problem solving activity is seldom linear; an individual always goes back and forth when proceeding to the desired outcome. Also it is possible that the attack phase is difficult to observe or the review phase is missing. Generally speaking, this perspective could provide an overview of the entire problem solving process so that a clearer relationship between steps could be identified and studied. Mason's model, however, does not indicate the internal or external forces that impact the movement from one phase of process to next. Between each process, distinct motives/stimuli might exist, initiated by the individual or outside information that can either facilitate or prevent making progress towards a more general understanding and ultimately, more efficient problem solving performance. Mason's model as used in this research was modified in order to demonstrate certain internal (self-initiated) and external (interviewer-initiated) forces influencing mathematical work of the children.

Each interview episode was videotaped. We first reviewed each episode repetitively to track the distinct problem solving phases of each of the children on each of the tasks during each problem solving episode. A problem by problem performance model was developed for each child and then a cross problem performance analysis was completed.

A detailed description of the processes each child used, strategies they employed and metacognitive behaviors they exhibited was completed. Every strategy and representation used by the participants was identified and recorded. Following the completion of each case study analysis, the three cases served as data sources for the overall analysis.

Results

Table 2 provides an overview of particular behaviors and performances of children as they relate to average amount of time they spent on tasks, average number of instances of self-initiated questions, average number of times they switched strategies, average number of self-initiated testing and justifying episodes. As the data illustrate, although the three participants varied greatly in the average amount of time they spent on tasks, their performance along the self-initiated constitutive elements of the problem solving process was consistent, suggesting potential patterns of thinking and actions. The average numbers of self-initiated questions and times shifts in strategy usage had the least variety of items, indicating a less diverse use of these two behaviors. The average numbers of justifying answers, which included self-initiated justification and interviewer-initiated justification, varied more than the previous two items. The average number of scaffolding questions that the interviewers asked was the item with the most variety, which was also the least natural item for participants. A detailed cross case analysis of subjects' mathematical practices is offered in the following section.

	Average length of PS episode	Average number of self initiated questions	Average number of shifts in strategy usage	Average number of justifying episodes	Average number of interviewers' scaffolding questions
Liza	10'54"	0	1	1.5	1.75
Jazzy	9'57"	0.5	1	0.75	5.25
Yoni	7'57"	0.5	0.5	0.25	0.5

Table 2. Overview of participants' particular behaviors and performances

Patterns of Mathematical Problem Solving Performance among Children

Based on each student's problem solving episodes, Liza, Jazzy, and Yoni's general problem solving practices (despite content and heuristics) are illustrated in Figures 1, 2, and 3 respectively.

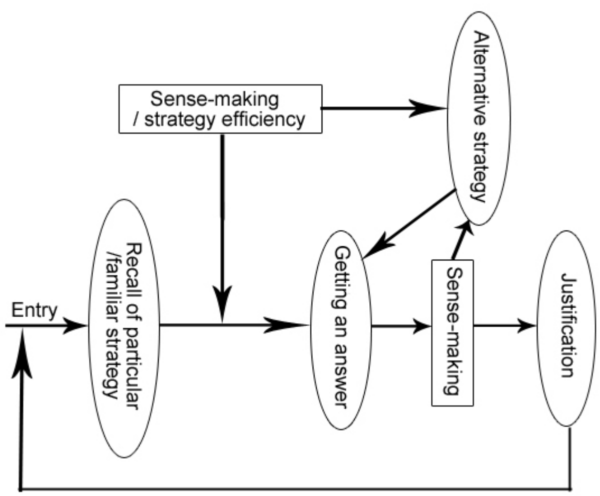

Figure 1: Liza's general problem solving orientation

Compared to the other two students, Liza's general problem solving process had a unique feature: sense-making. Sense-making was her way of self-monitoring, which was presented throughout all problem solving episodes. After she reached an answer, sense-making was her premier way to justify her response. It was one of the factors that could influence her switch of strategy. Liza had a belief that she could solve most problems eventually, thus she was more likely to deliberately re–enter the problem in order to gain a better understanding of the problem.

Jazzy's problem entry phase was different from other students. She always started her activity with manipulating numbers in order to get a sense of the problem. Her intra-task strategy usage depended largely on whether the strategy she used was by numerical or non-numerical. She tended to switch strategy instead of modifying information when she was not using a numerical strategy.

Yoni's general problem solving orientation was to stick with one method regardless of success or failure. He seldom justified his answers and assumed a problem was solved when he arrived as an answer (either right or wrong). His low intra-task strategy flexibility could be due to his self-confidence regarding his mathematical ability.

All three participants showed a high degree of involvement in solving the assigned problems during the interviews. They took ownership of the tasks and attempted to attack, review and solve them. The intensity of their involvement in tasks was reduced or diminished if they failed to see patterns, fully understand the information given, or make connections between what they knew and the contexts under study. An additional inhibitive factor included their ability to define mechanisms for gauging their own success in solving problems when using strategies most familiar to them.

The children's ability to identify relevant from irrelevant data, either embedded in the problem or deduced as the result of their own work, was a pivotal influence on their successful problem solving as evidenced by their willingness to reflect on options or reconsider approaches. Preoccupation with using familiar techniques learned in school curriculum served as a primary motive for participants' reluctance to focus on extending their understanding of the problems, reflecting systemically on what was given, or to even test and justify their answers.

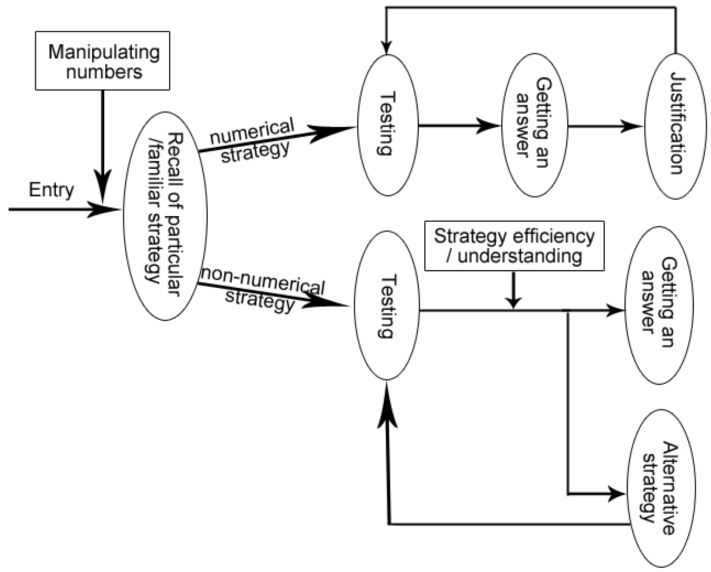

Figure 2: Jazzy's general problem solving orientation

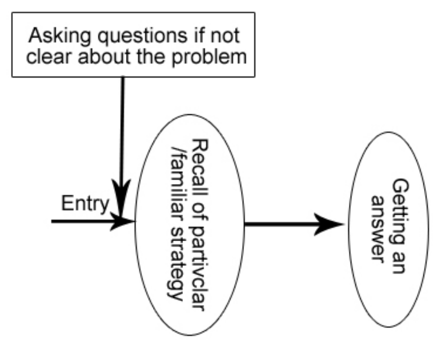

Figure 3: Yoni's general problem solving orientation

The children's particular orientation and their personalities influenced how they entered the problems during the initial phase, the degree of persistence they showed in solving them, and whether they tried to access additional strategies or engaged in metacognitive actions. The one subject with the least amount of interest in school mathematics and its content seemed most flexible in changing strategies. Her need for understanding and sense-making, as articulated during both interview sessions, may have been the primary force behind her natural desire to constantly examine the context at hand and to switch her approaches. On the other hand, the most academically successful student among the three, and the one with most sophisticated mathematical tools, appeared least flexible in his thinking and choices. Indeed, his attempts to use procedures he had learned in school prohibited him from taking the initiative to justify or verify his own answers or monitor his progress reflectively.

All three participants showed the tendency to enter problems using the technique of testing numerical values. They made, or refused to make modifications to their initial choices of numerical values to understand the problem better. Once, and if a deeper understanding of the problem was achieved, they were more willing to switch strategies. Most notably, they were also more successful in the use of newly adopted approaches. Despite this, those with greater control over numerical manipulation tended to remain loyal to the use of this approach. A shift from one strategy to another was the result of either a significant change in their level of understanding of the problem, or provoked by interviewers' questions.

All three subjects showed the tendency to use concepts and procedures most recently addressed in school at the time of data collection, regardless of whether these concepts were relevant to the problem under study. This was most notable when they worked on the geometry task. With the exception of Jazzy, the two other participants experienced difficulty when abstractions of specific knowledge became a focus of work.

The children's ability to access different representational modes was also driven by the contexts they had previously experienced in school experiences. The use of drawing a picture for illustrating the problem became only natural for two of the participants (Jazzy and Liza) when their initial attempt at using numerical data for answering questions seemed too cumbersome to be practical. Even when they were successful in use of the strategy they remained skeptical of the accuracy of their own responses. Formalizing and authenticating the final answer derived using this approach was endorsed to an outside authority (the interviewer), as opposed to self conviction.

Discussion

The results of this work provide additional evidence suggesting that self-monitoring is positively correlated with success in performance on certain mathematical activities (Cohors-Fressenborg, Sjuts, & Sommer, 2004; Cohors–Fressenborg et al., 2010). Liza used sense-making as a way of self-monitoring her progress on tasks and towards gauging her problem solving process accordingly. Jazzy used numerical computation as a way to self-regulating her actions and increasing her control over tasks, performed better. Yoni, who did not exhibit self-monitoring/regulating consistently during his problem solving processes, was not always successful in solving problems. Hence, we highlight that self-monitoring/regulating could be a significant influence on successful problem solving on both routine and non-routine tasks, consistent with findings of previous.

Our results also indicate that intra-task strategy flexibility usage does not imply success at reaching correct answers on tasks (Elia, Heuvel-Panhuizen, & Kolovou, 2009). However, we posit further that the level of intra-task strategy flexibility usage might depend largely on the individual's level of confidence and preference for the use of certain strategies. These constructs may not ensure that correct answers across different subject areas and heuristics might be reached. Instead, they may prevent the individuals from moving forward in securing an enhanced level of understanding of the problem.

Our data also revealed inconsistency in the same individual's mathematics problem solving behaviors across different subject areas and/or heuristics usage. This result is distinct from the conclusion of previous research that indicates most individuals exhibit consistent problem solving behaviors (Muir, Beswick, & Williamson, 2008). The factors that may impact the consistency in behaviors include the preference for the use of specific approaches and orientations (visual, graphical, pictorial, etc.), experience with specific subject area (number theory, algebra, geometry), familiarity with the heuristic needed to solve the problem, and personal belief about one's own mathematical ability and confidence in problem solving.

Personal orientation could largely impact one's problem solving behaviors throughout the entire process (i.e. Jazzy's numerical orientation). Personal belief about one's own knowledge and ability could impact one's confidence: Liza believed she could eventually solve all problems and Yoni believed he was good at mathematics; both of them exhibited noticeable confidence during their problem solving episodes. On the other hand, Jazzy's belief about problem solving ("the only right answer") influenced her attitude during the problem solving process: she asked for the right answer even when she was convinced by visual evidence.

Lastly, perhaps a puzzling finding of the study is the relationship between children's claimed level of confidence with mathematics and their problem solving performance. In virtually all past literature focused on the connections between affect and problem solving performance of children, the conclusion had been drawn that confidence and success in problem solving are directly related: the more confident an individual was in his/her mathematical ability, the better performance on problem solving was observed. Our research provides conflicting results. As described earlier, the most mathematically confident individual in this study, Yoni, showed the lowest degree of flexibility in thinking or control over tasks. It is not quite clear at this point what measures were used in previous work for determining the problem solvers' levels of confidence and whether claims were carefully studied. This issue merits further study.

REFERENTIAL COMMUTATIVITY: PRESERVICE K-8 TEACHERS' VISUALIZATION OF FRACTION OPERATIONS USING PATTERN BLOCK

Günhan Çağlayan
Columbus State University
sezen@columbusstate.edu

John Olive
The University of Georgia
jolive@uga.edu

This paper examines ten K-8 preservice teachers' visual representations of fraction operations using the four main pattern blocks. Data consist of figures made using the pattern blocks, drawn colored representations, and detailed written comments and algebraic formalism. The theoretical framework is drawn from representational theories and analyses of fraction operations, and work on coordination of different levels of units. The main result is that only those teachers meaningfully coordinating the different referent units in the fraction situations, were the ones consistent in their representations and reasoning, and in successfully establishing referential commutativity for multiplication of fractions.

Introduction

The usual way of representing a fraction numerically, is the expression $\frac{a}{b}$ where *a* is a whole number and *b* is a nonzero whole number. This representation has several interpretations such as part-whole, quotient, operator, and measurement (Kieren, 1980; Skemp, 1986; Olive, 1999; Olive & Steffe, 2002). In the *part-whole* meaning, the referent unit 1 is defined, the denominator indicates the number of congruent pieces into which the unit 1 is partitioned, and the numerator indicates how many of those congruent parts are selected. In the *sharing equally (partitive) division* model, the fraction is interpreted as the equi-partitioning (Olive & Steffe, 2002) of the quantity, *a,* into *b* congruent parts (shares), with the fraction, $\frac{a}{b}$ being the share of one person, relative to the referent unit for quantity, *a*. For example, if we share 3 chocolate bars among 5 friends, each friend gets 3/5 of ONE chocolate bar.

The repeated subtraction (*measurement* or *quotitive division*) interpretation attends to the instruction "How much (or how many) of quantity *b* is (or are) there in quantity *a*?" or "What is the measure of quantity *a* in units of size *b*?"

Children need to be aware of how the same quantity can be represented by many fractions (i.e. *fraction equivalence*) before the exploration of +, −, ×, and ÷ operations with fractions. Children should be able to recognize and create fractions equivalent to a given fraction, because they will frequently need to determine an equivalent fraction in order to add, subtract, multiply, or divide, in a way that makes sense to them (Sowder et al., 1998). For example, in adding or subtracting fractions, in the process of obtaining fractions of equal denominator, students must be able to refer to their knowledge about fraction equivalence.

In dealing with multiplication of two fractions, the understanding of what the multiplier, the multiplicand, and the product refer to is of paramount importance. The referent units for the multiplier, the multiplicand, and the product respectively are the multiplicand, the whole unit, and the whole unit. The algorithm $\frac{a}{b} \times \frac{c}{d} = \frac{a \times c}{b \times d}$ is effortless to memorize and to perform; however, to render fraction multiplication meaningful, children must be aware of the referent units for these fractions and what the product really indicates. Moreover, while both $\frac{a}{b} \times \frac{c}{d}$ and $\frac{c}{d} \times \frac{a}{b}$ yield the same numerical answer, the order matters if we want to conceptualize the referent units involved, namely the fact that the referent units are being swapped between the multiplier and the multiplicand. As will be explained in the results section of this study, although fraction multiplication is *algebraically* commutative, that commutativity is definitely not so obvious to construct referentially. Construction of referential commutativity requires proficiency in simultaneously coordinating various fraction relations and different levels of units meaningfully.

As for the division of fractions, the understanding that the referent unit for both the dividend and the divisor is the same unit whole, is necessary in order to make sense of the division operation. Moreover, it is equally important to realize that the quotient has no reference to the original unit whole; the quotient must be seen as a relation between the dividend and the divisor in order to develop an in-depth understanding of fraction division. For example, when dividing ¾ by ½ in order to find out how many ½ lb-bags of coffee we could make from ¾ lb of coffee, the answer is one and a half *bags* (not pounds of coffee). While fraction division has traditionally been related with the crude invert and multiply algorithm, most children and adults do not make sense of how this algorithm works (NCTM, 2000). Awareness of referent units for fraction division is crucial in order to develop any meaning for the algorithm.

This study investigates the above assertions (with special emphasis on referential commutativity of fraction multiplication) by analyzing the work of ten pre-service K-8 teachers.

Theoretical Framework

The theoretical framework of this study is drawn from the work by Steffe and Olive involving representations of operations with fractions and referent unit coordination (Olive & Steffe, 2002; Steffe & Olive, 2010). These researchers postulated a series of fractional schemes as a foundation for the construction of fraction operations (Olive & Steffe, 2002, p. 436). They also reported facility with whole-number sense as one of the main prerequisites of fractional thinking and reasoning (the *Reorganization Hypothesis*, Steffe, 2010). Their work with children in grades three through five involved children's representations and actions in fractional situations using electronic manipulatives called TIMA (Tools for Interactive Mathematical Activity)(Olive, 2000).

The idea of a representational system is also relevant to the research presented in this paper. This construct comprises written symbols, thinking aloud, physical manipulatives, and drawn representations (Behr et al., 1983). In what follows, we focus on K-8 pre-service teachers' drawn and physical representations of five main fraction operations modeled with pattern blocks, and on their abilities to connect their visual and written formalism.

Context and Methodology

This study investigates pre-service K-8 teachers' construction of fraction operation problems (equivalence, addition, subtraction, multiplication, division) using physical manipulatives (the four main pattern blocks). Ten pre-service K-8 teachers, whom the first author met weekly for two weeks in two-hour sessions, were selected from his "algebra for teachers" class to participate in this study. They demonstrated their solutions for each problem with both the actual pattern blocks and colorful drawings on a triangular grid (Figure 1). They also explained their reasoning in detail for each task with reference to their physical and drawn representations.

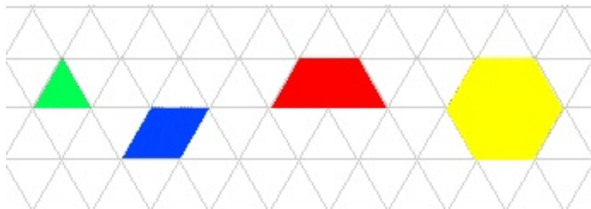

Figure 1 - The Four Main Pattern Blocks on Isometric Grid

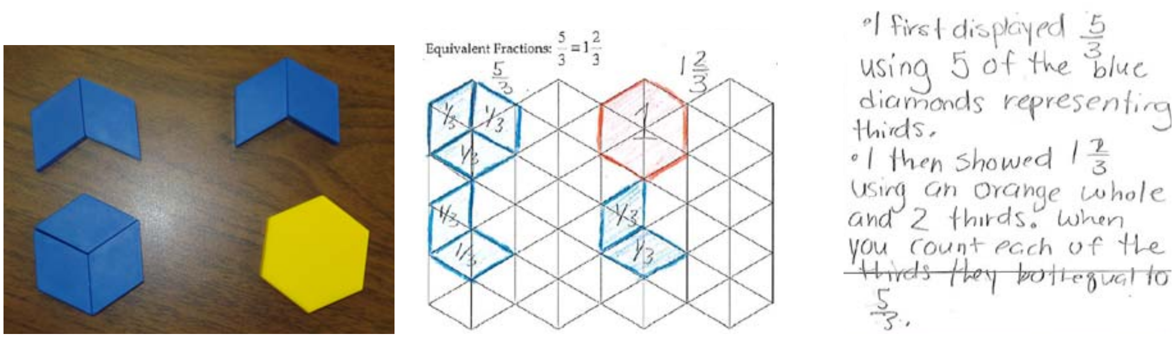
Our data consists of photographed physical representations, and scanned drawn representations along with written arithmetic formalism and detailed comments. The purpose of creating these scanned versions was to conduct a retrospective, preliminary thematic analysis in order to find possible themes for a detailed analysis. The dataset was then revisited multiple times in order to generate a thematic analysis (using constant comparison methodology) from which the following results emerged.

Results & Analysis

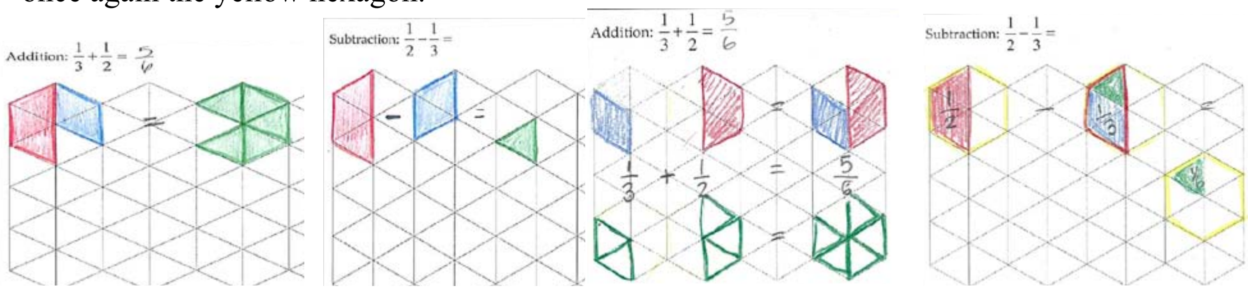
For the equivalence problem $\frac{5}{3} \equiv 1\frac{2}{3}$, all ten teachers pretty much came up with the same physical and drawn representations. Several of them even clarified their construction using a *counting the thirds* strategy (see Figure 2). We can infer that Edie relied on this strategy by explicitly labeling the thirds that are being counted and also by referring to the whole unit, the yellow (or orange) hexagon, at each step of her counting. Lauren used a similar reasoning by writing *3 "one thirds" equal one, so 5 thirds will have 2 "one thirds" left over with one yellow whole*.



2a 2b 2c

Figure 2: Edie's Physical (2a) & Drawn (2b) Representations & Written Work (2c)

For the addition and subtraction tasks, not all teachers were as explicit with reference to the referent unit, the yellow hexagon, at each step of their construction. Moreover, although the instructions required explanation for each step, not all teachers, for instance, thought about using the idea of common denominator and involving that in their physical and drawn representations. As depicted in Figure 3, both Lauren and April arrive at the correct final answer; however, April's thinking seems to be more sophisticated than Lauren's in that she not only refers to the referent unit yellow hexagon (for the addends in the addition task, and for the minuend and subtrahend in the subtraction task), but she also decomposes each fraction into smaller pieces (green triangles representing sixths), thus making sense of the situation. She also clarifies both in her writing and her physical and drawn representations that the referent unit for those sixths is once again the yellow hexagon.



3a 3b 3c 3d

Figure 3: Lauren's (a b) and April's (c d) Drawn Representations for the + and − Tasks

All teachers succeeded in establishing the referential commutativity of addition in dealing with the problems $\frac{1}{3}+\frac{1}{2}$ and $\frac{1}{2}+\frac{1}{3}$ in constant comparison of their physical and drawn representations. They also invalidated the commutativity of subtraction with very creative constructions. Multiplication and division tasks, on the other hand, were rather cumbersome for many of the participants. There were some who overcame this difficulty by appropriately relating the multiplier, the multiplicand, and the product (the dividend, the divisor, and the quotient in the division tasks) to their referent units. Only two participants were able to induce a referential commutativity for fraction multiplication, the most sophisticated behavior resulting from this research study. For the multiplication problems $\frac{1}{3}\times\frac{1}{2}$ and $\frac{1}{2}\times\frac{1}{3}$, many teachers constructed and drew both the multiplier and the multiplicand, the former being irrelevant, a non-operative interpretation of the problem situation. Several teachers swapped the role of multiplier and multiplicand. We begin the discussion on multiplication with these problematic representations. Emma modeled the first multiplication problem as the product of a red trapezoid and of a blue rhombus (Figure 4a). Kristie not only included both $\frac{1}{2}$ and $\frac{1}{3}$ in her constructions, but also swapped their roles as well (Figure 4b-c). Her referent units for $\frac{1}{2}$ and $\frac{1}{3}$ respectively were the whole unit (yellow hexagon) and $\frac{1}{2}$ (the red trapezoid). Her interpretation of $\frac{1}{2}\times\frac{1}{3}$ is actually $\frac{1}{3}\times\frac{1}{2}$, and vice versa. While she is very clear in establishing the referent unit of the product $\frac{1}{6}$ (green triangle) as the yellow hexagon, we postulate that Kristie failed to establish referential commutativity of multiplication due to the interchange of referent unit roles. Both Kristie and Emma used their same approaches for the other multiplication problem as well.

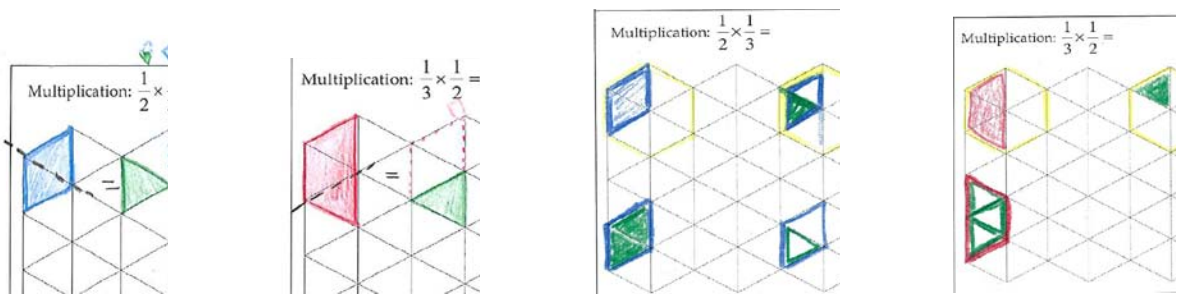
Figure 4: Emma's (4a) and Kristie's Constructions for $\frac{1}{2}\times\frac{1}{3}$

Lauren was one of the few who established the referential commutativity of multiplication in a meaningful and appropriate manner. For the half of a third problem, she started by constructing the third as the blue rhombus. She then bisected this third using a dashed line, as depicted in Figure 5a. She was aware of the fact that constructing a half (red trapezoid) was irrelevant in the problem situation. She also understood that the referent unit for the multiplier (the half) was the multiplicand (the third). It is also worth noting that she did not specify whether the product (the sixth) has the whole unit as the referent unit. She followed a similar approach for the third of a half problem, as depicted in Figure 5b.



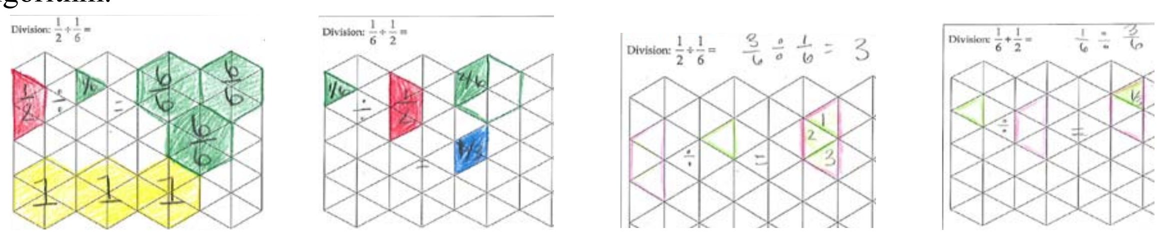
5a ***5b*** ***5c*** ***5d***

Figure 5: Lauren's (a, b) and April's Constructions for Fraction Multiplication Tasks

We can say that April followed a reasoning pattern similar to Lauren's, in that she was aware of the fact that constructing a half (red trapezoid) was irrelevant in the problem situation (Figure 5c). She also successfully interpreted the referent units of the multiplier and the multiplicand. As can be detected in Figures 5c-d, April took the whole thing one step further by also specifying the referent unit of the product "the sixth" as the yellow hexagon unit. Both Lauren and April established referential commutativity, but April's representations can be considered to be more sophisticated than Lauren's.

Teachers overall seem to have successfully applied the "How many of … are there in …" (or "how much of … is there in …") view in their representations of fraction division problems. Some teachers were very explicit in their reference to the yellow hexagon as the referent unit for the dividend and the divisor. Some others perhaps over-generalized this reference for the quotient by attempting to construct the quotient using the physical or drawn representations. What was the quotient's referent unit then? Was it the yellow hexagon, the dividend, or the divisor? Or something else? We begin our discussion on fraction division with Emma's drawn representations for the problems $\frac{1}{2}\div\frac{1}{6}$ and $\frac{1}{6}\div\frac{1}{2}$. Emma not only constructed both the dividend and the divisor, but she also drew the quotient as well (Figures 6a-b). She basically arrived at this construction with reference to her purely algebraic formalism using the invert-and-multiply method. In her interpretation, the quotient of the first problem, 3, is referred to the 3 yellow hexagon whole units. In fact, this corroborates our theory about Emma's view of fraction multiplication in which she constructed both the multiplier and the multiplicand (Figure 4a). For Emma, all these elements have to be represented using a pattern block.

Edie, on the other hand, seemed to have meaningfully constructed all the constituents in fraction division task. She explained "*How many sixths are there in a half? Equivalently, how many green triangles are in a red trapezoid? There are three sixths in a half.*" In her drawing, she also illustrated her way of counting those three sixths by labeling them as 1, 2, and 3, respectively (Figure 6c). Edie followed a similar reasoning for the other division problem by stating ""*How many halves are in a sixth? There is* $\frac{1}{3}$ *of a half in a sixth*." In her drawing, Edie used the idea of labeling, in an attempt to count, for which this time she used a fraction (Figure 6d). And that fraction, 1/3, the quotient, has nothing to do with the blue rhombus. It is true that the blue rhombus represents one third of the yellow hexagon whole unit, but in the context, as constructed by Edie, it refers to the quotient 1/3 with referent unit 1/2 (the red trapezoid), which also happens to be the divisor. We also observe that Edie meaningfully divides both the half by the sixth, and the sixth by the half algebraically, without reference to the invert-and-multiply algorithm.



6a 6b 6c 6d

Figure 6: Emma's (a, b) and Edie's (c, d) Constructions

We conclude our findings with April's performance on fraction division tasks. We consider April's reasoning as the most sophisticated one in that she makes use of a variety of meaningfully connected fraction ideas. April was one of the few making sure to refer to the yellow hexagon whole unit and including it in her drawn and physical representations, whenever relevant (Figures 3d, 5c-d). For the division (of the half by the sixth, and the sixth by the half) problems, she proceeds in a manner very similar to Edie's (Figure 6c-d). The only difference is that April also includes the yellow hexagon in her drawing, which is an indication that she is aware that the dividend's referent unit is the yellow hexagon whole unit (She also uses the idea of labeling the sixths the same way Edie does). This stacking approach, which can be thought of coordination of referent units at different levels, is a powerful tool in making sense of fraction division. We look at April's coordination of referent units through her physical and drawn representations for the multiplication task $\frac{1}{2}\times\frac{2}{3}$ and the division task $\frac{1}{6}\div\frac{1}{2}$ simultaneously. For the multiplication task, she explains "*There are two 1/3 portions in 2/3; 1/2 of that is one 1/3 portion*." She also relates the multiplier, namely the 1/2, to its referent unit 2/3 (two blue rhombi); the multiplicand, namely the 2/3, to its referent unit yellow hexagon; and the product, namely the 1/3, to its referent unit yellow hexagon (Figures 7a-b). For the division task, she explains "*Division is how many or how much of a given will go into another given portion. 1/3 of*

1/2 will divide into 1/6 of a whole. Therefore 1/6 ÷ 1/2 = 1/3." She also relates the dividend, namely the 1/6, to its referent unit yellow hexagon; the divisor, namely the 1/2, to its referent unit yellow hexagon; and the quotient 1/3 to its referent unit red trapezoid (Figures 7c-d).

Figure 7: April's Constructions

April's referent unit coordination scheme for the fraction multiplication and fraction division tasks can be tabulated as follows:

Fraction Multiplication		**Fraction Division**	
Components	*Referent Units*	*Components*	*Referent Units*
Multiplier	Multiplicand	Dividend	Whole
Multiplicand	Whole	Divisor	Whole
Product	Whole	Quotient	Divisor

Table 1. April's Referent Unit Coordination Scheme

Conclusions and Discussion

This study aimed to investigate the visual representations of five main fraction operations (equivalence, addition, subtraction, multiplication, and division) created by K-8 pre-service teachers using pattern blocks. Analysis of these participants' physical and drawn representations, accompanied by their algebraic formalism and verbal reasoning, helps us to determine important insights into their sense-making of the mathematics they are exploring. These insights have direct implications for the teaching of fractions in a hands-on-activity based environment. Mathematics teachers should be more conscious and explicit in modeling problems because their models may lead to a misinterpretation of the problem situation, or even the solution to the problem, as depicted in this present study. For example, although some students were confident with their algebraic solutions for the multiplication tasks (using the multiply the numerators and denominators algorithm) and division tasks (using the invert-and-multiply algorithm), their interpretation of the processes differed considerably, when they were asked to represent these tasks using the drawn and physical representations. In particular, Emma's representations of fraction multiplication and fraction division indicate that she may not have a meaningful concept for these operations with fractions. She appears to lack the necessary three levels of units (Olive & Steffe, 2010) to mentally coordinate the relations among multiplier, multiplicand and product, with respect to their roles in the situation and their respective referent units. This lack of coordination is even more apparent in her representation of fraction division (see Figure 6a-b). These necessary relations are depicted in April's referent unit coordination (Table 1 above).

Although fraction multiplication is algebraically commutative, the representation of that commutativity requires sophisticated reasoning. Construction of referential commutativity requires proficiency in simultaneously coordinating various fraction relations meaningfully. Awareness of the referent units for each component (multiplier, multiplicand, multiplier), ability to recognize which fractions are operators and which are quantities, and ability to connect the representations of these to the written explanations and algebraic formalism are essential in establishing referential commutativity of multiplication within a representational system (Behr et al., 1983).

Research indicates that the multiplicative conceptual field is very complex and includes many concepts of mathematics, other than multiplication itself (Behr, Harel, Post, & Lesh, 1992; Harel & Behr, 1989; Harel, Behr, Post, & Lesh, 1992). "*Additive reasoning develops quite naturally and intuitively through encounters with many situations that are primarily additive in nature*" (Sowder, Armstrong, Lamon, Simon, Sowder, & Thompson, 1998, p. 128). Building up multiplicative reasoning skills, on the other hand, is not obvious; schooling and teacher guidance are essential to acquire a profound understanding and familiarization with multiplicative situations, especially with respect to fractions (Hiebert & Behr, 1988; Resnick & Singer, 1993). This present study indicates the importance for teachers (and students) to develop three levels of units structures and the skill to coordinate those units (Olive & Steffe, 2010).

STUDENTS' DISTRIBUTIVE REASONING WITH FRACTIONS AND UNKNOWNS

Amy Hackenberg
Indiana University
ahackenb@indiana.edu

Mi Yeon Lee
Indiana University
miyelee@indiana.edu

To understand relationships between students' quantitative reasoning with fractions and their algebraic reasoning, a clinical interview study was conducted with 18 middle and high school students. The study targeted a balanced mix of students with 3 different multiplicative concepts, which are based on how students coordinate composite units (units of units). Students participated in two 45-minute semi-structured interviews and completed a written fractions assessment. This paper reports on how students with the second and third multiplicative concepts demonstrated the use of a distributive operation in fraction and algebraic problem solving.

Fractional knowledge is regarded as important for algebraic reasoning (Kilpatrick & Izsak, 2008; National Mathematics Advisory Panel [NMAP], 2008; Wu, 2001), in part because such knowledge is a basis for typical algebra topics such as ratios and slopes of lines. More generally, fractional knowledge is important for learning algebra because it helps students advance their multiplicative reasoning (cf. Thompson & Saldanha, 2003). For example, generating strategies for multiplying fractions can help students develop a distributive operation (Hackenberg & Tillema, 2009): to determine 1/5 of ¾ of a yard a student can take 1/5 of each of the three one-fourths of the yard. So, 1/5 of ¾ is 1/5 of (¼ + ¼ + ¼). Thinking of 1/5 of ¾ in this way might be considered algebraic because it highlights how the distributive property emerges from reasoning and is powerful for solving problems. However, little research has focused on how students' ways of operating with fractions may influence their algebraic reasoning (Lamon, 2007).

The purpose of this paper is to examine the distributive reasoning with fractions and unknowns of 18 middle and high school students who participated in a clinical interview study. The study was designed to investigate relationships between students' quantitative reasoning with fractions and their algebraic reasoning in the area of equation solving. In this paper we assess whether students with different multiplicative concepts demonstrated the use of a distributive operation in their quantitative reasoning with fractions and their algebraic reasoning.

The research questions addressed in this paper are:

1) Do middle and high school students show evidence of a distributive operation in solving problems that involve sharing multiple units fairly? If so, how do they reason distributively?
2) Do middle and high school students show evidence of a distributive operation in solving problems involving unknowns and fractions? If so, how do they reason distributively?
3) What differences are there in the distributive reasoning of students with different whole number multiplicative concepts?

A Quantitative and Operational Approach

Quantitative Reasoning

Following Thompson and colleagues (1993; Smith & Thompson, 2008), we conceive of quantity and quantitative reasoning as a basis for helping students build fractional knowledge and algebraic reasoning. A *quantity* is a property of one's concept of an object, and to conceive of a quantity requires a person to conceive of a measurement unit, of the property as subdivided into some number of these measurement units, and of a way to enumerate the number of these units to find a value of the quantity (cf. Thompson, 1993).

Approaching fractions as quantities means that we pose problems to students in which fractions are measureable extents, or lengths; these lengths may represent other quantities as well (e.g., weight). Approaching algebraic reasoning from a quantitative perspective means that unknowns are quantities for which a value is not known, but for which a value could be determined. So unknowns are potential values of quantities. In working with students we routinely ask them to make drawings of quantitative relationships, and we aim for students' fraction and algebraic notation to reflect the quantitative reasoning in which students engage.

Operations and Schemes

Our work is also based on conceiving of mathematical thinking in terms of people's mental actions, or *operations* (von Glasersfeld, 1995). Operations that are critical for fractional knowledge include *partitioning*, or marking a part into some number of equal pieces, as well as *iterating*, or repeatedly instantiating a part to make a larger fraction. The operation under investigation in this paper is a *distributive* operation. At the start of the study we characterized this operation as applying a process to a composite unit (a unit of units) by applying that process to some segmentation of the units that make up the composite unit. For example, to take 2/5 of 3 pounds a student could take 2/5 of each of the unit pounds that make up the 3 pounds. Our findings address whether this conceptualization of a distributive operation is sufficient.

Operations are the components of *schemes*, goal-directed ways of operating that consist of an assimilated situation, activity, and a result (von Glasersfeld, 1995). For example, if a student has constructed a partitive fraction scheme, then a situation of the scheme is a request to make a new length that is 2/5 of a foot. The activity of the scheme involves partitioning the foot into five equal parts, disembedding one of those parts, and iterating the part twice. The student then assesses this result in relation to what she expected. We take students' *reasoning* to be the functioning of their schemes and operations in on-going interaction in their experiential worlds.

Multiplicative Concepts

For us, a *concept* is the result of a scheme that people have *interiorized*—i.e., reprocessed so that the result is available prior to operating. We use students' whole number multiplicative concepts as a tool for understanding differences in how students build fractional knowledge (e.g., Hackenberg, 2010). These multiplicative concepts are based the number of levels of units a student has interiorized; to progress from one concept to the next requires a major reorganization of operations. Although this study included students with three different multiplicative concepts, this paper reports only on students with the second and third multiplicative concepts, as derived from prior research (Hackenberg & Tillema, 2009; Steffe, 1994), because students with the first multiplicative concept did not show evidence of a distributive operation.

Students with the second multiplicative concept (MC2 students) have interiorized two levels of units. These students have the potential to treat a length as a unit containing some number of equal units, and they can do so prior to operating in a situation. For example, these students can treat a length that represents one foot as a unit containing five units—a unit of units structure—without having to actually make the partitions. These students can also make three levels of units in activity. For example, they can insert three parts into each of the five parts in the 5/5-foot segment and determine that they have made 15 parts in all. However, once they do so, the 15/15-foot segment is not likely to retain its structure as unit of five units each containing three units (Hackenberg, 2010; Hackenberg & Tillema, 2009).

Students with the third multiplicative concept (MC3 students) have interiorized three levels of units. Prior to operating, these students can treat lengths as a unit containing some number of units, each of which contains some number of units—a unit of units of units structure. So, in the example above, MC3 students can do what MC2 students do, but they can also retain views of the 15/15-foot segment as a unit of 5 units each containing 3 units, and they can switch to viewing the segment as a unit of 3 units each containing 5 units. Being able to flexibly switch between such unit structures can be useful for constructing a variety of fraction schemes (e.g., Hackenberg, 2010; Steffe & Olive, 2010).

Methods

A clinical interview study was chosen as appropriate methodology to explore the research questions because a strength of clinical interviewing is "the ability to collect and analyze data on mental processes at the level of a subject's authentic ideas and meanings, and to expose hidden structures and processes in the subject's thinking that could not be detected by less open-ended techniques" (Clement, 2000, p. 547). Interview studies are a tool for generating scientific knowledge because dynamic, on-going discussion is a basis for formulating explanatory models (Clement, 2000; Steffe & Thompson, 2000) for experienced phenomenon.

Seven seventh grade students, 10 eighth grade students, and one tenth grade student participated in the study. Participant selection occurred via classroom observations, consultation with students' teachers, and one-on-one, task-based selection interviews to assess students' multiplicative concepts. Six students with each multiplicative concept were invited to participate. Four of the MC2 students were enrolled in an 8th grade pre-algebra class; one was taking an advanced 7th grade mathematics class; and one was taking a 7th grade mathematics class for struggling students. Four of the MC3 students were enrolled in an algebra class, and two were taking an advanced 7th grade mathematics class.

Students participated in two 45-minute semi-structured interviews, a fractions interview and an algebra interview. All students completed the fractions interview prior to the algebra interview, but the time between interviews varied from about 3 weeks to 4 months. The interview protocols were refined in a prior pilot study (Hackenberg, 2009), and quantitative situations were used as a basis for all problems. The protocols were designed so that the reasoning involved in the fractions interview was a foundation for solving problems in the algebra interview. For example, in the fractions interview students were posed this problem:

> F2. *Fair Sharing of Multiple Identical Bars Problem:* Here are five candy bars (congruent rectangles). Can you show how to share them fairly among seven people, and determine the fair share for one person? Draw the amount one person gets.

In the algebra interview, students were posed a similar problem but with each bar assigned a weight of *h* ounces:

> A1. *Weight of Multiple Identical Bars Problem:* Here are five identical candy bars (congruent rectangles). Each candy bar weighs some number of ounces. Let's say that *h* = the weight of one bar. How much does 1/7 of all the candy weigh? Write an expression for this result.

In working on A1, students were also encouraged to draw a picture to demonstrate how they saw their expression. In addition to the two interviews, students completed a written fractions assessment (Norton & Wilkins, 2009) to triangulate claims about their fractional knowledge.

Each interview was video-recorded with two cameras, one focused on the interaction between the researcher and student, and one focused on the student's written work. The videos were mixed into one file for analysis, which occurred in two overlapping phases. First, the researchers viewed video files and took detailed notes (Cobb & Gravemeijer, 2008). The aim of this phase was to formulate a model of each student's fraction schemes and equation solving activity, to the extent possible over two interactions. To develop these models the researchers built on constructs from prior models (e.g., Hackenberg, 2010; Steffe & Olive, 2010; Tzur, 2004). These models provided the basis for responding to the first two research questions.

In the second phase of analysis, the researchers looked across the students to articulate differences in how students with different multiplicative concepts solved the problems in each interview. This phase included assessing differences in students' distributive reasoning with knowns and unknowns and writing syntheses of differences for students with each multiplicative concept. This phase allowed the researchers to address the third research question in this paper.

Analysis and Findings

Four of the MC2 students demonstrated some evidence of a distributive operation in the fractions interview, while only one of the MC3 students did so. In this section we present data and analysis to support this finding, which was surprising, since prior to the study we conjectured that a distributive operation required the third multiplicative concept. Then we examine the students' work on the algebra interview to help illuminate the finding.

Distributive Reasoning in the Fractions Interview

MC2 students. Of the four MC2 students who demonstrated evidence of a distributive operation in the fractions interview, two demonstrated it immediately upon sharing three identical candy bars fairly among five people, which we'll call problem F1, as well as in working on F2. The other two students showed some evidence of a distributive operation over time in working on F1 and F2. We present an example of each of these two types of evidence.

In work on F1, Lisa immediately divided each of the three bars into five equal parts and said that each person would get one-fifth from each bar. She seemed certain, and she called the fair share that she drew three-fifths. When asked whether the share was 3/5 of all the candy or 3/5 of one bar, she said it was 3/5 of all the candy. Upon further questioning, she said 3/5 referred to "kind of both" (all the candy and one bar), because the share was 3/5 from one bar and 1/5 from each of three bars. Twenty seconds later, when asked if each person got 3/5 of all the candy, she said no. She noted that there were five people so one share was one-fifth of all the candy. She solved F2, directly following F1, in the same say. She said, "Each person will get one-seventh of all the candy, because there are seven people. And they will get one-seventh of each [bar]." She said each person would get five-sevenths.

This data excerpt demonstrates that Lisa has constructed a distributive operation of some kind, in that to take find 1/5 or 1/7 of multiple identical units she took 1/5 or 1/7 of each of those units. However, for some time in working on F1 she named the fair share 3/5 of *all* the candy. Our interpretation is that to determine a share, Lisa made a unit of units of units in activity: All of the candy was a unit of three units, and she partitioned each of those units into five units. Once she determined a share, she continued to view all the candy as the referent for the result, even though she also she viewed each bar as a unit of five units. Lisa said that one person's share was 1/5 of *all* the candy only after she thought again about five people sharing all of the bars; then she viewed the share as 1/5, consistent with viewing all of the bars as a length partitioned into five equal parts (a unit of units). So, she appeared to view the results of her activity as different two-levels-of-units views, but not as a three-levels-of-units view. A second MC2 student operated similarly to Lisa.

In contrast with Lisa, Sheila was one of the two MC2 students who seemed to develop a distributive operation in the process of the interview. Her fractions interview was one of the first in the study, and the interviewer inadvertently posed F1 with four people instead of five. Sheila solved this version of F1 by partitioning each of the first two bars in half, and then she partitioned the third bar into fourths. She said that each person would get "one-half plus one-fourth." In working on F2 Sheila first partitioned each of the five bars into fourths, and she numbered the fourths from 1 to 7 sequentially, as if trying to determine whether the there would be an equal number of parts for each of seven people. She then tried again but partitioned each bar into fifths, again numbering sequentially. On her third try, she partitioned each bar into sevenths, numbered them sequentially, and said that each person would get "five-sevenths." That is, each person would get all the pieces with the same number on them (person 1 gets all the 1's).

So, Sheila's work on F1 and F2 is not evidence of a distributive operation. However, in the course of the interview, she introduced the idea of numbering the pieces to try to pull out an equal amount for each of the seven people. This idea seems to be a possible root for a distributive operation, in that through it Sheila determined that she could make fair shares by taking one part out of seven from each of the five bars.

MC3 students. In contrast, the only MC3 student to demonstrate a distributive operation in working on F1 and F2 was Liam. In working on F1, Liam immediately said that you could divide each bar into five parts, but "that would be kind of cumbersome." So, he drew his three bars stacked vertically and then partitioned them vertically, all at once, into fifths. He then drew out one column (consisting of three parts) as the share for one person. He called one share 3/15 and then 1/5 of all the candy. When asked for the size of the share in relation to one bar, he paused and appeared to do some calculation. He justified his answer of 3/5 of one bar by saying that one column was the same as three parts horizontally, which was 3/5 of a bar. He solved F2 similarly, although he determined the size of one share in relation to one bar, 5/7, first. To determine the fraction of all the candy, he calculated 5/7 x 1/5 and found 5/35, or 1/7. He said he had multiplied because one share was 5/7 of a candy bar, and a candy bar was 1/5 of the total.

Although his process is somewhat different from Lisa's, it still implies the construction of a distributive operation because one column consists of one part from each bar. However, Liam may not have been aware of this pattern in his thinking. For example, when asked in F2 whether his result of his calculation to determine the fraction of all the candy, 1/7, made sense, he pointed out that the seven shares in the five bars could be seen in five horizontal rows (5/7 of each bar) and then two more columns, each containing five parts. He did *not* point to each column.

The other MC3 students did not reason distributively in the fractions interview, although some of them made sophisticated solutions. For example, Suzanne tried out a fractional amount of each bar as the share for one person and then looked to see what was leftover. In F2 she first tried a share of 2/3 of a bar, and knew she could give that to 5 people, because there were 5 bars. She then saw that she had five-thirds leftover, which left an extra one-third after two more people each got 2/3 of a bar. So, then she tried a share of ¾, followed by 4/5, followed by 5/7.

Distributive Reasoning in the Algebra Interview

In working on A1, five of the MC2 students did not demonstrate distributive reasoning with unknowns. Only Sheila's work on this problem indicates that she was continuing to develop the distributive reasoning that had emerged in the fractions interview. First we present Lisa's response to A1, followed by an analysis of Sheila's response. Then we discuss the ways of operating of the MC3 students on A1, again highlighting the work of Liam and Suzanne.

MC2 students. After being posed A1, Lisa again demonstrated a possible distributive operation by partitioning each of the five bars into seven equal parts and saying that she would take "one from each." However, when asked to draw out that amount, she believed that it would be a whole bar. After she had insisted on this result for over two minutes, the interviewer counted the pieces when taking one from each bar, and Lisa said that the result would only make 5/7 of a bar. When asked how she knew that result was one-seventh of all of the candy, she repeated her process (taking 1/7 of each, and that will be 5/7). The interviewer pressed for another fraction name for the result in relation to all of the candy, and she said 5/7. Then the interviewer asked whether the result would be more or less than the weight of one bar, *h*. She said less, because it was less than one bar. When asked for an expression, she said she did not know how to write it, and she wrote down "H <".

This piece of data sheds more light on the nature of Lisa's distributive operation. Her initial response to A1 was similar to her initial response to F2, allowing us to corroborate that Lisa has constructed a mental action—accompanied by material manifestations—for taking 1/7 of all of the bars by taking 1/7 from each bar. However, in working on A1 she did not appear to realize for some time that that her action would of necessity produce *five* pieces; she thought it would be a whole bar. So she appeared to lack awareness of the result of her operation. In addition, once she had made the result, she did not appear to have any way outside of her initial action to justify that the share she produced was one-seventh of all the candy. In fact, in A1 it's not clear that Lisa viewed the result as one-seventh of all the candy. It was almost as if the initial problem of finding one-seventh of all of the bars became lost to her once she arrived at her result, five-sevenths. We account for this as we did with her work on F2, by appealing to her multiplicative concept. Lisa made three levels of units in activity by partitioning each of the five bars into seven. However, once she did that, she did not appear to retain the structure of the bars as a unit of five units each containing seven, and we have no evidence that she switched to a view of the entire collection as a unit of seven units each containing five.

In working on A1, Sheila operated similarly to Lisa in that she immediately divided each bar into seven equal parts and colored the first part of each bar. When asked for the weight of that, she said "There are five, so five-sevenths of one candy bar." The interviewer asked her to write an expression using *h* to show the weight of this amount. Sheila wrote 5/7*h*. In explanation, she said that she had multiplied five-sevenths and *h*.

Because Sheila had worked so swiftly on A1, the interviewer posed A2:

> A2. *Weight of Three Different Bars Problem:* There are three candy bars on the table, each of different weight (three non-congruent rectangles). The first bar weighs *a* ounces; the second bar weighs *b* ounces; and the third bar weighs *c* ounces. How much does three-fifths of all the candy weigh? Write an expression to show your result.

Sheila partitioned each of the three bars into five equal parts, colored the first piece of each bar, and wrote "3/5*b*". Then she tried to fit the bars together in some way. The interviewer clarified that the bars had no particular relationship to each other and decided to pursue finding just one-fifth of the weight. Sheila then wrote that the weight was "3/15*b*." When asked what 1/5 of the first bar weighed, Sheila answered "1/5*a*." The interviewer asked similar questions for the other two bars, and Sheila answered similarly. When asked about the weight of all three parts together, Sheila pointed to her expression "3/5*b*." The interviewer then asked her to write an expression that included *a*, *b*, and *c*, using her ideas about the weights of one-fifth of each bar. Sheila wrote "3/5·c·b·a" and said, "multiplying 3/5 by the third bar, by the second bar, and by the first bar."

Sheila's work on A2 helps illuminate the nature of her distributive operation that appeared so fluidly in her work on A1. Like Lisa, Sheila had constructed a mental action that we refer to as distributive. Unfortunately, on A1 the interviewer did not press Sheila for the fraction name of the result in relation to all the candy, so we cannot draw conclusions about whether she could justify that 5/7 of the weight of one bar was 1/7 of the weight of all of the bars. However, in working on A2, like Lisa, Sheila did not appear to be aware of the result of her activity. Furthermore, in A2 Sheila's work does not indicate that she viewed 1/5 of the weight of all the candy either as the sum of 1/5 of the weight of each bar, or as 1/5 of the sum of the three weights. We account for this by appealing to Sheila's multiplicative concept: Once she had partitioned each bar in A2, the problem likely became a unit of 15 units, and so a response like "3/15*b*" was a reasonable response for the weight of 1/5 of those units.

MC3 students. In contrast with the MC2 students, four MC3 students demonstrated distributive reasoning with unknowns in the algebra interview. Liam's work on A1 showed a distributive operation more clearly than his work on F2. He wrote the result as $(5h)/7$ and $5h \cdot 1/7$. When asked to show that in the picture, he partitioned each bar into sevenths and said to take one from each, gesturing to the first part from each bar. He drew out this amount, and when asked how much that was of *h*, he said 5/7. However, in his work on A2, Liam only arrived at $(a + b + c) \cdot 3/5$ to express 3/5 of the weight of three bars of different weight. Despite several opportunities, he did not ever articulate 3/5 of the weight of the bars as $3/5a + 3/5b + 3/5c$.

In her work on A1 and A2, Suzanne seemed to develop her distributive reasoning even more than Liam. On A1 she first wrote $5h \cdot 1/7$ as her expression. To make her drawing, she partitioned each bar into seven equal parts and marked the last part of each bar. She said you could put all of those parts together to make 1/7 of all the candy. She drew out that amount and wrote $5/7h$ for its weight. When asked whether the two expressions were the same, she noted that multiplying 5 times 1/7 produced 5/7. On A2, Suzanne wrote two expressions for the weight of the three different bars and explained that the first one, $3/5(a + b + c)$, meant that you added all the bars together and took 3/5 of it. The second one $(3/5a + 3/5b + 3/5c)$ meant that you took 1/5 of each weight and then added. Based on this work, we attribute a distributive operation to Suzanne in which she had developed awareness of the result of the mental action.

Discussion and Conclusions

In this section we summarize our responses to our three research questions. First, MC2 students can develop a distributive operation in which they take a fractional amount of each unit to make a fractional amount of multiple units, and they may believe that this action accomplishes this goal. However, these students do not necessarily distinguish the fractional meaning of the result in relation to the unit versus the multiple units. In addition, they do not necessarily have a way to justify that their method works. We attribute this to their interiorization of two, but not three, levels of units, as we have discussed above. The main issue is that after partitioning multiple units, the multiple bars becomes a unit of units for these students, rather than a three-levels-of-units structure. This finding causes us to refine our definition of a distributive operation to include being able to distinguish different referent units in the results of operating.

Second, our study supports the conclusion that MC3 students have constructed the means for constructing a distributive operation. Our analysis of what is required to develop awareness of the result of the action, and a way to justify that the action produces a correct result, relies on being able to switch three-levels-of-units structures—a hallmark of the third multiplicative concept. However, third, our study also shows that even though MC3 students have this kind of power at their disposal, they will not necessarily use it to construct a distributive operation unless given opportunities to do so, i.e., unless instruction and tasks are organized favorably for this.

So, one implication of this study for teaching is to work on sharing multiple units in such a way that students construct a distributive operation that they can further develop in algebraic contexts. This can make it possible for discussions of whether 5*h* * 1/7 is the same as (5/7)*h* to have quantitative, not just numerical, meaning—an issue that appears to be within the cognitive powers of MC3 students. Although such work may be challenging for MC2 students, an open question is whether it may be influential in helping them advance their multiplicative concepts.

STUDENTS' COMBINATORIAL REASONING: THE MULTIPLICATION OF BINOMIALS[1]

Erik Tillema
Indiana University Purdue University Indianapolis
etillema@iupui.edu

Three clinical interviews were conducted with each of 15 sixth grade students to test conjectures about the relationship between their level of multiplicative reasoning and their solution of combinatorics problems that could involve single and multi-digit multiplication. The problems that involved multi-digit multiplication were designed with the intent of investigating whether students engaged in binomial multiplication. The conjectures about the relationship between students' multiplicative reasoning and their solution of combinatorics problems that could involve multi-digit multiplication were refined as a result of students' problem solving activity: Students who had not constructed the most advanced multiplicative concept were able to engage in a form of binomial multiplication.

Curriculum writers have responded to recommendations to incorporate combinatorics problems into K-12 curricula (e.g., Lappan, Fey, Fitzgerald, Friel, & Phillips 2002). These recommendations have been based on arguments that such problems have the potential to support both process and content standards outlined by the National Council of Teachers of Mathematics (Srirman & English, 2004). In response to these changes in curricula, researchers have produced a small body of research that has investigated students' combinatorial reasoning (Jones, Langrall, & Mooney, 2007). However, this body of research remains small, and so relatively little is known about when particular problems are appropriate to introduce to students, how teachers can support students' understanding of these problems, and how such problems are compatible with extant goals of the curricula. Therefore, research that aims to address these issues is critical for successfully and coherently incorporating such problems into extant curricula.

The study reported on in this paper addresses these issues by investigating how 15 6th grade students at three different levels of multiplicative reasoning solved two-dimensional combinatorics problems and how they used such problems to reason about multi-digit multiplication. The study involved three clinical interviews—one unrecorded selection interview and two hour-long video recorded interviews. Each interview was conducted one-on-one with study participants. In the first video recorded interview, students solved two-dimensional combinatorics problems that could involve single digit multiplication like the Outfits Problem.

> *The Outfits Problem:* You have three pairs of pants and four shirts. An outfit is one shirt and one pair of pants. How many different outfits could you make?

In the second video recorded interview, students solved combinatorics problems that could involve multi-digit multiplication like the Card Problem.

> *Card Problem:* You have the ace through king of hearts (13 cards). Your friend has the ace through king of clubs (13 cards). Use an array to show all of the possible 2-card hands you could make that consist of one heart and one club. On your array show the number of 2-card hands that have two face cards (Jack, Queen, King), that have exactly one face card, and that have no face cards. Use the sections of your array to determine the total number of 2-card hands you can make.

In both interviews, students were encouraged to use *arrays* to symbolize the solution of these problems. The following research questions guided the study:

1) How do students at different levels of multiplicative reasoning reason about two-dimensional combinatorics problems that can involve single digit multiplication?
2) How do students at different levels of multiplicative reasoning reason about multi-digit multiplication in the context of solving combinatorics problems?

Literature Review

English (1991, 1993) has studied kindergarten through 8th grade students' understanding of two-dimensional combinatorics problems like the Outfits Problem. She concluded that many 6th grade students were ready to begin analyzing the structure of such problems, whereas younger students were less ready to do so, even though they could solve the problems with concrete materials. However, English has exclusively studied how students could use two-dimensional combinatorics problems as a basis for reasoning about single digit multiplication.

Researchers who have studied students' understanding of multi-digit multiplication have primarily used repeated groups problems not combinatorics problems (e.g., Ambrose, Baek, & Carpenter, 2003). Moreover, they frequently have *not* used array representations for these problems (Verschaffel, Greer, & De Corte, 2007), even though array representations are often included in researchers' classification of situations involving multiplication (e.g., Greer, 1992). Izsak (2004) is one of the few researchers to investigate elementary grade students' use of arrays to represent multi-digit multiplication problems (although he did not use combinatorics problems). Izsak found that students in the 4th grade classroom he studied were more successful in solving multi-digit multiplication problems than U.S. students in earlier large-scale studies (e.g., Mullis, Martin, Beaton, Gonzalez, Kelly, Smith, 1997). This finding suggests that array representations may be fruitful for helping students develop an understanding of multi-digit multiplication. However, because Izsak's study is one of the few that has investigated how students use arrays to understand multi-digit multiplication, further research is needed (Vershcaffel, Greer & De Corte).

A second finding of Izsak's (2004) study, which is supported by Ambrose, Baek, & Carpenter's (2003) findings, is that students tended not to partition *both* the multiplier and multiplicand when computing multi-digit multiplication problems. For example, to solve 13 x 13, some students partitioned either the multiplier or multiplicand into 10 and 3, but they did not partition both 13s into (10 + 3). When students partition both numbers into two parts, they are multiplying two binomials together, as opposed to multiplying a monomial times a binomial. Problems like the Card Problem were designed for this study to open the possibility for students' to solve the problems using the multiplication of two binomials.

Methodological and Analytic Framework

Methodology

The study used clinical interview methodology (Clement, 2000). Clinical interviews allow "the ability to collect and analyze data on mental processes at the level of a subject's authentic ideas and meanings, and to expose hidden structures and processes in the subject's thinking that could not be detected by less open-ended techniques" (Clement, p. 547). When using this methodology, a researcher formulates conjectures about these mental processes (Confrey & LaChance, 2000; Steffe & Thompson, 2000). These conjectures are formulated based on conceptual analysis of the mathematical domain and prior research with students in this domain.

Problem sequences are then carefully designed so that they allow for testing these conjectures (Cobb & Gravemeijer, 2008). During data collection and analysis, conjectures are refuted or not refuted based on how students operate to solve problems. When a conjecture is refuted, the conjecture becomes open to being refined so that it can be tested in future studies.

Analytic Tools

The two primary analytic constructs used to characterize students' mental processes were *schemes* and the *mental operations* that constitute these schemes. A scheme is a goal-directed way of operating that has three parts—an assimilatory mechanism, an activity, and a result (von Glasersfeld, 2001). When a student is presented with a problem situation, the problem situation may trigger records of prior operating, and in doing so the student may come to recognize the situation (assimilate it) as one that involves a particular type of activity. The activity of a scheme involves mental operations like partitioning, disembedding, and uniting (three mental operations, which will be discussed below). Finally, the student's activity produces a result (i.e. a solution to a problem).

Framework for Participant Selection

Steffe (1994) has identified three distinctly different levels of multiplicative reasoning for elementary grade students. These different levels of multiplicative reasoning are a result of learning and development, and they open possibilities for, as well as constrain how, students operate mathematically. The different levels of multiplicative reasoning have been used as a framework to study students' reasoning as it pertains to the solution of problems involving both whole numbers and fractions. However, these levels have not been used as a basis for studying students' combinatorial reasoning. In this section, I give a brief overview of how students operating at the different levels typically solve repeated groups multiplication problems.

Students operating at the first level of multiplicative reasoning are able to coordinate two levels of units in activity. That is, to determine the number of doughnuts a person has if the person has 4 packages, with 8 doughnuts in each package, these students coordinate two counts—one count tracks the number of doughnuts and the other the number of packages. This coordination of two levels of units often involves double counting like the following: one, two, three, four, five, six, seven, eight, that is one package; nine, ten, eleven, twelve, thirteen, fourteen, fifteen, sixteen, that is two packages, etc. The two units that these students are able to coordinate are the number of doughnuts and the number of packages, but they have to make this coordination as part of the activity they use to solve a problem.

Students operating at the second level of multiplicative reasoning are able to take the coordination of two levels of units as given, which means that they do not have to make a coordination between two counts as part of their activity. Instead, a number word like 8 automatically means both 1 package and 8 doughnuts. Students who operate with the second multiplicative concept are likely to solve the doughnut problem by reasoning that 8 and 8 is 16 because 8 and 2 is 10 and 6 more is 16. Here the number word 16 would mean 16 doughnuts and 2 packages. In reasoning in this way, these students are able to operate on 8 by partitioning it into two parts (i.e., breaking 8 into 2 and 6), and disembedding both of the parts in order to strategically unite them with another group of 8 (e.g., 8 and 2 makes one group of 10, and 6 more makes one group of 10 with 6 ones). To finish solving the problem they would likely continue this sequential process of adding 8 more onto the previous amount, using strategic ways of partitioning the numbers to help them calculate the total amount.

Students operating at the third level of multiplicative reasoning are no longer constrained to sequentially combining amounts and using addition to solve repeated groups multiplication problems. Instead these students might determine the number of doughnuts a person has if the person has 12 packages of 8 doughnuts by reasoning that 10 packages of doughnuts would be 80 doughnuts and that 2 more packages of doughnuts would be 16 doughnuts, which would yield a total of 96 doughnuts. In solving the problem in this way, these students are able to reason that 12 groups of 8 is composed of 10 groups of 8 and 2 groups of 8, and they can use that to determine the total amount. In doing so, they treat the 12 groups of 8 as a unit of 12 units each containing 8 units. That is, they treat the 12 groups of 8 as itself a unit that can be operated on, which means that they are reasoning with a third level of unit. Reasoning with the third level of unit enables them to partition 12 groups of 8 into two parts, a unit of 10 units each containing 8 units and a unit of 2 units each containing 8 units. Then they disembed each part, evaluate each part using multiplication (i.e., ten 8s is 80 and two 8s is 16), and subsequently unite the two parts together (i.e., 80 and 16 is 96).

Students' Schemes for Solving Two-Dimensional Combinatorics Problems

In a prior study with three eighth grade students, all of whom were operating at the third level of multiplicative reasoning, Tillema (under review a) identified a scheme that students used to solve basic two-dimensional combinatorics problems. The scheme entailed students *assimilating* such situations using *two composite units* (*two input quantities*). In the case of the Outfits Problem, the two composite units were 4 shirts and 3 pants. The *activity* of their scheme involved two key mental operations—ordering and pairing. Students used an *ordering* operation when they supplied a qualitative property that they used to differentiate the units of a composite unit. For example, in the Outfits Problem when a student used colors, a qualitative property, to differentiate among the three shirts, the student ordered the shirts. Students then used a *pairing* operation when they created a correspondence between one unit of each composite unit and applied their unitizing operation to this correspondence. That is, to be engaged in pairing a student created a correspondence between a shirt and pants and then applied her unitizing operation to this correspondence to create an outfit, an output unit.

Students produced the output units by following a lexicographic ordering (cf. English's, 1991, 1993 odometer strategy). A lexicographic ordering is similar to a dictionary ordering—the word "aa" appears before the word "ab" and all words that begin with "a" appear before all words that begin with "b". So, for example, in the Outfits Problem students followed a lexicographic ordering when they created the outfit that contained the first shirt and first pants prior to creating the outfit that contained the first shirt and the second pants, and they created all outfits that contained the first shirt prior to creating any outfits that contained the second shirt. For these reasons, students' schemes for solving these problems were called a *lexicographic units pairing scheme* (LUPS).

To differentiate the extent to which students carried out the pairing operations as part of the activity of their scheme, two ways that students treated the units of an input quantity were defined. A student treated the units of an input quantity as *particular units* when she repeated the pairing operations that she used with one of the units with all of the other units of that quantity. For example, in the Outfits Problem, a student treated the pants as particular units when she paired the first shirt with the first pants, the first shirt with the second pants, and the first shirt with the third pants because she repeated the pairing operations between the first shirt and each particular pants. In contrast, when a student did not need to repeat the pairing operations with one or both input quantities, the student operated with a *representative unit*. For example, a student might operate as described above, and then say, "you could do that with all of the other shirts." In this case, the student treated the first shirt as representative of how all of the other shirts would function, which enabled her *not* to carry out all of the pairing operations with the other shirts. Based on this distinction between particular and representative units, four different levels of the LUPS were identified.

Study Design and Guiding Conjectures

Selection Interviews

The selection interviews were used to identify at least three 6th grade students at each of the three different levels of multiplicative reasoning, and involved a total of fifteen students. The students all attended a magnet school in an urban school district in the Midwest. They were selected from a pool of 65 possible students all of whom had the same 6th grade teacher.

During the selection interviews, I presented problems to students with the intent of determining whether a student were able to coordinate two levels of units in activity (the first level of multiplicative reasoning), take the coordination of two levels of units as a given (the second level of multiplicative reasoning), or take the coordination of three levels of units as given (the third level of multiplicative reasoning). The interview protocols involved both whole number and fraction problems that were intended to elicit this information, but none of the problems involved any type of combinatorics problem.

Design of the First Interview

During the first interview, students were presented with two-dimensional combinatorics problems like the Outfits Problem. They introduced themselves or the researcher introduced to them three ways—lists, tree diagrams, and arrays—to represent these initial problems. During students' solution of these initial problems, the researcher emphasized the use of arrays as a way to symbolize such problems. The intent of posing these problems was to test three conjectures about the relationship between the different levels of multiplicative reasoning and the different levels of the LUPS.

Conjecture 1: Students operating at the first level of multiplicative reasoning will be constrained to the second level of the lexicographic units pairing scheme (LUPS).

Conjecture 2: Students operating at the second level of multiplicative reasoning will be constrained to the third level of the LUPS.

Conjecture 3: Students operating at the third level of multiplicative reasoning will operate at the fourth level of the LUPS.

Design of the Second Interview

During the second interview, students were initially presented with problems like the Restaurant Problem.

The Restaurant Problem: A meal at a local restaurant consists of one salad and one entrée. The restaurant serves 6 different kinds of salad and 14 different kinds of entrées. 10 of the entrees have meat. Illustrate with an array the total number of meals that are vegetarian and the total number of meals that are non-vegetarian.

These problems all involved one two-digit number (14 in the case of the Restaurant Problem) and one one-digit number (6 in the case of the Restaurant Problem), and again the researcher emphasized using arrays as a way to symbolize these problems. These problems were used to test the following conjecture.

Conjecture 4: Students operating at the third level of multiplicative reasoning will be the only students to solve these problems using distributive reasoning.

If students were able to solve problems like the Restaurant Problem, then they were presented with problems that had the potential to involve the multiplication of two binomials like the Card Problem, which is symbolized below using an array (Figure 2).

Figure 2: An array for the Card Problem.

In the Card Problem, 13^2 can refer to the total number of 2-card hands a person could make, while $(10 + 3)^2$ refers to this same total once a person has thought about breaking the hearts and clubs into non-face and face cards. Similarly, each of the following, 10^2, (10 x 3), (3 x 10), 3^2, refers to parts of the array: 0 face cards, 1 face card, or 2 face cards. This reasoning can lead to the development of the following equivalences: $(13)^2 = (10 + 3)^2 = 10^2 + (10 \text{ x } 3) + (3 \text{ x } 10) + 3^2 = 10^2 + 2 \text{ x } (10 \text{ x } 3) + 3^2 = 100 + 30 + 30 + 9 = 169$. Problems like the Card Problem were used to test the following conjecture.

Conjecture 5: Students operating at the third level of multiplicative reasoning are the only students who will experience these types of problems as involving the multiplication of two binomials.

Initial Findings and Discussion

Based on preliminary data analysis from this study there was no evidence that refuted conjectures 1, 2, 3. That is, all students in the study operated as the conjectures predicted they would operate. However, conjectures 4 and 5 needed to be refined as a result of this study. Providing data exemplars of students' reasoning that provides evidence for these claims will comprise a major component of the presentation of this paper. Here, I present exemplars of data to discuss how conjecture 5 has been refined as a result of the study.

Conjecture 5 stated that students operating at the third level of multiplicative reasoning are the only students who will experience the Card Problem as involving the multiplication of two binomials. The findings from the study indicate that students at both the second and third level of multiplicative reasoning were able to solve problems like the Card Problem. However, there were qualitative differences between the students' solutions of the Card Problem depending on whether they were operating at the second or third level of multiplicative reasoning.

Students who were operating at the second level of multiplicative reasoning solved the problem by first pairing a particular card (e.g., the two of clubs) with a representative card from the other suit (e.g., the two of hearts), and could take that as indication of producing the first thirteen pairs (i.e., all pairs that could be made with the two of clubs). They repeated the pairing operation with each of the thirteen clubs (i.e., treated the clubs as particular units), and could then state that the total number of two-card hands would be 13 x 13 and symbolize this multiplication problem using an array. Students could then find in their array the four sections shown in Figure 2, but to quantify each of these sections they had to re-engage in pairing operations for each section of the array. So, for example to determine the number of two-card hands that contained only face cards the students had to pair a particular face card (e.g., the king of clubs) with a representative face card from the other suit (e.g., the king of hearts), which they took as indication of producing the first three two-card hands that contained only face cards. They engaged in this pairing operation again for the remaining two clubs that were face cards to establish that there would be a total of 3 x 3 or 9 two-card hands that contained only face cards. They had to repeat these operations to establish the multiplication problems for the other three parts of the array. In doing so, they established that the array could be quantified using one multiplication problem (13 x 13) or four multiplication problems (3 x 3, 10 x 10, 3 x 10, and 10 x 3), but these two ways of quantifying the array remained two separate ways to view the array and were not integrated into a single structure (scheme).

Students who were operating at the third level of multiplicative reasoning solved the Card Problem by pairing a representative unit (e.g., the two of clubs) with a representative unit (e.g., the two of hearts). Because they treated both one club as a representative unit and the one heart as a representative unit, they were able to take a single pairing operation as implying all of the two-card hands that they could make. That is, they reasoned, for example, that the two of hearts was representative of any of the hearts that could be paired with the two of clubs, and so 13 two-card hands could be made with the two of clubs. Subsequently, they treated the two of clubs as representative of any of the clubs in the deck and so could take it as indicating the number of times that they would produce 13 two-card hands without actually having to make these two-card hands by pairing cards together. They could symbolize this pairing operation using an array. Once they produced the array they were able to determine the four sections of the array without having to engage in any further pairing operations. Rather they simply partitioned the two composite units they used in assimilation, 13 and 13, into two parts, and this implied to them partitioning the array into four sections. Moreover, they could identify a multiplication problem for each section of the array without having to use pairing operations to re-establish the multiplication problem for each part of the array. This enabled them to generate the equivalence that $13 \times 13 = (10 + 3) \times (10 + 3) = 10 \times 10 + 3 \times 10 + 10 \times 3 + 3 \times 3$, and see these two ways of quantifying the array as part of a single structure (scheme).

In the presentation, there will be a discussion of each of the 5 conjectures and video data will be used to support the statement of the conjecture or to discuss how the conjecture was refined as a result of the study.

WHERE'S THE PROOF? PROOF IN U.S. HIGH SCHOOL GEOMETRY CONTENT STANDARDS

Karl W. Kosko

Patricio Herbst
University of Michigan
pgherbst@umich.edu

This study examined High School Geometry standards from recent individual states' and the Common Core Standards (CCSSM) featuring reasoning and proof. We examined specificity of content and use of proof or reasoning as a process in the language of standards. Results indicated standards with proof as its primary process are more likely to have higher specificity of content, and vice versa. Further, the CCSSM were found to have higher content specificity and more consistent use of proof as a primary process than the vast majority of states' standards.

Background and Objectives

Since the publication of *A Nation at Risk* almost 30 years ago (NCEE, 1983), an ever increasing emphasis has been given to assessment and content standards. The publication of the *Curriculum Standards for School Mathematics* by the National Council of Teachers of Mathematics (1989) helped initiate development of content standards written by individual states (Porter, 1994). The NCTM Standards (1989) did not have a specific standard strand for proof but included it within the Reasoning Standard. Some noted this absence, noting that proof "is the backbone of mathematics" (Wu, 1996 p. 1534), and after many "mathematicians objected to what they considered…an under emphasis on proof" (Kilpatrick, 2003, p. 1), the following *Principles and Standards for School Mathematics* (NCTM, 2000) included a more prominent role to mathematical proof across the grades through the more explicit Standard on "Reasoning and Proof." In spite of this greater emphasis on proof, some reports on individual states' mathematics content standards have shown either a lack of emphasis on proof and reasoning or vague descriptions of its use by students (Klein et al., 2005; Raimi & Braden, 1998; Reys et al., 2006). In 2010 yet a new set of standards is being put forth in the form of the *Common Core State Standards for Mathematics* (CCSSM) (CCSI, 2010b). These Standards uphold all of the NCTM Process Standards including Reasoning and Proof; they also underscore constructing and critiquing arguments as a mathematical practice for students to learn. Given past reports concerning the role of proof and reasoning in state content standards, and considering the implementation of this new set of standards across the nation, we argue that it is useful to examine both the emphasis and specification of proof and reasoning in the various states' content standards, as well as those of the CCSSM. We have chosen to focus on standards concerning High School Geometry both for the historical importance proof has taken in American Geometry curriculum (Herbst, 2002) and for the sake of clarity in comparisons of both proof and reasoning in standards across the U.S.

Theoretical Perspective

Content standards have been developed in the U.S. for at least a century (Porter, 1994), and since the publication of *A Nation at Risk* (NCEE, 1983), the pressure for standards has increased dramatically. Porter (1994) notes that the publication of the NCTMs' *Curriculum Standards for School Mathematics* (NCTM, 1989) spurred states into writing their own content standards In addition to NCTM, various organizations have focused on developing and examining standards, including the National Center on Education and the Economy (NCEE), Council for Basic Education (CBE), the Mid-continent Regional Laboratory (McRel), the Council for Chief State School Officers (CCSSO), the Thomas B. Fordham Foundation, and the American Federation of Teachers (AFT). These and other organizations provided specific standards, guidelines and/or evaluations of standards as various states continued to publish and edit their documents (Porter, 1994). Of particular interest for the current investigation are the evaluations that have been conducted of different state mathematics standards, as these will provide a frame of reference to both the historical development and evolution of such evaluations as well as the development of reasoning and proof in mathematics content standards, with specific focus on secondary Geometry.

The first evaluation of state standards was conducted by the AFT (Gandal, 1996): The report examined whether states were developing standards, how such standards were assessed and implemented, and the detail provided within the different standards. That report concluded that 30 states had sufficiently clear and specific mathematics standards. The organization's most recent report in 2001 concluded that 44 states had clear and specific mathematics standards (AFT, 2001). The CBE produced a similar finding in their 1998 report *Great Expectations?* (Joftus & Berman, 1998), suggesting that only three states (Alaska, Montana, and Nebraska) had a low level of rigor in their mathematics content standards. All of these reports have provided general descriptions of the mathematics standards and not details regarding specific topics, in particular, not specific accounts of the role of proof or mathematical reasoning in state standards.

In contrast, the Fordham Foundation sponsored a report on state mathematics standards that did provide detail on specific mathematics content. The first of these reports (Raimi & Braden, 1998) examined the standards of 46 states and the District of Columbia. Contrary to reports by AFT and CBE (Gandal, 1996; Joftus & Berman, 1998), Raimi and Braden (1998) found that many states were not providing clear or specific standards. Specifically when focusing on mathematical reasoning, the report cited only five states as having a sufficient degree of clarity and focus. Further, the report notes that only 17 states explicitly indicate that proof should be taught in mathematics. A more recent report by Klein et al. (2005), suggests that this trend has not changed much in that "the majority of states fail to incorporate mathematical reasoning directly into their content standards…many state documents do not ask students to know proofs of anything in particular. Few states expect students to see a proof of the Pythagorean Theorem or any other theorem or any collection of theorems" (p. 21).

While not focusing on High School Geometry, Reys et al. (2006) provide a similar and concurrent finding to Klein et al. (2005), stating that "reasoning is not well articulated or integrated across K-8 standards documents…most state standards fail to address reasoning aspects in a thorough and comprehensive manner across grade levels and content strands" (Reys et al., 2006, p. 9). Given that Reys et al. examined specific elements of mathematical content in a comparable manner to Klein et al., it appears that many state standards do not provide clear or specific standards on mathematical reasoning.

The reports thus far referenced provide two types of reports, those that paid specific attention to the way mathematics was described in standards (e.g., Klein et al., 2005; Reys et al., 2006) and those that did not (e.g., Gandal, 1996; Joftus & Berman, 1998). This breakdown generally describes the reports that appear most prominent in the literature. Further, there tends to be a general depiction of standards as 'mostly good' in earlier years, and 'mostly in need of improvement' in recent years. These criticisms added to the lack of commonalities have led to the development of the Common Core Standards.

The Common Core Standards

In June 2009, the National Governors Association (NGA) and the Council of Chief State School Officers (CCSSO) announced a new initiative to develop a common set of standards for mathematics and language arts. This initiative was called the Common Core Standards Initiative (CCSI), and included 46 states, the District of Columbia, and two U.S. territories (CCSI, 2010a). As of June 2, 2010, this total included two additional states and a working draft of the standards had been developed. The standards were developed to be "fewer, clearer, and higher" (CCSI, 2010b, p. 1) as compared to previous standards in many states. Among the criteria used in designing the standards are the NCTM process standards and the strands of mathematical proficiency from the National Research Council's report *Adding It Up* (Kilpatrick, Swafford, & Findell, 2001; see also CCSI, 2010b). Yet, numerous citations to various reports, assessments, and standards are cited as works consulted (see CCSI, 2010b for a full description). A review of the documents and descriptions of the Common Core Standards by CCSI suggest a specific focus on a number of topics that have surfaced in mathematics education, including mathematical modeling and quantitative literacy. Continued reference to reform-oriented documents and sources also convey the notion that the Common Core Standards are reform-oriented. Additionally, some organizations, such as NCTM "diligently monitored the development of CCSSM and advised NGA and CCSSO throughout the process" (p. ix, NCTM, 2010). Yet, CCSI (2010c) specifically states that the Common Core Standards are a set of expected learning goals for students and do not constitute a curriculum nor do they advocate specific materials or teaching practices to be used. This appears to be a different goal for designing content standards than some states have used, where content standards were written as documents intended to reform teaching more so than specify content (see Thompson, 2001 for a relevant description).

As is customary with newly published standards documents, a large amount of skepticism and criticism has been levied against CCSI. For example, Zhao (2009) stated that "the Common Core Standards Initiative or any such movement to create national standards risks America's future by destroying its traditional strengths in cultivating a diverse and creative citizenry" (p. 52). Tienken (2009) expressed concerns that the Common Core Standards would only serve to increase an 'achievement test drive mentality' in the U.S. Providing a more even-handed critique, Porter, McMaken, Hwang, and Yang (2010) compared the Common Core Standards to the state standards in place and found that "the common core does represent considerable change…" but are not "…more focused as some might have hoped" (p. 8). However, Porter et al.'s description of their analysis does not provide content-specific focus in regards to reasoning or proof. Therefore, it appears there is a need for a transparent and clear examination of the way that reasoning and proof are represented in the Common Core Standards as compared to the existing state standards.

A main objective of the CCSSM (2010b) is to provide mathematics standards that are clear, specific, and rigorous. According to some reports (Klein et al., 2005; Raimi & Braden, 1998) many of the states' standards the CCSSM will be replacing, however, have not provided clear or specific standards regarding proof or reasoning in High School Geometry. Yet, since Klein et al.'s (2005) depiction of proof and reasoning in various states' standards, many states have published revisions of their standards, and therefore may have provided more sufficiently clear and specific expectations of students regarding reasoning and proof. Additionally, there is currently no available examination of reasoning and proof in the High School Geometry standards in CCSSM. In this paper we provide a current and comparative account of the depiction of reasoning and proof in the CCSSM and various states for High School Geometry. In order to accomplish this goal, the following research questions will be examined:

1. To what extent do different state content standards describe reasoning or proof in association with specific mathematical content?
2. To what extent do different state content standards characterize reasoning or proof as processes engaged by students?
3. Is there a relationship between the extent to which reasoning or proof are characterized as processes that students engage in and the extent to which such reasoning and proof standards refer to specific mathematical content?

Methods

Standards documents from all 50 states were collected and coded for analysis. These documents were collected from the websites of each state's department of education. However, various states have different formats for organizing their standards in High School mathematics, such as by course, by grade band or benchmark, or by specific grade level. Given our focus on High School Geometry, it was decided that standards in the format of a course would have the Geometry course standards examined. For those states with benchmarks or grade level formats, the standards for the Geometry strand (or equivalent) was used for the full range of High School standards provided by each state. In some cases, advanced level standards were provided. To ensure a fair comparison, we examined only those standards expected of every student. In addition to taking into account varying format and structure, different states may represent the same content with a different number of standards. In other words, one state may say in one standard what another state says in three. This phenomenon was taken into account by recording the number of High School Geometry standards each state had, and using this number to calculate mean emphasis on reasoning and on proof.

As our focus was on the presence and emphasis of standards outlining mathematical reasoning and proof in Geometry, we examined the standards documents for the presence of standards that referred to these mathematical processes. For proof, standards were identified through the use of words such as proof(s), proving, or prove present in a standard's statement. Explicit use of these words was necessary for the standard to be counted as a "proof" standard, as this ensured that such a standard would be interpreted by those using the document in practice as referring to proof. A similar process was used for coding reasoning, by using words referring to logic as indicators of such standards. Words such as inductive, deductive, conjecture, logic, reason, and their cognates were used as indicators. Once standards were identified as being a proof and/or reasoning standard, they were coded for their specificity to which they referred to the mathematics concepts involved.

As noted by certain reports (e.g., Klein et al., 2005; Reys et al., 2006) many standards lacked a degree of specificity in descriptions of mathematical reasoning and proof. Rather, a state may provide a number of standards requiring that proof be taught, but may not specify what mathematical content should be associated with proof. Therefore, we developed three categorizations to distinguish the degree of content specificity in a standard. The first, low specification, is a standard that makes either no reference to a particular mathematical concept, or where such specification is vague, e.g., New York standard "*Write a proof arguing from a given hypothesis to a given conclusion.*" A standard with medium specification is a standard that makes reference to a set of mathematical concepts, but still lacks a degree of specificity, e.g., CCSSM standard "*Use congruence and similarity criteria for triangles to solve problems and to prove relationships in geometric figures.*" While this example indicates the action of proving relationships in the area of triangle congruence and similarity, the standard does not specify any theorems or specific properties. Standards coded as having high specification were standards that make reference to a set of mathematical concepts with specific identification of such concepts, e.g., Michigan standard "*Know a proof of the Pythagorean Theorem, and use the Pythagorean Theorem and its converse to solve multi-step problems.*" This example makes reference to a specific concept, the Pythagorean Theorem, rather than a category or set of concepts.

In addition to coding for concept specification, each standard was examined for transitivity. In Systemic Functional Linguistics (Halliday & Matthiessen, 2004) transitivity is a system of linguistic resources with which language supports the ideational metafunction (i.e., the way language represents the world). Transitivity permits to represent the world as sequences of processes involving participants and circumstances. Canonically, processes are realized by verbs and participants by nominal groups. To illustrate our analysis of transitivity note, for example, Delaware standard "*<u>Reason</u> deductively to justify a conclusion or to create a counter-example;*" this contains three verbs (reason, justify, create), but *reason* represents the transitive process associated with this standard. Similarly, in Delaware standard "*<u>Use</u> appropriate technologies to model geometric figures and to develop conjectures about them*" the verb *use* represents the transitive process for the standard. What interests us here is the difference between these two examples in the way that reasoning is expressed as an expectation of students. Whereas *to reason* is the actual process students are expected to engage in the first standard, the second standard expects students *to use* technologies in specific ways, one of which is reasoning. Reasoning in the second standard acts as what Halliday and Matthiessen (2004) would refer to as a participant in the clause. As can be noted in the two examples given, other verbs can represent transitive processes for clauses nested within the main clause (clause complex). To account for such use of proof and reasoning terms as transitive processes and/or participants, we ranked such usages of identified words and terms in regards to the degree to which they were a primary process.

The Pennsylvania standard "*<u>Write</u> formal **proofs** to <u>validate</u> **conjectures** or arguments*" contains the primary process of *to write*, which we coded as having a distance of zero from the primary process. *Proofs* is a participant in this clause, as is *to validate conjectures*. However, *proofs*, while not a primary process, is relatively closer to the primary process than *conjectures*. Therefore, we coded *proofs* as being a distance of one away from the primary process, and *conjectures* as a distance of two away from the primary process. In this way, we accounted for the semantic emphasis placed on proof and reasoning in various standards.

Results

The number of standards for High School Geometry varied dramatically from state to state, with some states having as few as 5 and others having as many as 74. The Common Core Standards included 42 individual standards for High School Geometry while the mean for states was 21.98 (SD = 15.47). This means that the Common Core Standards do indeed have more standards for Geometry than most states, although some states do have more.

Approximately 24% of the CCSSM Geometry standards (n = 10) featured proof while the average for states was 11.7% (SD = .118), indicating that CCSSM provided proportionally more standards featuring proof than the typical state document. The CCSSM had an average specificity score of 2.90 for proof standards while the mean specificity score for states' proof standards was 1.88 (SD = .59). This indicates that the CCSSM standards featuring proof tended to be more specific in regards to mathematics content than the typical state document. The CCSSM proof standards had an average transitivity distance of 0.10, while the average transitivity distance for the various states' standards featuring proof was 1.24 (SD = .60). This indicates that the CCSSM proof standards tended to treat proof as the primary transitive process while various states did not do so as consistently. Taken altogether, the CCSSM provide a greater emphasis on proof in their Geometry standards than the most current state standards, and also provides more specific and clear standards with a strong emphasis on the action of proof. While some states showed stronger tendencies on at least one of the three criteria (overall emphasis, specificity of content, transitivity distance), no state showed higher scores on more than one indicator. Some states did appear somewhat comparable to the CCSSM proof standards: California, Florida, Indiana, and Michigan. With the exception of these states, the CCSSM in proof for High School Geometry show clear and definitive improvement in specification and increase in focus.

While the CCSSM show an increased focus on and specification of proof in High School Geometry, this trend was not as evident when examining other forms of mathematical reasoning. The CCSSM emphasized logical reasoning in mathematics in 5% of their standards. While the mean for states was a 14% emphasis, there was a large degree of variance (SD = .14). However, the CCSSM Geometry standards that featured reasoning showed a transitivity distance of 1.00, while the average for varying states was 1.26 (SD = .42). Further, only two states had lower averages than the CCSSM regarding transitivity distance, indicating that the CCSSM was similar to many states in regards to specifying reasoning as the primary process in its standards. Additionally, the CCSSM appear to provide more specificity (M = 3.00) than did the typical state (M = 1.68, SD = .81) regarding mathematics content in standards featuring reasoning for High School Geometry. Overall, the descriptive statistics for High School Geometry standards featuring reasoning indicates that CCSSM provides fewer relative standards, but with more specificity and a slightly stronger emphasis on the act of reasoning.

Correlation analysis between standards' content specificity and transitivity distance indicated a strong and negative relationship for standards featuring proof ($\rho = -.42$, $p < .05$). This indicates that the closer the distance between proof and the transitive process, the more specific a standard tended to be regarding mathematics content. However, when examining the same relationship for standards featuring reasoning, virtually no relationship was found ($\rho = .00$, $p = .98$). This indicates that an excessive amount of variance is present in many of the states' content standards regarding the specification of mathematics content and the use of reasoning as a transitive process. Practically speaking, the correlation found for proof standards indicates that standards which describe proof as the primary process students are expected to engage in tend to also provide more specific connections to mathematics content, and vice versa. However, the near zero correlation found for the same relationship in reasoning standards indicates little consistency in the way reasoning is described in various High School Geometry standards across the nation.

Discussion

While many concerns have been expressed regarding the CCSSM (e.g., Porter et al., 2010; Tienken, 2009; Zao, 2009), the results presented here may give cause for some mindful consideration of potential benefits of the CCSSM in regards to reasoning and proof, at least as it concerns High School Geometry. The results presented here indicate that the CCSSM provide a greater emphasis on proof with more specificity to the content and a clearer representation of the process than the vast majority of states' standards. Further, while the CCSSM does not have, proportionally, as many High School Geometry standards featuring forms of reasoning other than proof, the standards tend to be more specific to the content and have a clearer representation of the process than the majority of states. Therefore, in regards to proof and reasoning in High School Geometry standards, the CCSSM appear to show an improvement over state standards in general.

By articulating specific aspects of mathematics content, the CCSSM provide a clearer message to what teachers are expected to have High School students prove and reason about. For example, the CCSSM provides a list of theorems for students to prove regarding triangles (e.g., base angels of isosceles triangles are congruent; the medians of a triangle meet at a point). The CCSSM do not indicate how teachers are expected to engage students in such proofs or in what format students should write those proofs. Teachers are provided not with a blanket expectation of having students “construct proofs about triangles” that might be met with token proof exercises whose conclusions are not memorable (Herbst, 2002); rather they are provided clear guidelines that tie proof practices to important content that students need to learn. As such, we consider this a general improvement over many of the state content standards currently in use.

Another aspect of the CCSSM High School Geometry standards featuring proof that we consider beneficial to both teachers and students is the predominate use of *prove* as the primary transitive process. With the exception of one out of ten standards featuring proof, the CCSSM are consistent in emphasizing proof as the primary process. The benefit of writing “*prove theorems about lines and angles*” rather than “*write proofs about lines and angles*” is the activity conveyed by one wording over the other. Many states use words such as *write*, *construct*, *know*, or *use* as the primary process for standards featuring proof, and this leads to potentially different interpretations of what students are expected to do. Do students memorize proofs when the primary process is *know*? Does their engagement in proof come in the form of writing when the primary process is *write*? While these questions are rhetorical, they demonstrate the bias that can come when using words other than *prove* as the primary process for standards concerning proof. As such, the CCSSM does not convey bias in the way students are expected to engage in proof, but only in the content they are expected to prove.

The results of the present study provide evidence in support of the adoption of the CCSSM in regards to High School Geometry standards featuring reasoning and proof. However, the present analysis is narrow in focus, and several other mathematical strands and grade levels might need to be examined in a similar manner to properly understand both the potential benefits and drawbacks of implementing CCSSM. For example, while the present results concerning proof standards were generally positive, the results concerning reasoning standards indicate a need to use reasoning as the primary transitive process in CCSSM.

The results of the current study do support the implementation of CCSSM in regards to High School Geometry standards featuring proof and reasoning, but our discussion and conclusions should not be taken as a wholesale endorsement of the CCSSM document. Rather, as specified, further examination of CCSSM is needed. Further, by examining specific aspects of the CCSSM document, rather than an overarching depiction of the document as a whole, we are better able to either validate or make recommendations for improvement out of a solid base of knowledge.

MATHEMATICAL KNOWLEDGE FOR TEACHING PROOF: EVIDENCE FROM AND IMPLICATIONS FOR PROFESSIONAL DEVELOPMENT

Kristin Lesseig
Washington State University Vancouver
kristin.lesseig@vancouver.wsu.edu

Research suggests that the enhanced role of proof in mathematics classrooms presented in current standards and reform policy poses great challenges for teachers and will require substantial teacher learning. However, to date there is little research detailing what mathematical knowledge might be useful for teaching proof or how professional development might afford such learning. This paper presents a framework for Mathematical Knowledge for Teaching Proof that couples research on justification and proof in mathematics and mathematics education with Ball and colleagues' (2008) conceptualization of Mathematical Knowledge for Teaching (MKT). An empirical study of teachers' proof-related activity in professional development demonstrates the utility of this framework and provides further insights into mathematical knowledge for teaching proof.

Few can dispute the increased attention that reasoning and proof have been afforded in mathematics education research and practice (Hanna & deVilliers, 2008; National Council of Teachers of Mathematics, 2009). Both NCTM (2009) and the Common Core State Standards (2010) recommend that all students learn to construct and evaluate mathematical arguments and demonstrate a variety of reasoning and proof techniques. More notably, these documents call for an enhanced notion of proof that elevates proof beyond a topic of study in advanced mathematics courses, to a tool for learning mathematics at all levels.

However, the research summarizing students' difficulties constructing proofs and their reliance on authority or empirical arguments to justify a general claim suggests that these recommendations are not easily accomplished (Harel & Sowder 2007; Healy & Hoyles, 2000). Similar research has shown that teachers often rely on ritualistic aspects of proof and fail to distinguish between non-proof arguments and valid deductive reasoning when both constructing and evaluating proofs (Martin & Harel, 1989; Knuth, 2002; Simon & Blume, 1996). Moreover, recent classroom studies show that teachers struggle to support students even when using a curriculum designed to promote reasoning and proof (Bieda, 2010). For example, teachers' methods of grouping and sequencing proof strategies or inability to follow up on students' ideas often inhibit students' ability to construct a valid proof (Martin & McCrone, 2003; Bieda, 2010). Other studies have linked teachers' methods of questioning and providing examples to students' development of authoritarian or empirical proof schemes (Harel & Rabin, 2010).

Clearly, supporting all students to learn about and engage in mathematical proof poses great challenges for teachers and will require substantial teacher learning. However, to date there is little research detailing what mathematical knowledge might be useful for teaching proof or how professional development might afford such learning.

Purpose

The purpose of the larger study was to detail Mathematical Knowledge for Teaching Proof (MKT for proof) and to investigate MKT for proof in professional development (PD). To advance the construct of mathematical knowledge for teaching proof, research on proof and mathematical knowledge for teaching was coordinated with an empirical study of teachers' engagement with proof in professional development. Specifically, the study aimed to address the following questions:

1. What does research suggest teachers need to know about proof and proving that would be useful for their work with students?
2. What mathematical knowledge for teaching proof is evidenced in professional development focused on justification and proof?

This paper describes how an initial framework for MKT for proof was developed based on an extensive literature review. A sample of findings from one segment of the larger investigation of teachers' proof activity in PD is then provided to further highlight elements within this knowledge framework.

Theoretical Considerations

Two ideas underlie the conceptualization of mathematical knowledge for teaching proof developed through this study: (i) an enhanced notion of proof as a means to support mathematical understanding at all levels and (ii) the important role of teachers' mathematical knowledge-in-use (knowledge accessed when engaging in acts of teaching) for considering a knowledge base for teaching.

Recognizing the critical importance of proof in learning mathematics, recent reform efforts call for proof to be a regular and ongoing part of students' K-12 mathematics experiences (NCTM, 2000). To support proof as a sense-making activity, there is a need for a definition that promotes a consistent meaning of proof throughout the grades. For this reason, Stylianides' (2007) definition of proof was adopted for this study. Put simply, proof refers to a mathematical argument that is based on accepted statements, valid modes of argumentation, and representations that are known by or are within the conceptual reach of the classroom community. Further, to identify and describe the mathematical knowledge teachers need to engage students in practices consistent with this reform-oriented view of proof, the entire range of activity associated with proving must be considered. These proving activities include identifying patterns, making conjectures, testing examples, and providing non-proof arguments, as well as constructing proofs.

Secondly, a situative perspective on learning informs both the conceptualization of mathematical knowledge for teaching proof and the ways in which it might be investigated in PD settings. This perspective takes seriously the ways in which mathematical knowledge is attuned to the specific demands of teaching (Adler & Davis, 2006). Defining mathematical knowledge for teaching proof thus involves consideration of what, when, and how knowledge is required and used to meet the demands of the classroom. Central to a situative perspective is the recognition that cognition is situated in particular contexts, social in nature, and distributed across the individual, other persons, and tools (Putnam & Borko, 2000). Accordingly, mathematical knowledge evidenced in interaction as teachers participated in proof-related activities was the focus of the qualitative analysis.

Methods

Developing MKT for Proof Framework

To develop a framework for MKT for proof, research on mathematical proof, students' difficulties with proof, and classroom studies of teaching practices related to proof were reviewed, coordinated and synthesized. Proof ideas drawn from the literature were categorized using four domains of MKT introduced by Ball and colleagues (2008). Tables 1 and 2 below provide a snapshot of elements included in this MKT for proof framework. Common Content

Knowledge (CCK), the subject matter knowledge held in common with others who use mathematics, includes the ability to construct a valid proof as well as common understandings of the nature of proof. Elements within CCK reflect essential proof knowledge and skills desired of students but also directly address findings that teachers often attend to the form of proof rather than substance and fail to see the generality in an argument (Dreyfus & Hadas, 1987; Martin & Harel, 1989).

For their work with students, teachers need more than CCK. Fundamental understandings of proof must be developed, "unpacked," and explicitly connected to the work of teaching. This Specialized Content Knowledge (SCK) is pure mathematical knowledge uniquely needed for teaching proof. While mathematicians may know how proofs depend on previously known definitions, to deal with issues that arise in the classroom, teachers also need to know a range of possible definitions and understand how an argument might look different depending on the definitions that are accepted. To guide their instruction, teachers also need to understand the relationship between the proving task and valid or efficient methods of proof such tasks evoke (Stylianides & Ball, 2008). Thus, knowing that a claim about a finite number of cases can be verified through a systematic list, but that a generic example or deductive argument would be needed to prove a more general claim would be considered SCK.

Table 1. Subject Matter Knowledge for Teaching Proof

Common Content Knowledge	**Specialized Content Knowledge**
Ability to construct valid proof Use definitions, theorems to build a logical progression of statements Analyze situations by cases & use counterexamples **Nature of Proof** *A theorem has no exceptions* *A proof must be general* The validity of a proof depends on its logic	**Explicit Understanding of Proof Components** •Accepted Statements: range of definitions or key theorems, role of language & defined terms •*Modes of Argumentation: recognize range of valid methods, distinguish between empirical and deductive arguments* •*Modes of Representation: variety of visual, symbolic, verbal methods to express general argument* **Relationship between proving tasks & activity**

Elements within pedagogical content knowledge arose from studies documenting students' typical responses when asked to produce or evaluate mathematical proofs as well as classroom studies that illustrated where proof instruction fell short. Although these studies did not specifically explore teachers' knowledge, inferences can be made regarding knowledge or resources teachers might have drawn upon to support students' understanding of proof. As indicated in table 2, Knowledge of Content and Students (KCS) includes detailed knowledge of students' thinking as well as attention to the proof-related resources available to students. Knowledge of Content and Teaching (KCT) intertwines knowledge of proof from the other domains with methods of representing or drawing out key proof ideas in classroom instruction. For example, knowing that students typically rely on authority or empirical justification (Harel & Sowder, 2007) guides instructional decisions and questions or examples teachers may use to encourage students' progression toward deductive arguments.

Clearly, no one idea within MKT for proof is unique, nor is this meant to be a comprehensive list of everything a teacher needs to know. However, this framework provides a rare synthesis of research and begins to detail the mathematical knowledge of proof that would be useful for teachers' work with students. As described next, delineating knowledge of proof in this way provided a common analytic tool to make sense of teachers' proof work across different professional development activities.

Table 2. Pedagogical Content Knowledge for Teaching Proof

Knowledge of Content and Students	Knowledge of Content and Teaching
Detailed knowledge of student thinking • Explicit knowledge of proof schemes • Recognizing characteristics of external, empirical, and deductive proof schemes • Students' tendency to rely on authority or empirical examples • *Progression from inductive to deductive proof* **Developmental aspects of proof** Ability to size up arguments in terms of: • Definitions & statements available to students • *Representations within students conceptual reach* • *Forms of argumentation appropriate for students' level*	**Relationship between instruction and proof schemes** **Questioning strategies** • To elicit justification beyond procedures • *To encourage thinking about general case* **Pivotal examples or counterexamples** • To extend, bridge or scaffold thinking • To focus on key proof ideas **Explicit knowledge of proof connections** • *Linking visual, symbolic or verbal proofs of same concept or theorem* • Comparing proofs in terms of accepted definitions and argument structure • *Lifting general argument from numerical example or specific diagram*

Investigating MKT for Proof in Professional Development

The empirical study used to test and refine this framework, drew upon an existing research project designed to support teacher leaders' understanding and facilitation of mathematically rich PD. Although teachers' knowledge of proof was not the central project purpose, the focus on generalizing patterns and number concepts and explicit attention to norms for justification and explanation made the project an ideal site to investigate MKT for proof. Within this project, K-12 teacher-leaders participated in either three or four two-day seminars during the school year. During these seminars, teachers worked on a number of mathematics tasks, analyzed videocases of PD sessions centered on the same mathematical tasks, and engaged in additional activities designed to connect these experiences to their own practice.

Given the goal of detailing MKT for proof, all math tasks, discussion prompts, video data logs, and seminar agendas were reviewed to select tasks in which teachers were asked to make conjectures, prove claims, and engage in explicit conversations about proof in the context of teaching. Two mathematical tasks, Consecutive Sums and Halving and Doubling, were selected. This paper reports on teachers' seminar work associated with the Halving and Doubling task. In particular, video data of two small groups and one whole group discussion for each of eight activities directly related to the Halving and Doubling task were analyzed. These activities included teachers 1) doing the math task; 2) viewing PD video to compare two teacher justifications; 3) viewing video to consider an additional conjecture 4) discussing MKT in relation to video; 5) revisiting video to consider facilitation of the task; 6) planning PD session using task; 7) discussing justification article (Lannin, 2005); 8) reflecting on their own PD enactment of task with colleagues.

Analysis

To address the second research question, what MKT for proof is evidenced in PD, all

Halving and Doubling video was reviewed to develop a coding scheme that would capture the nature of teachers' conversations in relation to proof. Initial coding indicated when teachers referred to visual or algebraic models, tested specific examples, explicitly used the terms "conjecture," "generalization," or "proof," as well as when discussions moved to student or teaching concerns. Studiocode (2010), a video analysis software, was used to facilitate the coding and analysis of each of the small group and whole group discussions. The data matrix features of Studiocode then allowed for both in-depth analysis of a proof topic as well as an indication of how and if this proof idea was evidenced across the range of seminar activities. For example, all instances of teachers using the word "proof" or attempting to understand a generic example could be gathered and viewed in succession to facilitate more focused coding. As patterns emerged from this analysis, integrative memos (Emerson, Fretz & Shaw, 1995) were written to summarize elements of proof consistent across teachers' discussion. It was only at this stage that proof ideas emerging from seminar activity were mapped back to the MKT framework.

Results

To illustrate this mapping, findings from analysis of teachers' seminar activity provided here are organized around the four domains of teacher knowledge: CCK, SCK, KCS, and KCT, within the MKT for proof framework. Elements in tables 1 and 2 corresponding to these reported findings have been italicized to further highlight the relationship between the teachers' proof activity within Halving and Doubling and categories of MKT for proof.

CCK: Nature of Proof

Teachers Recognized the Need for Proof to be General

Across all small and whole group conversations teachers used phrases that clearly related to the general nature of proof. Teachers recognized flaws in arguments that were based on a few specific cases or did not explicitly demonstrate that the conjecture was valid for *any* numbers. When evaluating ways of verifying the conjecture, comments such as the following were typical:

> "I like the algebraic model that you came up with and then also the area model because you can show that for *any* string of numbers if you half it and then add to the end - that is essentially what you are doing" (sg1 – doing math)
>
> "In the rectangle the use of a and b *is an attempt to generalize* and regardless of what it looks like visually, the a and the b represent variables and therefore *any case*." (wg - comparing videocase teacher work)

Teachers both pressed for generalization in their own mathematical work and recognized attempts the teachers in the PD videocase made toward presenting general arguments.

SCK: Explicit Understanding of Proof Components

Teachers Connected a Variety of Visual, Symbolic, and Verbal Methods Used to Express Argument

Teachers went beyond noting that a proof must be general to explore a variety of visual, symbolic, and verbal methods. In their own mathematical work small groups explored the problem through the use of numerical tables, array models, and algebraic expressions. More importantly, as illustrated in the two previous quotes, teachers considered how those representations could be used to express a general argument. As teachers continued to evaluate and connect various methods of verifying the conjecture, they grappled with ways in which a visual diagram might move beyond a specific case to provide a generic example or connect to an algebraic proof. Discussions such as the ones prompted by the teacher comments below firmly situated teachers in the realm of SCK for proof.

> "I don't know that your method lends itself to an algebraic proof or justification because it is only showing concrete, discrete numbers its not showing me how I would connect a variable standing for any number…
> So what would we need to add to my model, my proof to meet that criteria?" (sg2 – role playing after video viewing)

KCS: Developmental Aspects of Proof

Acceptable Proof Depends on Forms of Argumentation and Representations Appropriate to Grade Level

In both teachers' discussions and actions it was evident that when considering what might be an acceptable proof of the Halving and Doubling conjecture, teachers considered what knowledge and skills students at a given grade level typically possess. Teachers made explicit statements that what constitutes a proof might depend on the grade level you were teaching and "where your students are at." In terms of representations, teachers asked questions about whether students had a grasp of variable, or were comfortable with area or array models to represent multiplication. And in considering forms of argumentation that might be accessible to students, teachers acknowledged students' ability to see generality in the array diagrams but wondered if elementary students would be capable of constructing a deductive argument.

KCT: Explicit Knowledge of Proof Connections

Teachers Discuss Scaffolding from Examples or Visual Proof to Symbolic Representations by Capitalizing on a Key Idea or Generality

When discussing representations and forms of argument students may or may not understand, teachers often described specific teaching strategies they may employ. For example, in this statement below, a teacher is imagining how he might lead a class discussion of the problem by exploring patterns across numerical examples and then moving students toward the use of variables to make a more general argument:

> "I might bring up multiple examples, then say 'what I'm hearing you say is no matter what numbers we use, the operation stays the same so let's put a letter in'" (sg1 - doing the math)

Teachers further explored ways in which visual array or area models might be introduced to make connections between a specific example and a more general argument using variables. Importantly, teachers were able to bring out key mathematical ideas underlying the generalization (reciprocal properties, conservation of area, commutativity, etc.) when suggesting strategies to move students from example-based proofs toward more general arguments.

Discussion

Two findings from the Halving and Doubling teacher discussions in particular shed light on previous research regarding teachers' understanding of proof and what MKT for proof might entail. First, it is worth repeating that although teachers recognized essential features of a valid proof, this was not always evidenced in their acceptance of a proof. For example, as highlighted earlier, teachers made clear statements that proof must be general. It must work for *any* number and testing only specific numbers was not enough to prove the general claim. And yet teachers also discussed how in 3rd grade, it might be okay to use specific numbers in an array diagram, or how they might begin instruction by having students look for patterns in a table. Or, teachers might follow up on a valid general argument by asking how it would work for fractions, odd numbers, or negative numbers. In other words, while empirical justification clearly was not enough proof, teachers saw pedagogical value in posing questions about different classes of numbers or in exploring visual representations. As teachers, they saw the value of testing examples or using specific visual representations for helping students make sense of the mathematics involved and providing a foundation for algebraic proof. This finding makes us step back and reconsider the research on what teachers “understand” about proof. While previous research has suggested that teachers fail to recognize the generality of proof, here we see a sophisticated understanding of generality that is clearly tied to the context of teachers' work.

A second, and closely related finding, is that teachers moved fluently across the four domains of knowledge. Teacher talk within all eight seminar activities took up multiple dimensions of the MKT for proof framework. Interjections about what representations students have access to or what numbers to use in examples were intermingled with explanations of teachers' own proof constructions. Teachers' genuine questions about generic examples or the difference between inductive and deductive reasoning led directly to issues of students and of teaching. This finding further highlights the situated nature of teachers' knowledge and calls to question PD models focusing on either mathematics or pedagogy. As discussed next, this has implications for how the mathematics education field might begin to detail, research, and develop MKT.

Implications

First and foremost, this study contributes to the growing research on teacher knowledge by detailing critical aspects of mathematical knowledge of proof that support teachers' work with students. Recent research addressing teacher learning has identified *mathematical knowledge for teaching* as a key construct in teacher education (Ball, Lubienski & Mewborn, 2001). However, most attempts to specify mathematical knowledge for teaching have focused on elementary content. This investigation extends the work to mathematical knowledge useful for promoting proof, a key mathematical practice, K-12.

Further, this research provides a common framework for analyzing MKT for proof in both classroom and PD settings. The framework supports research on the teaching of proof by serving as an analytic tool to identify mathematical resources teachers access as they engage students in proof activity. The framework can also be used to make sense of teachers' proof-related activity in PD by connecting specific teacher activity such as constructing proofs versus comparing proofs presented in a videocase to the domains of teacher knowledge evidenced in discussions. This work supports further research on what “effective” PD to develop teachers MKT for proof might entail.

Finally, the findings related to teachers' fluent movement across knowledge domains help advance theory about the complex relationship between subject matter and pedagogical content knowledge. Investigation of conversations in which teachers move fluidly from talking about the mathematical ideas embedded in a proof to thinking about students and teaching can help the field better understand those connections between the four domains of knowledge - CCK, SCK, KCS, and KCT. This close relationship has implications for both researching and designing activities that might support teachers' development of MKT.

REASONING-AND-PROVING IN GEOMETRY TEXTBOOKS: WHAT IS BEING PROVED?[1]

Samuel Otten	Nicholas J. Gilbertson	Lorraine M. Males	D. Lee Clark
Michigan State University	Michigan State University	Michigan State University	Michigan State University
ottensam@msu.edu	gilbe197@msu.edu	maleslor@msu.edu	clarkd40@msu.edu

As calls are made for reasoning-and-proving to permeate school mathematics, several textbook analyses have been conducted to identify reasoning-and-proving opportunities outside of high-school geometry. This study looked within geometry, examining six geometry textbooks and characterizing not only the justifications given and the reasoning-and-proving activities expected of students but also the nature of the mathematical statements around which reasoning-and-proving takes place. The majority of reasoning-and-proving exercises focused on particular mathematical statements, whereas the majority of expository mathematical statements were general in nature. Although reasoning-and-proving opportunities were numerous, it remained rare for reasoning-and-proving to be made an explicit object of reflection.

Background

Mathematicians and mathematics educators are calling for reasoning-and-proving[2] to become a central component of the mathematical experiences of students (Hanna, 2000; Stylianou, Blanton, & Knuth, 2009). One argument behind this call is that reasoning-and-proving is integral to the discipline of mathematics and thus an essential piece of an "intellectually honest" (Bruner, 1960) mathematics education. Such a perspective is reflected in the mathematical practices of the *Common Core State Standards for Mathematics* (2010), which include abstract reasoning, the construction of viable arguments, and the critique of others' reasoning. Another argument for the inclusion of reasoning-and-proving throughout the school mathematics curriculum is that, by reasoning through and proving mathematical results, students can develop deeper conceptual understanding of mathematical ideas as well as greater procedural fluency (de Villiers, 1995; Dreyfus, 1999; National Council of Teachers of Mathematics, 2009).

In the United States, however, reasoning-and-proving has not been ubiquitous in school mathematics but has traditionally been confined to a single geometry course in high school (Herbst, 2002). To document this current landscape and to prepare the way for a more comprehensive treatment of reasoning-and-proving, researchers have recently been studying the opportunities that exist for reasoning-and-proving in curriculum materials other than geometry. Kristen Bieda (personal communication, January 18, 2011) is in the process of coding a variety of elementary-level textbooks and Stylianides (2009) has examined an NSF-funded middle school series. At the high-school level, Davis (2010) explored an integrated textbook series and Senk, Thompson, and Johnson (2008) analyzed non-geometry courses, such as algebra, advanced algebra, and precalculus, from six different textbook series. Davis found that 12% of the problems in a particular integrated textbook related to reasoning-and-proving. Senk and her colleagues found this number to be only 6% in the textbooks they analyzed, even though their analysis focused on the chapters where reasoning-and-proving seemed most likely to occur. Senk, Thompson, and Johnson noted that the exposition sections of non-geometry textbooks gave more attention to reasoning-and-proving than the exercises; nevertheless, 40–50% of the stated mathematical properties were left unjustified.

In this study we contribute to the efforts described above by characterizing the nature of reasoning-and-proving opportunities in geometry textbooks themselves. Although we agree with the premise that it is important to understand the current state of reasoning-and-proving outside of geometry as efforts are undertaken to integrate reasoning-and-proving into those domains, we would add that it is equally important to understand reasoning-and-proving opportunities in geometry, where they are most plentiful. In other words, we should strive to understand and reflect upon the way we are handling reasoning-and-proving in geometry so that we may inform the process of expanding it to other courses and grade levels.

Analytic Framework

All of the curriculum analyses cited above have focused on the types of reasoning-and-proving activities that students are expected to perform, presenting data on how often students are asked to notice patterns, make conjectures, test conjectures, or develop arguments. Although many of the documented difficulties that students have with reasoning-and-proving (see Harel & Sowder, 2007, for a review) may be attributed to insufficient opportunity to engage in such practices, it also seems to be the case that students have fundamental misunderstandings of reasoning-and-proving, even after significant exposure. For example, Chazan (1993) found that some geometry students do not understand what has been proven by a deductive argument. Soucy McCrone and Martin (2009) reported on students, also from geometry, who viewed the purpose of proof to be the mere application of recently learned theorems, similar to the way in which recently learned formulas are applied in subsequent student exercises.

We employ the necessity principle as an interpretive frame to make sense of these phenomena and to guide our analysis. The *necessity principle* (Harel & Tall, 1989) is a standard for pedagogy that involves presenting subject matter in a way that encourages learners to see its intellectual necessity, "[f]or if students do not see the rationale for an idea, the idea would seem to them as being evoked arbitrarily; it does not become a concept *of the students*" (p. 41). The fact that many students do not understand the role of reasoning-and-proving in mathematics and view it as being required of them arbitrarily (Tinto, 1988) is evidence that the necessity principle is being violated with respect to reasoning-and-proving. Furthermore, the well-documented overreliance on empirical forms of argumentation (Harel & Sowder, 2007) suggests at least two possibilities: (a) students do not recognize the limitations of empirical reasoning or the intellectual necessity of deductive reasoning, or (b) students recognize the need for deduction but lack the resources or capabilities to successfully develop such arguments and so give an empirical argument rather than leave an item blank. If the latter is the case, then it is important to continue examining the opportunities that exist for students to engage in various reasoning-and-proving activities. But if it is the former, we must push further and consider whether or not those reasoning-and-proving activities are necessitating deductive reasoning.

With these considerations in mind, we developed our analytic framework by building upon past frameworks (particularly Senk et al., 2008) with the addition of a dimension for the mathematical statement around which the reasoning-and-proving activities are taking place. In particular, we distinguish between general and particular mathematical statements (see Figure 1). Our rationale is that general statements intellectually necessitate deductive forms of reasoning because empirical means cannot establish truth for an infinite class of objects. Thus, having students engage in reasoning-and-proving around general mathematical claims has the potential to better satisfy the necessity principle than particular mathematical claims. (This also happens to better align with the disciplinary practices of mathematicians.) We do not mean to imply that all reasoning-and-proving opportunities should be around general statements or that there is no benefit to exercises of a particular nature; we are simply arguing for the value of including this dimension when examining reasoning-and-proving opportunities in textbooks.

Type of Statement	Definition	Examples
General	A statement made about an infinite class of mathematical objects or an infinite number of mathematical situations.	(1) All isosceles triangles have congruent base angles. (2) Any lines l and m that are perpendicular to the same line n are parallel to one another. (3) Let a, b, and c be natural numbers. Then $a^{b+c} = a^b \cdot a^c$.
Particular	A statement made about a single or finite number of mathematical objects or situations. Note: A particular statement may be easily translated into a general statement, as in (2) to the right which may be reinterpreted as a statement about any such overlapping segments. This awareness of generality is non-trivial, however, and thus statements such as (2) remain categorized as particular.	(1) In the given diagram, angle *ABC* has a measure of 65 degrees.  (2) If $PR = QS$, then $PQ = RS$.  (3) If $2x+y=10$ and $y=4$, then $x=3$.

Figure 1. General and particular mathematical statements.

Method

This study focused solely on stand-alone high-school geometry textbooks and so did not include analysis of geometry units within integrated textbooks. The six textbooks included in our analysis were *CME Geometry* (CME Project, 2009), Glencoe McGraw-Hill *Geometry* (Carter, Cuevas, Day, Malloy, & Cummins, 2010), Holt McDougal *Geometry* (Burger et al., 2011), Key Curriculum *Discovering Geometry* (Serra, 2008), Prentice Hall *Geometry* (Bass, Charles, Hall, Johnson, & Kennedy, 2009), and UCSMP *Geometry* (Benson et al., 2009). These were chosen to overlap series as much as possible with previous analyses (i.e., Senk, Thompson, & Johnson, 2008) so that comparisons would be possible. The six included series together span nearly 90% of the U.S. high school population (Dossey, Halvorsen, & Soucy McCrone, 2008).

Within each chapter of the six student edition textbooks, we randomly selected for analysis a minimum of 30% of the canonical sections (i.e., not special exploration or technology investigation sections). Additionally, chapter review exercises were coded for each chapter as a representation of the textbook authors' own identification of key ideas. This process resulted in an actual sampling of 44% of sections across the textbooks, totaling 285 sections and 12,468 exercises. Within the sampled sections, both exposition and student exercises were coded by the authors using the framework in Figure 2. Double-coding was performed on a 20% sample of the included sections yielding 95% agreement on statement-type and 91% agreement on justification-type within exposition sections, and 92% agreement on statement-type and 93% agreement on activity-type within student exercises.

	Exposition	Student Exercises	
	Properties, Theorems, or Claims	Related to Mathematical Claims	Related to Mathematical Arguments
Mathematical Statement or Situation	• General • Particular	• General • Particular • General with particular instantiation provided	• General • Particular • General with particular instantiation provided

Figure 2. An analytic framework for reasoning-and-proving in geometry textbooks.

Results

As shown in Table 1, student exercises involving reasoning-and-proving were much more prevalent in geometry textbooks than in even the most reasoning-and-proving focused units of non-geometry or integrated high-school textbooks. CME contained the most reasoning-and-proving exercises with nearly 38% falling into at least one of the reasoning-and-proving activity categories from Figure 2. The other geometry textbooks ranged from approximately 20% to 27% of exercises related to reasoning-and-proving.

Table 1. Percent of student exercises involving reasoning-and-proving.

Textbook Series	Geometry		Non-Geometry	
	No. of Exercises Analyzed	Reasoning-and-Proving (%)	No. of Exercises Analyzed	Reasoning-and-Proving (%)
CME	1058	37.8	--	--
Glencoe	2730	24.3	2117[a]	3.7[a]
Holt	2531	23.6	2042[a]	3.7[a]
Key Curriculum	1489	26.7	916[a]	8.0[a]
Prentice Hall	2479	19.5	2446[a]	5.6[a]
UCSMP	2181	27.6	1739[a]	6.2[a]
Core Plus	--	--	1114[b]	12.3[b]

[a] Senk, Thompson, & Johnson (2008).
[b] Davis (2010) differed from the other studies in this table by including patterns as reasoning-and-proving.

The types of reasoning-and-proving activities expected of students are presented in Table 2. In four of the books, 13–15% of the reasoning-and-proving exercises (or 3–5% of the total exercises) involved students *developing a mathematical proof*. In two books, CME and Glencoe, such items comprised 25% and 28%, respectively (or approximately 7% of the total). The most common reasoning-and-proving activities were to *investigate a statement* (i.e., determine the truth-value of a mathematical claim) and to *develop a rationale* (i.e., to explain or justify an answer or result in a manner that is not necessarily a proof).

Table 2. Nature of reasoning-and-proving activities expected of students.

Textbook Series	Type of Activity by No. of Reasoning-and-Proving Items (%)					
	Develop a Proof	Develop a Rationale	Find a Counter-example	Investigate a Statement	Make a Conjecture	Other
CME	25	36	7	45	16	3
Glencoe	28	48	4	30	17	5
Holt	13	42	4	39	8	16
Key Curriculum	13	52	26	42	20	6
Prentice Hall	15	54	1	46	19	11
UCSMP	14	44	3	36	14	5

Note: Rows sum to more than 100% because exercises often involved more than one activity. "Other" includes fill-in-the-blanks of a proof, provide or argue from a proof outline, and evaluate a given proof.

Table 2 does not answer the question, what sorts of mathematical claims do students have opportunities to reason about or prove? Figure 3 depicts the percentages of reasoning-and-proving exercises that involved a *general mathematical statement*. This graph excludes general statements for which a particular instantiation was provided to the student, because in such cases the student may reason about the given object as they would any particular object without realizing the general implications (as was found by Chazan, 1993). Figure 3 compares the percentages of general statements in exercises with the percentages in textbook exposition.

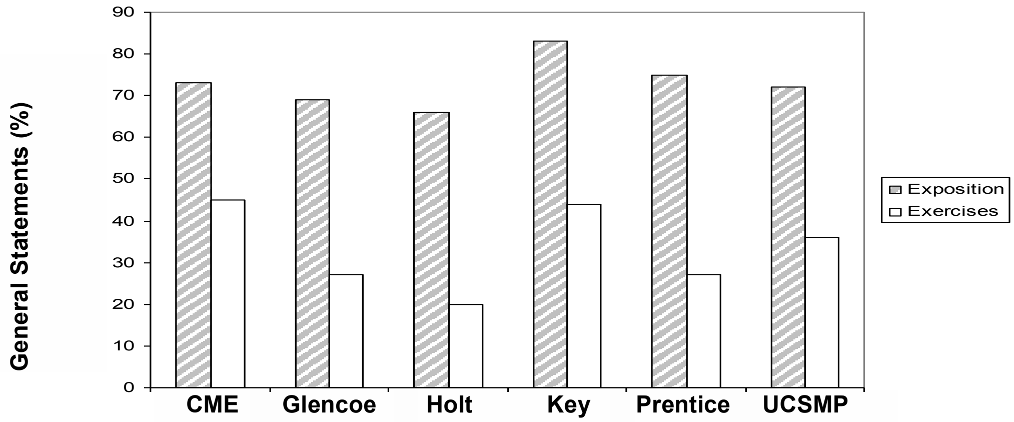

Figure 3. Nature of mathematical statements in exposition versus student exercises.

Most reasoning-and-proving exercises involved particular mathematical statements. In Glencoe, Holt, and Prentice Hall, approximately two-thirds of the reasoning-and-proving exercises were of a particular nature. In UCSMP, the number is 58%. CME and Key Curriculum had lower percentages of particular-type exercises—52% and 48%, respectively—but even in these textbooks, general statements were used in less than half of the reasoning-and-proving exercises. In textbook exposition, on the other hand, at least 66% of the statements containing a mathematical claim or result were of a general nature, with most textbooks falling above 70% (see Figure 3). Expository statements of a particular nature were especially infrequent in Key Curriculum and UCSMP, but were noticeably present in Glencoe (26%), Holt (24%), and Prentice Hall (20%). These particular statements that did appear in the exposition were almost always in the form of "worked examples." From this perspective, particular statements essentially appeared in exposition only when the textbook authors were modeling the behavior of students, for whom reasoning-and-proving exercises around particular statements are common.

Finally, we note results with respect to statements and exercises *about* reasoning-and-proving (see Table 3). For example, an exposition section may note that a deductive argument builds upon definitions or previously proved theorems, or an exercise may ask a student to write about the process of proof by contradiction. Within the 285 coded sections (out of 653 total sections), there were only 98 statements that made reasoning-and-proving an explicit object of reflection, and nearly half of these were found in a single book, UCSMP. Of the 12,468 coded exercises, only 67 asked students *about* the reasoning-and-proving process (as opposed to asking them to engage in that process). Therefore, although we saw in Table 1 that reasoning-and-proving is relatively common in geometry textbooks, opportunities are rare even in geometry to step out of the process and reflect on the core mathematical practice of reasoning-and-proving.

Table 3. Reasoning-and-proving not as an activity but as an object of discussion or reflection.

Textbook Series	No. of Statements *about* Reasoning-and-Proving	No. of Exercises *about* Reasoning-and-Proving	Percent of Total Exercises Analyzed
CME	13	4	0.38
Glencoe	8	17	0.62
Holt	15	17	0.67
Key Curriculum	14	13	0.87
Prentice Hall	7	2	0.08
UCSMP	41	14	0.64

Discussion

In this paper, we have presented top-level results of an investigation of the reasoning-and-proving opportunities in six different high-school geometry textbooks. Even in geometry, the traditional home of reasoning-and-proving, students were asked to develop a mathematical proof in less than 7% of the textbook exercises, and statements or questions about reasoning-and-proving as a mathematical practice were rare. The most common reasoning-and-proving activities were to provide a rationale (not necessarily a proof) and to determine the truth-value of a mathematical claim. Interestingly, students were expected to make judgments about truth much more frequently than they were expected to provide deductive arguments—the disciplinary process by which truth is established. With respect to the prominence of rationale exercises, one might contend that an "explain" prompt provides students with an opportunity to develop a proof because a key function of mathematical proofs is explanation (de Villiers, 1995). However, the question remains: Do students realize that a proof would be an effective response to an "explain" exercise? Answering this question would take us beyond the realm of textbook analysis.

The necessity principle (Harel & Tall, 1989) implies that it would be beneficial to help students recognize the intellectual need for deductive forms of reasoning by, for example, providing them with opportunities to reason around general mathematical claims for which empirical arguments falter. Our analysis has revealed that the majority of reasoning-and-proving exercises in geometry textbooks are around particular, not general, mathematical statements. In exposition sections, on the other hand, the majority of mathematical statements are general in nature. This discrepancy may shed light on such phenomena as geometry students believing that proof is merely an application of recently learned theorems (Soucy McCrone & Martin, 2009), because indeed students are applying the theorems presented in exposition sections to prove things about contrived, particular situations, or geometry students believing that mathematical knowledge is created by others and not themselves (Schoenfeld, 1988), because indeed the most significant mathematical results are general in nature and likely found in textbook exposition.

Pursuing these potential connections requires further research, and one might be skeptical of the merits of this course of study. Perhaps it is necessary for key results to be explicated in exposition sections so that they may be officially established in the classroom canon. Moreover, one could argue that it is necessary to provide students with numerous particular statements to prove because practice is essential and there are not enough relevant general statements to allow for this practice. In response to these points, we would again cite the research literature which shows that the status quo of reasoning-and-proving in geometry is not producing the student outcomes the mathematics education community hopes to see. Yes, it is important to establish important results into a collective space, but it is also important to reflect upon how the process of establishing those results may influence students' notions of who is capable of generating mathematical knowledge. Yes, it is important to allow students to practice reasoning-and-proving, but it is also important to consider whether the nature of the practice we afford them aligns with actual mathematical practice. In the end, our goal is for students to have success with reasoning-and-proving but also to see its intellectual necessity and value.

Endnotes

1. This work was supported by a grant from the College of Natural Science at Michigan State University. We thank Kristen Bieda and Sharon Senk for their insightful feedback.
2. We join Stylianides (2009) in hyphenating reasoning-and-proving to emphasize the inseparability of the reasoning process that leads to a proof and the resulting proof product.

USING CONCEPTUAL BLENDING TO ANALYZE STUDENT PROVING

Michelle Zandieh
Arizona State University
zandieh@asu.edu

Kyeong Hah Roh
Arizona State University

Jessica Knapp
Pima Community College

We explore ways that university students handle proving statements that have the overall structure of a conditional implies a conditional, i.e., $(p \rightarrow q) \Rightarrow (r \rightarrow s)$. We structure our analysis using the theory of conceptual blending. We find conceptual blending useful for describing the creation of powerful new ideas necessary for proof construction as well as for describing the creation of blends that slow or hinder student efforts at proof construction.

Introduction

The purpose of this paper is to illustrate the power of the theory of conceptual blending to clarify issues that students have in proving statements having the overall structure of a conditional implies a conditional, i.e., $(p \rightarrow q) \Rightarrow (r \rightarrow s)$. This logical structure occurs often in statements to be proven at the university level. For example, since the definition of A is a subset of B ($A \subseteq B$) is a conditional statement ($x \in A$ implies $x \in B$), then a simple set theory statement such as "If $A \subseteq B$, then $A \cup B \subseteq B$" has this logical form.

The research literature indicates that students' misunderstanding of logical rules and misinterpretation of logical statements result in their difficulty with structuring their proofs (Brown, 2003; Duran-Guerrier, 2003; Harel, 2001; Roh, 2010; Selden & Selden, 1995). Students tend to structure their proofs in terms of the chronological order of their thought processes instead of rearranging it with careful consideration of proper implications (Dreyfus, 1999). The literature also shows that students are often unable to bring useful syntactic knowledge to mind. Such knowledge includes formal definitions (Knapp, 2006) as well as theorems and properties (Weber & Alcock, 2004) of the mathematical concepts. Likewise, research calls attention to various forms of personal knowledge of mathematical concepts. Such knowledge is internally meaningful to an individual student (Pinto & Tall, 2002; Vinner, 1991), and helps a student recall conceptual ideas to apply when attempting to construct a proof (Knapp & Roh, 2008). Because of its private and informal nature, students' personal knowledge is often insufficient for them to know how to get started on a proof (Moore, 1994). Raman (2003) suggested the *key idea* as a means of connecting personal intuitive ideas and procedural knowledge when constructing a proof. When students possess a key idea for a proof, it gives them conviction and the basis for the formal mathematical proof.

Theoretical Background: Conceptual Blending

Fauconnier and Turner (2002) posit conceptual blending as a powerful unifying theory to describe how people think across multiple domains. They argue that blending "makes possible … diverse human accomplishments … [in] language, art, religion, [and] science [as well as being] indispensable for basic everyday thought" (p. vi). This theory has begun to be used to describe student understanding of mathematical concepts (Gerson & Walter, 2008; Megowan & Zandieh, 2005; Núñez, 2005). In this section we give a brief example describing three of the main mechanisms of the theory of conceptual blending.

Conceptual blending is a subconscious process that entails the blending of two or more mental spaces (inputs) to form a new stable conceptual model for use in reasoning (See Figure 1). A mental space consists of an array of elements and their relationships to one another, being activated as a single unit. Two (or more) mental spaces are activated and crucial elements of each are integrated and *mapped* to a third space to form a blended space. As part of *completing* the blend, a conceptual frame may be recruited to help organize the information in the blend. Once the blend is complete it can be manipulated to make inferences or answer questions. This manipulation is referred to as *running* the blend. The blended concept is treated as a simulation that can be run imaginatively according to principles and properties that the input spaces bring to the blend.

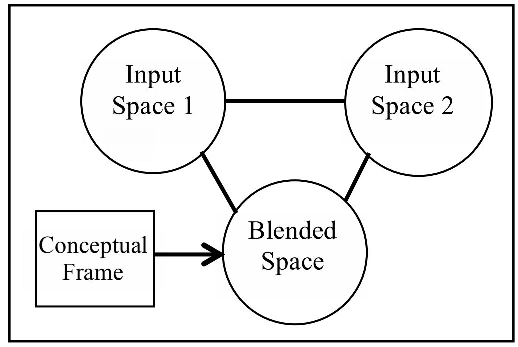

Figure 1. Generic blending diagram

For example Coulson and Oakley (2001) consider the nursery rhyme "the cow jumps over the moon." Children easily comprehend this statement by blending an input space of animals which includes cows, a second input space for the moon and sky, and a conceptual frame of jumping. In the blended space the cow is mapped to the thing that jumps and the moon is mapped to an object which is jumped over. Whereas children easily construct this blend, adults might have to inhibit their notions of reality and instead bring to bear a "nursery rhyme" frame which allows them to think of real things, the cow and moon, in impossible situations. Running the blend might include imagining the cow taking off from the ground, being over the moon, and landing on the ground on the other side of the moon.

Methods and Setting

The data for this study was originally collected as part of a semester long teaching experiment (Cobb, 2000) in an upper division geometry course at a university in the USA. Data consisted of videotape recordings of each 75 minute class session as well as copies of student written work. For the purpose of this paper we chose to analyze one day of class where we recognized something powerful was happening with student reasoning. Maher and Martino (1996) refer to such occasions as "critical events." The class period consisted of a brief introduction of the problem by the teacher (the first author), followed by small group work on the problem and whole class discussion. For the purpose of this paper we focus on the small group consisting of students we call Andrea, Nate, Paul and Stacey. The curriculum consisted of a series of activities in which students would need to define, conjecture, and prove results in geometry on the plane and the sphere (Henderson, 2001). This study focuses on one day late in the semester in which students were asked to prove either Euclid's Fifth Postulate (EFP) implies Playfair's Parallel Postulate (PPP) or PPP implies EFP.

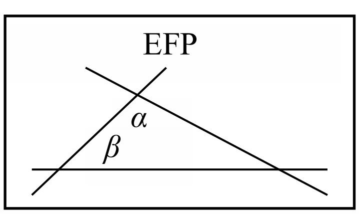

Figure 2. Euclid's Fifth Postulate

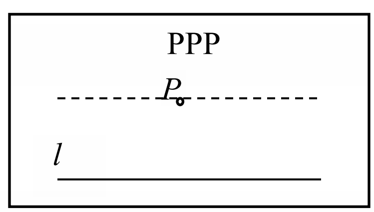

Figure 3. Playfair's Parallel Postulate

Henderson (2001) states EFP as, "If a straight line intersecting two straight lines makes the interior angles on the same side less than two right angles, then the two lines (if extended indefinitely) will meet on that side on which are the angles less than two right angles," (p. 123) and PPP as, "For every line *l* and every point *P* not on *l,* there is a unique line *l'* which passes through *P* and does not intersect (is parallel to) *l*" (p. 124). The instructor told the students that the two postulates are equivalent and gave them the option to "*use*" EFP in order to prove PPP or vice versa. In her introduction of the task the instructor drew the two figures shown (see Figure 2 and Figure 3) while explaining each of the postulates. The instructor's initial drawing showed only the part of the statement that was given. For example, for the PPP picture (see Figure 3), she initially just drew the bottom line, *l*, and a point, *P*, not on that line. However, when she explained the conclusion of each statement she completed the picture and these completed pictures were left on the board for students to reference. A second visual reference was available to students. The two pictures in the book for these two statements were also completed pictures similar to what the teacher had drawn.

Results and Analysis

In our first pass through the data, we noticed that elements of conceptual blending occurred both in students structuring of their proof and in their combining of the pictures and statements of EFP and PPP. We then read through the data looking to specify what blends the students were creating. We noticed the students were creating three types of blends: structural, geometric, and a combination of the two. We also noticed that the same blends occurred whether students were attempting to prove EFP implies PPP or PPP implies EFP. To better illuminate when each blend occurred in the data, each of the authors color coded a portion of the data and then all three authors came to a consensus on the coding for each of the following aspects:

- How students were blending the pictures associated with EFP and PPP: the key geometric blend (KGB) used by most students or Stacey's geometric blend (SGB).
- The logical construct that the students were using to frame their proof: a simple proving frame (SPF) or a conditional implies conditional proving frame (CICF).
- The direction of the proof: EFP implies PPP (EtoP) or PPP implies EFP (PtoE).

As we coded the data it became clear that there were four combined blends each of which could be described as an episode. In Figure 4 we summarize the evolution of student thinking through the four episodes, highlighting the three aspects of the combined blend: a structural blend (SPF or CICF), a geometric blend (KGB or SGB) and the direction of the implication (EtoP or PtoE). In addition to the main blend, we note a secondary blend if there were contrasting remarks or questions from other students during the episode that seemed to refer to a different combined blend.

Episode		*Main Blend*				*Secondary Blend*			
	Time	*Structure*	*Direction*	*Geometry*	*Presenter*	*Structure*	*Direction*	*Geometry*	*Presenter*
E1	9:00-	SPF	EtoP	KGB	Paul	CICF	EtoP	KGB	Nate
E2	15:13-	SPF	EtoP	SGB	Stacey				
E3	17:48-	SPF	PtoE	KGB	Andrea	CICF	EtoP	KGB	Nate
E4	24:38-	CICF	EtoP	KGB	Nate	SPF	EtoP	KGB	Paul

Figure 4: Summary of the progression of student proving ideas.

As illustrated in Figure 4, we found conceptual blending useful for describing the evolution of student thinking while proving. Using the three aspects of the combined blends, we were able to track the progression of the main thrust of the small group discussion as well as the contrasting voices in those discussions. In a longer paper (Zandieh, Roh, & Knapp, 2010) we describe the blends involved in each episode. Here we focus on three salient examples that illustrate the power of blending to describe student reasoning that moves the proof construction forward as well as student reasoning that slows proof construction.

The Key Geometric Blend (KGB)

From the beginning of Episode 1, students looked for a way to blend together the picture and statement of the two postulates geometrically and conceptually. They did this by creating the key geometric blend (KGB) which turned out to be the key idea of the proof for the students.

Stacey: Because no matter what we can put any P out there [reaching out her arms to touch her finger tips together] at our point of intersection [pointing to Andrea's notebook]. [Nate: That's a good point.] And then we know that, that it is unique [tracing a line with her pen], that it is not going to come back and intersect somehow. [...]

(Silence 1 minute -- Paul flips pages, Stacey flips pages (x2))

Paul: Well, if you assume the first one [EFP], would there be three cases that $\alpha + \beta < \pi$, $\alpha + \beta = \pi$, or $\alpha + \beta > \pi$? And then the uniqueness part of it would be proved by the $\alpha + \beta = \pi$ and in that case they wouldn't meet.

As students flipped pages between the picture and statement for EFP and the picture and statement for PPP they began *mapping to a blend.* The two figures in the text functioned as input spaces for a blended space (see Figure 5). Paul's three cases take the EFP picture and lay it on the PPP picture such that the bottom line from each of the input spaces (*m* from EFP and *l* from PPP) is mapped into the bottom line of the blended space. The transversal (*n*) from the EFP input space is included in the blended space, and the top line from each space is mapped into a line in the blended space. Finally, the point *P* from the PPP space is mapped onto the intersection of the transversal and the top line from EFP in the blended space (see Figure 5). To *complete the blend* the students brought to bear their previous geometric knowledge of lines and angles. Notice that Paul imagined three different possible locations of the top line in the blended space and coordinated the different geometric positions with different sums for $\alpha + \beta$. We would say Paul's idea of three cases comes from *running the blend*. After Paul's comment, Andrea and Nate also contributed to running the blend by imagining that if $\alpha + \beta > \pi$, then the lines would intersect on the other side.

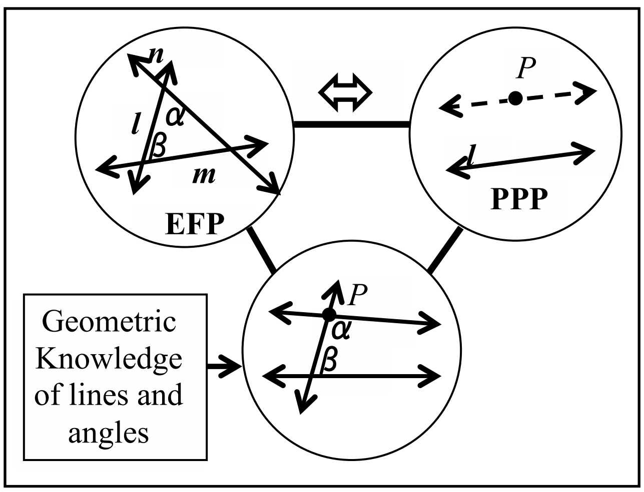

Figure 5. Key Geometric Blend (KGB)

The KGB was also involved similarly when the students attempted to prove the other direction, PPP implies EFP, in Episode 3. The main difference for the students in Episode 3 was that the blending of the two pictures was created by a slightly different mechanism. Andrea started with the PPP picture and constructed a transversal to create line *l* of the EFP picture. This construction does not change the basic content of the KGB, but it is significant in that it allowed students to see additional relationships in the geometric blend focusing on the case when the two lines are parallel transports of each other.

Andrea: If we assume this [points to PPP picture] and draw a transversal through here, through P and through this line. So we know that since these are parallel that they add to 180, right? Because they are supplementary, whatever.

Having agreed upon the sum of the angles being 180 degrees, Andrea then made her full argument more clearly as follows:

Andrea: So say that we rotate this line so that it makes it less than 180, the sum less than 180. [Nate: Yeah]… Oh, so, right! So that since we know that this is a unique line because we've assumed that there is only one line. So we rotate it so that it is a different line, then we know that it is going to intersect because there is only the one line that won't intersect.

The students continued to discuss the issues involved in Andrea's proof idea for a few more minutes, but ultimately returned to trying to prove EFP implies PPP. Although Andrea's proof was not completed, the KGB was fundamental to this discussion as it was in Episode 1 when Paul introduced the idea. In addition, both discussions of the KGB (in Episodes 1 and in Episode 3) played into Nate's idea for the proof that was discussed in Episode 4. Examples of this occur in the next two sections. The KGB was fundamental to discussions of the proof in Episodes 1, 3, and 4 and in the final write up of the proof. The KGB was the central idea of the proof, the key idea of the proof in the sense of Raman (2003). So the result of the blend was powerful for proving. In addition, the students ran the KGB over and over imaginatively as they worked out issues in the proof.

Simple Proving Frame (SPF) vs Conditional Implies Conditional Frame (CICF)

We introduce and compare two proving structures that the students used in their proofs of statements of the form $(p \rightarrow q) \Rightarrow (r \rightarrow s)$: the Simple Proving Frame (SPF) and the Conditional Implies Conditional Frame (CICF). By SPF, we refer to a proving frame where there is a given statement (premise), then a series of implications, then a conclusion (see Figure 6). There is nothing inherently wrong with the SPF or trying to apply it to a conditional implies a conditional statement. However, unless a student has particular theorems to work with that allow a direct proof from $(p \rightarrow q)$ to $(r \rightarrow s)$, then a simple proving frame (SPF) may be inadequate.

Generic SPF	Case 1: $(p \rightarrow q)$	Case 2: $(p \rightarrow q) \Rightarrow (r \rightarrow s)$
Given $\boxed{}$ … Series of Implications … Then $\boxed{}$	Given p … Series of Implications … Then q	Given $(p \rightarrow q)$ … Series of Implications … Then $(r \rightarrow s)$

Figure 6: Simple Proving Frame (SPF)

The students began to work on the task by looking at the pictures and statements of the two postulates described on two sequential pages in their book. As they began to think about which direction might be easier to prove and how to prove it, three of the four students each flipped back and forth between the two pages multiple times. We describe their deliberations in terms of a simple blend in which the two input spaces are the two postulates (see Figure 7). The students then were bringing the SPF to bear on the problem by putting EFP in the place of what is given and PPP in the place of the conclusion. To the extent that there is resolution in this early discussion the students seem to have created a blended space that is structured by the SPF with EFP as the given and PPP in the conclusion.

On the other hand, the CICF is substantially different from the SPF that the students used in Episodes 1-3. By CICF we refer to proofs of statements of the form $(p \rightarrow q) \Rightarrow (r \rightarrow s)$, where one starts with *r* and uses a series of implications including $p \rightarrow q$, to reach the conclusion, *s* (see Figure 8). In Episode 4 Nate began to lay out his case for the CICF more directly.

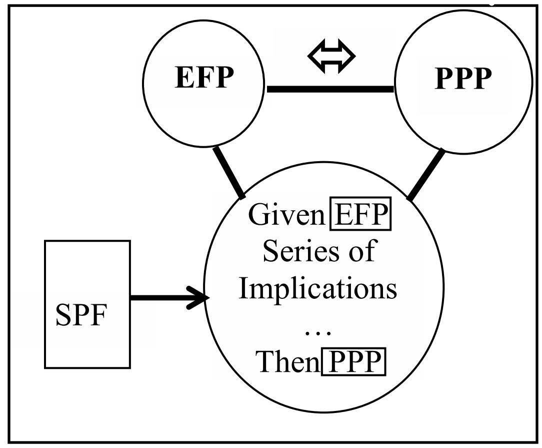

Figure 7. A structural blend of SPF from EFP to PPP

Nate: […] If we assume this [points to a drawing of EFP] is true? [Andrea: Okay, so this way?] This [EFP] is true for a moment. [Andrea: Okay.] Now we have our little point over there and we draw this line. We know that if this line is such that the angles on the one side are less than 180, that it is not parallel based on this assumption [EFP]. We know that if they are greater than 180, we can apply this assumption again and show that they do [intersect] on the other [side]. Can we use our parallel transport proof to show that the boundary condition when they are equal to 180, that this angle is congruent to this angle and therefore they are parallel and therefore they don't intersect?

Nate first established that he was assuming EFP is true and therefore was proving PPP. Next, he hinted at the premise of PPP, "we have our little point over there and we draw this line," suggesting that he was starting with *r* of the $(p \rightarrow q) \Rightarrow (r \rightarrow s)$. He then stated how he could use EFP in the middle of the proof, "we can apply this assumption." This is the use of $(p \rightarrow q)$ in the series of implications. He also hinted at what else may be needed to get to the conclusion of PPP. As we will see in the next section, Paul, Stacey, and Andrea initially struggled with Nate's proof structure. Towards the end of the discussion they began to think Nate's idea might work. This was aided by the teaching assistant visiting the group and being supportive of Nate's idea. Following her departure the group prepared a presentation for the class based on Nate's idea. As the group began work on their presentation the three dissenters made contributions indicating that they understood Nate's blend.

Generic CICF	For the case of $(p \rightarrow q) \rightarrow (r \rightarrow s)$
Given … Use … Thus	Given *r* … Then *p* Since *p* and $(p \rightarrow q)$ Then *q* … Thus *s*

Figure 8. The CICF

Blending the Premise and Conclusion

As explained above, students initially, from Episode 1, wanted to use a simply proving frame (SPF) that would start with EFP and end with PPP. Since the SPF is a legitimate proof technique in many situations and one that students were very familiar with, this is understandable, and might have even led to a proof if the students had appropriate theorems for this. However, in this case, the problem with using SPF was compounded by students blending the premise and conclusion of EFP in a way that lost the implication structure. We illustrate this with a transcript from Episode 4. As explained in the previous section, Nate had suggested his proof idea which used CICF. Other students in this group saw a similarity between their and Nate's idea in the sense of using three cases (KGB). However, they struggled with Nate's proof structure.

Paul: So, we don't even need to necessarily have the three cases, do we? Just we need to prove that one case – uniqueness on that one. Because we are assuming they meet on this side so I don't think it really matters if. [Stacey: Exactly. Agreed.] […]

Nate: I disagree because you are applying EFP to your specific cases. You're not assuming that α and β are less than. In order to apply it, you have to show that α and β are less than. […]

Paul: I think you are assuming that.

Stacey: Yeah, it assumes. Because we are assuming the whole EFP.

Andrea: We're assuming EFP.

Stacey: We're saying if we got two lines that are going to intersect on this one side, the interior ones right there are going to be, they have to be less than π.

Nate: Right, right. But now we are drawing a picture where we're going to say that α and β are less than and therefore we can apply EFP to show that they intersect. […]

Paul: If we're assuming that, then how can we say that they are going to be equal to π? Do you know what I am saying?

Nate: Well, that's my point. You have to draw three cases. You have to draw when they sum less than, when they sum equal, and when they sum greater than. And you have to apply EFP to two of those cases.

For Paul, Stacey and Andrea assuming EFP meant that they were assuming both the premise and the conclusion of EFP. In part, we see this as a faulty use of the SPF proof structure, the notion that we are starting with "all" of EFP and we will end the proof with the statement of PPP. In addition to the problem of using the SPF structure there is more specifically the idea that assuming "all" of EFP causes EFP to lose its implication structure. We describe this as a blending of the premise and the conclusion of EFP. Using blending theory we would say that there is a blend with two input spaces, (1) the premise of EFP ($\alpha + \beta < \pi$) and (2) the conclusion of EFP (the two lines intersect on the same side as α and β). The relationship between these two input spaces is that of an implication. However, when the two spaces are mapped to the blend, they are mapped to the same diagram with the implication having been compressed to an "and" or a simple coexistence without any implication structure. When the students were running this blend in the context of proving EFP to PPP using the SPF, they concluded that both the premise and conclusion of EFP were given, so it was not necessary to consider the cases when $\alpha + \beta > \pi$ or the lines didn't intersect, since students were assuming as part of EFP that the lines intersected and $\alpha + \beta < \pi$.

Summary

We find conceptual blending useful for describing the creation of powerful new ideas necessary for proof construction as well as for describing the creation of blends that slow or hinder student efforts at proof construction. We noted how students blended the two pictures of EFP and PPP and ran that blend in ways that allowed them to create a key idea (KGB) for the proof. This blending continued to serve as the foundation for the proof even through its final configuration. In addition, Nate's use of CICF was eventually blended with the KGB to construct the final, correct proof that this group presented to the class. On the other hand, there were two cases of student blending that served to hinder or slow their proving. In the first case we saw that students' initial use of an SPF structural blend hampered their efforts to structure their proof. The students did not have the necessary theorems to complete a proof of this conditional implies conditional statement using an SPF. In a second case we saw students treating "all" of EFP as given. EFP was treated as a collection of parts without maintaining the appropriate implication structure between these parts. As a result, the students' conceptual blends led them to blend the premise and conclusion in ways that obscured the implication relation between them. Consequently, their heavy reliance on this proof frame in the initial discussions slowed their efforts. It is our suggestion that instruction should be more explicit in contrasting the use of SPF and CICF.

LEARNING TRAJECTORIES: FOUNDATIONS FOR EFFECTIVE, RESEARCH-BASED EDUCATION

Douglas H. Clements
University at Buffalo, State University of New York
clements@buffalo.edu

Approaches to standards, curriculum development, and pedagogy are remarkably diverse; however, recent years have seen a growing movement to base each of these on learning trajectories. In this paper, I discuss and compare the various terms and conceptions of this construct, present our definition, differentiate between our conception and that of others', and briefly review some of our recent evidence in the area of early childhood mathematics paper.

Throughout history, approaches to standards, curriculum development, and pedagogy have been remarkably diverse. Recent years, however, have seen a growing movement to base each of these on *learning trajectories*. Examples include the National Council of Teachers of Mathematics' *Curriculum Focal Points* (2006) to the National Research Council's report (2009), and most notably the Common Core State Standards (CCSSO/NGA, 2010, for which the "progressions" of a learning trajectory were developed first—the standards followed). Here I compare and contrast different notions of this important concept and summarize results of recent empirical work illustrating its potential.

The term "curriculum" stems from the Latin word for racecourse, referring to the course of experiences through which children grow to become mature adults. Thus, the notion of a path, or trajectory, has always been central to curriculum development and study. In his seminal work, Simon stated that a "hypothetical learning trajectory" included "the learning goal, the learning activities, and the thinking and learning in which the students might engage" (1995, p. 133).

Building on Simon's definition, but emphasizing a cognitive science perspective and a base of empirical research, "we conceptualize learning trajectories as descriptions of children's thinking and learning in a specific mathematical domain, and a related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking, created with the intent of supporting children's achievement of specific goals in that mathematical domain" (Clements & Sarama, 2004, p. 83). The term "learning trajectory" reflects its roots in Simon's constructivist perspective (in emphasizing students' learning). However, although the name appears to focus on learning more than teaching, both Simon's and our definitions clearly involve teaching and instructional tasks. Some interpretations and appropriations of the learning trajectory construct emphasize only the "developmental progressions" of learning (what Simon calls hypothetical learning processes) during the creation of a particular curricular or pedagogical context. That is, they only describe levels of thinking through which students develop, which we believe is but one part of the learning trajectory construct. Some terms, such as "learning progressions" are used ambiguously, sometimes indicating only developmental progressions, and at other times, also suggesting a sequence of instructional activities. Although studying either psychological developmental progressions or instructional sequences separately can be valid research goals, and studies of each can and should inform mathematics education, we believe the power and uniqueness of the learning trajectories construct stems from the inextricable interconnection between these two aspects. Both these aspects (developmental progressions of thinking and instructional sequences) serve the most important, but often least discussed, aspect of learning trajectories—the goal. Our learning trajectories base goals on both the expertise of mathematicians and research on students' thinking about and learning of mathematics (Clements, Sarama, & DiBiase, 2004; Fuson, 2004; Sarama & Clements, 2009a). This results in goals that are organized into the "big" or "focal" ideas of mathematics: overarching clusters and concepts and skills that are mathematically central and coherent, consistent with students' (often intuitive) thinking, and generative of future learning (Clements, Sarama, et al., 2004). Once the mathematical goals are established, research is reviewed to determine if there is a natural developmental progression (at least for a given age range of students in a particular culture) that can be identified within theoretically- and empirically-grounded models of children's thinking, learning, and development (Carpenter & Moser, 1984). That is, researchers build a cognitive model of students' learning that is sufficiently explicit to describe the processes involved in students' progressive construction of the mathematics described by the goal across several qualitatively distinct structural levels of increasing sophistication, complexity, abstraction, power, and generality.

What, if Anything, is "New" in the Learning Trajectories Construct?

When we discuss learning trajectories, some (commendably) skeptical colleagues ask what is really different. If curricula have always been "courses" or paths (and frequently "horse races" through them), and if psychological and educational theories always postulated series of goals, then is this not simply renaming old (and palpable) ideas? At certain simple levels, the answer is positive. Most of these notions describe or dictate a series of educational goals. All have some theoretical perspective on why one goal might follow another.

In contrast, these theories often differ markedly on the details, and the learning trajectories construct as we define it builds upon theories and research of years past, as any theory should, but is distinct from previous formulations and constitutes a substantive contribution to theory, empirical research, and praxis. For example, early educational psychology considered educational series or sequences on the accumulation of connections. "We now understand that learning is essentially the formation of connections or bonds between situations and responses, that the satisfyingness of the result is the chief force that forms them, and that habit rules in the realm of thought as truly and as fully as in the realm of action" (Thorndike, 1922, p. v). Thus, curricular sequences could be logically arranged to establish connections between simple situations (addends) and responses (sum) and then later connect these and other bonds to complete more difficult tasks (e.g., multidigit addition) and even to develop mathematical reasoning. However, conceptual, meaningful learning was not the focus, but rather simple paired or associated learning. Also, potential differences and nuances of learning in different subject matter domains were not considered.

Bloom's taxonomy of educational objectives and Robert Gagné's "conditions of learning" and "principles of instructional design" (Gagné, 1965; Gagné & Briggs, 1979) postulated that Thorndike's theory was too simple and that there were "types of learning" and that certain types, such as stimulus-response learning (e.g., Thorndike's "bonds") were prerequisite to other types (e.g., discrimination learning, concept learning, rule learning, and last, problem solving). For a specific topic, or a specific domain within a topic such as mathematics, these could be assembled in "learning hierarchies"—sequences of pairs consisting of a subordinate skill whose acquisition is hypothesized to facilitate the learning of a higher-level skill. These, then, specified a "learning route"—certainly one early form of a learning trajectory. Such routes would be determined by logical analysis (logically identifying what subordinate competence is required by a superordinate competence) and empirical task analysis (Gagné, 1965/1970).

In a similar manner, others continued to promote task analysis as a way to develop complex hierarchies of skills. Some researchers similarly based these hierarchies on logical and task analyses, but gave more weight to extant findings in educational—and especially psychological—research to perform “cognitive” or “rational” analyses—with follow-up empirical validation studies whenever possible (Resnick & Ford, 1981). Work from this perspective increasingly used the computer metaphor (i.e., information-processing theories), and often actual computer models, in their analyses (Hoz, 1979; Klahr & Wallace, 1976).

These approaches determined hierarchies of educational goals and were the basis of many “scope and sequences” in the educational literature (see Baroody, Cibulskis, Lai, & Li, 2004, for an extended discussion and somewhat different perspective). The view of learning of the earlier approaches was generally that of knowledge acquisition, with the environment providing input that was “received”—that is, imitated and mentally recorded by the student.

Other researchers attended more to students’ thinking and cognitive development. Some devised developmental learning theories in attempts to integrate structural views such as those of Piaget with views based on task analysis and information-processing models. Later theoretical efforts in cognitive science extended these efforts to focus on the importance of domain-specific learning and development (Davis, 1984; Karmiloff-Smith, 1992).

In historical parallel, several theories, from Piagetian (Piaget & Szeminska, 1952) to field theories (Brownell, 1928; Brownell & Moser, 1949) and later developmental and cognitive science theories (Case & Okamoto, 1996) emphasized students as makers of meaning. Similarly, cognitively- and constructivist-oriented research programs explicated the concepts and skills children build as they move from one level to the next within a mathematical domain (Baroody, 1987; Carpenter & Moser, 1984; Steffe & Cobb, 1988). Unfortunately, those applying these studies practically often oversimplified and misconstrued their results and implications, emphasizing laissez–fair or outdated “discovery” approaches (Clements, 1997).

Learning trajectories as we have defined them (and our overaching theory of Hierarchic Interactionalism, see Clements & Sarama, 2007a; Sarama & Clements, 2009a) owe much to these previous efforts, which have progressed to increasingly sophisticated and complex views of cognition and learning. However, the earliest applications of cognitive theory to educational sequences tended to feature simple linear sequences based on accretion of numerous facts and skills. This was reflected in their hierarchies of educational goals and the resultant scope and sequences. Learning trajectories include such hierarchies, but are not as limited as these early constructs to sequences of skills or “logically” determined prerequisite pieces of knowledge. Learning trajectories are not lists of everything children need to learn, as are some scope and sequence documents; that is, they do not cover every single “fact” or skill. Most important, they describe children's *levels of thinking*, not just their ability to correctly respond to a mathematics question. They can not be summarized by stating the mathematical definition, concept, or rule (cf. Gagné, 1965/1970). So, for example, a single mathematical problem may be solved differently by students at different (separable) levels of thinking in a learning trajectory. Levels of thinking describe *how* students think about a topic and *why*—including the cognitive actions-on-objects that constitute that thinking.

Further, the ramifications for instruction from earlier theories were often based on transmission views, which hold that these facts and skills are presented and then passively absorbed. In comparison, learning trajectories have an interactionalist view of pedagogy.

To further elaborate these differences, consider the three components of learning trajectories.

Goal

The explication of the *goal* is important and distinguished from previous theories of learning that tended to either (a) apply the same theories and procedures to all domains, ignoring subject matter, or (b) accept the goal as arbitrary or "given" by existing standards or curriculum. In contrast, as stated, our learning trajectories base goals on both the expertise of mathematicians and research on students' thinking about and learning of mathematics. Thus, in contrast to earlier approaches, both domain-specific expertise and research on students' thinking and learning in that domain play a fundamental role in determining the mathematical goal—the first component of learning trajectories.

Developmental Progression

The *developmental progressions* of learning trajectories are much more than linear sequences based on accretion of numerous facts and skills. They are based on a progression of levels of thinking that (as does the goal) reflects the cognitive science view of knowledge as interconnected webs of concepts and skills. It is important to describe the nature of these levels and differentiate them from 'stages' (such as Piaget's).

A *level* is a period of time of qualitatively distinct cognition, as are stages; however, there are at least four important distinctions between levels and stages. First and most important, they do not apply across domains but only within a *specific* domain. Second, the period of time is generally far shorter, and can be months or days (especially given efficacious instruction), rather than a period of years for stages.

Third, although—like Piaget— Hierarchic Interactionalism postulates that subsequent levels are built upon earlier levels, there are two important differences. (a) The order of magnitude of difference in durations indicates a distinctly different cognitive "distance" between successive states. Informally, the "jump" between contiguous levels is far smaller than the jump between Piagetian stages (admittedly, measuring such distances, for this distinction and related theoretical notions such as Vygotsky's Zone of Proximal Development, remains an open problem). (b) The Hierarchic Interactionalism theory of levels makes no commitment (as does the Piagetian theory of stages) that the actions-on-objects of level $n + 2$ must be built from those of level $n + 1$. In Piagetian theory (Piaget & Szeminska, 1952), for example, stages are long periods of development characterized by cognition across a variety of domains qualitatively different from that of both the preceding and succeeding stages. Further, in Piagetian theory, stage $n + 2$ necessitated passing through stage $n + 1$ *because* stage n + 1 constructed the elements from which stage $n + 2$ would be built.

Levels in Hierarchic Interactionalism are not "stages." Rather, in many cases the cognitive material may be present at level n, requiring only a greater degree of construction or generalization to construct the pattern of thinking and reasoning defining level $n + 2$. We return to this issue when we discuss students "skipping" a level or "jumping ahead."

Fourth, although levels of thinking can be theoretically viewed as nonrecurrent (Karmiloff-Smith, 1984), students not only can, but frequently do, "return" to earlier levels of thinking in certain contexts. Therefore, Hierarchic Interactionalism postulates the construct of nongenetic levels (Clements, Battista, & Sarama, 2001), which has two special characteristics. (a) Progress through nongenetic levels is determined more by social influences, and specifically instruction, than by age-linked development. (At this point, this only implies that progression does not occur by necessity with time, but demands, in addition, instructional intervention, although certain levels may develop under maturational constraints.) (b) Although each higher nongenetic level builds on the knowledge that constitutes lower levels, its nongenetic nature does not preclude the instantiation and application of earlier levels in certain contexts (often, but not necessarily limited to, especially demanding or stressful contexts or tasks). There exists a probability of evoking each level depending on circumstances. Again, Figure 1 illustrates that earlier levels do not “disappear”; people do not “jump” from one type of thinking to a separate type, but rather build new ways of thinking upon the previous patterns of thinking. This process is codetermined by the probabilities of instantiation and conscious metacognitive control, which increases as one moves up through the levels, allowing more intentional application of various cognitive strategies. Therefore, students have increasing choice to override the default probabilities. The use of different levels is environmentally adaptive; thus, the adjective “higher” should be understood as a higher level of abstraction and generality, without the implication of either inherent superiority or the abandonment of lower levels as a consequence of the development of higher levels of thinking. Nevertheless, the levels would constitute veridical qualitative changes in thinking and behavior.

Each level in Hierarchic Interactionalism’s developmental progressions is characterized by specific mental objects (e.g., concepts) and actions (processes) (e.g., Clements, Wilson, & Sarama, 2004; Steffe & Cobb, 1988). Specification of these actions-on-objects allows a degree of precision not achieved by previous theoretical and empirical works. Further, the research methods that generate and test these mental models are distinct from methods used in earlier research. Strategies such as clinical interviews are used to examine students' knowledge of the content domain, including conceptions, strategies, intuitive ideas, and informal strategies used to solve problems. The researchers set up a situation or task to elicit pertinent concepts and processes. Once an initial model has been developed, it is tested and extended with teaching experiments, which present limited tasks and adult interaction to individual children with the goal of building models of children’s thinking *and learning*—that is, transitions between levels are the *crux* of these studies—which is another way learning trajectories differ from many earlier research programs. Once several iterations of such work indicate substantive stability, it is accepted as a working model. Thus, the developmental progressions’ levels of thinking and explication of transitions between levels describe in detail the following: (a) what students are *able* to do, (b) what they are *not yet able* to do *but should be able to learn,* and (c) *why*—that is, *how* they think at each level and how they learned these levels of thinking. This distinguishes learning trajectories’ developmental progressions from earlier efforts to develop educational sequences that, for example, often used reductionist techniques to decompose a targeted competence level only into subskills, based on an adult’s perspective.

Instructional Tasks

The *instructional tasks* of learning trajectories are much more than didactic presentations or external “models” of the mathematics to be learned. They often include these elements, but they are fine-tuned to develop the level of thinking that a particular student needs. Learning trajectories differ from instructional designs based on task (or “rational”) analysis because they are not a reduction of the skills of experts but are models of students’ learning that include the unique constructions of students and require continuous, detailed, and simultaneous analyses of goals, pedagogical tasks, teaching, and children’s thinking and learning. Such explication allows the researcher to test the theory by testing the curriculum (Clements & Battista, 2000).

This early interpretive work evaluates components using a mix of model (or hypothesis) testing and model generation strategies, including design experiments, as well as grounded theory, microgenetic, microethnographic, and phenomenological approaches. The goal is to understand the meaning that students give to the instructional objects and tasks. The focus is on the *consonance* between the actions of the students and the learning trajectory; that is, does the instruction task engender, in a student at level *n*, the cognitive actions-on-objects that are described as accounting for the type of thinking and problem-solving at level *n* + 1. If not, other tasks can be tried, based on a detailed account of the students' responses. (Discrepancies may also reveal a need to alter the developmental progression.) Questions such as the following direct the inquiry. Do students use the tools provided (e.g., manipulatives, tables or graphs, software tools or features) to perform the actions, either spontaneously or only with prompting? If prompting is necessary, which type is successful, and does this differ for different students? Are students' *observable* actions-on-objects enactments of the desired cognitive operations in the way the model posits, or merely trial-and-error manipulation? Are there indications of an internalization of these; that is, indications that students are building mental actions-on-objects and thus developing *n* + 1 level of thinking? In this way, the developer/researcher creates more refined models of the thinking of particular groups of students (the developmental progression) and describes what elements of the instructional tasks, including specific scaffolding strategies, are observed as having contributed to student learning. The objective is to connect the developmental progression with the instructional tasks.

The tightly interwoven and interacting connections among the three components of a learning trajectory—goal, developmental progression, and instructional tasks—encompassing levels from the microscopic and individual student's cognition to the cultural surround, are a major distinguishing features of the learning trajectory construct. There are not two different paths (see footnote 1)—a learning path and a teaching path—but one *learning trajectory* with three components borne of the same theoretical and empirical parents.

Scientific experiments that examine, evaluate, and extend these connections and components include conceptual analyses and theories. They are tested *and iteratively revised* in progressively expanding social situations, which results in greater contributions to both educational theory and practice (Clements, 2007).

Empirical Support

We initially reviewed research in early mathematics because we believed that learning trajectories should be the backbone of our *Building Blocks* research-and-development curriculum project (Clements & Sarama, 1998), which was developed based on a Curriculum Research Framework (Clements, 2007) that itself puts learning trajectories at the core. Our work in that and several subsequent projects convinced us of the usefulness of the construct, with effect sizes from .72 to 2.12 (Clements & Sarama, 2007b; Sarama & Clements, 2009b; Sarama, Clements, Starkey, Klein, & Wakeley, 2008). The effect size of the *Building Blocks Pre-K* curriculum was .72. Longitudinal analyses with follow-up interventions focused *only* on learning trajectories (i.e., the teachers in kindergarten and first grade used their regular curriculum, but studied the research-based learning trajectories) continues these gains (Sarama, Clements, Wolfe, & Spitler, 2011). We believe these results indicate that the use of learning trajectories in curriculum development and professional develop have consistent, substantial, benefits.

This systematic review of mathematics educational technology literature identified 1356 manuscripts addressing the integration of educational technology into mathematics instruction. The manuscripts were analyzed using three frameworks (Research Design, Teacher Knowledge, and TPACK) and three supplementary lenses (Data Sources, Outcomes, and NCTM Principles) to produce a database to support future research syntheses and meta-analyses. Preliminary analyses of student and teacher outcomes (e.g., knowledge, cognition, affect, and performance) suggest that the effects of incorporating graphing calculator and dynamic geometry technologies have been abundantly studied; however, the usefulness of the results was often limited by missing information regarding measures of validity, reliability, and/or trustworthiness.

Educational technology (i.e., digital technology, as opposed to other forms of educational tools such as overhead projectors or physical manipulatives) is promoted to mathematics teachers as a research-based strategy for improving student outcomes. Although research on mathematics educational technology appears at first glance to be ubiquitous, the usefulness of this research to practitioners and researchers is limited by lack of attention to research design and validity, reliability, and threats to validity (Rakes et al., 2011). Additionally, much of the research appears to be unorganized, with topics such as graphing calculators studied often, while other topics such as virtual manipulatives understudied (Ronau et al., 2010). The purposes of this systematic review were to (1) examine the evidence of technology impact on the teaching and learning mathematics in K-13, graduate, teacher development, and adult education using three frameworks (Comprehensive Framework of Teacher Knowledge [CFTK], Research Design, and Technology, Pedagogy, and Content Knowledge [TPACK]) and three supplementary lenses (Data Sources, Outcomes, and NCTM Principles) and (2) assess the utility of each framework for guiding the synthesis of mathematics educational technology research.

Theoretical Framework and Background

Three frameworks were applied to the analysis in the set of mathematics educational technology studies discovered by the systematic review: Research Design, CFTK, and TPACK. The research design framework was used to guide the investigation of the types of research approaches used in mathematics educational technology research. The complex nature of questions pertaining to educational technology effectiveness requires a variety of research designs such as (1) experimental or quasi-experimental studies, (2) large-scale studies, (3) studies with sufficient statistical information to be included in meta analysis and mixed-methodology studies, (4) studies with rich analysis of student content knowledge, and (5) studies that address the complexities of learners, classrooms, and schools (Bell, Schrum, & Thompson, 2008; Means, Wagner, Haertel, & Javitz, 2003). However, without explicit attention to the alignment of the research design to the questions of interest, the validity and reliability of the measures used, and the threats to validity within the chosen design, the reported outcomes will be less likely to have been founded on scientific principles or to be replicable (Shadish, Cook, & Campbell, 2002). The usefulness of such studies to practitioners and researchers will be, therefore, limited without robust attention to research design issues. The Research Design framework (Ronau et al., 2010) was compiled from several sources to address pertinent issues across a wide range of research types (e.g., Creswell, 2009; Shadish et al., 2002; Shavelson & Towne, 2002; Teddlie & Tashakorri, 2009). For a detailed description of the Research Design framework, see Rakes, Wagener, and Ronau (2010).

Within the past few years, two new teacher knowledge frameworks have been proposed that have the potential to support the research community in responding to questions on the impact of technology on learning. The Comprehensive Framework of Teacher Knowledge (CFTK; Figure 1) provides a three-dimensional model for addressing multiple aspects of teacher knowledge and their interactions (Rakes, Ronau, & Niess, 2010; Ronau, Rakes, Wagener, & Dougherty, 2009; Ronau, Wagener, & Rakes, 2009). This model transforms current understanding of teacher knowledge from a linear structure to a three dimensional model, as shown in Figure 1, by pairing six inter-related aspects into three orthogonal axes: 1) Field, comprised of Subject Matter and Pedagogy; 2) Mode, comprised of Orientation and Discernment; and 3) Context, comprised of Individual and Environment. For a detailed description of the CFTK aspects and dimensions, see Ronau and Rakes (in press).

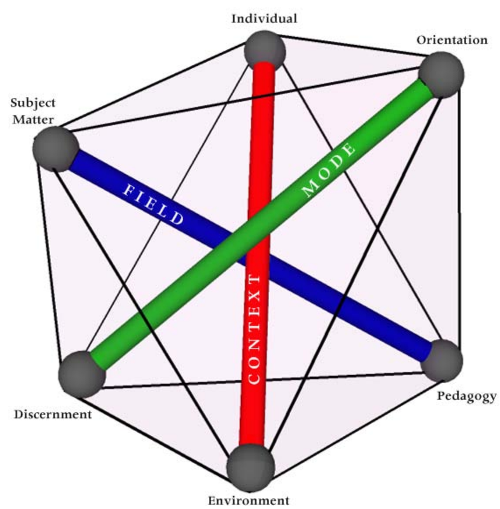

Figure 2. CFTK framework of teacher knowledge as a three-dimensional structure.

The Technology, Pedagogy, and Content Knowledge (TPACK) framework defines the knowledge needed by teachers to integrate technology into the pedagogy of particular subject matter (e.g., Mishra & Koehler, 2006; Niess, 2005). In its entirety, TPACK consists of a set of descriptive knowledge components embedded in an educational Context, Content Knowledge (CK), Pedagogical Knowledge (PK), and Technological Knowledge (TK), and a series of interactions, Pedagogical Content Knowledge (PCK), Technological Pedagogical Knowledge (TPK), Technological Content Knowledge (TCK), and TPACK. The initial TPACK framework has been extended to provide benchmarks of the development of this knowledge as shown in

Figure 2, including recognizing, accepting, adapting, exploring, and advancing (Niess, Lee, & Sadri, 2007).

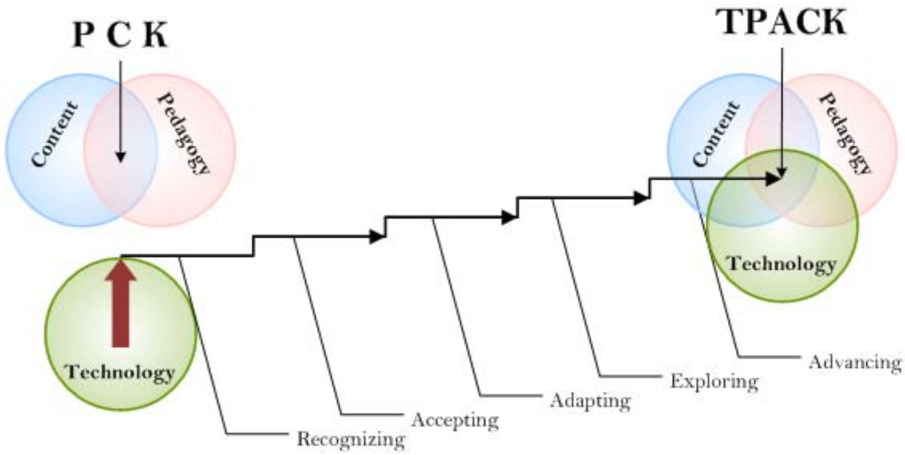

Figure 3. Model of teacher thinking and understanding as that knowledge develops toward the intersection identified as important by TPACK.

Based on feedback through peer debriefing (Rakes et al., 2010), three additional lenses (Data Sources, Outcomes, and NCTM Principles) were added to provide a more comprehensive snapshot of the research landscape, guiding practitioners to choose best practices and for guiding future research directions.

Using these frameworks and lenses, we began our investigation with two overall questions: (1) To what degree do the three frameworks, Research Design, CFTK, and TPACK, capture the scope of mathematics educational technology research? (2) What Data Sources, Outcomes, and NCTM Principles are addressed in mathematics educational technology research? To what degree, and how, implicit/explicit?

Method

A research synthesis (Cooper & Hedges, 2009) was conducted to address the two overall questions. To identify the most representative sample that was relevant to the questions of interest (i.e., construct validity), a wide array of databases were searched using terms to restrict the sample based on three inclusion criteria: (1) The study needed to examine a technology-based intervention; (2) The intervention needed to target the learning of a mathematics concept or procedure; (3) The manuscript needed to be available in the English language. The database platforms and individual databases included EBSCOWeb (ERIC, Academic Search Premier, PsychInfo, Primary Search Plus, Middle Search Plus, Educational Administration Abstracts), JSTOR (limited to the following disciplines: Education, Mathematics, Psychology, and Statistics), OVID, ProQuest (Research Library, Dissertations & Theses, Career & Technical Education), and H. W. Wilson Web (Education Full Text). From these databases, 1356 manuscripts (journal articles, book chapters, technical reports, conference proceedings, master's theses, and doctoral dissertations) were identified as being potentially relevant to the questions of interest.

The initial coding database was pilot tested with three articles and two coders to help refine the coding database. Refinements based on the results of this pilot test were examined with all six researchers coding the same, original three articles. This process was repeated through three more iterations of refinement and coding of 27 more articles (i.e., 30 articles were group coded).

After the analysis of 473 manuscripts, a number of coding issues emerged that required attention. Extensive team discussions led to a number of coding clarifications to improve team alignment, including how to: code studies with meta-analyses and/or systematic reviews, mixed methodology designs and single subject designs, action research, and survey research; code purposive and convenience sampling, subject dialog data, and modified and validated instruments; and record evaluative comments when deemed necessary. Finally, a number of coding form issues was addressed. The existing database of 473 studies was aligned with this new set of procedures and understandings, and the team developed a new process of coding the remaining studies that paired each of the six coders with all the other coders to provide a mixed set of double coding for the remainder of the studies. The new coding design created a completely counter-balanced design with all six coders that provided greater inter-rater reliability and content validity of the coding. With this plan, every manuscript was coded by two members of the coding team, and each member coded 59 studies with every other member. Any discrepancies between coder and re-coder were recorded and discussed by the pair and by the full team as needed.

Preliminary Results

At the time of the writing of this paper, 473 manuscripts have been coded and cross-validated (i.e., double coded and checked for accuracy). Twenty four of these manuscripts were screened out because they were not relevant to the questions of interest (i.e., did not address the learning of mathematics concepts and procedures, did not involve technology, or was not available in English), leaving 449 manuscripts in the sample. Initial results were examined by grouping the manuscripts into four categories (not mutually exclusive) of outcomes: Student Achievement and Learning; Student Orientation, Discernment, and Learning Behavior; Teacher Knowledge; and TPACK. The manuscripts and their 449 characteristics were analyzed through descriptive statistics as an initial method for interpreting the landscape of mathematics educational technology research.

The Role of Educational Technology in Student Achievement and Learning

Of the relevant manuscripts, 218 addressed educational technology in mathematics with a view of improving student achievement and learning. As shown in Table 1, over half (N=113) were dissertations and many of the remainder (N=69) were journal articles. Over half (N=118) were purely quantitative studies. The remaining studies were qualitative (N=36), mixed methods (N=43), non-research (N=9), meta analysis/systematic review (N=6), literature driven (N=5), or single subject (N=1). Performance assessments (e. g., tests, performance tasks, grades, GPA, etc.) were the most common sources of data used in these manuscripts, while journals (all types), focus groups, and non self-report surveys were the least used.

The manuscripts in this subsample most commonly addressed the Algebra NCTM Content Standard (N=159) and the Problem Solving Process Standard (N=89). Graphing calculators (N=43), tutorial software (N=39), and dynamic geometry software (N=25) were the more regularly studied technologies. In regards to information on measures of reliability and validity for the quantitative and mixed methods studies, approximately 41% of the manuscripts addressed reliability, 30% addressed validity, and 57% addressed threats to validity. For the qualitative and mixed methods studies, 60% attended to trustworthiness where approximately 62% of these studies attended to only one form of trustworthiness.

Type of Manuscript by Research Design	Non-research	Quali-tative	Quanti-tative	Mixed Methods	Single Subject	Meta-Analysis/ Sytematic Review	Liter-ature	Total
Book Chapter	0	1	1	0	0	0	1	3
Conference Paper	1	2	1	2	0	0	1	7
Disserta-tion	0	15	59	34	1	4	0	113
Journal	8	16	35	6	0	1	3	69
Master's Thesis	0	2	18	1	0	0	0	21
Report	0	0	4	0	0	1	0	5
Grand Total	9	36	118	43	1	6	5	218

Table 1. Student achievement and learning manuscripts by research design.

The Impact of Educational Technology on Student Orientation

Of the relevant manuscripts, 126 had examined the impact of educational technology on student orientation (i.e., the affective domain), discernment (i.e., the cognitive domain), and learning behaviors (e.g., student dialog and collaboration). The manuscripts consisted of 71 dissertations and 39 journal articles. Of these, 62 used purely quantitative analyses, 28 used purely qualitative methodologies, and 27 used mixed methodology. Self-report orientation survey data and performance assessment data were the two most common types of data sources; the top seven data sources are listed in Table 2. The Algebra NCTM Content Standard (N=32) and the Problem Solving Process Standard (N=23) were the most commonly addressed NCTM standards. Graphing calculators (N=24) were the most common type of calculator-based technology, followed by non-scientific calculators (N=16). The three most frequently used nonweb-based software were tutorial software (N=15), dynamic geometry (N=13), and algebra (N=12). Distance learning stood out among the web-based technologies (N=10) as these other technologies were often not addressed or addressed in only one or two manuscripts. Only 27% of the quantitative and mixed methods studies addressed issues surrounding validity, 61% addressed threats to validity, and 42% addressed reliability. Of the qualitative and mixed methods studies, 73% attended to trustworthiness, with 55% that attended to only one form of trustworthiness.

Data Sources	Number of Studies
Self-Report Orientation Survey Data	83
Performance Assessment Data	76
Observation Data	42
Interview Data	37
Content Analysis Data	28
Self-Report Polls and Census Survey Data	13
Researcher Journal Data	8

Table 2. Top seven data sources for student orientation.

The Interaction of Teacher Knowledge Aspects in Educational Technology Research

Teacher Knowledge was examined as an outcome in 72 manuscripts, of which 39 were journal articles and 26 were dissertations. The most common research design was qualitative (N=35), followed by non-research (N=15), mixed methods (N=11), and quantitative (N=8). The four most frequently used data sources were observation data (N=42), interview data (N=30), content analysis data (N=29), and self-report orientation survey data (N=24). Graphing calculators, dynamic geometry software, and spreadsheets were the most commonly studied technologies. The Algebra Content Standard (N=20) and the Problem Solving Process Standard (N=11) were the most commonly addressed NCTM standards. The distribution of CFTK aspects and interactions from this sample was compared to the distribution reported in Ronau and Rakes (in press) for teacher knowledge studies across multiple subject matter domains. The average number of aspects examined in mathematics educational technology ($\bar{x}$ = 1.53, SE = 0.207) appeared to be smaller than the average number of aspects examined across multiple subject matter domains ($\bar{x}$ = 2.16, *SE* = 0.119). This difference appeared to be statistically significant ($t_{df=71}$=3.74). This result may indicate that the research field in mathematics education technology may be considering less complex perspectives of teacher knowledge than other subject matter domains. Reliability was attended to in 32% of the quantitative and mixed methods studies, with validity and threats to validity attended to in 11% and 53%, respectively. Trustworthiness was addressed in 65% of the qualitative and mixed methods studies, where 60% addressed only one form of trustworthiness.

	Graphing Calculators	Dynamic Geometry	Spread-sheets	Graphing Software	Algebraic Software	Statistics Software	Tutorials
Number of Studies	22	19	14	7	5	5	5

Table 3. Top seven technologies for teacher knowledge.

The Use of TPACK to Guide Educational Technology Research

TPACK, as a guiding framework of the knowledge teachers need for integrating educational technology in mathematics, was employed either explicitly or implicitly, in 219 manuscripts, of which 102 were journal articles and 85 dissertations. Of these manuscripts, 72 used purely quantitative methodologies, 48 used purely qualitative methodologies, 27 used mixed methodologies, and 61 did not employ any type of research design (i.e., anecdotal support of hypotheses or descriptions of techniques). Performance assessment was the most commonly used data source (N=86). The NCTM Content Standards considered most often were Algebra (N=67), Geometry (N=45), and Number & Operations (N=37), while Problem Solving (N=35) was the most commonly considered Process Standard. Graphing calculators (N= 54) and dynamic geometry software (N=49) were the two most common types of technology used. Only 24% of the quantitative and mixed methods studies addressed validity issues, 81% addressed threats to validity, and 39% addressed reliability. Of the qualitative and mixed methods studies, 65% attended to trustworthiness, with 63% that attended to only one form of trustworthiness.

Summary

Several patterns were common among all four outcome groups. Dissertations and journal articles were the two most common types of manuscripts, with quantitative studies being the most prevalent research design among three of the four areas (all except teacher knowledge outcomes). Also among these three areas, performance assessment and self-report orientation survey were the two most often used data sources. The most common NCTM Content and Process Standards addressed in all four areas were Algebra and Problem Solving, respectively. Graphing calculators were consistently the most frequently used calculator-based technology, while dynamic geometry was either the most commonly used or second most commonly used non-web-based technology for all four areas. Web-based technologies were the least frequently used type of technology among all four areas.

Missing information regarding measures of validity, reliability, and/or trustworthiness was prevalent. Overall, approximately 40% of the quantitative and mixed methods studies addressed reliability, 27% addressed validity, and 64% addressed threats to validity. Trustworthiness was attended to in approximately 65% of all qualitative and mixed methods studies.

Discussion

The completion of the study will provide a searchable database of educational technology studies from 1968 to 2010, containing key information organized by three frameworks and four lenses. With this data, we will be able to better describe the landscape of educational technology research in mathematics, providing significant detail about the type, quality, content, and alignment of the studies. Doctoral students and advisors will benefit from an analysis of the 600+ dissertations in the sample, providing a guide to over- and under-studied dissertation topics (e.g., impact of graphing calculators in algebra). The research team will be able to identify gaps in the research base with respect to a number of study characteristics organized by the frameworks and lenses described above, as well as the depth and quality of areas well-studied. Detailed coding of research design features will allow for rigorous examination of the evidence currently available to the field in the form of meta-analysis and qualitative research syntheses. The systematic nature of this review will provide a foundation for future investigations and replication. Additionally, once the initial coding is completed, the task of updating the database with newly released manuscripts can easily be accomplished. Finally, this study will also include an evaluation of the utility of each of the three frameworks and four lenses used in the analysis to capture the perspective and the critical details of educational technology research.

OPPORTUNITIES TO CONCEPTUALIZE LINEAR RELATIONSHIPS IN UNITED STATES MATHEMATICS TEXTBOOKS: BEYOND Y=MX+B

Linda Arnold
The University of Tennessee
larnold5@utk.edu

Ji-Won Son
The University of Tennessee
sonjiwon@utk.edu

This study examined opportunities provided for students to conceptualize linear relationships, as reflected in five United States mathematics textbooks. Texts represented a broad spectrum of types: commercial, so-called "back to basics", and NSF funded. Analysis of allocation, topic choice, presentation, context, and cognitive level was completed. Analysis results revealed that students are being asked to grapple with linear relationships at increasingly younger ages, limits in the models they are asked to use, limits on discussion of concepts and connections, lack a real world context for most problems, and lower levels of cognitive expectation. The results indicate a significant gap between learning goals from intended curricula, and the potentially implemented curricula contained in many current U.S. textbooks. Conclusions suggest ways in which the present curriculum may be transformed.

Linear relationships are important because they measure a basic way in which one quantity changes in relation to another. Frequently expressed as equations, graphs of lines and tables, almost all are functions. Linear functions are one of the foundational types of functions for students to understand in mathematics. As early as the 1920s, it was recognized that "without functional thinking there can be no real understanding or appreciation of mathematics" (Breslich, 1928, p.42). In the present day, calls for reform recognize that "the concept of function is an important unifying idea in mathematics (NCTM, 1989, p. 154).

Along the same line, recently published Common Core State Standards (2010) makes it clear that 8th graders should be able to: "Construct a function to model a linear relationship between two quantities. Determine the rate of change and initial value of the function from a description of a relationship or from two (x, y) values, including reading these from a table or from a graph. Interpret the rate of change and initial value of a linear function in terms of the situation it models, and in terms of its graph or a table of values" (Common Core Standards, 2010, mathematics, grade 8, function, para. 4).

This standard is noticeably written in terms of concepts: "rate of change", "initial value", and "situation it models" and puts the emphasis on connections between descriptions, tables, and graphs. Reasoning and sense making, highlighted here, are cornerstones of mathematics (NCTM, 2009), and so must be integral to learning about linear relationships. Then how should linear relationships be presented in classrooms?

Despite a robust link between instructional attention to concepts and students' level of understanding, Hiebert and Grouws (2007) reported that "typical classrooms in the United States focus on low-level skills and rarely attend explicitly to the important mathematical relationships"(p. 2). Students tend to regurgitate "y = mx + b" and manipulate equations mechanically. Is it possible that textbooks have contributed to this problem by limiting expectations and opportunities for students? Have textbooks provided opportunities for students to learn about linear relationships in conceptual, connected terms?

Textbooks, as potentially implemented curricula, give messages of what students might know and be able to do. Although various factors influence student learning and teachers deviate their textbooks, Donavan, Bransford & Pelligrino (1999) reported that students' learning, in fact, is highly correlated with curricular treatment of topics. Many researchers generally agree that the curriculum, especially the curriculum embodied in textbooks, has a large influence on learning and teaching (Son & Senk, 2010; Valverde, Bianchi, Wolfe, Schmidt & Houang, 2002). Therefore, recognizing the influence of textbooks on student learning, we sought to examine the following question: "What opportunities for students to learn about linear relationships are presented in five commonly utilized United States textbooks?" Various types of mathematics textbooks, such as commercial, so-called "back to basics", and NSF funded were examined. Answering this question will help us find a better way to enhancing student learning about linear relationships through textbooks.

Theoretical Framework

A growing body of research has analyzed textbooks in order to understand their potential effect on students' mathematical learning. While some studies focus exclusively on content analysis (e.g., Fuson, Stigler, & Bartsch, 1988), other researchers examined problems presented in textbooks (e.g., Li, 2002). This study examined both the content and problems presented in textbooks. In analyzing the content, we looked at allocation, and topics. In analyzing problems, we looked at context, response type and cognitive level, which were identified by researchers (e.g., Li, 2002; Son & Senk, 2010). In particular, to analyze cognitive level, we built on Webb (2000)'s framework as shown in Table 1, which will be discussed in Methods.

Level	**Characteristics**
1: Recall	Recall of a fact, information, or procedure
2: Skill/Concept	Use information or conceptual knowledge, two or more steps etc.
3: Strategic thinking	Requires reasoning, developing plan or a sequences of steps, more than one possible answer
4. Extended thinking	Requires investigations, time to think and process multiple conditions of problems

Table 1. Depth of Knowledge Levels

Methods

In this study, we analyzed five textbooks, as addressed in Table 2. Similar to Slavin and Lake's framework (2007), three categories of textbooks were selected: (a) "Back to Basics," which originated in the 1970s and early 1980s, (b) "National Science Foundation (NSF) funded" texts, which originated in the 1990s in keeping with mathematics reform standards and (c) "Commercial Texts", which are typically reissued every five to seven years. In addition we selected, (d) a historic text, which was which originated in the 1960s. We felt these categories allowed us to examine representative types of texts currently available to students and the historic text allowed comparison. Each textbook was part of a series and represented the point in the series where linear graphs were first introduced.

Code Name	Origins	Date of Edition	Grade Level	Categorical Description (quotes: Slavin & Lake, 2007)
Historic	1960s	1965	9th	Commonly used Algebra text: 1960s & '70s
Back to Basics	Early 1980s	2001	8th	"A back-to-the-basics curriculum that emphasizes building students' confidence and skill in computations & word problems."
NSF Funded	1990s	2003	9th	"Textbooks developed under funding from the National Science Foundation (NSF), that emphasize constructivist philosophy… problem solving, manipulatives, and concept development …with relative de-emphasis on algorithms."
Commercial Text One	various	2005	8th	"Commercial textbook programs which include computational fluency but also are written to help students develop concepts."
Commercial Text Two	various	2005	8th	"Commercial textbook programs which include computational fluency but also are written to help students develop concepts."

Table 2. Textbooks Examined

- Historic = Dolciani, M. P. (1965). *Modern Algebra Book 1.* Boston, MA: Houghton Mifflen.
- Back To Basics = Saxon, J. H. (2001). *Pre-Algebra.* Norman, OK: Saxon Publishers, Inc.
- NSF Funded = Fendel, Resek, Alper, & Fraser. (2003). *Interactive Mathematics Program: Integrated High School Mathematics: Year 1.* Emeryville, CA: Key Curriculum Press.
- Commercial Text One = Larson, Boswell, Kanold, & Stiff. (2005). *Pre-Algebra.* Evanston, IL: Houghton Mifflen.
- Commercial Text Two = Malloy, Boswell, Willard, & Sloan. (2005). *Pre-Algebra.* New York, NY: Glencoe/McGraw Hill.

Analysis involved two broad foci: content analysis and problem analysis, as presented in Table 3. Content analysis included examination of (a) allocation and (b) topic presentation. Problem analysis included examination of (a) contextual features, (b) mathematical features, and (c) cognitive performance requirements.

Analysis Category	Description
Content	
● Allocation	(a) What are the number of problems allocated to the topic? (b) What percent of the textbook does the topic occupy? (c) How much time do students spend on the topic?
● Topics	(a) Sub-topics presented including slope and y-intercept (b) Breadth of presentation of further topics
Problem	
● Context	(a) Real world context (b) Exclusively numeric exercises
● Response Type	(a) Single response number, point, or vocabulary word (b) Equation only (c) Graph only (d) Table only (e) Extended response, such as “explain” or “describe” (f) Mixed response, i.e., some combination of the above
● Cognitive Level	(a) Recall (b) Skill/Concept (c) Strategic Thinking (d) Extended Thinking

Table 3. Analytical Foci of the Study

Summary of Results

Content Analysis Results

Results from Analysis of Allocation

We examined allocation, which involved the number of problems, as well as the proportion of time and text devoted to the topic. Table 4 shows both trends and some interesting constants from historic to current textbooks.

Text	Historic	Back to Basics	NSF Funded	Commercial Text One	Commercial Text Two
Grade Level	9^{th}	8^{th}	9^{th}	8^{th}	8^{th}
Total Number of problems	315	44	44	304	305
Percent of text devoted to linear relationships	7.3%	1.1%	8.7%	8.0%	9.6%
Approximate class time	Under 3 weeks	N/A	About 3 weeks.	About 3 weeks.	Just under 3 weeks.

Table 4. Results from Analysis of Allocation

The historic textbook and two commercial texts have much in common with respect to the total number of problems given, percent of text devoted to the topic and approximate class time. Each used a very similar number of problems; about 310, and similar timing: about 3 weeks. In fact, all but the “back to basics” text introduced linear relationships by spending about 3 weeks on them, devoting an entire unit (chapter) to the topic. The percent of material showed a slight general increase: from 7.3% in 1965 to 9.6% in 2005. This may indicate growing emphasis on linear relationships in modern and more technological times.

The introduction to graphing linear equations has been "moved down" to the 8^{th} grade level from historic to current textbooks. This seems to be part of a general trend. Indeed, Common Core Standards now expect that students will see the material in 8^{th} grade.

Compared to other textbooks, the back to basics text did not use chapters, but reviewed many topics each day. It was not possible to determine the exact amount of time focused on linear relationships, hence the "N/A" in the table above.

Results from Analysis of Topics

Table 5 summarizes the various separate objectives pertaining to linear relationships in the five textbooks. We further analyzed topics presented in textbooks, the breadth of presentation by answering the following questions: (1) Were a large number of sub-topics presented, stretching beyond such things as equation, slope, intercept, graphs and tables? (2) If so, this might affect the depth to which those more foundational conceptual topics could be covered.

Textbook	**Objectives beyond points, equation, slope, intercept, graphs & tables**
Historic Text	Equation of a line through two points, a line with a given slope through a given point, and a line parallel and/or perpendicular to a given line through a given point. Points where lines intersect. Graphing parabolas.
Back to Basics	Students do not go beyond plotting three points and sketching a line.
NSF Funded	Students do not go beyond the topics above, though they explore these in conceptual depth.
Commercial Text One	Equation of a line through two given points, a line though one point, though a given parallel and/or perpendicular line. The equation of a line of best fit. Graphing inequalities.
Commercial Text Two	Direct variation and inverse variation. Lines of best fit. Equation of a line through two points and equation of a line from a table. Graphing systems of equations, and inequalities.

Table 5. Breadth of Presentation: Topics

As shown in Table 5, large numbers of sub-topics (objectives) were included in a majority of the texts. The back to basics text, however asked only that students produce a table with three points, graph the points, and draw a line through the graph in their initial foray into linear relationships. The commercial and historic textbooks included numerous sub-topics.

The United States curriculum has often been criticized as "a mile wide and an inch deep" (Common Core State Standards, 2010). We examined how this tendency toward broadness remains from historic to current textbooks. Surprisingly, a very large number of objectives are presented in the commercial texts, just as in the historic text of about forty to fifty years ago. A plethora of topics was not attempted by the back to basics and NSF funded text, however.

Problem Analysis Results

Results from Analysis of Context

Table 6 shows the frequency of two categories of contextual features. Contextual features involve whether a setting is given for the problem, or whether it is devoid of real world context and merely in the form of an "exercise".

Text	With Context	Without Context
Historic	1%	99%
Back to Basics	0%	100%
NSF Funded	100%	0%
Commercial #1	15%	85%
Commercial #2	12%	88%

Table 6. Problem Context

There was a great deal of variation between texts when it comes to providing real world context. The back to basics and historic texts essentially did not include it. In more recently published commercial texts, a middle ground approach was utilized, with an average of 12.5% of problems including some context. In contrast, all problems in NSF funded reform texts were presented in regard to a real-life situation. In this case, the situation involved one over-arching unit theme problem. Thus, students could relate all problems in this text to real life applications. This indicates that students with the NSF funded text will learn linear relationship differently from students with other textbooks.

Results from Analysis of Response Type

Response types were categorized as single number/word, equation, graph, table, written word, or mixed. Single point coordinates were coded with single numbers. Written words (plural) in response might have required a phrase or a sentence to explain or justify, but sometimes called for a longer response in the form of sentences or paragraphs. A mixed response was some combination of responses, for example, “Make a table, then plot a graph”.

Text	Single Number	Equation	Graphic	Tabular Response	Written Words	Mixed Response
Historic	50%	17%	19%	0%	6%	7%
Back to Basics	0%	0%	39%	0%	0%	61%
NSF Funded	34%	21%	9%	2%	30%	5%
Commercial #1	37%	20%	14%	1%	24%	4%
Commercial #2	48%	11%	18%	0%	11%	11%

Table 7. Response Types

Regarding limits on these models, it was striking that single numbers were the most common type of response in most of the texts. Equations and graphs tended to be the second most common. Tables were rare as an exclusive response type, but were often included in a mixed response. The NSF funded text allowed for the greatest number of written word responses, which were almost entirely absent in historic and back to basics texts, and comparatively rare in at least one of the commercial texts. Written word responses and mixed responses, the response types most oriented toward multiple representations and connections between models, were generally limited, except as noted. Kilpatrick, Swafford and Findell (2001) stress that multiple representations and connections are important for fostering understanding. Analysis of response type indicates that students with the NSF funded textbook will be provided more opportunities to learn linear relationships with multiple representations and connections.

Results from Analysis of Cognitive Expectation

Cognitive Expectation refers to the type of problem solving required which consists of four levels: recall facts (level 1), concepts (level 2), strategic thinking and evidence (level 3), and extended thinking (level 4). Table 8 shows the percentage of each cognitive expectation in each textbook.

Text	Level 1: Recall	Level 2: Skill/Concept	Level 3: Strategic thinking	Level 4: Extended thinking
Historic	83%	11%	7%	0%
Back to Basics	100%	0%	0%	0%
NSF Funded	0%	0%	0%	100%
Commercial #1	61%	20%	16%	3%
Commercial #2	71%	11%	17%	1%

Table 8. Results on Cognitive Expectation

The large numbers of problems devoted to recall were linked to a procedural presentation of how to do these problems in textbook examples. Thus, the NSF funded textbook was able to attempt greater depth of presentation in comparison with other texts. It should be noted that all 44 problems in the NSF funded text were grouped into a single theme, and so they were coded as one, single, extended problem with 44 parts. However, none of problems in the historic and back to basics texts were at Level 4, and thematic connections between problems, such as those in the NSF funded text, were rare.

Regarding Level 3 "Strategic Thinking," there was an increase in problems of this level from the 1960s to the present. This shows that we may presently be moving toward problems of somewhat higher cognitive demand. Even though an average of only about 34% of problems were conceptual and strategic in the commercial texts, these problems take more time than mere recall problems. Thus, while it is impossible to say for sure, it is possible that students in commercial texts have the opportunity to spend well over half their time or more on conceptually oriented problems.

It is striking, however, that a large percentage of problems in the four non-NSF funded texts were categorized into Level 1, demanding no more than 'recall'. Also, it is comparatively rare for students to work on extended thinking problems if teachers use the historic, back to basics, or commercial textbooks.

Discussion and Implications

This study presents different student opportunities to understand linear relationships in a majority of texts examined from historic to current textbooks. There were numerous similarities between the historic textbook and the present day commercial texts. These included the number of problems, and the time devoted to the topic. The method of presentation was either largely or moderately procedural in these texts. The NSF funded text, on the other hand, showed the greatest difference from the historic text. All of its problems involved real world context and were geared toward extended thinking, in the form of a project, something the historic text did not include.

Regarding content, students using commercial texts who are just being introduced to linear equations are expected to master a broad array of objectives, such as "find the equation of a line between two points" and "find the equation of a line through a given point with a given slope". A deeper curriculum, providing more time for actual understanding of concepts such as slope and y-intercept, may be in order. This finding suggests that students may be limited with regard to models, timing, topics and expectations. In contrast, however, students may be receiving an overly broad a treatment of the topic, a treatment which lacks sufficient depth.

In particular, this lack of depth can be seen in problem presentation. The back to basics and historic texts showed a high degree of orientation toward mere procedural presentation. The NSF funded text, in contrast, was highly oriented toward conceptual problems, with commercial texts somewhere in between. Similarly, regarding real world problem context, historic and back to basics texts tended to provide little, commercial texts a moderate amount, and the NSF funded text provided real world context for all problems. Finally, continuing this theme, cognitive expectations tended to be largely procedural in the historic and back to basics text, to include some mix of procedural and conceptual orientation in commercial texts, and to be almost entirely conceptually oriented in the NSF funded text.

This study also revealed that there was a difference between a high degree of cognitive expectation and a high degree of symbol manipulation. A problem on finding the equation of a line between two points, for example, requires lengthy manipulation of equations, but can be done with little or no conceptual basis. Are we failing to give students enough problems with high cognitive expectation, all the while "feeling good" because we ask more of them in terms of what they do with symbols? It is important for future researchers to address such questions. None of the texts examined appeared to sufficiently address all five strands of mathematical proficiency articulated by Kilpatrick, Swafford and Findell (2001). The NSF sponsored text came the closest, addressing adaptive reasoning, strategic competence, conceptual understanding and productive disposition. However, it failed to address procedural fluency.

This study has implications for curriculum developers, school administrators and teachers. All three groups can help students gain better opportunities to understand linear relationships. This study stresses the important role of teachers. Teachers need to recognize the gap between the intended and potentially intended curriculum and modify their textbook. They can use supplementary materials for the NSF text, for example, providing practice with procedures. Supplementary materials for commercial texts might provide practice with extended thinking problems and additional real world context.

Curriculum developers also should recognize the gap between the intended deeper curriculum in such documents as the Common Core State Standards and the potentially implemented curricula in current textbooks. They should try to minimize this gap by providing context, attending to depth of conceptual topic presentation, calling for a balance of response types, including sufficient procedural practice, and calling for appropriately deep levels of cognitive expectation.

School administrators need to consider the types of textbooks they select. If they want to increase student understanding, reasoning and sense making, they need to choose textbooks which emphasize all five strands of mathematical proficiency, where possible, like those suggested above.

Future research may reveal optimal blends for the factors examined in this study. For example, while the study reports on the percent of problems with a real world context, it is up to future research to reveal whether or not it is helpful for all problems to be set in a context.

To sum up, the data revealed some limited learning opportunities. They indicate that though students are being asked to grapple with linear relationships at increasingly younger ages, that they are limited in the models they are asked to use for linear relationships, that discussion of concepts and connections is often limited, that the majority of problems lack a real world context, and that a majority of problems address lower levels of cognitive expectation. Often, linear relationships are presented in textbooks in a way that, while very broad, in keeping with detailed and lengthy individual state standards, does not aim for depth of understanding. The results therefore revealed a significant gap between learning goals as set forth in intended curricula, and the potentially implemented curricula contained in many current U. S. textbooks.

This cross case analysis synthesizes results from two qualitative studies on mathematics content courses for prospective elementary teachers: one from the U.S. interviewed instructors, one from Canada interviewed students. Results were examined for common themes. Salient commonalities were found. Two will be discussed here: the role of affect in student learning and the role of connections to the elementary classroom.

Pervasive concerns about the adequacy of the mathematical preparation of elementary teachers (Ball, Hill, & Bass, 2005; Rowland, Huckstep, & Thwaites, 2005) have prompted many institutions of higher education to require specialized mathematics content courses for prospective teachers. These courses, referred to here as *Math for Teachers* (MFT) courses, aim to provide deep understandings of elementary mathematics concepts in order to develop prospective teachers' confidence and flexibility in teaching mathematics (Kilpatrick, Swafford, & Findell, 2001;Williams, 2008). MFT courses are most often taught in mathematics departments by mathematics faculty.

The research described in this paper presents results from a cross-case analysis of two existing studies on MFT courses. The two studies are briefly described here.

The *instructor-focused* study examined ten instructors' perspectives on a MFT course at several institutions in southwestern Canada (Oesterle & Liljedahl, 2009). The purpose of the study was to provide insights into the instructors' approaches in the course and how their beliefs impacted pedagogical decisions. Data from the semi-structured, individual interviews (1 hour in duration) were analyzed for emergent themes using constant comparative analysis. These themes include: instructor identity, tensions, resources, student knowledge, student affect, orientation to mathematics, orientation to teaching, and classroom environment.

The *student-focused* study explored the perspectives of 12 elementary education majors (i.e., prospective elementary teachers) who had completed MFT courses at a university in the southeastern United States (Hart & Swars, 2009).The study was inspired by concerns over the poor success rates of elementary education majors enrolled in these courses. Data collection included semi-structured, individual interviews (approximately 1 hour in duration), and constant comparative analysis was applied to the data, revealing three major themes: (1) domains of mismatch (2) affective reactions, and (3) classroom practices. The domains of mismatch theme had three sub-themes: mismatch with elementary classroom, mismatch in programmatic emphasis, and mismatch in mathematics content.

Overview of Relevant Research

These two extant studies were framed by prior research on mathematics knowledge-for-teaching (e.g. Ball & Bass, 2003) and instructor beliefs about mathematics (Ernest, 1989). Of relevance to both studies, and of particular interest in this paper, is the literature pertaining to: the role of affect, beliefs and efficacy in prospective elementary teacher learning (e.g., Di Martino

& Sabena, 2007; Thompson, 1992; Swars, Hart, Smith & Smith, 2007); post-secondary mathematics content courses for elementary teacher (e.g., Lubinski & Otto, 2004; Philips, 2007); and perspectives on and characteristics of effective university mathematics instruction (e.g., Schulze & Tomal, 2006; Weinstein, 2004). While there is an abundance of literature on the significant role of beliefs and affect in the pedagogical practices of teachers, far fewer studies are available on mathematics content courses for elementary teachers and those found were primarily limited to outcomes of reform-based approaches in these courses. Scant studies have looked at characteristics of effective post-secondary mathematics instruction in traditional (i.e., non-MFT) mathematics courses.

Theoretical Perspective and Research Question

This cross-case analysis, as well as the two original studies, is grounded in phenomenological interpretation (Burch, 1990). Students and instructors individually reported their perspectives on the MFT courses. Through the interviews, participants reflected on and retrospectively identified the significant or memorable events from their MFT experiences. Through this process, they recovered and verbally reenacted the meaningful components of their lived experiences.

For this cross-case study, we were interested in determining what intersections might exist between the perspectives of instructors of a MFT course and the perspectives of students in the MFT courses. More specifically, we asked this research question: *What common themes exist in instructor perspectives and student perspectives on mathematics content courses for prospective elementary teachers?*

Methods

Participants and Setting

The student-focused study involved twelve students (11 females and 1 male) from one urban university in the southeastern U.S. The students had completed three or four MFT courses. They were randomly selected from 4 cohorts of students in the elementary teacher preparation program with a combined size of 99 students, thus representing approximately 12% of the total population. Collectively they had taken 42 sections of MFT courses. At the time of the original study, all of the students were in the last semester of the program and completing student teaching.

Although the instructor-focused study gathered data from ten instructors, for the purpose of this paper examples will be drawn from the transcripts of only two: Harriet and Bob (pseudonyms). The divergent perspectives they offer on teaching the MFT course provide a sufficient basis for illustrating the common themes identified in this analysis. Harriet and Bob are both experienced instructors, having taught in mathematics departments for 22 and 13 years respectively. Harriet is relatively new to teaching the MFT course but had taught the course six times over three years, while Bob taught it nine times over nine years. Both have Master's degrees in mathematics but neither took mathematics education courses nor had formal teacher training. Harriet was initiated into teaching the MFT course by a colleague with a Master's degree in mathematics education who taught MFT courses for many years. Bob's first forays into teaching the course were guided by his institution's curriculum, the textbook, and informal discussions with colleagues.

Data Collection and Analysis

Data collection for the two extant studies was described in the background section of this paper. To conduct the cross-case analysis for this present study, we created a matrix with the results from the two studies, specifically examining the data for convergence. This analysis revealed two commonalities across the themes, including *connections to the elementary classroom* and *student affect*, as shown in Figure 1.

Student-focused Study	Instructor-focused Study
• *affective reactions*	• *student affect*
• classroom practices	• instructor identity
• domains of mismatch	• resources
a. elementary classroom	• *orientation to teaching*
b. programmatic emphasis	• tensions
c. mathematics content	• orientation to mathematics
	• student knowledge
	• classroom environment

Figure 1. Themes and commonalities of the two extant studies.

Cross-case Results

The Students' Perspectives on Connections to the Elementary Classroom

After experiencing other courses in their teacher preparation program, the students were acutely aware of disconnections between their experiences in the mathematics content courses and other experiences in the program. The students frequently described an inability to position the mathematics content coursework within their growth as educators, which led to perceptions of lack of usefulness or relevance of the courses as evidenced by this statement: '*I mean a lot of us were always questioning, you know, why we have to take these math courses…It's not even necessary.*' Similarly, another student stated, '*The reason why we were taking those courses was never brought to our attention. We had no clue why we were taking those classes, no clue…It seemed very unnecessary.*' Another student said:

> *It [mathematics courses] had no connection to elementary schools. Anybody could take those courses. I don't think we ever talked about kids. I seriously don't think we ever talked about teaching or students or anything like that. I just don't remember ever that connection.*

Another student explained the lack of connection with elementary classrooms as:

> *In our [elementary] classrooms right now, you know, they're not graphing how many bagels and coffee people are going to eat and drink tomorrow. It was just not very logical for, you know, a kindergartner.'*

The following statements further support this sentiment:

> *They're [mathematics instructors] blind to what we are actually doing with our lives'; '[Elementary] Students were never even brought up… I mean, students or when you get your own classroom were never brought up'*; and '*We're thinking we're learning something about how to be teachers. But, in reality we're learning how to get through their math courses.*

The participants did indicate positive experiences in some of the courses. In particular these related to modeling pedagogical methods that might be used in an elementary classroom or using materials that elementary students use. For example, one student commented:

> [The Number & Operation course instructor] *was big on you know . . . we would do that in class, it wasn't like, take this home and do this but we actually* [did activities in class] *and we did a lot of group work and that was really good too.*

One student provided a specific example of making strong connections:

> *We had to do a project in geometry where we had to go to like a specific county and get a book and find a geometry lesson, but that was just a project and we presented it to the class . . . so just different things like that, just to make it real to us.*

One student noted that the positive experiences and factors that made it positive occurred in her methods course, not in the content course.

> *No* [not in the content], *this happened in my methods course, mainly because she* [the methods instructor] *took out the manipulatives, showed us what they were going to be doing, she basically took curriculum from those grade levels and put it in front of our faces.*

Ideas for changing the courses were proffered, including*: 'Get some teachers who were actually qualified in elementary [teaching]… They actually know what children are going through and that would help;' 'They [mathematics instructors] could talk to elementary teachers;'* and '*Maybe have us students say, hey, this is what is going on in my [elementary] classroom.'*

The Instructors' Perspectives on Connections to the Elementary Classroom

Harriet's descriptions of her goals and strategies for teaching the MFT course are permeated with comments related to mathematics-for-teaching knowledge (Ball & Bass, 2003) and how her students' learning relates to their future as teachers. When asked if there is anything that she teaches MFT students about fractions that she would not teach other students, she states:

> *The fact that there are different models, there are different ways of picturing what's going on, and that they are appropriate for [...] what may work well for some situation, or for some [elementary school] student, may not work for some other one*.

She also emphasizes connections between mathematical ideas both within and across grade levels. She explains:

> *At all times I connect it [the course content], as far as I can, to what goes on at different levels. What you might do with a grade 1 class, how that connects to what they're going to see in, you know grade 4 or 5 or something like that, how that connects to what they might do in high school and how that connects to what I'm doing in Calculus. Because they've got to see how it's connected, and how we build bigger and bigger [...] understandings of sets of numbers, or calculations.*

Harriet does not just pay lip-service to these ideas. She describes assignments that allow her students to build their mathematics-for-teaching knowledge, such as analysis of pupil errors and discussion of alternative solutions.

In contrast, Bob makes very little reference to mathematics-for-teaching knowledge. His emphasis is instead on developing a strong understanding of fundamental mathematics and communication skills. Varieties of algorithms and models form part of his course content, but he does not specifically address how they can be applied differently at various grade levels.

Bob needed to be pressed by the interviewer to consider what aspects of the course content might be particularly relevant to prospective teachers as opposed to general learners of mathematics. Initially his comments revolve around his teaching methods, such as the use of group work and manipulatives, but he makes no reference to any special mathematics knowledge for teaching. Eventually he describes challenging his students to think about the kinds of questions that they will encounter as teachers:

> *. . . what kinds of questions will you encounter? And why is it important that you to be able to communicate your ideas effectively, […], why should you understand this material to the most, [...], fundamental and basic level, and understand all of the structure?*

He adds:

> *when you get some of these obtuse questions, that are seemingly [...] obtuse, you have to be able to appreciate it and be able to differentiate whether that's something that can lead you into a teachable moment*

His response appears to be a justification for his goals of developing strong mathematics content knowledge and communication skills. For Bob, mastery of the subject content along with general pedagogical skills, seem to be sufficient for the teaching of mathematics—a traditional and prevalent point of view (Hill et al., 2007).

The Students' Perspectives on Student Affect

A second theme across the interviews was students' affective reactions to the coursework experiences. Many statements described negative emotions, for example, they used words such as '*emotional wreck', 'so stressed', 'very belittling', 'discouraged', 'terrified', 'struggling',* and *'frustrating'.* A student asserted, '*I felt like I was just hanging on. Just trying to dig myself out of a hole, and I kept falling down.'*

The students also portrayed the courses as having deleterious influences on their mathematics teaching efficacy beliefs and self-efficacy beliefs, which were often linked with the classroom practices of the instructors. Most often, descriptions of ineffective pedagogy were related to traditional approaches to instruction. The students mentioned a preponderance of 'lecture,' 'note-taking', and 'power point presentations,' and asserted the 'classes were not hands-on.' In describing how the courses impacted teaching efficacy beliefs, a student stated, '*I felt less confident [about teaching mathematics] when I walked out of those classes because it's just so much and it just seemed so unnecessary… It was just very discouraging.'* In response to a question on how the courses prepared her to teach elementary mathematics, a student stated the courses made her, '*Feel less prepared. Feeling more scared, definitely.'* One student attributed this negative impact on her teaching efficacy to the attitude of the instructor of the course, '*The attitude was if you don't get this [math content], you won't be able to teach it, basically.'*

Students also commented on how the experiences in the courses influenced their self-efficacy beliefs in mathematics, as represented by this student's statement:

> *[I felt] terrified, struggling, especially in geometry. It was just, it was very frustrating because I didn't get it. I didn't understand why we're doing what we were doing, how we were coming out with the answer, and especially if I didn't get the answer right.*

Further, another student stated:

> *Like geometry… I came out of there in tears. I felt very disappointed. I felt stupid. I felt alone. And, I know that I am an intelligent person, or I have the potential to learn something. If I don't know it, I'm willing to give up my time and my efforts. But, I felt like my efforts didn't matter.*

Similarly, another student said:

> *It (mathematics courses) made me feel so low in math. Even though I knew those math courses, I would never be teaching that stuff… It totally lowered my self-esteem in mathematics*.

The Instructors' Perspectives on Student Affect

Both Bob and Harriet describe their students as suffering from mathematics anxiety and lacking confidence in their ability to do mathematics. However, there are considerable differences in their perspectives and pedagogical approaches to these negative affective states.

Harriet observes that her students: '*are very anxious around problem solving. They are just* *terrified, most of them, of a problem they haven't seen before*.' Her efforts to address this seem to be centered on changing their ideas of what the enterprise of mathematics is all about. She tries to convince them that '*we're supposed to have fun with this*' and tells her students that '*you may never have seen it; you might not get all the way through it. But what I'm looking for is how far did you get, and how well can you explain what it is that you got*', shifting the focus away from getting the right answer toward less threatening goals.

By the end of the course she hopes her students have grown in confidence and also '*they have more of a sense of play [...] I think they're more flexible. They think they're more flexible. They're not as scared if [...] that someone will ask them a question that they can't answer.*'

Bob describes his students as believing that mathematics is arbitrary and incomprehensible: '*So many things seem magical to them'*. He affirms that '*it's not your standard sort of math group, it's one that has encountered some challenges along the way, and it hasn't always left them with a positive impression of mathematics.'* In his view, their confusion and anxiety is closely linked to their skills:

> *In many cases, some of the very elementary arithmetic operations are in fact, confused in their minds and so when they hit upon things, in particular when you hit rational numbers, as an example, that's one place where students have a great deal of anxiety and they would demonstrate poor understanding of ideas.*

More than once he describes the MFT course as a second start for these students. He attempts to reshape their beliefs and attitudes by providing them with opportunities to see the logical structure of mathematics and deepen their understanding. For Bob, the course '*focuses on a very sound fundamental ability to appreciate it [mathematics], in a theoretical way, why things work, as opposed to technical aspects of how do you do mathematics.*' However, although he believes that improved skills will lead to increased appreciation and confidence, he confesses that the realities of the course conspire against this occurring. Early in the interview he expresses a wish that his MFT students develop a love of math, but when asked about whether this goal is accomplished, he admits: '*in terms of the other goal, for love of math? Unfortunately, the course is so packed, that in some ways, I think they do get a little bit beaten by the end, and they're just tired*.' This statement illustrates Bob's realization that the volume of content covered in a limited time is at odds with his affective goals.

Discussion

Although the two groups of participants in these studies were in different settings, they provide two distinct viewpoints on a similar experience: MFT courses. When juxtaposed the data reveals salient commonalities. The findings provide important insights into issues and concerns around creating experiences in MFT courses that best support elementary prospective teachers' learning of mathematics; they also enrich our understandings of the realities of MFT classrooms, revealing both the affordances and the constraints.

The student voices emphatically call for the need for connecting the mathematics to the elementary classroom. Without this connection, the students were not able to find relevance in their learning. This need is recognised in the literature (Philip, 2007). Ball and Bass (2003) also strongly advocate for this link:

> *Practice in solving the mathematical problems they will face in their work would help teachers learn to use mathematics in the ways they will do so in practice, and is likely also to strengthen and deepen their understanding of the ideas.* (p. 13)

The instructor-focused study reveals how differently instructors may perceive the need for incorporating these connections. Harriet is very aware that these links help to motivate her students, helping them to see why a deeper understanding of mathematics is required of them in this course as compared to their previous mathematics courses. For Bob, making these connections is not an explicit part of his course. One reason for this may be that as a mathematician his lack of experience in elementary classrooms limits his ability to do so. However, Harriet also lacks such experience. Another possibility is that Bob takes such connections for granted. His inability to identify content in his course that would be particularly relevant to future teachers of mathematics as opposed to general mathematics students reflects a lack of awareness of specialized mathematics knowledge-for-teaching. For Bob, subject content knowledge and pedagogical knowledge are distinct. He sees his role as supporting the development of the former.

With regard to the theme of affect, the student-focused study reports an alarming number of negative comments, indicating increases in students' anxiety and decreases in self-efficacy. Both instructors were acutely aware of the impact of affect and described their students as coming into the course with high mathematics anxiety and lack of confidence. However, their perceptions about the cause of the anxiety and strategies for addressing it were quite different. For Bob, the source is students' lack of fundamental skills. As a result, his solution is to help them see the logical structures of mathematics and develop these skills, though he acknowledges that the sheer volume of the material he must cover, in fact, adds to his students' stress. For Harriet the source is negative past experiences and a perception of mathematics as rigid. Her efforts focus on moving students away from the 'one right answer' view of mathematics, helping them develop more flexibility in approaching mathematical problems and to just have *fun*.

From the students we hear that traditional instructional methods of lecture, power point presentations, and drill and practice tended to elevate anxiety and decrease efficacy, while reform approaches such as small group work, hands-on learning, and opportunities to share and discuss were less stressful and increased efficacy. They also shared that the instructor having a caring manner, an approachable demeanour, and a perceived willingness to help supported their learning. This echoes Schulte & Tomal (2006) cited above. Regardless of their perceptions of the source of their students' anxieties, knowledge of this research could help inform instructor choices with respect to how to address concerns around student affect.

The voices of the students in the student-focused study lend support to concerns that mathematicians in mathematics departments may be unprepared to take on the task of preparing elementary teachers. The lack of connections of content with the elementary classroom and traditional teaching approaches seem to contribute to frustration and anxiety as well as decreased self-efficacy. However, the instructor-focused study shows that though lack of explicit connections to elementary learning may occur, this need not be so. The differences between Harriet and Bob in this regard may have been the result of the mentorship Harriet received, suggesting a potential means for supporting the mathematicians who teach these courses.

Another side of this issue is that mathematicians, at their best, have much to offer future teachers, even at the elementary school level (Hodgson, 2001; Williams, 2008). Jonker (in review) describes mathematicians in mathematics departments as 'stewards of their discipline,' 'passionate about mathematics', and 'eager to share their excitement with students and concerned about the place of mathematics in the world.' The challenge is to create opportunities for conversations between mathematics educators and mathematicians so that students in MFT courses are better prepared to teach mathematics to elementary children.

REFRAMING FAILURE: AN ANALYSIS OF HIGH SCHOOL MATHEMATICS TEACHERS' LEARNING

Nicole A. Bannister
Clemson University
nbannis@clemson.edu

This paper examines how teachers engaged in equity-oriented reforms learn through interactions in teacher groups. Analysis of teachers' framing of a freshman mathematics student failure problem showed that over time teachers' frames shifted from invariable framings based on student characteristics and systemic issues to actionable framings based on classroom systems contributing to student failure, thereby promoting teachers' concentration on courses of action linked to instruction. By joining the frame analysis and community of practice literatures, this study contributes an empirical example of development within teacher community alongside analytic tools for documenting teachers' learning within these groups.

Research suggests that teachers' participation in a strong teacher community has the greatest potential for yielding the kinds of teacher learning that produces equitable student outcomes, though what that learning is or how it might be taking place is largely unaccounted for in the literature (Gutiérrez, 1996; Horn, 2005; Little, 2003; McLaughlin & Talbert, 2001). This "black box" of teacher learning (Little, 2003) has resulted in schools and districts moving forward with well intentioned yet underconceptualized reforms involving *professional learning communities,* based on an inferred causal connection between teachers' participation in these communities and improved student achievement. Many teachers have nevertheless been required to spend professional development time participating in what Grossman and colleagues (2001) call *pseudocommunities*, characterized by members "playing community" and behaving "*as if* we all agree" (p. 955), which surely sidesteps the important work that needs to be done inside of the professional learning community to achieve equitable student outcomes. This paper addresses this phenomenon by examination of the professional community as a learning resource for teachers. The research question driving this investigation asked: *How do teachers engaged in equity-oriented reforms learn through interactions in teacher groups?*

Theoretical Framework

Teachers' Learning in a Community of Practice

Teachers' participation in their professional communities is a social endeavor. This activity catalyzes a dual process of participation and reification, which is the fundamental process through which learning happens (Wenger, 1998). This learning-as-a-social-phenomenon stance supports a more general conception of teacher community, meaning that these groups do not necessarily have a certain level of functioning, improvement-oriented stance, or meet some other criterion; rather, they are the places where learning unfolds (Coburn & Stein, 2006). By adopting a *community of practice* perspective – which Wenger (1998) characterizes as communities where members are mutually engaged in an activity, held together by a joint enterprise, and have a shared repertoire of customs for praxis – *learning* is defined as a change in participation within that community. This definition of learning recognizes the co-construction and distribution of knowledge across teachers and takes the wider social context into consideration. This framing is critical for this study because it allowed for an equity-oriented description of the teacher group in my study with the understanding that such a description is neither unitary nor consistent, which helped me see teacher groups for what they are: key sites for negotiation of meaning related to their joint enterprise (Coburn & Stein, 2006).

Frame Analysis as a Means for Capturing Learning

This study aimed to understand teachers' learning through interactions in a community of practice context, and so conceptual tools that capture learning as changes in participation within the group are needed. Theoretical and empirical work on frame analysis proved useful for making sense of these interactive learning processes as they unfold (Benford & Snow, 2000; Goffman, 1974; Snow & Benford, 1988). Snow and Benford (1998) use the verb *framing* to conceptualize the signifying work of spreading ideas, meaning making, and mobilizing others into action. I borrowed conceptual tools from this work and coupled this literature with the communities of practice literature because of their common interest in understanding the processes surrounding participants' interaction, with focus on "how people use interpretive frames strategically to shape others' meaning-making processes in an effort to mobilize them to take action" (Coburn, 2006, p. 347). By analyzing teachers' framing processes, I gained analytic purchase on making sense of teachers' engagement in these negotiation of meaning processes, such as how participation in teacher groups and reification of equity-oriented reforms shaped their ideas and guided the community's action. It stands to reason that teachers' collective engagement in framing processes is likely to generate evidence of and describe changes in teachers' participation in a community of practice (Wenger, 1998), which I interpret as evidence of learning. Thus, examination of the ways in which teachers engage in framing processes through interactions in teacher groups stands to result in more manageable units of interactions for the analysis of their learning.

Methods

Context, Settings, and Participants

This research takes place in the context of *Adaptive Professional Development,*[1] a larger design-experiment project situated in part at Clark High School (all names are pseudonyms), a diverse, large, urban comprehensive high school in a large northwestern school district in the US. Our research team worked with the Clark mathematics teachers using a mutual appropriation approach – that is, we collaborated with the teachers to create activities that fit theoretical principles about equitable mathematics teaching while serving the teachers' goals (Cole, 2006). Our precepts included pedagogical principles about equitable mathematics teaching, such as the use of pedagogical strategies to engage learners in important mathematical ideas (Boaler, 2002; Horn, 2006; Moses, 2001). In addition, we used learning principles for teachers, such as prioritizing providing teachers with collaborative time in the school day to make sense of new practices in their classrooms (Horn, 2005, 2007; Horn & Little, 2010).

During the 2004-2005 school year, I followed the interactions of the mathematics department at Clark in my role as a researcher. I observed classrooms, attended department meetings, and provided classroom support to teachers. Susan, a veteran teacher, confided that she struggled with issues related to students, teaching, and mathematics. She asked for my help and so I provided her with additional classroom-based support several days per week, such as co-planning instruction, revisiting content, modeling teaching, making sense of student work, and interpreting student interactions. However, even with this support Susan still faced a crisis: over 75% of her freshmen students were failing her first-year mathematics course. This crisis caused the other teachers of first-year mathematics to examine their pass rates, and the results were stunning: more than 50% of students taking the first year (9th grade) mathematics course at Clark were failing. Teachers were in a panic over these data and asked our research team to help them make changes to their existing curriculum and pedagogy with the aim of improving all the success of all students.

Realizing the ambitious nature of the Clark teachers' plans for implementing starkly different pedagogical and curricular equity-oriented reforms, our team designed an intervention for the 2005-2006 school year to support their reforms. We created the "Freshman Team" intervention by providing the four teachers of first year mathematics with an extra planning period (in addition to their personal planning period) so that they would have dedicated time each day during the school day to collaborate around issues of teaching and curriculum. We also helped Clark find a new teacher trained in equity-geared teaching practices who could take on the "missing" four first year classes, in addition to being a part of the collaborative team and having her own personal planning period. The Team was composed of five teachers: Susan (10+ years experience), Zack (3+ years experience), Rose (30+ years experience), Julie (5+ years experience), and Linda (new teacher). The Team met during every sixth period meeting, and in a typical week they had three 50-minute meeting and one 110-minute meeting.

Research Strategies

I crafted a case study around the Freshman Team at Clark because this method focused the investigation and analysis on the complexities and particulars of teachers' learning around about struggling students in context of equity-oriented reforms (Merriam, 1998). Sustained attention to one group and context fostered in-depth exploration and analysis of the "richly brewed particulars" (Dyson, 2005, p. 2) of teachers' learning. These choices ultimately allowed me to use the case of Clark to theorize about teacher learning inside teacher community more generally and respond to a need for case studies of this nature (NAE, 2008).

My study targeted high school mathematics teachers because they teach a high status, high stakes content area that consistently plays a gatekeeper role for students (Moses, 2001; NRC, 1989; Schoenfeld, 2002). Making matters worse is the fact that a disproportionate number of poor and minority students compose this group, meaning that working-class students and students of color are marginalized in their mathematics classes more than their peers (Moses, 2001). These harsh realities have renewed interest and urgency in creating *equitable mathematics classrooms*, which I characterized as spaces where we cannot distinguish high performers from low performers based on race and social class (Schoenfeld, 2007). Following Martin's (2006) lead, "race is viewed here as socially, politically, and relationally constructed so that issues of marginalization, power, dominance, and devalued social status assume prominence" (p. 198). Moreover, these classrooms are spaces where "mathematical identities, excellence, and literacies of marginalized students" (Gutierrez, 2008, p. 357) are supported.

I focused my study on teachers engaged in equity-oriented reforms for two reasons. First, in keeping with prior reasoning, a specific portrait of teacher learning about equity-oriented reforms directly speaks to single-system attempts to change disparities in student achievement by educators. To achieve this goal, I selected a group of teachers who not only chose to engage in equity-oriented reforms but who also had some success with their efforts to improve equitable outcomes. This particular group is made more exceptional as case of teacher community because it was designed for optimizing teachers' learning (e.g., attending to issues of equity through conversations about curriculum and pedagogy became a part of teachers' daily work) and had considerable external support by our research team.

Second, there is presumably a greater impetus for teachers engaged in equity-oriented reforms to question their assumptions and practices, thereby rendering their learning more visible. I made this assumption because a major goal of equity-oriented reforms involves providing *all* students with opportunities for making sense of essential mathematics ideas. It follows that the conditions surrounding teachers' enactments of reform, such as instruction and classroom culture, must also align with this goal in order to yield equitable outcomes. As such, my focus on a group of well-resourced, highly motivated teachers collectively engaged in equity-oriented reforms was a strategic choice for increasing observable instances of teachers' collective sensemaking about these reforms.

I collected a variety of qualitative data about the teachers' work, including audio records and fieldnotes of Team meetings, artifacts from Team meetings and activities, and teacher interviews. Primary data were transcriptions of audio records from Team meetings. The data corpus was designed to capture teachers' framing of the struggling student problem over time in context of their equity-oriented reforms. The data set included 35 records of Freshman Team meetings, 31 of which were from weekly long meetings. Of the 35 meeting records, 26 had fieldnote records and 32 meetings had audio records.

Data Analysis Procedures

I began data analysis by strategically reducing my data set using my unit of analysis, *episodes of pedagogical reasoning* (EPRs), which Horn (2005) defines as "units of teacher-to-teacher talk where teachers exhibit their reasoning about an issue in their practice" that are "accompanied by some elaboration of reasons, explanations, or justifications" (p. 215). My decision-rule for locating EPRs was based on topical shifts related to struggling students. After, four episodes were selected for closer analysis because they contained extended talk about the struggling student problem. I selected episodes that (a) represented development across time, (b) had three or more Team members present, (c) had quality records available, and (d) had substantive discourse dominated by teachers.

Date	Oct. 2005	Jan. 2006	March 2006	May 2006
Diagnostic Frames for Struggling Students	Fixed Student Attributes	Personal and Systemic Issues	Classification Schemes for why Students Struggle	Status, Race, and Tracking
Proposed Solutions (Prognostic Frames)	Inform parents of problem and changes students need to make	Conceptual solutions (e.g., see students as capable, students should take math in evening)	Student and peer observations; Email students' other teachers for strategies and extra support	Expand implementation of and training in Complex Instruction
Location of Problem ⇩ Location of Solution	Student *Invariable*	Personal Circumstances, The System *Invariable*	Abilities Students are not Good at Yet ⇩ *Actionable* ⇩ Classroom-based Interventions	Classroom Enactments of Society and The System ⇩ *Actionable* ⇩ Classroom-based Instructional Responses

Figure 1: Overview of Teachers' Framing Practices

The transcripts and corresponding meeting summaries for selected EPRs were coded using three core framing tasks identified by Snow and Benford (1988) to help identify how teachers framed the struggling student problem in context of their equity-oriented reforms. Specifically, I looked for (a) *diagnostic frames* to understand how teachers conceptualized the struggling student problem; (b) *prognostic frames* to understand how teachers conceptualized interventions related to the struggling student problem; and (c) *motivational frames* to understand how teachers made a case for their framing. After coding the transcripts of the EPRs for these framing moves I looked for themes within and across the data (see Figure 1 for an overview).

Results

Finding 1: Evidence of Within-Group Development in a Teacher Community

Teachers' Shifting Frames Show Development within a Teacher Community over Time.

The Freshman Team teachers concentrated on diagnosing struggling students in the episode from October (EPR 1), including invariable student characteristics related to work ethic and classroom behavior. Though teachers agreed to send home good news cards, call parents, and mail home letters with improvement strategies, by locating their diagnoses within the context of fixed student characteristics teachers had little access to actionable responses proximal to everyday instruction. In January (EPR 2) teachers' initial diagnoses of struggling students were challenged by information learned from reviewing academic histories of identified struggling students: ELL students and special education students were not supported when they were mainstreamed into a regular classroom, some students only recently performed poorly, and some struggling students had slipped by unnoticed. Participants put forward conceptual strategies such as encouraging students to take an evening class, moving students to work with another teacher, and seeing students as capable. Teachers were once again left with little actionable responses proximal to everyday instruction, though their diagnoses generally shifted away from simple assignment of blame, such as struggling students are students who "choose to fail," and trended towards external factors that influenced students' performance, such as lack of ELL support and special education transitions.

In March (EPR 3) teachers used classification schemes (Horn 2005; 2007) to diagnose the "core group of struggling students that seem to drive the whole school crazy," which included locally meaningful categories like the Taylors (smart students who are lazy) and the Paiges (students who are very far behind their peers academically). Teachers went beyond these categories and offered reasons why these students perpetually struggle, such as with students like Autumn, who had never experienced what it felt like to be successful in math class. Teachers presented myriad strategies for action, including the systemic response of generating a school-wide list of struggling students so that a comprehensive effort could be made to help them. More proximal classroom responses included strategies such as using a new teacher to help run triage with difficult students, peer and student observations, and emailing struggling students' other teachers for ideas and to garner additional support for students. This episode highlighted teachers' increasing specificity with their diagnoses of why students' struggle, resulting in a larger repertoire of actionable responses and focus on classroom-based intervention strategies.

In May (EPR 4) teachers considered the effects of status and race on the struggling student problem. Rose made the diagnosis that "white kids automatically have more status" because of Clark "not having a middle" and "not having a good pool of white kids" in Math 1. Though Rose's prognosis was unclear, Julie extended the status problem idea Rose originated by diagnosing the growing racial divide of students caused by the tracking practices that were in place at Clark. Julie made meaning of Rose's "not having a middle" and "not having a good pool of white kids" comments by linking these problems to tracking (as opposed to suggesting abstractly that they need more "good" white kids in Math 1 at Clark). Teachers talked through the pros and cons for a variety of solutions to the tracking problem, such as offering a within-class Honors option, using harsher grading schemes, calling all classes Honors, giving placement tests, and detracking altogether. Rose ended the episode with the diagnosis that the most important strategy for these issues relates to groupwork, thereby linking the problems of status, race, and tracking with the Team's pedagogical reforms. Though teachers' diagnostic frames reflected classroom enactments of society and the system, their solution frames reflected classroom-based instructional responses.

What is important to note is that teachers' diagnoses in later episodes contrasted earlier diagnoses, especially the in the first and second episodes where teachers were focused on understanding the attributes of struggling students. While teachers continued to use frames related to fixed attributes and personal circumstances, their primary diagnoses shifted towards the nuances behind why particular students struggle and status-related issues. While the former frames places the onus for achievement primarily on the students, the latter provide teachers a means for action. Teachers' frames became more nuanced in their representation of the struggling student problem, disentangling issues of ability from school-savvy and systemic problems like racism and tracking. Thus, there is a preponderance of evidence that shows how teachers developed and drew upon a larger repertoire of frames of the struggling student problem over time, with focus and priority given to solution frames that were related to everyday instruction. More generally, by tracking teachers' shifting frames around problems of practice, the case of the Clark Freshman Team offers a counternarrative to static characterizations of teacher community and shows within-group development in a teacher community over time.

Finding 2: Evidence of Teachers' Collective Learning

Teachers' Collective Learning is Manifested through their Framing Practices.

Examination of teachers' framing practices across episodes yielded teachers' evolving narratives of the struggling student problem, which I claim made teachers' learning in the Freshman Team community of practice more transparent. Teachers' participation in the Team gave them the opportunity to engage in extended talk about the struggling student problem. Participation in these conversations fostered teachers' reification of the struggling student problem, evidenced by the different frames they used to diagnose problems, propose solutions, and give rationale for their ideas. The participation and reification processes worked in tandem to coordinate and localize the meanings of these frames. The prior result showed how teachers' reification of the struggling student problem changed through interactions in their teacher group. These shifts served to mark and describe changes in teachers' participation in a community of practice, which is a process Wenger (1998) characterizes as learning. This analysis thus showed that the Clark teachers' collective learning was manifested through their framing practices.

As an illustration, in October (EPR 1) each teacher participated in the Team debriefing and reified the struggling student problem through diagnoses that centered on fixed student attributes. In January (EPR 2) teachers developed a community-owned framing for why students struggle (struggling students must not understand anything and must be used to failing, which is a status problem), which depended on teachers modifying another teacher's framing. In March (EPR 3) teachers reified potential classroom-based interventions using specific students as representative cases for a larger group of struggling students. Teachers intertwined their category systems and frames and then negotiated meaning around these frames through the processes of participation and reification, out of which their classroom-based interventions emerged. This resulted in conversation turns that contained different kinds of linked frames that had the overall effect of building resonance for their ideas with the Team. In May (EPR 4) teachers again intertwined and linked their framing practices to negotiate the meaning of status, race, and tracking in context of the struggling student problem. What is significant is how the Team negotiated the meaning of all these frames; the Team haggled over every offered frame. This important process helped the Team iteratively make progress on their collective understanding of these issues.

Teachers increasingly used a variety of linked frames to help build resonance for their ideology, courses of action, or rationale for action, which likely contributed to which frames were picked up or ignored by the Team. What is more, teachers moved towards using the group to negotiate the meaning of these frames, which corresponded to episodes with more actionable solution responses. By examining shifts in the Team's framing of the struggling student problem in the context of their engagement in fundamentally temporal, fundamentally social learning actions, this dissertation documented the Team's movement towards more classroom-based actionable responses and away from less obvious actions based on invariable student characteristics. These shifts accounted for a change in participation in the Freshman Team, which contributes an empirical example for teachers' learning in a community of practice.

Discussion

This paper aimed to describe high school mathematics teachers' learning as they took on issues of equity in their workplace group. As with many stories of learning, my data tell a developmental story, though not a linear one. My analysis thus required tools that could preserve the messiness of learning and at the same time tell a nuanced learning story in a productive way, which I accomplished by joining the communities of practice and frame analysis literatures. Analysis showed that teachers' frames shifted from invariable framings based on student characteristics, personal circumstances, and systemic issues to actionable framings based on classroom systems that contributed to student failure, which promoted teachers' concentration on courses of action linked to their instructional practices. As a result of this analysis, this study yielded significant findings about teachers' shifting framing practices and learning, and advanced the literature with analytic tools for making sense of teachers' development, shifting frames, and learning in context of teacher groups.

As is often the case with the study of rich data, this analysis raised issues that merit further study. For example, the process of offering frames appears to catalyze a response by the group, creating potential for group interactions around this framing. Through more research is needed to confirm my speculation that offering and then discussing rams around problems of practice yields productive learning opportunities inside of teacher community, my hypothesis is that this avenue of research would generate findings that help explain how opportunities to learn connect with teachers' learning inside teacher community. A limitation of my analysis is that I do not make claims about teacher's individual learning, though my speculation is that an individual's consistent orientation to invariable frames closes off learning opportunities readily available and important to the group. This raises an emerging analytic issue concerning learning opportunities alongside analysis of individual learning that merits further study. Moreover, I predict that my use of key conceptual tools from frame analysis was but the tip of the iceberg when it comes to the application and utility of the larger social movement literature to the teacher community and teacher learning literatures; in any case, more research needs to be conducted to understand the interplay of these literatures and open up an entirely new way for conceptualizing this work.

PERSPECTIVES ON INSTRUCTOR MODELING IN MATHEMATICS TEACHER EDUCATION

Cassondra Brown

Susan Nickerson
San Diego State University
snickers@sunstroke.sdsu.edu

We unpack the notion of mathematics teacher educators modeling teaching in mathematics teacher education courses. Specifically, we investigated what practicing teachers gained from mathematics teacher educators' modeling by examining: (1) What do mathematics teacher educators believe they model about effective instructional practice? (2) What do practicing teachers notice about the mathematics teacher educator's pedagogy and identify as effective mathematics teaching? (3) In what ways do these perspectives align in mathematics courses for practicing teachers? The results provide insight into what and how teachers learn from engaging in inquiry-oriented teaching. We discuss the implications for the education of mathematics teachers.

Introduction

While research has pointed to the benefit of student-centered instruction and collaborative, inquiry-oriented learning environments in both K-12 and college mathematics courses (Boaler, 1998; Bowers & Nickerson, 2001; Goos, 2004; Rasmussen, Kwon, Allen, Marrongelle & Burtch, 2006), many mathematics courses are still taught rather traditionally. Borg (2004) points to what Lortie (1975) calls the 'apprenticeship of observation' to explain the prevalence of traditional mathematics instruction. With respect to teaching practices, the notion of apprenticeship of observation suggests that teachers learn about teaching long before they enter the classroom. Their education as teachers starts when they themselves are students and their experiences influence the ways in which they think about the teaching and learning of mathematics (Ball, 1988). Many teachers' experiences as learners of mathematics, from elementary through college, primarily involved their teacher in the role of the provider of information, in what has been called a factory model of education (Callahan, 1962). Since teachers bring their own experiences as learners of mathematics to their practice, it is not surprising that the way teachers teach mathematics is not often substantially different from how they learned mathematics (Hiebert & Stigler, 2000; Sowder, 2007; Thompson, 1992). The fact that teachers were educated in a traditional system has been described as "…perhaps the greatest obstacle to these reforms" (Simon, 2008, p. 17).

It has been suggested that if teachers learn from their experiences as mathematics students then mathematics teacher educators should model desired instructional practices in teacher education and professional development programs (Borasi, Fonzi, Smith, & Rose, 1999; Loughran & Berry, 2005; NCTM, 1991; Simon & Schifter, 1991; Sowder, 2007). The implication is that an important factor in helping teachers enact these shifts is to engage them as learners in inquiry-oriented mathematics communities. How might this learning occur and what might be learned?

We report on instructor modeling in three mathematics courses for practicing teachers. We investigated what mathematics teacher educators believed they model, what practicing teachers noticed, and the ways in which these perspectives were aligned. The mathematics courses for practicing teachers discussed in this report are a part of a university-based professional development group. As with many mathematics professional development programs, the goal is to move teachers forward in their thinking about content and student learning so teachers can work to help increase student achievement in mathematics (Nickerson, 2010, Sowder, 2007). These professional development programs are designed to provide extra preparation for teaching mathematics by providing opportunities for teachers to deepen their content knowledge and by collaboratively reflecting on their teaching and student learning.

Theoretical Perspective

We view learning as inherently social and seek to account for individual perspectives within evolving social practices. We are concerned with the "negotiation of meaning." We focus on individuals' perceptions of the mathematics teacher educator's pedagogy to give an account of what mathematics teacher educators believe their instruction conveys, what individual teachers notice and describe the social conditions in which the teaching acts of note were situated. Neither the social processes nor the individual's interpretations can be considered without the other.

The notion of *perceptual lived experience* (Loughran & Barry, 2005) suggests that some learning occurs by "living through" experiences. Loughran and Barry give an example in which student teachers develop perceptual rather than conceptual knowledge of a situation. In their example, the student teachers as students in a classroom setting experience the emotions, images, needs, values, volitions, and frustrations of individuals in the situation, which develops their perceptual knowledge of learning environments instead of their conceptual knowledge. While this kind of learning is rather passive, the learner gleans ideas about the "how to" of the activity by simply being a part of the situation.

Intent participation (Rogoff, Paradise, Arauz, Correa-Chávez & Angelillo, 2003), a related, more deliberate form of learning from experiences in a situation, describes learning from keen observation and listening to ongoing activities in which the learner participates or expects to participate in the future. Both perceptual lived experience and intent participation suggest that learning occurs through the (implicit) modeling of an expert, where the expert provides an example of the required performance. From these perspectives, teachers have the opportunity to learn about the practice of teaching by engaging in an inquiry mathematics classroom.

Another way teachers can learn about the practice of teaching through modeling in teacher education is that the teacher can learn as an *apprentice* to an "expert" teacher. Here the learner is not unaware of the intentional modeling of practice. Apprentices learn through methods of observation, scaffolding, and increasing independent practice (Collins, Brown & Newman, 1989; Lave & Wenger, 1991). Student teachers and observers can be viewed as apprenticing from master teachers, teacher coaches, and teacher educators. The learner can be seen as a cognitive apprentice (Collins et al, 1989; Schoenfeld, 1992) where instructional practices are learned through observation, guided experience and participation.

In the mathematics teacher education courses in this study practicing teachers participated in mathematics classes, and thus learning about instructional practice looked quite different. In mathematics teacher education like the courses in this study, the mathematics teacher educators are not teaching along side teachers in teachers' classrooms. The mathematics teacher educators must make connections to K-12 classrooms through anticipation exercises, discussions of possible trajectories in classroom situations, and reporting back experiences. In these courses, the connections often took the form of commentary by the mathematics teacher educator that was related to a mathematical activity the teachers themselves were engaged in. The mathematics teacher educators prompted discussion among the teachers, asking them to anticipate how it might apply in a classroom situation. Also, the teachers discussed their own teaching as they reported on a predetermined task that all of the teachers in the class tried with their own students, called "try-ons" in this context. This anticipation and reporting back on teaching experiences with a more experienced mathematics teacher educator can provide a means of scaffolding the learning of reform teaching.

The constructs of perceptual lived experience, intent participation, and apprenticeship share a situated perspective on learning from the milieu. They all suggest that knowledge is developed and deployed in activity and is not separable from or ancillary to learning and cognition (Brown, Collins, & Duguid, 1989). Thus, learning the teaching profession stems, at least in part, from the teaching teachers see and experience as learners and the activity they engage in as professionals. Moreover, how teachers learn about practice affects how they view the practice of teaching.

Method

In this study we observed the mathematics professional development of a large urban university in the southwestern United States. Data was collected in three cohorts: a primary elementary cohort (grades k-3), an upper elementary cohort (grades 4-6), and a middle school cohort. Our data encompassed teachers' and mathematics teacher educators' reflections on a year of professional development and with respect to two classes. We drew on a three-step methodology (Busse & Ferri, 2003) and complementary accounts research methodology to develop a rich account from the data (Clarke, 1997). The facets of the methodologies include: observation, interview, stimulated recall and analysis of complementary perspectives.

The data set consisted of:

1) Audio recorded pre-session interviews with four mathematics teacher educators.
2) Video of the six individual classroom sessions (two consecutive classes for each of the three cohorts).
3) Stimulated recall interviews (SRI) with the mathematics teacher educators (MTEs), one for each class session.
4) Semi-structured interviews with a subset of the practicing teachers, part of which included stimulated recall interview.
5) Researcher fieldnotes of the six classroom sessions and interviews.
6) Reflection surveys, given to all 49 practicing teachers in the three cohorts at the end of the first session.
7) Quantitative surveys, given to all 49 practicing teachers in the three cohorts at the end of the second session.

The mathematics teacher educators were interviewed pre and post observation. In pre-session interviews, MTEs were asked to reflect generally on what instructional practices they believe they model as they teach. Then classroom data was collected in two consecutive classes for each of the three cohorts. The class sessions were videotaped and a researcher took fieldnotes. Both the MTEs and the classroom teachers were interviewed within a day or two using stimulated recall interviews (SRI). In the SRIs, it was the interviewees that pointed to noteworthy aspects. The surveys asked all the teachers to reflect on what was modeled throughout the year.

The videos of the classroom sessions were reviewed to create a descriptive timeline of classroom events to aid in analysis. Several participants were interviewed to enable the coding and subsequent creation of an integrated data set of complementary perspectives. The initial interviews with the MTEs suggested the coding categories aligned with the NCTM Professional Standards for Teaching. The transcript of the classroom sessions were analyzed in a cyclical process of coding and search for confirming and disconfirming evidence (Strauss & Corbin, 1990) to delineate the categories of modeled instructional acts. Once we developed what we thought to be an exhaustive group of codes, we coded a few episodes separately and compared codes for inter-rater reliability. The coders were in agreement 78% of the time and discussion resolved discrepancies. The primary causes of discrepancies were related to sub-codes of the categories.

The data allowed for analysis on two levels, (1) globally on modeling throughout the year of professional development and (2) locally on modeling in two consecutive class sessions. The pre-session interviews with the mathematics teacher educators, the reflection surveys and the individual interviews with eight practicing teachers provided data on perspectives on what the mathematics teach educators modeled about practice in general. The stimulated recall interviews with the mathematics teacher educators and the practicing teachers provided data on specific events. Both levels were important to examine. Globally, with respect to the year, because though a specific instructional act may not have occurred in a particular session or one may not have noted certain aspects of instruction in a given event does not imply the action is not common or that it has not been noted elsewhere. Locally, with respect to two consecutive sessions, is important to examine because interpretations of a specific event may vary. An analysis of both levels has the capacity to highlight how implicit and explicit modeling conveys teaching practices.

Analytical Framework

An initial analysis of the classroom videos and the interviews began with the NCTM *Professional Standards for Teaching Mathematics* with respect to the four categories of tasks, discourse, environment and analysis. Using a cyclical process for confirming and disconfirming evidence (Strauss & Corbin, 1990) the pre-session interview data and the classroom data (fieldnotes and classroom video) informed the elaboration of the four categories derived from the NCTM *Professional Standards for Teaching Mathematics*. This process allowed for the emergence of parallel categories for describing the mathematics teacher educators' pedagogy. The parallel categories characterize the mathematics teacher educators' pedagogy as the participants are engaged as mathematics learners and as mathematics teachers. The emergent codes were used to categorize and coordinate the mathematics teacher educators and the practicing teachers' perceptions of classroom events.

> Teachers' learning about instructional practice in mathematics teacher education is often not restricted to learning about classroom mathematics instruction. There are also opportunities for teachers to learn about other facets of the teaching profession. The current reform movement in mathematics education has a strong underlying theme of the professionalism of teaching. This view recognizes the teacher as a part of a learning

community that continually fosters growth in knowledge, stature, and responsibility (Dufour, 2005; NCTM, 1991, Author). Reform recommendations suggest that teachers ought to collaboratively plan instruction, reflect on practice, create and reflect on new practices, and support one another's professional growth (NCTM, 1991). Such interactions allow teachers in a school and its administrators to continuously seek and share learning and then act on what they learn. This type of communication and collaboration with a focus on inquiry about student learning are important aspects of what researchers call a "professional learning community" (Dufour & Eaker, 1998; Astuto, Clark, Read, McGree & Fernandez, 1993; Hord, 1997).

Results

An initial analysis of the pre-session interview data revealed that the mathematics teacher educators modeled more than the teaching of mathematics, they also modeled participation in the collective inquiry process of a community of mathematics teachers. The mathematics teacher educators were not explicit in their discussion about modeling the collective inquiry part of the teaching profession; however, their discussion related to developing the teachers' pedagogical content knowledge pointed to the teachers' engagement as professionals in the mathematics teacher education sessions. The emergent framework, summarized in table 1 (see next page), characterizes the mathematics teacher educators' pedagogical moves with respect to the participants' engagement as learners and teachers.

This first result, the emergent analytical framework, made it possible to characterize the mathematics teacher educators' pedagogy as described by the mathematics teacher educators and participating teachers and observed by the researchers. These characterizations describe the mathematics teacher educators' pedagogy as they engage teachers as learners and as professionals.

Teachers can learn about the practice of teaching from MTE modeling. In the Reflection Survey 1 and teacher interviews, the participants noted teaching actions related to the categories worthwhile tasks, discourse, tools, and learning environment in the analytical framework. Reflection Survey 1 asked the teachers to describe what they have done in their classes to support student learning drawing from what they have learned in prior mathematics content sessions. The teachers reported that they had incorporated specific activities and tools that they found useful in their own learning in the sessions. The teachers reported that they had adopted practices like engaging students in mathematical conversation (discourse), specifically, through questioning and prompting students to share out and provide justification. The teachers also reported incorporating wait-time and letting students struggle with difficulty, facets of the learning environment from the analytical framework.

While both the mathematics teacher educators' and the participants' utterances point to the mathematics teacher educators' pedagogy as the participants were engaged as both learners of mathematics and as mathematics teachers, the emphasis was on participants' engagement as learners, as opposed to their engagement as teachers. This was more so the case for the teachers than for the mathematics teacher educators. The teachers pointed to the pedagogy as they were engaged as a learner in about 86% in their reflections on the year and 88% in their reflections on the two sessions.

The teachers in the primary and upper elementary cohorts noted pedagogy related to their engagement as learners almost exclusively, while the middle school teachers reported it in only about 71% of their coded utterances. On average in the pre-session interviews where the mathematics teacher educators reflected on the year, they emphasized mathematics pedagogy they believe they model as the teachers were engaged as learners in about 71% of the coded utterances. In the stimulated recall where the mathematics teacher educators reflected on the two sessions noted such engagement in about 78% of the coded utterances. Like the teachers, the mathematics teacher educators from the elementary cohorts more frequently discussed instructional acts where the participants were engaged as learners. The middle school cohort facilitator, MTE-Karla, emphasized pedagogy related to the participants' engagement as teachers and as learners almost equally, reflecting the dual purpose of the mathematics teacher education. This points to the likelihood that the difference is due to the intended purposes of the mathematics professional development sessions and the mathematics courses.

The pedagogical moves most noticed by both the mathematics teacher educators and the teachers were characterized under the categories of tasks and discourse. The mathematics teacher educators and the teachers highlighted the way the mathematics teacher educator modeled the use of tasks, specifically noticing tasks that problematized the mathematics and prompted the teachers to make connections between mathematical ideas and among representations. These tasks were seen as promoting discussions of the mathematics. Both the mathematics teacher educators and the teachers pointed to the scope of tasks, particularly the large amount of time spent on a single task devoted to developing mathematical concepts in learning situations.

Table 1: Summary of Analytical Framework.

	Classroom Community of Mathematics Learners	Community of Mathematics Teachers
Tasks	Worthwhile **Tasks** are the projects, questions, problems, constructions, applications, and exercises in which teachers engage intended to develop teachers' mathematical content knowledge.	**Tasks** are the projects, questions, problems, constructions, applications, and exercises in which teachers engage intended to develop the teachers' understanding of the students' mathematics.
Discourse	Classroom **Discourse** refers to the ways that mathematics teacher educators mediate discourse about mathematical ideas to focus discussion on concepts and solution paths instead of answers.	Classroom **Discourse** refers to the ways that mathematics teacher educators mediate discourse about practice to focus discussion on teaching, student learning and/or thinking.
Tools	**Tools** are objects, tangible or intangible that the MTE and/or teacher's use in learning situations to reason, make connections, solve problems, communicate and enhance discourse.	**Tools** are objects, tangible or intangible that the MTE and/or teachers use to reason or enhance learning about or discussion of lesson planning, student learning, thinking and understanding, and so on.
Environment	**Environment** represents the setting for which the development of each teachers mathematical power is fostered.	**Environment** represents the setting for which the development of each teacher's knowledge for teaching is fostered.
Analysis	Ongoing **Analysis** is the systematic reflection in which mathematics teacher examine relationships between what they and their students are doing and what students are learning.	Ongoing **Analysis** is the systematic reflection in which mathematics teacher educators engage in analysis to foster teachers' participation in the Collective Inquiry Process

While the teachers pointed to tasks and discourse, some pointed to how the coordination of the pedagogical moves related to structuring learning environment, specifically structuring the sessions. The teachers' discussion about discourse often pointed to discourse in task situations, collaborative work on tasks and sharing ideas. The teachers specifically mentioned how the mathematics teacher educator pushed for justification and asked questions as opposed to giving answers. As a part of this, the teachers did point to a facet of the learning environment category, reporting that the mathematics teacher educators allowed them to struggle with difficulty. The teachers characterized the mathematics teacher educators' instruction as Socratic, that is, the mathematics teacher educators asked questions that helped them shape their thinking and move them forward in their thinking. The teachers reported that they try to incorporate these facets of the mathematics teacher educators' pedagogy in their own teaching.

There are aspects of ongoing analysis that the mathematics teacher educators believe they model that are not noticed by the teachers. There is a belief among the mathematics teacher educators and the teachers that a deeper understanding of the mathematics content better prepares teachers to present challenging tasks and ask questions that help students move forward in their thinking. However, the mathematics teacher educators' report that one of the purposes of questioning as the teachers are engaged in tasks is ongoing analysis of the teachers' thinking. The mathematics teacher educators note that their questions are driven by the need to develop conceptual models of the teachers' thinking. The teachers did not note developing conceptual models as a reason for being able to ask "good" questions; the teachers pointed to experience, mathematical knowledge, and being well prepared for the lesson as key to the mathematics teacher educators' ability to ask questions that move them forward in their thinking. This perhaps points to one of the reasons for differences in the emphasis the mathematics teacher educators and the teachers put on the category of ongoing analysis.

Conclusions

In general the mathematics teacher educators and practicing teachers reported that the mathematics teacher educator modeled student-centered instruction as conveyed in the NCTM *Professional Standards for Teaching Mathematics* (1991), but also facets of the collaborative work of teachers outside of the classroom. This work outside of the classroom might include teachers collaboratively planning instruction, reflecting on practice, creating and reflecting on new practices, and supporting one another's professional growth.

This research informs the body of knowledge about teaching the practice of teaching mathematics. The work described in this report makes recommendations regarding modeling by mathematics teacher educators based on an analysis of empirical data. It provides insight into *what* and *how* teachers learn from modeling reform teaching. Specifically, the study draws on an analysis of data from three classrooms to illustrate how explicit discussion about mathematics teaching and implicit modeling of instruction supported practicing teachers' noticing of the instruction they experienced, and how engaging in facets of the teaching profession that take place outside of their interactions with students has the potential to foster the enculturation of teacher into a professional learning community of mathematics teachers.

AN ANALYTIC FRAME FOR EXAMINING TEACHERS' COLLABORATIVE MATHEMATICS WORK TO DEVELOP SPECIALIZED CONTENT KNOWLEDGE

Matthew P. Campbell
Oregon State University
campbmat@onid.orst.edu

Rebekah Elliott
Oregon State University
elliottr@science.oregonstate.edu

A common practice in mathematics professional development to enhance teachers' content knowledge is to engage them in solving and discussing mathematics tasks. Yet, what is entailed in these experiences and how teacher discussions afford or constrain opportunities to develop teachers' knowledge of mathematics is not fully understood. In this paper, the authors provide a research-based framework to analyze teachers' mathematical productions (verbal reasoning and written inscriptions) used in collaborative mathematical work that illustrates the complexity of considering teachers' opportunities to learn and how discussion of mathematics may or may not be resources for learning.

Introduction

To better understand the mathematical knowledge teachers need to prepare them for their work, Ball and colleagues (Ball, Thames, & Phelps, 2008) have analyzed detailed records of practice to identify the content and pedagogical knowledge demands of mathematics teaching developing a practice-based theory of mathematical knowledge for teaching (MKT). From this work, some of the *mathematical* demands that are unique to the field of teaching have been outlined and include: recognizing what is involved in using a particular representation, linking representations to underlying ideas and to other representations, and giving or evaluating mathematical explanations (Ball et al., 2008). These demands become even more prevalent when teachers facilitate the development of students' mathematical understanding by selecting high-level mathematics tasks, orchestrating student discourse around the task, advancing students' mathematical justifications, and helping students seek connections between previous and new knowledge.

Mathematics professional development (PD) is considered one setting in which teachers may deepen their content knowledge used for teaching (Ball & Cohen, 1999). While mathematics content in PD is often overlooked or superseded by other issues of teaching (Hill, 2004), one common way to keep mathematics central is to engage teachers with activities and discussions around mathematics tasks (Jaworski, 2007). These activities often situate mathematical work in examinations of student work or representations of practice such as narrative or video cases (Kazemi & Franke, 2004; Silver et al., 2007). While *practice-based* (Ball & Cohen, 1999) activities are invaluable to mathematical and pedagogical learning, there is still much to learn about how teachers collectively do mathematics in ways that support their mathematical learning (Suzuka et al., 2010). This paper highlights research on teachers' collective opportunities to learn mathematics and shares a framework for analysis of teachers' mathematical work.

The most common rationale for engaging teachers in mathematical work is to advance teachers' mathematical content knowledge. However, this goal takes on varying levels of focus and specificity across studies. Recent research and development efforts have advanced that the purpose of doing mathematics in professional education (teacher preparation and PD) is to develop teachers' specialized content knowledge (SCK) needed to meet the demands of teaching (Ball et al., 2008; Elliott et al., 2009a; Lo, Grant, & Flowers, 2008; Suzuka et al., 2010). Programs like those discussed by Lo and her colleagues (2008) and Suzuka, Sleep, Ball, and their colleagues (2010) engage teachers in solving mathematics tasks and analyzing solutions, alternative strategies, and multiple representations in order to enhance teachers' content knowledge and connect it to the demands of teaching.

To develop teachers' knowledge, researchers have also asserted the need for teachers to justify their own mathematical reasoning. Simon and Blume (1996) considered how pressing on preservice teachers' mathematical justifications supported the emergence of learners' understandings of mathematical concepts. Other researchers have found that teachers' and teacher-leaders' justifications invoked or developed MKT through the unpacking of key mathematical ideas (Elliott, Lesseig, & Kazemi, 2009). Such mathematical work provides teachers with both a deeper understanding of the mathematics they use in the classroom as well as more facility to use this knowledge in a classroom in which students' reasoning is central (Stylianides & Ball, 2008).

Fostering meaningful mathematics learning for teaching in PD is no easy task. One prevailing issue that impacts this work is that doing mathematics with teachers is different from doing mathematics in the classroom (Elliott et al., 2009a). This is due in part to the fact that teachers tend to hold mathematical knowledge differently than students. While teachers may have previous experience with mathematical content, they often do not have a deep understanding of or facility with developing justifications that explain mathematical ideas (Lo et al., 2008). To meet the mathematical demands of teaching, teachers need not only *a* method for solving a math task, but a repertoire of solutions and justifications that unpack why methods work. Yet, a number of studies have found that teachers were less likely to positively evaluate justifications that use non-standard methods, those potentially more likely to be accessible to students who are not formally trained in proof, or to distinguish arguments that provided a mathematically valid reason rather than a thorough explanation of *how* a solution was developed (Bieda, 2010; Knuth, 2002).

Despite the struggles researchers have uncovered on engaging teachers in mathematical work that unpacks key mathematical ideas the importance of providing teachers with opportunities to do this work in PD is not diminished. Indeed, these struggles point to a need for more research to be done to understand the potential learning opportunities made available to teachers during collaborative mathematics work. If we expect teachers to have opportunities to learn mathematics for teaching in PD, leaders need understandings of what makes a discussion productive and how discussion might stay focused on key mathematical ideas. Similarly, the research community needs tools for analyzing discussions that coordinate argumentation with attention to teachers' specialized content knowledge. Detailed images of mathematics discussions among teachers could serve professional educators learning how to facilitate PD oriented to SCK and researchers who are trying to build a knowledge base on teacher learning.

We advance that researchers need opportunities to share the analytic work entailed in examining collaborative mathematical activity in order to construct more rigorous means of evaluating how conversations advance teachers' learning of mathematics for teaching. To this end, we share our coding system and examine the utility of it. Using data from a teacher-leader research project, we will illustrate how the framework examines what is entailed in teachers' mathematical discussions and how key mathematical ideas are potentially drawn upon. The framework and the data illustrations are a basis for a discussion on the import of frameworks that examine the depth of conversation, key mathematical ideas, and teachers' opportunities to learn MKT, in particular SCK. As such, we intend that this discussion will open up a dialogue for other researchers to consider how we might investigate teachers' collective mathematical work.

Context

The seminars from which data for this paper are drawn are part of a five-year research and development project, *Researching Mathematics Leader Learning* (RMLL) investigating how teacher-leaders develop mathematically rich learning environments for teachers. The project's framework and design evolved to focus on developing teachers' SCK as a key purpose for engaging in mathematics during PD. RMLL seminars provided opportunities for teacher-leaders, who were also teachers of mathematics, to do mathematics, discuss the mathematics, and consider the mathematical entailments of the tasks they solved (other activities were part of RMLL seminars, but not central to this paper). For this paper we will refer to RMLL participants as teachers since we investigate their collective mathematical work and not activities central to their leading. Participants in this study (n = 70) were volunteers involved in one of two phases of RMLL seminars and were becoming, or already were, leaders in their schools, districts, and regions charged with facilitating mathematics PD. Most participants were current part- or full-time classroom K-12 teachers. A few participants were full time leaders of mathematics PD.

Using data on participants' mathematical productions in small and whole group discourse, RMLL researchers have focused on justification as a means to understand the mathematical work at play and the normative aspects of these interactions (Elliott et al., 2009b). This previous work inventoried what participants reported as acceptable justifications, what participants' solution methods entailed, and made claims about how justifications allowed for an understanding of the underlying mathematics (Elliott, Lesseig, & Campbell, 2010). The intent of our previous work was to provide images of mathematical justification productions that invoke and develop SCK.

We have come to realize that a focus on teachers' solution methods and justifications without considering the collective talk elaborating teachers' solutions severely limits how we might understand doing mathematics in PD and teachers' opportunities to learn. As a result, we consider teachers' justification episodes through a new lens drawing on research on mathematical discussions of both students and teachers.

Theoretical Considerations

We are interested in the collective work of teachers solving mathematics tasks with a facilitator. Guided by a situated learning perspective (Putnam & Borko, 2000; Wenger, 1998), this study examines the entailments of learners' participation in collective activity. Specific to our study, we investigate the collective work of a group of teachers solving mathematics tasks and the potential resources made available through their work to learn mathematics for teaching.

Previous studies have considered the nature of students' mathematical discussions as well as the mathematical learning opportunities they afford or constrain. In an account of students' collective mathematical learning, Cobb (2002) considers the mathematical ideas that students take up, entailments of classroom discussion, and how students use tools and inscriptions. We saw these foci as central in how to examine the collective participation of teachers in mathematical activity. Considering community discourse in terms of the three foci allows for the documentation of emergent practices, which account for mathematical learning of the community (Cobb, 2002). In his study Cobb uses Toulmin's (1958) scheme for argumentation to examine classroom discussion. Similarly, Forman and colleagues (1998) in their analysis of a mathematics classroom advance that Toulmin's argument analysis is a valuable tool for examining the mathematical reasoning used to solve tasks. In general, both research projects use a classification of utterances as *claims*, *warrants*, and *backings* to examine the structure of conversation to infer what we consider to be depth of a conversation. *Claims* are assertions in need of argumentative support because the audience has called them into question or the rules for social interaction require such support. *Warrants* explicate how conclusions have been drawn from accepted givens. *Backings* strengthen the acceptability of warrants, essentially serving as the "why" that refers to the structure of the key mathematical ideas at play.

Considering the benefits of the approach to analyzing classroom mathematical practices used by Cobb (2002) and Forman and colleagues (1998), we took into consideration recent studies that have taken a similar theoretical and analytical stance in examining teacher discourse around mathematics tasks. Steele's (2005) analysis of mathematical and pedagogical discussions in a mathematics methods course also used Toulmin's (1958) argument model as a basis for analysis. In addition to the focus on claims, warrants, and backings (referred to as "bridge statements" and "evidence"), Steele also considered the potential responses to an argument adding "challenges" and "connections" as elements of the community's discourse structure and important for considering the depth of a discussion. Implicit in Steele's analysis is how deep conversations afford teachers opportunities to learn mathematics, although he does not take this up directly. Steele's work instead considers how argumentation may be driven by the underlying disciplines informing the conversation to explain how mathematical discussion differ from pedagogical discussions. We have found Steele's analysis helpful to consider the depth of conversation, and we use a similar analytic tool to explicitly examine learning opportunities for teachers.

Researchers who directly consider the entailments of teachers' discussions have reported conflicting results when examining the nature of mathematical and pedagogical conversations to advance teachers' learning. Crespo (2006) dubbed teachers' talk during mathematical work to be *exploratory*, in that it tended to be interactive, consisting of unprompted interruptions, disagreements, and tentativeness, and pedagogical talk as *expository*, more definitive in nature. Exploratory discussion allowed teachers to make public numerous mathematical ideas, but here the analyses did not explore the nature of the mathematical ideas, nor how ideas contributed to teacher learning. Crockett (2002), in another study, noted that teachers working on a mathematics task were so invested in reaching a correct answer that they missed out on examining the mathematical value and assumptions in the problem. Steele, Crespo, and Crockett provide valuable insights on teacher discourse of mathematics. However, each shares slightly different levels of detail and conflicting results for supporting teacher learning through teachers doing and discussing mathematics.

To fill the knowledge gap in understanding how teachers doing mathematics in PD may contribute to their development of SCK, we came to understand that our analyses must take up discursive interactions as mathematical justifications unfold in relationship to drawing on key mathematical ideas. Research on students' and teachers' mathematical discourse allowed us to conceptualize teachers' math argumentation accounting for both how and what math ideas are justified.

Methods

Our work looking at teachers' discussions around mathematics tasks and our consideration of how to analyze such work has been an iterative process. We developed our coding scheme based on the theoretical considerations uncovered in the literature and by reviewing data first individually, then together. An initial selection of video-data that included a variety of teachers across our two-phase research design, two different mathematics tasks that center on algebraic reasoning, and instances from early and late in RMLL seminars were examined to develop the window. After a code window was developed, an individual researcher would code the data and a second researcher would verify codes. Any differences in coding were resolved through discussion to arrive at 100% agreement.

Figure 1 illustrates the coding window used to analyze teachers' mathematical discussions in both small and whole group settings. Data were analyzed using the video analysis software, *Studiocode*. Participants' written mathematical inscriptions were also examined to look closely at what is referenced in video and the mathematical nature of the inscription.

Each video episode was coded as follows: Each discussion was coded into *idea units* based on the main speaker and the claim being argued or challenged. Each idea unit was then further described using elements of the argument structure: claim, warrant (referred to here as *evidence-how*) and backing (referred to here as *evidence-why*). Evidence-why codes were distinguished by levels of justification (Simon & Blume, 1996) to describe the backing for a solution. In addition to those elements of an initial argument we have also included challenges to a claim (e.g., press for justification, stumbling) and connections (e.g., to other solutions, across multiple representations) from the main speaker or the rest of the group. Finally, we coded when teachers explicitly identified key math ideas or implicitly discussed key math ideas embedded in their arguments. In using this code, we are not suggesting that an individual teacher knows a particular key idea. Instead, we are highlighting the ideas that are made public that have potential to serve in the development of SCK. Because our teachers, at times, would narrate their experience by talking about themselves as learners or how the work connected to other experiences we coded their narrations as *meta-talk* and *accounts of experience* to capture teachers' disclosures made during math activity.

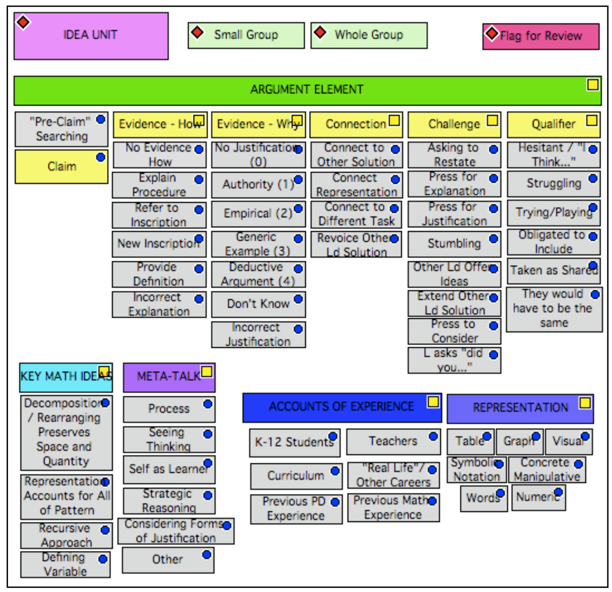

Figure 1. *Studiocode* Coding Window

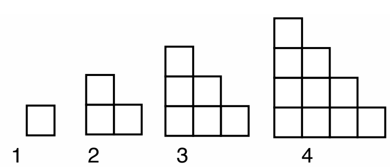
Discussion of an Illustration of Teachers' Collaborative Mathematical Work

To illustrate how a consideration of both teachers' justification productions and the argumentation structure of a teacher group support the interpretation of complex discourse of teachers in PD, analyses from our larger project will be discussed here. Data for the discussion in this paper came mid-way through the RMLL seminars where participants were engaged in collaborative discussions of solutions to a math task (the *Staircase* task; see figure 2). The *Staircase* task is a commonly used task in PD with the potential to highlight important mathematics ideas such as understanding how models can be decomposed and rearranged while preserving space and quantity and mapping relationships among representations, in particular how the composition of a figure is accounted



1. Build the next two staircases.
2. Describe the 10th staircase.
3. What is the relationship between the staircase number and the number of cubes it takes to build the staircase? See if you can find a rule to represent that relationship.

Figure 2. The *Staircase* Task

for in a symbolic expression.

The episode shown here is a discussion among three Phase I participants: Wendy, Hal, and Erica (all pseudonyms). The transcript of the segment, our coding of this instance, as well as the relevant inscriptions can be found in Figure 3. In the episode, Wendy is presenting her solution to the *Staircase* task, which she mentions relates to a solution that Hal just presented. She begins by verbally recounting the way she recomposed the visual model in order to create a "duplicate" staircase. In the process of drawing a connection between her visual model and her symbolic solution, Wendy stumbles. Her next move we code as a new solution, because it uses her inscription differently. Wendy considers the re-conceptualizing of the inscription and its correspondence to a symbolic expression. Her restated idea exhibited a more transparent link between her representations and the idea of a duplicate staircase (and, thus, needing to divide by two). This move makes available the idea that decomposition preserves quantity. Hal's revoicing of Wendy's idea provides evidence that this connection has been taken up publicly.

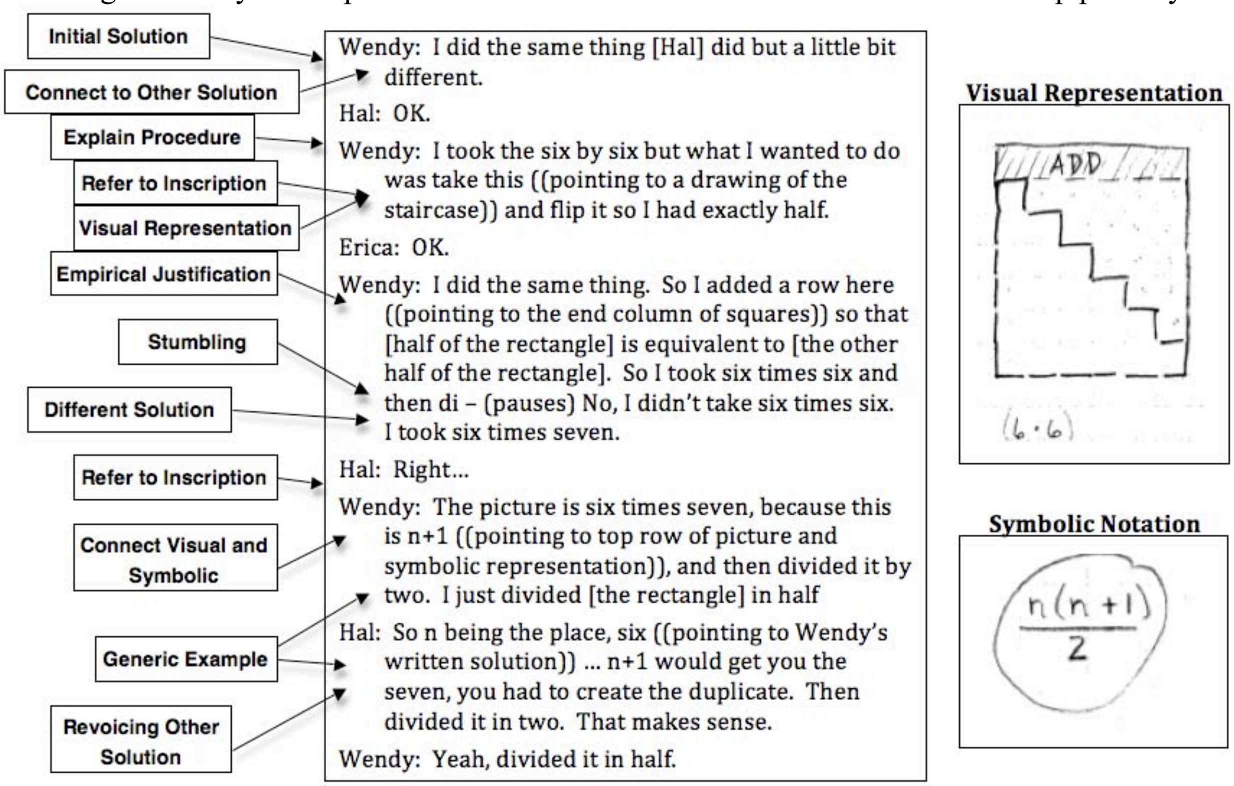


Figure 3. Teachers' Discussion and Inscription Around *Staircase* Task

What does this say about doing math in PD? In Wendy's first solutions we do not see her connect to a symbolic expression in a transparent way but she provides an explanation with a mention of another solution. We see that stumbling acts as a challenge that has opened up her reasoning as she connects her model to a symbolic expression such that the decomposition of the figure corresponds and is accounted for symbolically. Hal's later revoicing allows us to see his reasoning connected to her reasoning. As we examine the claims that these teachers are making – how they get supported, challenged, and used in the collective space – we are able to see the mathematical content that is emerging in the collective through the argument, interactions, and use of inscriptions. Further analyses of subsequent data will allow us to trace mathematical ideas across teacher discussion and consider what mathematical ideas are put on the table by this group, which seem to be taken up and unpacked through considerable discussion of claims, warrants (explaining how), backings (explaining why), challenges, connections and qualifiers. This analysis allows us to move our examination beyond an inventory of solutions and representational use. We are teasing out what is entailed in doing mathematics, the role of inscriptions and discourse. Subsequent data analysis will also examine the role of facilitation in teachers' collective mathematical work as the small group moves to a whole discussion.

Conclusion

In this paper we have provided the theoretical and analytic considerations for examining teachers' collective mathematical work accounting for argumentation, levels of justification, and key mathematical ideas. Previous research has accounted for teachers' argumentation without incorporating attention to justification or key mathematical ideas emerging in teachers' collective mathematical work. Important to note in these analysis is the role of our video coding tool, *Studiocode*, that makes it possible to examine over 20 episodes of teachers doing mathematics and provides methods for examining patterns across the 20 episodes to consider how teachers' mathematical learning emerges in the community.

The framework we have presented here affords ways of capturing the complexity of teachers' collaborative mathematics talk. With this framework, we are able to look at a wide range of data to better understand the aspects of collaborative talk that advance mathematical learning. The excerpt of data we chose for this paper also illustrates the framework's ability to highlight the opportunities for key mathematical ideas to emerge in discussion, such as "stumbles", outside challenges, and building connections across representations and solutions. As we continue to move forward with our examinations of teachers' collaborative mathematics talk in order to better understand these opportunities we plan to consider more deeply what stumbles or challenges provide teachers in their mathematical learning and uncover more aspects of collaborative work that facilitate the development of SCK.

GROWTH IN SECONDARY TEACHERS' CONTENT KNOWLEDGE AND PRACTICE IN DISCRETE MATHEMATICS

James A. Middleton
Arizona State University
jimbo@asu.edu

Mona Toncheff
Phoenix Union High School District

Susan Haag
Maricopa County Education Services

Thirty-five teachers teaching advanced topics in high school mathematics were engaged in a year-long intensive professional development project intended to increase their Mathematical Knowledge for Teaching in the area of discrete mathematics. Project activities embodied a models and modeling perspective on pedagogy and learning. Results showed that participating teachers' content knowledge improved significantly in discrete mathematics, their classroom practice improved significantly. Additionally, participating teachers' students outperformed their counterparts in a matched-control group in achievement. Results provide evidence of the effectiveness of mathematical modeling for developing teachers' mathematical knowledge for teaching, and on improving secondary mathematics teachers' practice.

With the recent push to increase the general mathematical competence of US high school graduates, the State of Arizona has instituted new standards incorporating significant aspects of discrete mathematics, including graph theory, combinations and permutations applied to the solution of conflict problems, probability and statistics, and shortest path algorithms (Standards Committee, 2008). This subject matter is becoming increasingly important in scientific and economic modeling, and is now considered essential background for college- and work-readiness.

Two problematic issues arise when attempting to infuse discrete mathematics content into the current high school curriculum. The first concerns the ability of teachers to effectively deliver high quality instruction given that discrete mathematics has historically been given only cursory (if any) treatment in their college-level mathematics courses (Rosenstein, Franzblau, & Roberts (1991, Eds). The second issue, and one that is at least as important as teacher knowledge is the fact that there is no coherent set of curricula (i.e., texts, materials) for teachers to use to structure their implementation of the new standards.

To address these concerns, a partnership was formed between a large Southwestern University, and a large urban school district to substantially increase the pedagogical content knowledge of high school mathematics teachers in the areas of discrete mathematics and mathematical modeling, and to create a coherent course of study around discrete mathematics appropriate for a 4th year of high school mathematics. The project worked toward four measurable goals and used formative evaluation as a guide for on-going program development and refinement to meet the goals.

Goals

1. Increase mathematical knowledge for teachers (MKT) for Junior-Senior level teachers (e.g., Hill, Ball, & Schilling, 2008);
2. Create a coherent, rigorous curriculum for fourth year courses that develop student knowledge and skills in Discrete Mathematics and modeling (e.g., Zawojeski, Lesh, & English, 2003)
3. Increase student achievement specifically focusing on fourth year courses that develop student knowledge in Discrete Mathematics and modeling
4. Develop student's content knowledge through the use of workplace technology

Goals were designed to ensure that this learning and growing expertise was sustained and shared with district instructors and colleagues.

Project Activities

The partnership identified 10 campus instructional leaders and an additional 25 mathematics teachers proportionally distributed by student population across high schools. The project developed an integrated system of PD, curriculum, and technology implementation in the area of Mathematical Modeling. Mathematical Modeling was chosen because it integrates all aspects of the College and Work-Readiness Standards in Arizona, because it draws easily upon students' prior knowledge of Algebra and Geometry, and because it provides important contexts for learning and applying discrete mathematics in realistic scientific and workplace scenarios Figure 1 (below) shows project activities arranged across the 14 months of project funding.

The meat of the program has been a monthly series of 8-hour professional development sessions designed to increase teachers' pedagogical content knowledge in modeling discrete mathematics topics. These sessions are bookended by week-long (40 hours each) Summer

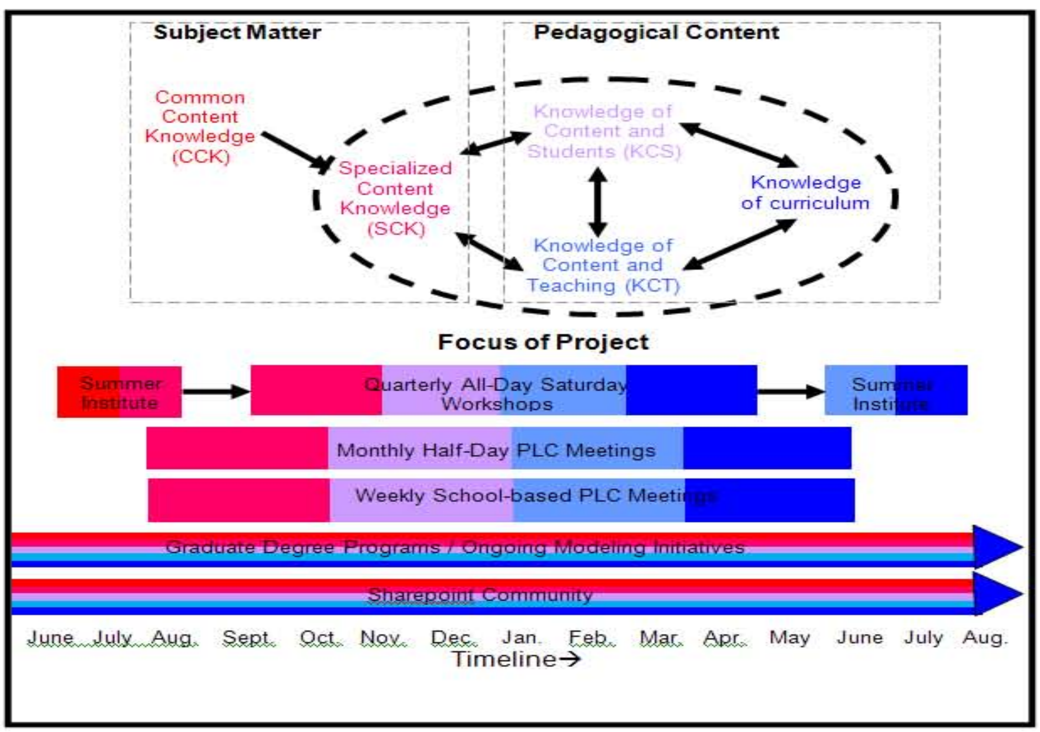

Figure 1. Professional development foci and timeline

Workshop. Teachers are organized across schools into curriculum development teams, tasked with designing the 4th-year curriculum structure and tasks for subsequent implementation in the 2010/2011 academic year (see Figure 1).

Initially, forty two teachers were provided 135 contact hours of professional development utilizing two 40-hour intensive summer workshops that introduced participating teachers to the content of discrete mathematics, including graph theory, combinatorics, probability and statistics. Institute faculty emphasized a variety of researched best practices, focusing on modeling high cognitive demand tasks in problem-based-learning scenarios. The use of readily-available software and mathematical technology was emphasized throughout these sessions. Technology included simulation tools, probeware and data analysis tools, and graphical/visualization tools. Throughout the school year, additional content instruction was provided to teachers in each of 9 additional 8-hour Saturday sessions.

Also throughout the school year teachers implemented these best practices by developing and piloting curriculum for a new 4th-year course designed to embody the College Ready and Work-Ready Standard for Arizona Mathematics. This course is targeted towards non-calculus-intending students, and is pedagogically based on mathematical modeling. Teachers engaged in iterative design cycles (Lamberg & Middleton, 2009) to develop and test lessons and whole units in their classrooms, videotaping their practice, and collecting student work samples for use in subsequent professional development. These data records were used to improve the designed courses and develop teachers' guides to assist other teachers in implementing the College and Work Ready Standards in their classrooms, focusing on discrete mathematics, probability and statistics. All work products were uploaded to the project Sharepoint® website to enable ready access for teacher teams to updated materials.

Evaluation

Participants

The project was evaluated using a pre-post, quasi-experimental design with a matched comparison group. Each school was asked to provide a comparison teacher for any participating teacher. Matched comparison was based on number of years teaching, grade level taught, and math courses taught. Twenty-seven project teachers completed all of the 135 hours of professional development, and had complete data. Forty teachers, who received no professional development in discrete mathematics or mathematical modeling comprised the comparison sample.

Measures

To measure teachers' practical change, the Reformed Teaching Observation Protocol (RTOP) was employed. The RTOP was developed as an observation instrument to provide a standardized means for detecting the degree to which K-20 classroom instruction in mathematics or science is "reformed". Pre-RTOP data have been used to assess the quality of instruction against an external metric of excellence, and fidelity of implementation. In addition, for teacher content knowledge, a cognitive growth instrument, The Discrete Math Content Measure (DMCM), was developed (the pre-test was administered in 2009 and the post-test administered in 2010). The overall reliability (Chronbach's Alpha) of the exam as a whole was 0.70. Student achievement was measured with AIMS scores and CRT (course) scores yearly.

Observational Protocol

There were five observers that completed the RTOP evaluations for the participant group. The observers completed RTOP training through center for Research and Innovation in Mathematics and Science education (RIMSE), with Arizona State University. Each participant and contrast group teacher was observed in a typical class where they taught discrete mathematics topics: Once in the Fall semester, 2009, once in the Spring Semester, 2010. There were no major differences in the timing or method of the administration of the RTOP evaluations in the pre or post RTOP.

Results

Teacher Knowledge

Results from the DMCM analysis shows a significant difference between the 2 groups (*p*-value = .00) as post-test scores for the Participant (*M* = 18.29) were higher than the comparison group (*M* = 11.95) See Table 1 Results from the DMCM analysis for the 27 program Participants show that there were gains from pre (*M* = 10.47, *SD* = 3.41) to posttest (*M* = 18.29, *SD* = 3.29), and the gains were significant (*p*-value = .00). Results from the analysis for the comparison group revealed that there was little change between pre-test mean scores (*M* = 11.42, *SD* = 2.72) and post test mean scores (*M* = 11.95, *SD* = 3.17) and the difference was not significant (*p* = .24).

Discrete Mathematics Content Measure: Participant Group			
Group	**Pre-score Mean (SD)**	**Post-score Mean (SD)**	**Significance p < .05**
Participant	**10.47** (3.41)	**18.29** (3.30)	**.00**

Table 1. DMCM comparison of participant and comparison groups

Teacher Change in Practice

Differences in pre- and post-classroom observation (RTOP) average scores indicate a positive gain in those items relating to reformed and inquiry-based classroom from mean of 59.78 at the beginning of the MSP to a mean of 68.56 following the MSP professional development intervention. The gains were significant (*p* = .028). The Post RTOP score (*M* = 68.56, *SD* = 17.29) revealed a nine-point gain from the Pre RTOP score (*M* = 59.78, *SD* = 17.59), and the gain was significant (*p* = .028). PUHSD had a 15% change in pre-post RTOP scores.

With regards to the relationship between teachers' RTOP scores and their student achievement, we found that, for our data, the Spearman rho between the RTOP & post-DMCM was to be .50, a moderate-to-high, statistically significant correlation (p = .007). This finding indicates that project teachers who learned more mathematics, also taught mathematics in a more reformed manner on average, and that this reformed practices was related to higher student achievement.

Student Achievement

The project measured student growth using the State Arizona Instrument to Measure Standards, a Criterion-Referenced test bench-marked on the State Mathematics Standard. Unfortunately, in the middle of the project, the State elected to change the test, and so pre- and post administrations are not measured on the same scale. Overall in the State, scores on the 2010 AIMS are lower than on the 2009 administration due to this change. For the 2010 administration of the Arizona Instrument to Measure Standards (AIMS), there were 610 students in participating classrooms, primarily 10th graders, taking the test for the first time. Of those students, 338 students (55%) scored proficient or above and 272 students (45%) scored basic or below. The comparison group teachers tested 899 students that were 10th graders. Of those students, 405 students (45%) scored proficient or above and 494 students (55%) scored basic or below. This provides some evidence to suggest that the teaching practices in the MSP program contributed to student learning.

Table 2. Descriptive Statistics on the AIMS-Mathematics test for Students of Participating and Control Group Teachers

A univariate post-test, experimental/control group model was applied to the analysis of student achievement data. The dependent measures included students' AIMS mathematics raw score, the ACT composite mathematics score, ACT Algebra/Coordinate Geometry score, and ACT Plane Geometry/Trigonometry score. It was hypothesized that students of teachers participating in the Modeling MSP would show greater student achievement on these outcome measures than teachers who had not participated in the program. In addition, because typical high school courses (e.g., Algebra 1, Geometry, Algebra II, etc) would show different levels to which course content fit the content in the MSP, we analyzed differences in student achievement by course, and we accounted for the interaction effect between project participation and course by performing a factorial analysis. All family-wise alpha coefficients were set to .05 (1-tailed). Table 2 shows results for the analysis of the AIMS-mathematics test by course and by participation.

Results indicate that students of participating teachers outperformed their peers in classes taught by control group teachers. When analyzing the main effect for course, as expected, students in higher level courses showed greater AIMS achievement. Most importantly, the main effect for overall mathematics achievement as measured by the AIMS-mathematics test was found to be superior for students of participating teachers when compared to their matched control group (F(1,1497) = 8.58, p = .048). In analyzing the interaction of the two conditions, the data show that for every class where comparison was possible, participating teachers' students outscored control group students. Overall, these differences are statistically significant (F (3,1497) = 3.87, p = .009). Details of the analysis are presented in Table 3 below.

Table 3. Univariate ANOVA--Effects of participation and course on student achievement on the AIMS-mathematics test.

These findings are in alignment with the goals of the project. Since all project activities were designed explicitly to embody the Arizona Mathematics Standard, it was expected that on a test of this Standard, students of teachers who had more experience learning the mathematics related to the Standard would perform better. Additionally, it provides evidence that modeling as an environment for enhancing teachers' understanding and pedagogical skill in applying the Standard content is a viable strategy.

In addition to the AIMS data, the ACT was utilized as a nationally-validated outcome measure to augment the AIMS data. We analyzed student achievement using three of the ACT scale-scores: ACT Mathematics Composite, ACT Algebra/Coordinate Geometry subscale, and ACT Plane Geometry/Trigonometry subscale. Results are mixed, showing no overall effect of project participation on ACT Mathematics Composite scores, or on ACT Plane Geometry/Trigonometry scores. A main effect for Course was detected for each of these subscales, with students enrolled in higher courses performing better on both (See Table 4 below).

On the ACT Algebra/Coordinate Geometry subscale, a significant main effect was found for Course, but not for Participation. The interaction effect, however was found to be statistically significant. A Scheffe post hoc test revealed that in Algebra II, the largest represented course in the study, Participating teachers' students outperformed those of Control teachers ($p < .05$).

Discussion

Results show that teachers, given an intense, sustained set of professional development experiences organized around mathematical modeling, can learn significant new content, change their practice to reflect modeling instruction, and increase the mathematical achievement of their students in the process. Several problems, however, have been identified related to attracting and retaining teachers over the long haul. In particular, retention of participants was an ongoing challenge. The number of original participants was identified as 60; however 43 instructors participated. Participants dropped out for various reasons: one teacher passed away, one was taking care of a dying parent, one started their Master's degree and had a time conflict, three teachers were involved in remediation and wanted to discontinue, two were getting paid to do Saturday School so there was a conflict with their schedules, and others stopped coming without explanations.

Moreover, implementing a two-week summer workshop may not be the most effective way to provide the bulk of the learning. Teachers experience a high level of mental fatigue and express feelings of being overwhelmed using this format.

RTOP observations and teacher comments continue to demonstrate the need to model and explicitly identify reformed teaching practices and an understanding of how students learn mathematics content. During the final weeks of the project, teachers were expected to implement specific instructional strategies in their classroom. During the RTOP Evaluation Dissemination session, were able to share experience and ask follow-up questions regarding each RTOP category and item. We conducted the RTOP Evaluation Dissemination after the first RTOP. The team felt that the process of identifying each item, addressing strengths and weaknesses in the overall group and modeling exemplar teacher performance (with MSP teacher participants) would help the majority of teachers be more successful in terms of developing pedagogical content knowledge and providing more effective mathematics instruction for their students.

As learning trajectories gain traction in mathematics education, we seek to understand the ways in which teachers may use them in interactions with students. This paper reports on one group of elementary teachers' use of their emerging knowledge of a learning trajectory to examine key pedagogical practices. Findings suggest that a learning trajectory helps teacher place student thinking at the center of these practices.

In this paper we examine the role a learning trajectory (LT) that characterizes students' progression from less to more sophisticated levels of understanding plays in teachers' analysis of classroom discourse orchestration. In the introduction of the *Common Core State Standards* (CCSSO, 2010), the authors of the document highlighted the role LTs played in the initial development of the new standards and reported that the development of the standards began with research-based trajectories.[1] LTs have been demonstrated effective in assessment design (Battista, 2004), curriculum development (Clements, Wilson, & Sarama, 2004), and as a tool for teachers to identify students' ideas in instruction (Furtak, 2009; Mojica, 2010; Wilson, 2009). By providing a framework for aligning evidence of student cognition with research findings on likely tendencies for the development of children's mathematical conceptions, LTs support teachers in locating students' ideas within a range of conceptual development and offer a theory of how mathematical ideas develop overtime (Wilson, 2009).

The recent release and adoption by many states of the Common Core State Standards recalls the question about the relationship between standards, professional development, and instructional practice. Cohen and Hill (2001) showed that in the absence of focused professional development on the content and the ways in which students learn that content, it is unlikely for new standards to result in changes in teachers' practices or increases in student achievement. Further, these authors indicated that professional development related to changes in standards should provide teachers with opportunities to explore and understand new standards through examining student thinking, work samples, and curricular connections if meaningful change is to occur. Thus, we propose that professional development focused on LTs can provide opportunities for teachers to examine both changes in content and the ways in which students think about that content in light of the new standards. Further, we seek to understand how participation in professional development that attends to LTs supports participants' examination of classroom mathematics instruction during whole class discussions.

Perspectives

Learning trajectories are descriptions of the qualitatively different levels of reasoning sophistication through which students' concepts pass as they evolve from informal ideas to complex understandings. With roots in Simon's (1995) hypothetical learning trajectory, LTs bring clarity to the intermediate understandings a student may have of a mathematical concept. LTs outline how those intermediate understandings relate to previous ideas as well as to those that will evolve from them. In our work we use Confrey et al.'s (2009) definition of a learning trajectory: "a researcher-conjectured, empirically-supported description of the ordered network of constructs a student encounters through instruction (i.e., activities, tasks, tools, forms of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time" (p. 347). In this definition, the role of instruction is highlighted, making teachers and the practices they employ to create learning environments for students central in the development of students' understanding of mathematical concepts.

Researchers have recently begun to investigate the ways in which teachers may use LTs in their practice. For instance, Wilson and Mojica (2010) reported that knowledge of an LT supported both practicing and prospective teachers in constructing models of students' thinking. Furtak (2009) concluded that knowledge of an LT helped teachers in viewing students' conceptions along a continuum of proficiency rather than simply "right" or "wrong." Wilson (2009) described how LTs assisted teachers in interpreting evidence of cognition when analyzing student work and in interacting with students during instruction. He suggested that LTs sensitize teachers to a variety of strategies used by students when gaining proficiency with a mathematical idea. He also conjectured that LTs provide a framework for teachers to organize students' work in class discussions. The research reported in this paper investigated this last conjecture further.

This study is part of a larger project that aims to conceptualize the notion of *Learning Trajectories Based Instruction*, broadly defined at the outset of the project as the ways in which teachers use their own knowledge of a LT to organize their instructional practices and participate in their professional communities. As the context for our investigation, we are working with one LT: the learning trajectory for equipartitioning (EPLT), which is the set of cognitive behaviors that have the goal of producing equal-sized groups (from collections) or equal-sized parts (from continuous wholes), or equal-sized combinations of wholes and parts, such as is typically encountered by children initially in constructing 'fair shares' for each of a set of individuals (Confrey et al., 2009). The EPLT describes how children's informal experiences with creating fair shares evolve over time to a robust understanding of partitive division. The proficiency levels of the EPLT document the strategies, practices, emerging relationships, generalizations and the misconceptions children experience through instruction as they mature to an understanding of $a \div b$ as creating b equal-sized parts of a.

As students engage in equipartitioning tasks, the EPLT describes how they work to coordinate three equipartitioning criteria: (1) students must create the *correct number* of groups or parts; (2) students must create *equal-sized groups or parts*; and (3) students must *exhaust the whole or collection*. Also, the EPLT outlines how different parameters affect the level of difficulty of the task, such as sharing a whole among eight people is less difficult than sharing a whole among five people. The trajectory goes on to characterize the practices of naming and justifying answers to equipartitioning problems. For example, children proceed from nonmathematical names for each share such as parts or pieces, to counts and then to numbers in relation to a unit. Three important emerging relationships are also considered in the trajectory: compensation, the idea that producing more equal-sized parts decreases their size; composition of splits, the idea that one split across another split affects the size of every part in a multiplicative way; and transitivity, the idea that non-congruent parts resulting from the same split on the same whole are of equal size.

To frame our examination of connections between teachers' experiences with EPLT and pedagogical practices that support the orchestration of productive mathematics discourse in the classroom, we draw on the work of Stein, Engle, Smith, & Hughes (2008). These authors proposed a set of five practices to examine teachers' work in supporting discourse: anticipating, monitoring, selecting, sequencing, and connecting. In this paper, we focus on the last three of these practices. *Selecting* is the practice of choosing particular students to share their work with the rest of the class to get certain ideas on the table while remaining in control of which students present and what the mathematical content of the discussion will likely be. *Sequencing* is the practice of making decisions about how to order the students' presentations to maximize the chances that the mathematical learning goals for task are achieved. *Connecting* is the practice of helping students develop relations among presentations and judge the consequences of different approaches for various problems, making sure students' presentations build on each other to develop powerful mathematical ideas.

Methods

The specific research question addressed in this study is: In what ways do teachers use their understandings of EPLT to select, sequence and connect students' mathematical ideas for whole class discussion? We conducted a design experiment within a school-based professional development setting. Design experiments are used to provide "systematic and warranted knowledge about learning and to produce theories to guide instructional decision making" (Confrey, 2006, p. 136). They "entail both 'engineering' particular forms of learning and systematically studying those forms of learning within the context defined by the means of supporting them" (Cobb, Confrey, diSessa, Lehrer, and Schauble, 2003, p. 9). The data set for the study is comprised of videos of professional development meetings and audiotapes (with transcripts) of small group discussion during the professional development. As it is usual for design experiments, data analysis consisted of constant comparison methods (Glaser, 1992; Strauss & Corbin, 1998), which allows for the creation of emerging categories in the data analysis and the refinement of these categories as they are contrasted with new information. The various sources of data were also used for triangulating information (Miles & Huberman, 1994) in search of both confirming and disconfirming evidences. As we examined the ways in which teachers engaged with one particular professional learning task, we coded the data for teachers' use of their knowledge of particular aspects of the EPLT to justify their arguments about how to select, sequence, and connect students' responses in whole group classroom discussion.

Participants

We partnered with one elementary school in a mid-size urban area in the southeast. Twenty-four K-5 teachers from this school volunteered to participate in the professional development. Only three of these teachers had less that 3 years of teaching experience and about half of the teachers had more than 10 years of experience. Many of the teachers have been at this school for a few years. Overall, this school has a yearly turnover teacher rate of 4% and a student population of approximately 600 students. The student population in the 2010-2011 school year was 35% Caucasian, 29% Hispanic, 25% African American, 7% Asian, and 4% other, with 54% of the children on free or reduced lunch.

Professional Development Design and Professional Learning Task

The professional development was designed to offer a total of 96 hours of work on the concept of EPLT over a period of 12 months. The initial 30 hours of professional development were offered as a Summer Institute, followed by 54 hours of face-to-face and web-based activity during the school year, ending with 12 hours the following summer. This report is based on the work conducted during the Summer Institute. The 30 hours of work for the institute were spread over 6 days, immediately before the 2010-2011 school year started. We worked with the teachers for 6 hours during the first 3 days, and then for 4 hours during the following 3 days. All meetings took place at the school, giving teachers the opportunity to also work on organizing their classrooms after the professional development meetings.

The research reported in this paper concerns a professional learning task that was posed to the teachers on the fourth day of the Summer Institute. On Days 1–3 teachers had investigated the concept of equipartitioning, the proficiency levels of the EPLT, and the parameters affecting the difficulty of tasks at a particular level. Through analysis of student work and video clips of children solving various equipartition tasks for collections and single wholes, teachers had discussed the equipartitioning criteria, naming practices, and emerging relations such as compensation, composition of splits, and transitivity.

We began Day 4 of the Summer Institute with a task that aimed to provide teachers with an opportunity to make explicit connections between their learning in the professional development and their classrooms instruction. In this task, we purposefully asked participating teachers to select, sequence and connect student work. Teachers were given a scenario where students in a second grade classroom had worked on the task of fairly sharing a rectangular cake among four people and the second grade instructor saw four different solutions to the task (represented in figure 1, labeled A, B, C, and D). In cross-grade-level groups, teachers were asked to discuss the following question: “How would you select and sequence the presentation of these solutions for a whole class discussion? Why?”

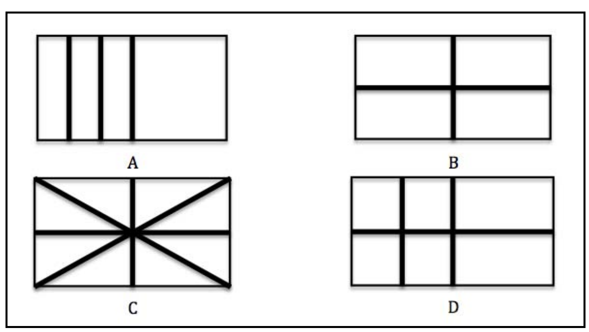

Figure 1. Representations of the approaches to sharing a whole among four.

After the small group discussions, the teachers viewed an 18-minute video recording of the actual second grade classroom. In the video the classroom instructor starts by having students share solution C. The students indicated that each person would get two pieces and that each piece was one-eighth. Next, a student shared approach A, and the instructor guided the students to see that each of the four pieces needed to be the same size and that if they were of equal size, then each could be called one-fourth. Approach D was shared next and students told the class that they realized that although they had not used all of the cake. The instructor concluded the sequence by having a pair of students share approach B, and made connections to the two-eights created in approach C and the parts created in approach D.

In the whole group discussion of the video, teachers examined the instructor's choices in selecting, sequencing, and connecting her students' responses. After each solution was shared with the second grade class in the video, the recording was paused and the teachers were asked to discuss the mathematical issues that arose as students shared a particular solution. They conjectured what they would do at that particular moment in the lesson if they were teaching it and examined the connections the actual instructor made.

Results

Selecting and Sequencing

Selecting and sequencing student work was not a trivial task for participating teachers. It elicited a rich discussion in the small groups and only one of the cross-grade-level small groups actually agreed on a sequence for presenting students' answer: D, A, B, and then C. One group reached consensus that they should begin with approach A, and another group agreed they would begin their sequence with approach D. The two other groups failed to reach a consensus, with one not being able to solve whether they would begin with A or C and the other debating whether to begin with A or D. In the process of these discussions, three aspects of the EPLT emerged in teachers' justifications for how they would select and sequence these particular students' solutions: the three equipartitioning criteria, students' misconceptions, known strategies for creating equal parts.

All of the small groups made reference to the three equipartitioning criteria as they worked to make sense of the four approaches. The teachers used the criteria both in understanding solutions A through D and in examining how they might sequence these solutions for discussion. In selecting a response to begin a classroom conversation, one teacher told her group, "I would start this one [*D*] just because I think this is the problem that…that they're not using the whole. They are thinking it's a cake and they've made four pieces but they've not used the whole." In another group, a teacher stated, "I would probably share the top left corner [A] also and then talk about, you know, first that you did use a whole; that you do have the right amount of pieces, and then really look into 'are the pieces equal?'" In trying to decide which of the criteria she should address first, one teacher questioned her group, "Did we ever establish that there is necessarily a hierarchy of those three criteria?" In this, the teacher was not only recalling the 3 criteria from the EPLT but was also adopting a perspective of student thinking as a continuum of least to most sophisticated. These examples are representative of the teachers' comments across the small groups. Being a pre-requisite for obtaining fair shares, all teachers considered that these criteria needed to be explicitly addressed in the classroom as they made sense of various students' responses.

Concerning the three criteria, approach C generated interesting discussion as one teacher questioned whether the student had created the correct number of parts. Other teachers wanted to use approach C to think about a ratio relationship. "The reason I would do it [C] is because it seems like you can turn that into a higher order, you know, solution. You can say, Okay, I see this one has eight wedges, whatever. Eight triangles. There are eight pieces and we have four [people]." For these teachers, although approach C showed eight pieces, it represented an opportunity to explore equivalent fractions. In another group, a teacher noted the same idea: "So that would be a really good teaching point if you want it. I mean, that… showing the eight could be a really powerful thing."

Teachers also made use of known misconceptions considered in the EPLT as they discussed how they would select and sequence students' solutions in their classrooms. Four of the small groups referred to the misconception that when creating equal-sized parts of a whole some children believe the number of cuts they make is the same as the number of parts they wish to create, usually in the context of making parallel splits. Though the work samples used in the activity did not depict this exact misconception, teachers recalled it in their group conversations. In particular, teachers were concerned that approach C could foster such misconception, as one teacher argued: "One of the dangers is them equating making just four cuts and then to always…it'll always work." Later she repeated: "there is a risk in this [C] if they're going to think 'oh, make four cuts, no matter what'." Similar exchanges happened in three other small groups. As teachers discussed their sequences of approaches for class discussion, erroneous conceptions documented by the EPLT influenced their analyses and considerations of how to chose and order the students' approaches.

In relation to students' equipartitioning strategies, two of the small groups explicitly discussed but all groups made at least some reference to students' use of "halving" and "repeated halving" as a strategy, as well as the relative ease of equipartitioning wholes into two equal parts. In the previous days of the Summer Institute, teachers had learned a variety of different strategies students use to equipartition a whole described in the EPLT, but in examining the given sample of student work, they repeatedly related to halving and repeated halving. As one teacher observed, "I guess given what we talked about last week, halving and halving is easiest. But I mean, like, you know, what would my reasoning be for sharing the easiest?"

Connecting

When watching the actual classroom video, the teachers drew on several ideas from the EPLT to describe the connections the instructor made and to conjecture others. As in the selecting and sequencing small-group exercise, teachers referred to the three equipartitioning criteria to understand the instructor's sequencing and to describe the relationships among the approaches. For instance after sharing the first approach [C], one teacher suggested that the teacher should focus on the number of parts created in subsequent discussion. In response to a question from the researcher about what the instructor may be thinking and where she could take the discussion, the teacher said, "Counting, like 'how many pieces did you make? Let's count them' and like see that there's more than four." After viewing the instructor's discussion of approach D in relation to C, and how two of the pieces created in C matched into one of the pieces created in D, one teacher commented, "And it was really nice how she made the connection back to the previous work to show the change." The three equipartitioning criteria helped teachers notice connections made by the instructor as well as suggest other connections that could have been made.

Another way that the EPLT informed connections teachers noticed was by calling attention to the issues of naming equal-sized parts in relation to the original whole. As the teachers observed the connections the classroom instructor was making in the video, they noted the different naming practices and commented on the instructor's support of its refinement. For example in approach A, a student first referred to a share as "a piece." One teacher commented, "Well she saw that you got a, uh, qualitative answer. We saw that before. A piece. And then she was trying to go for the quantitative one." Another teacher followed up on this comment about naming by pointing out the clarity of the instructor's language. She stated, "And she made a kind of subtle distinction too, because the child who attempted to answer what the second one was, said, 'A second fourth?' And so, she used that but she said, 'a second one-fourth.' Just to kind of clarify that." Thus, the teachers' exploration of the subtleties and challenges of naming parts of wholes supported their noticing of the connections the instructor made.

Perhaps the most profound way that the EPLT affected the connections the teachers suggested was their use of emerging relationships to examine links across students' approaches. While the instructor's connections in the video centered on the three equipartitioning criteria and on naming, participating teachers also focused on emerging relationships. For instance, regarding transitivity, after viewing how two of the small pieces in approach D produced a fourth, one teacher suggested posing a question relating these results to the eights generated from approach C. She stated, "It would have been interesting, I mean, if we had said, okay, well are these…are these two pieces the same [D]? Is it the same fair share as these two pieces [C]?" This led to a discussion among the teachers and PD facilitators about how to show that non-congruent parts are actually the same. Also, the teachers connected the issue of two-eighths and one-fourth to the ideas of compensation and composition of splits. In referring to approach B, one teacher summarized, "Composition of splits - so, if you make a new cut then it affects all the other pieces - but it also is compensation because now there are more people sharing the smaller one." This teacher was noticing that by splitting along the diagonals in approach B, the single split acts on multiple parts, the essence of composition. Further, it creates more equal-sized parts but that each of the parts is smaller. By providing teachers with a description of these relationships that emerge from engaging in equipartitioning tasks, the EPLT assisted the teachers in connections that may support students in gaining proficiency with these emerging relationships.

Discussion

In this paper we examined the ways in which teachers who participated in a 30-hour Summer Institute on the EPLT used their understandings of this particular LT to engage with the three key pedagogical practices of selecting, sequencing and connecting students' mathematical ideas. We noted that teachers used the three criteria for equipartitioning to support their work in all of these three key pedagogical practices and, in fact, these criteria guided most of teachers' decisions when engaged in these practices. Teachers highlighted the importance of supporting students as they develop these criteria by proposing to select and sequence tasks that highlight the criteria and also to use the criteria as a venue for connecting the selected strategies. Teachers also suggested ways to assist students in coordinating the criteria. We also noted that teachers used known misconceptions and splitting strategies when selecting and sequencing students' solutions, whereas they used their knowledge of naming and emerging mathematical relations to examine connections across solutions. Teachers suggested ways to confront students' misconceptions as well as to support the development of emerging relations, which represent more sophisticated levels of thinking in the EPLT.

We started our design experiment using Wilson's (2009) revised conjecture that LTs provide a framework for teachers to organize students' work in class discussions. By examining how teachers used the EPLT in three specific pedagogical practices, we can now further refine the initial conjecture. We contend that LTs allow teachers to put students' mathematics at the center of their instructional decision, bringing specificity to the ways in which teachers' engage with the three key pedagogical practices of selecting, sequencing, and connecting (Stein et al. 2008) student work to generate productive mathematics discourse. The trajectory allows teachers to focus on students' solutions and thought processes to orchestrate discourse, instead of attending to non-mathematical ideas such as what the majority of the class did or what the teachers wanted students to do. Additionally, LTs support teachers in drawing connections among students' ideas and in identifying emergent relationships that build toward more sophisticated understanding.

Endnotes

1. Although the CCSS used the term learning progression, we take learning trajectories and progressions to be synonymous and we have opted to consistently use the latter in our work.

PRESERVICE ELEMENTARY TEACHERS' USES OF MATHEMATICS CURRICULUM MATERIALS: THE ROLE OF DISEQUILIBRIUM AND HUMAN RESOURCES

Stephanie Behm Cross
Georgia State University
scross@gsu.edu

Gwendolyn M. Lloyd
Penn State University
lloyd@psu.edu

Over the course of two years, data was collected focused on preservice elementary teachers' engagement with mathematics textbooks and curriculum materials in two contexts: (1) a university mathematics education course, and (2) student teaching. To frame the results and suggest opportunities for learning, Feiman-Nemser and Buchmann's (1985) critical analysis of experience in teacher education is utilized. These "pitfalls" of teacher education, or particular types of "inappropriate learning" are used as frames to help highlight important ideas from this research. Results indicate high levels of disequilibrium surrounding preservices teachers opportunities for learning, and also point to the importance of human resources during university coursework and fieldwork. Implications for teacher education are shared.

In 1996, Ball and Cohen asked a critical question: what is, or might be, the role of curriculum materials in teacher learning? To address this question, growing numbers of teacher education courses engage preservice teachers in textbook analysis and adaptation, as well as in the use of *Standards*-based curriculum materials (Frykholm, 2005; Tarr & Papick, 2004). Moreover, many student teachers are placed in school settings where the use of *Standards*-based curriculum materials has been mandated (e.g., Van Zoest & Bohl, 2002). As Ben-Peretz (1984) points out, however, "The ability to grasp the full meaning of curriculum materials is a prerequisite for their professional use in classrooms. This ability has to be developed in pre- and inservice teacher education programs" (p. 11). If teacher education is to play a pivotal role in helping teachers learn from the use of mathematics curriculum materials, it is important to examine carefully the typical experiences and learning opportunities embedded in preservice programs.

Research Context and Results

Over the course of two years, data was collected focused on preservice elementary teachers' engagement with mathematics textbooks and curriculum materials in two contexts: (1) a university mathematics education course, and (2) student teaching.

Preservice Teachers Curriculum Use in a Mathematics Education Course

Research Context

Participants in the first part of the study were 23 preservice elementary teachers in an undergraduate mathematics course titled *Geometry and Computing for Teachers.* As part of a larger research study, students were engaged in using reform-based middle grades curriculum materials as the basis for all mathematical learning. During the fifth week of a 15-week semester, the preservice teachers were given copies of selected student pages from two different sets of instructional materials, one reform-based curriculum, and one traditional curriculum. The preservice teachers were asked to first give an open-ended analysis of each set of instructional materials, and then to respond to 10 questions focused on the comparison of the two sets of instructional materials.

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

Methods

Data for the first part of this research consists of the 23 preservice teachers' written responses to the assignment described above. To synthesize and interpret the teachers' written analyses of the two sets of instructional materials, the entire collection of papers was reviewed several times by two researchers. In particular, the reviews aimed to identify the criterion the teachers seemed to be using for reading and evaluating the instructional materials, as well as those factors that seemed to be primary in their ultimate decisions about which set of instructional materials they preferred. After these two large reviews, each of the 23 papers were more carefully examined to confirm the tentative themes developed during initial reviews. In all, each individual paper was reviewed at least four times to develop major themes.

Results

To synthesize and interpret the teachers' written analyses of the two sets of instructional materials, common themes were developed across all written components of the project. First, I found that the preservice teachers were in search of familiar (traditional) components in both sets of instructional materials. The majority of the teachers specifically cited their own past experiences with traditional mathematics textbooks and lessons as major influences on their interpretations of the two sets of instructional materials. Second, I found that the teachers tended to use traditional expectations to judge both sets of instructional materials. The influence of preservice teachers' familiarity with more traditional instructional material components was, at times, so strong that it led them to inaccurately describe the two sets of instructional materials or to arrive at questionable conclusions about the materials. Finally, teachers attempted to justify the differences between the two sets of materials. Although they were not asked to do so, the teachers were compelled to discuss why such different sets of instructional materials might exist. In one way or another, they each communicated a belief that each set of materials had been created for a different type or level of learner.

Preservice Teacher Curriculum Use During Student Teaching

Research Context

The participants in the second part of the study were two elementary student teachers, Heather and Bridget. Heather completed her student-teaching internship in Jameson County, where the *Standards*-based *Everyday Mathematics* [*EM*] curriculum program (University of Chicago School Mathematics Project [UCSMP], 2001) was in use, while Bridget completed her internship at a Coopersburg Schools, where the teachers utilized materials from the commercially-developed *Silver Burdett Ginn* [SBG] (Fennell et al., 1999) textbook series.

Methods

The majority of the data was collected through classroom observations (11 observations total) and both informal and semi-structured interviews (7 interviews total). Most observations took place in 2-3 day consecutive blocks and fieldnotes were recorded throughout the entire block of time devoted to mathematics. Artifacts and documents included Heather's lesson plans and student-teaching journals. Analysis of data began at the start of data collection for the study. All fieldnotes were typed within 48 hours of each classroom observation, coupled with analytic notes and memos written at the end of each file. More extensive analysis took place following the completion of data collection. Separate files were created to group data according to developing themes (e.g., lesson pacing, teacher direction, lesson objectives, curriculum script). As major themes developed, lesson segments and interview quotes that appeared to highlight the major aspects of Heather's curriculum use were selected for inclusion in this report.

Results

Below, I briefly describe Heather and Bridget's use of their mathematics curriculum materials for the design and enactment of instruction during their student-teaching internships.

Heather's use of standards-based curriculum materials. Each weekend Heather prepared for the upcoming week's mathematics activities using a copy of the *EM* teacher's guide to develop general plans for her lessons: "On the weekend I'll do an outline for the week and write down roughly what I'm going to do." Heather explained that she looked at the teacher's guide again each morning before teaching: "During specials or snack time, I'll just review the lesson for that day." Heather felt that detailed lesson plans were unnecessary because when she taught, she had "the teacher's manual up there." Although Heather typically planned on her own as she read through the lessons in the teacher's guide, she also consulted her cooperating teacher: "I would ask my cooperating teacher about any questions that came up when I was planning, like about different games or just questions that come up."

Typically, Heather attempted to conduct her mathematics lessons in the specific ways recommended by the 4 to 5 page lesson plans found in the first grade *EM* teacher's guide. She used the guide during instruction to refer to specific tasks and questions to ask students as well as the overall organization of lessons. Heather explained that she tended to rely on the book during instruction because of the detailed, scripted nature of the information contained in the teacher's guide: "I feel like the teacher's guide is a script, so I always have it with me. A lot of times, I feel like if I miss a paragraph in the book then maybe that will throw the lesson off." When Heather adapted the recommendations, her changes usually related to the amount of time to spend on each lesson component. She often experienced difficulty carrying out her lessons in the timeframe she had allotted and, as a result, she sometimes changed the nature of the activities to "make up time."

Bridget's use of a commercially-developed textbook. During her internship, Bridget used the workbook component of the SBG curriculum program and supplemented the workbook with additional tasks and activities. Each week, Bridget met with three other kindergarten teachers to plan for upcoming lessons. The focus of these planning meetings was on the selection of SBG workbook pages and worksheets: "I've been told several times that I needed to make sure that [the students] are getting plenty of paperwork." The teachers used a year-long curriculum plan to identify which pages of the SBG workbook could be used to address the state curriculum standards. Bridget explained that "the principal likes to know what [state standards] we're covering which day."

Although Bridget found the planning meetings to be helpful, she consistently made her own plans after the meetings. As Bridget explained, "The truth is, I am trying to use what they're giving me and add to it where I think it's lacking." For each lesson, Bridget evaluated the SBG workbook offerings according to her informal assessment of students' knowledge, the objectives presented in the state curriculum framework, and her own visions of mathematics instruction. To develop new mathematics activities for use in conjunction with the SBG worksheets, Bridget first consulted the state curriculum framework to identify specific mathematical content, and then tapped other resources, including pages from *Everyday Mathematics* that she copied from teachers in Jameson County, for instructional ideas that would address the needs of her students.

Discussion

The descriptions of preservice teachers' experiences with mathematics curriculum materials not only add detail to what we know about teachers' interactions with and uses of curriculum materials, but also have the potential to offer insight into the role of teacher education in guiding and supporting teachers' ongoing learning with these materials. To frame these results and suggest opportunities for learning, I use Feiman-Nemser and Buchmann's (1985) critical analysis of experience in teacher education.

Pitfalls of Experience in Teacher Education

Although a trust in firsthand experience in learning to teach is common, Feiman-Nemser and Buchmann (1985) examine early experiences in teacher education with a critical eye. The authors ask, "Is experience as good a teacher of teachers as most people are inclined to think?" (p. 53). To explore this question, Feiman-Nemser and Buchmann discuss teacher learning in the moment as well as the "potential learnings – insights, messages, inferences, reinforced beliefs – about being a teacher, about pupils, classrooms, and the activities of teaching" (p. 54). These "pitfalls" of teacher education, or particular types of "inappropriate learning" as described by the authors, are outlined in Table 1. I use these frames to help highlight important ideas from this research.

Table 1: Pitfalls of Experience (from Feiman-Nemser and Buchmann, 1985)

Pitfall	**Description of experience**
Familiarity pitfall	The familiarity pitfall stems from the tendency to trust what is most memorable in personal experience…. Ideas and images of classrooms and teachers laid down through many years as a pupil provide a framework for viewing and standards for judging what [is seen] now (p. 56).
Two-worlds pitfall	The two-worlds pitfall arises from the fact that teacher education goes on in two distinct settings and from the fallacious assumption that making connections between these two worlds is straightforward and can be left to the novice (p. 63).
Cross-purposes pitfall	The cross-purposes pitfall arises from the fact that classrooms are not set up for teaching teachers (p. 63). The legitimate purposes of teachers center on their classrooms, which generally are not designed as laboratories for learning to teach (p. 62).

Learning to Challenge what is Familiar about Curriculum during University Coursework

Research indicates that teachers teach in the ways in which they were taught (Ball & Feiman-Nemser, 1988; Lortie, 1975). Feiman-Nemser and Buchman's (1985) "familiarity pitfall" highlights this idea. The authors suggest that *unquestioned* familiarity is a pitfall in that it "arrests thought and may mislead it" (p. 56). The authors further emphasize, "People do not recognize that their experience is limited and biased, and future teachers are no exception. The 'familiarity pitfall' stems from the tendency to trust what is most memorable in personal experience" (p. 56).

The preservice teachers in my studies experienced the familiarity pitfall. Many brought ideas and images from their own schooling experiences to their teacher education coursework. When we asked our preservice teachers to evaluate and compare mathematics lessons – two fairly self-contained sets of instructional materials that dealt with the same mathematical topic but in different ways – many of their views about what should be in a lesson related very closely to what they had experienced as students themselves. Their past experience not only limited their view of what could possibly be incorporated into a mathematics lesson, but the strength of their conceptions also tended to cloud their interpretations of some qualities of the less familiar lesson activities.

The familiarity pitfall suggests the need for activities such as the mathematics lesson comparison. The selection of the instructional materials that we asked teachers to analyze for this lesson comparison was very deliberate – material sets with distinctly different conceptions of teaching and learning, but also sets of materials that were familiar and comfortable as opposed to materials that were unfamiliar and more closely aligned with the current reform movement in mathematics education. Contrasting familiar materials with newer, more innovative materials not only provided insight into the *strength* of the apprenticeship of observation (Lortie, 1975) as preservice teachers found traditional elements even when they were not there, but also created an entry point for discussion related to the power of past experience.

Teacher Learning about Curriculum Materials across Two Distinct Settings

Feiman-Nemser and Buchman (1985) also describe the "two-worlds pitfall" in teacher preparation. As suggested by the authors, preservice teachers will need guidance in recognizing how what they have learned as university students can help shape their perspectives and practices as teachers. Making these connections are not necessarily easy or automatic.

I examined the experiences of two elementary student teachers who taught in different classroom contexts and utilized different instructional resources to teach mathematics. I found that, in contrast to the inservice teachers in Remillard and Bryans' (2004) study who drew upon their own instructional repertoires as they interpreted and used their curriculum materials, the student teachers in my study turned to their cooperating teachers, peers, teacher education experiences, and other textbooks and materials. This finding suggests that resources such as these may be critical supports for student teachers when they use curriculum materials for mathematics instruction for the first time. Bridget, for example, relied heavily on her teacher education experiences – she pulled in activities from her mathematics methods courses and from the instructional resources she had come to believe were more innovative and closely aligned with her new views of mathematics teaching and learning. In addition to relying on ideas from her teacher education coursework, Bridget also needed to use the mathematics instructional resources mandated by her placement school – materials she felt were inappropriate for her students learning. She was caught in the "two-worlds pitfall" as she taught with mathematics instructional materials for the first time. Bridget worked hard to fulfill the requirements of her internship site by using the required workbook, but also needed to find ways to incorporate new instructional ideas she had learned throughout university coursework.

Classrooms as Sites for Teacher Learning about Curriculum Materials

As preservice teachers first enter classrooms, they are confronted with the responsibility of teaching while still learning how to teach. Feiman-Nemser and Buchman (1985) describe this experience as the "cross-purposes pitfall." This pitfall suggests the frequent disconnect between the responsibility of teaching and the need for critical reflection on teaching. It also highlights the idea that classrooms are not set up for teaching teachers.

During student teaching, Heather was caught in the "cross-purposes pitfall" as she found herself placed in a classroom with a cooperating teacher who had set routines and guidelines for students, and who used a detailed, *Standards*-based mathematics curriculum for instruction. When Heather entered her student teaching experience in the middle of the year, she easily assimilated into the order already established in her cooperating teacher's classroom. Heather was able to observe her cooperating teacher teach with the detailed mathematics curriculum, and was then able to step in to the already established instructional routine. Heather was afforded an opportunity to consider and learn about the complicated nature of *Standards*-based curriculum program enactment as she worked to understand how to use a particular set of curriculum materials well. For student teachers, relying heavily upon a curricular guide or on predetermined classroom norms might limit opportunities to move moment to moment and constrain certain aspects of learning to teach. Heather's experience with a *Standards*-based curriculum provided her an opportunity to understand the complicated nature of curricular resources, but also limited her chances to reflect critically on other aspects of curriculum enactment.

Teacher Learning with Mathematics Curriculum Materials

The preservice teachers in the two studies presented here found themselves immersed in professional development with mathematics curriculum materials, textbooks, and state curriculum guides during coursework and fieldwork experiences. To respond to Ball and Cohen's (1996) question, curriculum materials indeed played a substantial role in preservice teacher learning in my studies. Preservice teachers had the opportunity to:

- develop an understanding of the variety of mathematics instructional resources available for teaching *that were different from what was familiar and comfortable*;
- *negotiate balance* between university experiences and personal expectations for instructional resources and the expectations of schools in regard to mathematics curriculum;
- consider and learn about the *unexpectedly complicated nature* of *Standards*-based curriculum program enactment; and
- make decisions regarding lesson *adaptation* from a variety of mathematics instructional materials for particular students and for particular classroom contexts.

The results not only illustrate teacher learning with and about curriculum materials, but also point out opportunities within teacher education for preservice teachers to question well-established beliefs and practices regarding mathematics teaching and mathematics instructional resources. In other words, the opportunities for learning afforded to these preservice teachers as they interacted with mathematics curriculum materials display a common theme of *disequilibrium*. These studies also highlight possible missed opportunities for learning and the importance of *human resources* within teacher education as it relates to preservice teachers' encounters with disequilibrium. These ideas are explored further below.

The Role of Disequilibrium

As Wheatley (2002) describes, disequilibrium among preservice and inservice teachers is caused by a challenge to teachers' beliefs about their existing practices. Wheatley further suggests, "The psychological need to resolve such disequilibrium often pulls teachers into learning and change" (p. 9). It was when our preservice teachers encountered materials and practices different from what they were expecting or accustomed to that opportunities for learning seemed to arise. For example, for many of the preservice teachers who participated in the lesson analysis assignment, exposure to new curriculum materials allowed them to consider the methods in which they were taught mathematics. Many of the preservice teachers examining the curriculum materials encountered disequilibrium as they questioned prior certainties about effective lesson structures for the teaching of mathematics. This lesson analysis assignment positions teachers to encounter disequilibrium and confront tacitly-held beliefs about teaching built on what is inherently familiar and comfortable.

Heather too encountered disequilibrium as she utilized Standards-based mathematics curriculum materials during student-teaching. Quite the opposite of what she expected, Heather discovered how difficult it was to plan and teach with what she described as a detailed, scripted mathematics curriculum. What Heather thought she knew as she entered student-teaching – that mathematics would be planned – was challenged as she discovered the work and reflection necessary to use the curriculum materials effectively. Further, when Heather was encouraged to plan from alternative instructional resources for just one lesson, she felt more attuned to her students and the overall learning objectives. Heather's feeling of disequilibrium when using the EM curriculum, coupled with the opportunity to plan a lesson using different curricular resources, helped Heather to evaluate more critically her understanding of a Standards-based curriculum program prior to beginning full-time teaching.

The Role of Human Resources

Bumping up against disequilibrium when using mathematics curriculum materials for teaching and learning is not surprising. There is potential for learning when preservice teachers are asked to consider materials different from what they are used to, teach with methods and materials different from their philosophies about teaching and learning, and teach with complicated and detailed curriculum materials. However, as preservice teachers encounter disequilibrium amongst the pitfalls of experience in teacher education, it is important to articulate the role of human resources in this learning. As our understanding of the role of curriculum materials in teacher learning matures, it is important to reconsider the role of teacher educators, cooperating teachers, and field supervisors.

The familiarity pitfall stems from teachers' tendency to trust what is most memorable from past schooling experiences. Left unaddressed, preservice teachers may have a hard time viewing other alternatives as valid possibilities for their future teaching. This common pitfall within teacher education emphasizes further the importance of many instructional activity comparison assignments designed to enhance and challenge curricular knowledge, and the critical role of teacher educators in both the design of and facilitation of reflection surrounding such activities. Teacher educators need to help preservice teachers make sense, in a deep and conceptual way, of the variety of curriculum resources available to them both before and during student teaching experiences. They need to help preservice teachers realize that what they have experienced with mathematics curriculum materials and instructional resources as students is only one option amongst many possibilities in their future use of mathematics curricular resources.

To address the two-worlds pitfall, teacher educators might position themselves as critical supports, or safety nets, for preservice teachers as they make the transition from university coursework to classroom-based fieldwork. Helping teachers make connections between philosophical beliefs and actual classroom practice with mathematics instructional materials and pushing them to "act with understanding" (Feiman-Nemser & Buchmann, 1985, p. 64) is critical. For mathematics curriculum materials and instructional resources to play a role in teacher learning throughout student-teaching, teacher educators and university supervisors might need to expand their support and redefine their roles to stretch far beyond the walls of university classrooms. Cooperating teachers might also reconsider their role in the education of preservice teachers. If cooperating teachers viewed themselves as teacher educators rather than model teachers, they might be better positioned to help preservice avoid the "two-worlds" pitfall as it relates to developing curricular knowledge.

In light of the "cross-purposes" pitfall, cooperating teachers might also search out ways to support novice teachers to move beyond mere imitation towards purposeful and reflective decision-making with curriculum materials. Critical examination and use of many types of instructional resources during student teaching might help us work towards a compromise between the necessary responsibility of a preservice teacher to teach and his or her ultimate goal of learning about teaching. Although these modified roles might create new challenges within current teacher education practices, we must not underestimate the importance of human resources as we consider opportunities for teachers to learn with mathematics curriculum materials.

Final Thoughts

In order to position curriculum materials as tools for teacher learning, we need to move beyond mere exposure to specific materials and on curriculum use strategies, towards a focus on the critical analysis of curriculum materials and their use. Helping preservice teachers to (a) understand the philosophies that underlie curriculum materials, (b) make sense of their use of materials both before and during student teaching as they transition from the university to school settings, and (c) navigate the pitfalls of experience as they encounter learning opportunities in real classrooms is critical. As we design opportunities for preservice teachers to engage with mathematics curriculum materials, we must position all players in the preparation of teachers as critical supports amongst the pitfalls of experience within teacher education. With these human supports in place, engaging preservice teachers in activities and learning opportunities with the potential to create disequilibrium and reflection may position mathematics curriculum materials as clear tools for teacher learning and as vehicles for renewal and innovation in the teaching of mathematics.

In this paper, we summarize the findings of a research synthesis specifically related to the geometry and measurement content knowledge of elementary/middle school preservice teachers. Findings from this synthesis show that preservice teachers have weak conceptions in geometry and measurement content knowledge. However, instructional strategies that incorporate technology (e.g., dynamic geometry software or virtual manipulatives) or analyzing children's work, have been shown to strengthen preservice teachers' understanding.

Introduction

For the past several years, a working group has met at the Psychology of Mathematics Education-North American Chapter (PME-NA) annual conferences. With members sharing their individual research, common themes and interests emerged and discussions turned towards needs for future work. In order for the group to build on and extend the knowledge base in the area of mathematical content knowledge for preservice teachers, a common need that emerged was knowledge of the status of current related research. Thus, a synthesis of the current research was essential for the following reasons:

1. To design a program of study to develop elementary/middle school preservice teachers' mathematical content knowledge for teaching, we need to understand *what* content knowledge preservice teachers bring to their courses. "The key to turning even poorly prepared prospective elementary teachers into mathematical thinkers is to work from what they *do* know" (CBMS, 2001, p. 17).
2. In addition to knowing *what* knowledge the preservice teachers bring to their coursework, we need to understand *how* to build on that knowledge in meaningful ways to further develop the preservice teachers' mathematical content knowledge for teaching. We need more empirical evidence of what learning opportunities contribute most to more knowledgeable and confident teachers in order to make more informed changes to our preparation programs (Mewborn, 2000).
3. To identify future research directions, we need to know *what* has been established in terms of preservice teachers' content knowledge and *how* that knowledge has been developed and *what* we still do not know or understand.

Theoretical Framework

There has been a recent emphasis in the mathematics education community in describing the needed and desired mathematical content knowledge for teaching, with various descriptions emerging from research (e.g. Hill, Rowan, & Ball, 2005; Ma, 1999; National Research Council, 2001; Shulman, 1986). Building on the work of Shulman (1986), Hill, Ball, & Shilling (2008) describe a framework for distinguishing different types of knowledge included in a construct of mathematical knowledge for teaching. This framework distinguishes between subject matter knowledge and pedagogical content knowledge. The interest of the working group centered on synthesizing research on subject matter (content) knowledge described in this framework. Understanding this content knowledge is vital for mathematics educators as we develop content (and methods) courses to meaningfully prepare preservice teachers as well as knowing *how* to help preservice teachers understand the needed content knowledge for themselves.

Our guiding questions for this synthesis were: *What research has been conducted on elementary/middle school preservice teachers' content knowledge?* and *What is known from this research about preservice teachers' content knowledge?* This paper reports on the work related to the subgroup focusing on preservice teachers'geometry and measurement content knowledge.

Methods

We began our work using the ERIC database focusing on the years 1998 to 2009. For dissertation work, we chose to review those from 2006 to 2009 and conference proceedings 2004-2009. In addition to the publication date requirement, each research study had to be published in a peer-reviewed journal and focus on elementary or middle school preservice teachers' geometry and measurement content knowledge. Since not all countries use the same grade-level classification as in the US, we decided to look at children aged 3 - 12 (possibly up to 14) when including international studies. Key words used in various combinations during this search process included geometry, preservice/pre-service, elementary, teacher, mathematics, measurement, length, volume, area, and angle. This produced a total of 30 studies.

Each of the 30 studies went through an independent review that detailed the research questions, study type and research design, lens and/or approach used, selection and description of participants, conditions of and procedures for data collection, data analysis, findings, and conclusions/implications. When there was a discrepancy on the inclusion or exclusion of a study, discussion allowed for mutual consensus on a final decision. Excluded from our synthesis were studies that had: (a) a general description of content knowledge that lacked specific attention to geometry or measurement, (b) a selection of inservice teachers or college students majoring in mathematics as opposed to mathematics education, (c) a sole focus on perceptions about mathematics not connected to content knowledge needed for teaching, and (d) a focus on describing classroom practice or activities with a lack of attention to research design methods. After examining the 30 studies, only 11 met all of the review criteria.

When the PME-NA Working Group met again to discuss the status of all content area reviews, the group decided to conduct another search through the literature. This second phase of the search focused on the 25 journals that provided relevant research studies for any of the content areas during the first phase. This second phase was initiated to search for relevant research published in 2010 and to see if new studies surfaced that possibly were missed in the initial search. Two new studies were found for geometry and measurement; one was published in 2010 and the second was published in a year not included in the ERIC database for that particular journal. Thus, in our final analysis, only 13 studies matched our criteria to be included in our analysis of research describing elementary preservice teachers' knowledge of geometry and measurement.

Results

Characterizations of the data

Eleven studies focused on geometry and only two studies reported on measurement. Of the geometry studies, seven focused on preservice teachers' content knowledge relative to shapes and their attributes (diagonals, reflective symmetry, etc.), one examined visualization skills, and four focused on other general knowledge of geometry. Studies on shape focused on quadrilaterals, rectangles/rhombi, and triangles. Studies on measurement focused on perimeter, area, and volume.

In order to synthesize findings across the 13 studies, we examined study types and characterized the research questions that dealt with preservice teachers' geometry and measurement content knowledge. Three broad categories emerged: descriptive studies that examined the *status* of mathematical knowledge and understandings of preservice teachers; studies that *explored* the impact of some "treatment" in a mathematics content or methods course; and finally, comparison studies that examined *differences* between ideas/features, groups or looked for relationships between two entities. Italicized text emphasizes the key features of the questions in the studies for these three categories.

The Status of Preservice Teachers' Content Knowledge in Geometry and Measurement

Six studies had at least one research question that focused on what preservice teachers understand about specific topics in geometry and measurement. These topics included quadrilaterals, reflective symmetry, triangle altitudes, volume, perimeter, and area.

Across all of these studies, we found preservice teachers' understanding of geometry to be weak or limited. "Preservice teachers' understanding of geometry was limited with shapes and measurement aspects of shapes" (Aslan-Tutak, 2009, p. 158); "it was found that a large portion of preservice teachers has lack of content knowledge of reflective symmetry" (Son, 2006, p. 149); "the results presented in this study are that most of these participants lack the ability to articulate complete descriptions of rectangle and rhombus" (Pickreign, 2007, p. 6); "we found that many preservice teachers had the same poor concept images as primary or secondary students" (Gutierrez & Jaime, 1999, p. 272); "the diversity of responses offered by preservice teachers in this study could be comparable to what would be expected from students in an upper primary classroom" (Zevenbergen, 2005, p. 21); and "yet, even with an apparently better foundation in mathematics, the students appeared to have poor conceptual understanding (*in perimeter and area*)" (Menon, 1998, p. 365).

Pickreign (2007) attends to how teacher preparation programs might address the concern of such limited geometrical understanding of preservice teachers, very similar to our initial quote from CBMS, working from what preservice teachers do know:

> "This, however, raises serious questions to be answered if we are to affect the content knowledge of teachers of mathematics: Can sufficient experience with these geometric ideas be provided in teacher education programs to lead to more profound understandings? Are there other mathematical ideas that require such experience? What should characterize these experiences? Can these experiences be provided without adding time or credit hours to teacher certification programs? One option in addressing these questions might be to not address them. Instead, accept teacher education programs as entry level preparation and utilize continuing professional development to address the growth of teachers' profound understanding of fundamental mathematics." (p. 6)

Time appears to be a critical component. Perhaps teacher preparation programs will not be able to provide the needed extent of time to make significant change but it can lay important groundwork.

Exploring the Impact of a Treatment

Five studies had questions of an exploratory nature, investigating "what happens if", four in the area of geometry and one looking at volume.

Geometry studies explored how dynamic geometry softwares impact preservice teachers' understanding of proof, the influence of the analysis of children's work with quadrilaterals on preservice teachers' understanding of geometry content knowledge, the impact of instruction utilizing graphic organizers and concept attainment strategies on preservice teachers' understanding of altitudes of triangles and diagonals of polygons, and the influence of digital and concrete tangrams on preservice teachers' 2D visualization on tangram designs.

Findings from Christou, Mousoulides, Pittalis, and Pitta-Pantazi (2004) show dynamic geometry softwares, along with appropriate questioning, motivated the students in the study to justify their conjectures and enabled students to pass from "exploratory" geometry to deductive geometry. Aslan-Tutak (2009) found that incorporating analysis of children's work into activities while preservice teachers make sense of quadrilaterals had a significant positive affect on the preservice teachers' learning as determined by a repeated measures ANOVA. Cunningham & Roberts (2010) explored the impact of a treatment lesson involving instructional strategies designed to assist the development of preservice teachers' concept images and concept definitions related to altitudes of triangles and diagonals of polygons. These strategies included the use of graphic organizers along with the concept attainment model in the development of definitions. The combination of these strategies resulted in some improvement for the preservice teachers' understanding of triangle altitudes and diagonals of polygons. Spencer's work (2008) found that using both digital and concrete tangrams in a methods course did help improve 2D visualization skills of preservice teachers which, in turn, had a significant positive impact on their attitude toward geometry.

Zevenbergen's (2005) study explored the impact of various learning dispositions that were emphasized within a mathematics course module on volume. These dispositions included developing mathematical meaning of volume as opposed to only using algorithmic methods, emphasizing the development of measurement and spatial sense, and developing the capacity within the preservice teachers to identify errors in children's mathematical thinking. However, despite the various methods used in the course to develop these dispositions, there was a "worrying number of students" who had not achieved them (p. 21), with some students quite resistant to alter their thinking about how to learn mathematics. Responses to interviews of students in the course highlighted the power of the teaching practicum, with preservice teachers rejecting the nature of the work done in their mathematics course due to their experiences in the schools. "Ideally, it would be useful to expose students to schools and classrooms that demonstrate the values embedded within teacher education courses if such courses are to effectively change teaching practice" (p. 21).

These few studies suggest various instructional strategies can make positive change on preservice teachers' geometrical understanding, such as those incorporating technology, making use of graphic organizers and concept attainment, and analyzing children's work. Field work that provides similar experiences as found in preservice teachers' mathematics courses and the length of time devoted to concept development may be critical factors to maintain these positive changes.

Examining Associations and Differences

Six studies included research questions that examined relationships and/or differences. Studies examined differences in geometric reasoning levels between elementary and secondary preservice teachers and male and female preservice teachers, differences in content knowledge based on instruction, relationships between visualization skills and attitude towards geometry, differences in student learning environment, and differences in students' conceptions of geometry concepts.

Halat (2008) administered a *van Hiele Geometry Test (VHGT)*, based upon work of Usiskin (1982), to 281 Turkish elementary and secondary preservice teachers. He found "no statistically significant difference in regard to the reasoning stages between the pre-service elementary school and secondary mathematics teachers, and that although there was a difference with reference to van Hiele levels between male and female pre-service secondary mathematics teachers favoring males, there was no sex-related difference found between male and female pre-service elementary school teachers" (Halat, 2008, p. 1).

With respect to examining the impact of instructional strategies, Aslan-Tutak (2009) considered the impact of having supplemental geometry activities in a two-week unit during a methods courses, using control and treatment groups. The results showed the geometry knowledge of students, as measured by the *Content Knowledge for Teaching Mathematics (CKT-M)* test (Hill & Ball, 2004), in either group was increased significantly, however the grouping did not have any statistically significant affect on participants' knowledge growth. Lundin (2007) also used the *CKT-M* test to measure content knowledge differences of preservice teachers from two groups: those who had completed mathematics courses designed for elementary education majors and those preservice teachers who had completed the mathematics requirement through the completion of other mathematics courses. She found no statistically significant differences between the two groups based upon students' mean scores. Lundin suggests the lack of difference could be attributed "to the likelihood that mathematical content gained in regular math courses taken by the participants was as beneficial as the content knowledge gained in the courses examined in this study" (p. 78) or that the subjects in her study "did not make a transition from applying general mathematical content knowledge to the mathematical content knowledge required for teaching" (p. 79).

Spencer (2008) found a positive relationship between attitude toward geometry and 2D visualization with increased levels of 2D visualization corresponding to an increased attitude towards geometry. Two-dimensional visualization skills were improved by the use of concrete and/or digital tangrams.

Gerretson (2004) examined to see whether or not there was a difference in elementary preservice teachers' performance on similarity tasks when using dynamic geometry software as compared to paper-and-pencil learning environment using traditional tools (e.g., compass, ruler). Using a pre/posttest control group experiment using randomized blocks controlling for initial performance, she found a statistically significant difference in learning environments between the two treatment groups. "Fundamentally, software users outperformed non-software users even when prior knowledge variability was taken into consideration." (p. 18). Analysis suggests elementary preservice teachers using a paper-and-pencil learning environment encountered more difficulties particularly situated around similarity properties of unfamiliar shapes, whereas preservice teachers using dynamic geometry software had "acquired a greater knowledge base to access, network, and apply" (p. 19).

Fujita and Jones (2006) explored the nature of preservice teachers' *personal figural concepts* and *formal figural concepts*, particularly in the area of quadrilaterals, building on the work of Tall & Vinner (1981) with respect to concept image and concept definition and Fischbein's figural concept (1993). The study examined data from two groups of preservice teachers in Scotland. The groups were based on their year of study in the teacher education program; either first or third. For either group, the data indicate a gap exists between the *formal figural concepts* of preservice teachers and their *personal figural concepts* "such that their images are so influential in their personal figural concepts that they dominate their attempt to define basic quadrilaterals" (Fujita & Jones, 2006, p. 131). Preservice teachers rely on their images of shapes to construct definitions rather than examining and using properties of shapes.

In several of these comparison studies, despite further evidence of preservice teachers' limited conceptual understandings in geometry, growth in content knowledge was demonstrated. Growth occured where technology was incorporated into the learning environment and when supplemental learning activities examining children's work were utilized.

Discussion and Conclusion

Our synthesis was guided by two questions, determining what research has been done related to geometry and measurement content knowledge and synthesizing what we know from this research regarding preservice teachers content knowledge. We organized the research found into three categories; briefly, these were status, explorations, and comparisons.

Based upon the research examining the status of preservice teachers' knowledge of geometry content, there is a need for these courses to take the time to develop foundational knowledge of geometry and measurement.

Preservice teachers enter their teacher preparation programs with limited geometry and measurement content knowledge, relying more on their understandings from middle school than their high school geometry course and operating on low van Hiele levels of understanding, relying on their concept images of geometrical concepts, with poorly constructed concept definitions. Although one study found no significant difference in mean scores between preservice teachers who had taken mathematics courses designed for teachers and those who had not, others had positive findings. Studies that explored alternative methods of instruction with the use of technology, such as dynamic geometry systems and virtual manipulatives, provided encouraging results related to improving deductive thinking and 2D visualization skills. Other instructional strategies in this synthesis that promoted preservice teachers' learning of shape and their properties included using a graphic organizer and concept attainment model, and analyzing children's work. The importance of a "supportive" field component was also noted to help sustain the values of the teacher education program, otherwise it is likely preservice teachers would reject constructive methods of teaching mathematics.

Limitations to our synthesis include using only one database. Using multiple sources may have produced more studies. Expanding our search to include more than the previous ten years would also have included more research and perhaps more seminal pieces in the area of geometry and measurement.

This summative look at research on preservice teachers' geometry and measurement content knowledge shows a paucity of research published in peer-reviewed arenas in the past ten years. However, this limited research consistently shows that preservice teachers do not have a solid understanding of several fundamental concepts within geometry and measurement. In order to work from what preservice teachers *do* know (CBMS, 2001), it appears that a greater focus on developing strong foundational knowledge is needed in geometry and measurement courses. Yet this raises some questions:

- What do we perceive, as a community of mathematics educators, as the essential foundational geometry and measurement knowledge that content courses should include?
- If such "core" foundational knowledge can be determined, what are sufficient

experiences that would enable preservice teachers to acquire profound understandings of this core knowledge and when do these experiences occur in a teacher preparation program?

Further work of researchers mapping out the core mathematical content knowledge for teachers will be helpful in highlighting the gaps between what content knowledge is *needed* by preservice teachers and what knowledge they bring with them to their teacher preparation programs.

MAINTAINING COGNITIVE DEMANDS OF TASKS THROUGH SMALL GROUP DISCUSSIONS IN PRESERVICE ELEMENTARY MATHEMATICS CLASSROOMS

Enacting tasks at high levels of cognitive demand helps preservice teachers make sense of mathematical ideas and serves as a model for instruction. Small group discussions can be useful pedagogical tools for maintaining a task's cognitive demands. In this article, we contrast two small group discussions within a preservice elementary classroom to illustrate characteristics of productive small group discussions.

Introduction

Current research on mathematical tasks examines the levels of cognitive demands at which tasks are written, set up, and implemented in elementary and middle school classrooms in the hopes of shedding light on effective classroom instruction (Stein, Smith, Henningsen, & Silver, 2000). Tasks that require high levels of cognitive demands prompt students to explain their reasoning and make connections between different representations or procedures. Since reasoning and sense making are critical components of conceptual understanding, finding ways to maintain high levels of cognitive demand during task implementation is important. Research shows, however, that teachers often inadvertently reduce the cognitive demands of a task during its implementation by making problems easier to solve, often by providing students with too many hints or by removing prompts for student-constructed justifications (Stein, Grover, & Henningsen, 1996).

One way to maintain high levels of cognitive demands may be through the use of mathematical discourse. There is evidence demonstrating the benefits of using discourse in the mathematics classroom (Walshaw & Anthony, 2009). When students are pushed to articulate their ideas and listen to the thinking of their peers, they are able to make better sense of their own thinking. Serving as a basis for current reform efforts, the National Council of Teachers of Mathematics (2000) identifies communication as an essential standard of mathematics education, stating that students must learn to communicate their mathematical thinking to others and evaluate the mathematical thinking of their peers. Nevertheless, many classrooms continue to implement traditional teacher-centered instruction (Hiebert et al., 2005).

In this research report we will present an analysis of preservice elementary teachers' small group discussions regarding a mathematical task written at a high level of cognitive demand. Through careful examination of videotaped discussions, we will identify characteristics of small group interactions that maintained the level of cognitive demand inherent in the task. We will contrast them with other small group interactions that lowered the task's cognitive demand level. Focusing on small group discussion yielded new information as small group interactions provide opportunities for learning that whole class formats do not (Yackel, Cobb, & Wood, 1991). For example, preservice teachers may feel more comfortable sharing their ideas in a small group setting. Although our original intent was on examining the role of whole-class discussion in fostering preservice teachers' conceptual understanding, we began to quickly notice that small group interactions played a key role in helping preservice teachers make sense of important mathematical ideas.

Theoretical Framework

Research on mathematical tasks and their cognitive demands has been on-going for over twenty years. Mathematical tasks play a large role in determining the mathematics that students will see in the classroom (Doyle, 1988). Tasks that emphasize computation and memorization result in students acquiring procedural skills without understanding why they work; tasks that focus on solving rich, contextual problems help students attend to the concepts underlying the problems (Stein & Lane, 1996).

Research suggests that preservice teachers should become accustomed to solving cognitively demanding problems, since the expectation is they will be posing cognitively demanding problems to their own students (Stein et al., 2009). The cognitive demands of a task refer to the kinds of thinking processes entailed in the task (e.g. memorization, use of procedures, use of complex thinking and reasoning strategies). Stein and colleagues suggest that the cognitive demands of a task can change as the task moves through three phases of development – writing, set up, and implementation (Stein et al., 1996; Stein et al., 2000; Boston & Smith, 2009). For example, a mathematical task may be written at a high level of cognitive demand, but presented and/or implemented at a lower level of cognitive demand.

Rubrics have been developed to assess the cognitive demands of tasks as written and as implemented (Boston & Smith, 2009). The *Instructional Quality Assessment – Academic Rigor* (IQA-AR) rubric includes two forms, the *Potential of the Task* and *Implementation of the Task.* Both forms scores range from 0 to 4. A score of 0 indicates that the lesson tasks were nonmathematical in nature. Score levels 1 and 2 represent low-level cognitive demands. Score levels 3 and 4 represent high-level cognitive demands in which the connections to meaning and understanding are implicitly (score level 3) or explicitly (score level 4) required by the task.

When comparing tasks' levels of cognitive demands at the written and implementation phases, Suzuka and colleagues (2009) found that teacher educators have difficulty maintaining a task's cognitive demands when implementing the task in a preservice teacher classroom. Two primary reasons could explain their difficulty: sometimes teacher educators focus too heavily on the mathematics of the task, thereby disconnecting the task from the work of teaching; or, work focuses too heavily on pedagogical concerns without engaging preservice teachers in understanding mathematical content. In order to keep tasks focused on MKT development, the authors suggest asking preservice teachers to attend to their classmates' thinking, pressing preservice teachers to explain their own thinking, and being explicit about the connections between mathematical tasks and teaching.

While reform efforts during the past twenty years call for the use of classroom discourse (Senk & Thompson, 2003), research has also recently begun examining classroom communities where discourse is used to promote mathematical learning. Hufferd-Ackles, Fuson, and Sherin (2004) created the *Levels of Math – Talk Learning Community* framework, which identified four components of a math-talk learning community: questioning, explaining mathematical thinking, source of mathematical ideas, and responsibility for learning. Each component is rated from level 0 to 3 to reflect changes in how teachers and students interact to make sense of mathematical ideas. Classrooms at a level 0 are teacher-centered, where the teacher is the only questioner, students provide short answers and never elaborate on their thinking, the teacher is the only source of mathematical ideas, and students are passive listeners to what the teacher is saying. Classrooms at a level 3, however, are primarily student-centered, where students and teacher question one another, students provide more elaborate justifications of their mathematical ideas, and students take responsibility for helping each other learn mathematics.

Though research on mathematical discourse and small group interactions is abundant at the K-12 level, little is known about discourse in preservice teacher classrooms. Dixon, Andreasen, and Stephan (2009) conducted a classroom teaching experiment in a preservice elementary teacher mathematics content course in order to understand how classroom norms are established. They observed that making sense of others' reasoning was one of the most difficult, yet important, norms to establish. Research on discourse in preservice teacher classrooms also showed that math-talk learning communities (as defined by Hufferd-Ackles et al., 2004) can be established by prompting preservice teachers to question, explain, and clarify each others' thinking (Rathouz & Rubenstein, 2009). These studies, however, did not focus on small group interactions. As such, we do not yet have a clear picture of the characteristics of student-to-student talk in preservice teacher classrooms.

Methods

The study took place in the spring of 2010, during a semester-long preservice elementary mathematics content course at a large private university in the northeastern United States. It is the second course in a series of two required mathematics content courses for undergraduates seeking state certification as elementary or special education teachers. The course emphasizes preservice teachers' conceptual understanding of content and seeks to develop productive mathematical talk as a classroom norm. Each section consisted of approximately sixteen participants who were randomly assigned to four small groups. Two classroom sections of this course were videotaped and audio taped during eighty minute class sessions over a two-week period.

The curriculum used in the study was a four-part unit on geometric measurement created by the researchers. Our analysis focuses on a two-day lesson about surface areas of prisms and cylinders. Day one required participants to work through mathematical tasks regarding the lateral and total surface areas of prisms. Day two required participants to work through mathematical tasks focused on lateral and total surface areas of cylinders, as well as the relationship between the surface areas of prisms and cylinders. The tasks were written to be cognitively demanding, with repeated prompts for participants to justify their reasoning to others and make generalizations across topics.

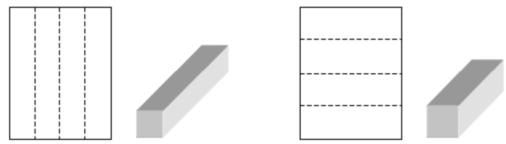
We used two sets of rubrics to collect data about each task and its implementation. We used the IQA-AR rubrics for the potential of the task and for the implementation of the task in order to assess the cognitive demands of the tasks before and during implementation, respectively (Boston & Smith, 2009). In order to assess the nature of student-to-student talk within small group discussions, we used the *Levels of Math Talk* framework (Hufferd-Ackles et al., 2004).

Results

During day one of the surface area task, small groups in both sections worked on a mathematical task consisting of four questions (shown below). Each group had to fold one piece of paper lengthwise and a second, identical, piece of paper widthwise, find each prism's dimensions, and calculate their surface areas. Participants then needed to identify similarities and differences between the surface area calculations of both prisms. Each group had approximately fifteen minutes to complete the task.

3. Take two pieces of $8\frac{1}{2}$ in. by 11 in. paper and fold them into two different rectangular prisms with square bases. Label one, Prism X, and the other, Prism Y. The large rectangle that is used to form each prism is called the "lateral surfaces rectangle." Note that the prisms are

missing their bases. On the drawing below, label the dimensions of both prisms.



Prism X Prism Y

4. a) What are the dimensions of the lateral surfaces rectangle for Prism X? How can we use the dimensions of the prism to find these measures?
   b) Calculate the area of the lateral surfaces rectangle of Prism X, the area of the bases of Prism X and the total surface area of Prism X.
5. a) What are the dimensions of the lateral surfaces rectangle for Prism Y? How can we use the dimensions of the prism to find these measures?
   b) Calculate the area of the lateral surface rectangle of Prism Y, the area of the bases of Prism Y and the total surface area of Prism Y.
6. Explain any similarities and differences between the surface area calculations in questions 2 and 3.

Cognitive Demand Analysis for Potential of Task

We rated this task at a level 4 cognitive demand using the IQA-AR rubric for potential of the task. The task engages participants in complex thinking because they are asked to compare and contrast two different orientations of seemingly identical prisms. They are asked to follow a procedure (creating two different prisms from the same sized sheet of paper) to illustrate an important mathematical concept (prisms can have the same lateral surface area but different total surface areas). In other words, the numerous computations of total and lateral surface areas required by the task serve a greater purpose – conceptual understanding of the differences between total and lateral surface areas of prisms. In the last question of the task, participants are prompted to provide explicit evidence of their understanding by comparing and contrasting the calculations that were performed on the two prisms. In doing so, they are making connections between two representations of a rectangular prism.

Instructor F's Small Group Discussion

Participants create the two paper rectangular prisms using sheets of paper with dimensions 8 ½ inches by 11 inches, following the instructions written in question 3. In the following small group discussion, participants are finishing their calculations of prism Y's surface area. After having found that the length of a side of prism Y's base is 2.75, they are helping each other with the rest of the calculations that need to be done in order to answer question 5. Once this is complete, they, move on to a discussion of question 6.

S1: We're saying that the lateral surface area would be 93.5 because it's the same piece of paper but the bases are going to change.
S4: So the base is?
S1: It would be 2.75 squared.
S4: 7.5625.
S2: Plus 2 times 7.56.

S1: Put another one [prism Y base area] because you need 2 of those. 108.625. So it's not the same.
S3: Well yeah because the squares [points to paper rectangular prism] are different sizes.
S3: The lateral surface areas are the same, but…
S2: Yeah, the lateral surface areas are the same.
S3: But the bases…
S2: The bases are different.
S3: …are different sizes, so the larger base is going to have a larger surface area?
S2: Yeah.
S3: Um, what number are we supposed to go up to?
S1: I think up to 6.
S3: Oh, okay…are you sure?
S1: Yup, that's why we had to do different squares on the…
S4: So why is the surface area different?
S1: Because this [points to paper rectangular prism]…they have the same lateral surface area [points to top of paper rectangular prism], but the boxes [points to base of paper rectangular prism] of the squares of the bases are different. Because these [points to bigger paper prism] squares are bigger so it makes it more.

In this discussion, the small group interactions result in a shared understanding of why the total surface areas of the two prisms differ. Initially, S2 and S1 notice that S4 has only added one base area to prism Y's lateral surface area, explaining two base areas are needed to accurately calculate total surface area. S3 revoices S1's remark that the total surface areas of the two prisms are not the same since their base areas differ. S3 and S2 again revoice the idea. Although S3 is satisfied with this explanation, S4 is not and asks the group to explain why the prisms' surface areas differ. S1 restates the explanation in his own words using folded paper prisms to illustrate his reasoning.

We rated this small group discussion at a level 4 in cognitive demand using the IQA-AR rubric for implementation of the task. There is clear evidence of participants' reasoning, as group members articulated an explanation for why the surface areas of the two prisms are different. When S3 responds to S1's initial comment that the surface areas are not the same, she is making sense of the mathematics. She could have simply stated that the surface areas differ because the two prisms are different, but this would have shown vague understanding. Instead, she states that the difference is a result of different sized bases. This shows that she understands that it is the base areas of the two prisms that distinguish one prism's total surface area from the others' – the lateral surface areas are the same. Also, S1 is making an explicit connection between representations when he lays one paper prism next to the other and points to their different sized bases.

We rated the small group discussion at a level 3 for questioning, explaining mathematical thinking, source of mathematical ideas, and responsibility for learning using the *Levels of Math Talk* framework. These high levels of math talk are due to the comfort with which group members express their ideas and help one another understand them. Participants initiate their own student-to-student talk without prompting from the instructor, and they do not hesitate to ask questions of each other to clarify ideas. Participants freely interject their own ideas throughout discussion, either correcting each others' mistakes as evidenced by S2's and S1's noting that S4 omitted one base to calculate the total surface area. Participants repeatedly justify their ideas and with little prompting from each other, as seen when S3 spontaneously began to articulate her explanation for why the surface areas differ. Participants in this group take responsibility for their own learning, as seen when S4 asks for clarification after the other group members were finished.

Instructor C's Small Group Discussion

Participants in this small group also worked on the same mathematical task as the group in Instructor F's class. In the following discussion, the group members are finishing their computations of the total surface areas of both prisms and need to explain any similarities and differences between the surface areas of the prisms.

S2: So we know the lateral surface area….
S1: Is 8.5, oh wait sorry what did you get for the lateral surface area?
S2: Is 93.5
S3: What's 93.5?
S2: Is the lateral surface area….one piece of paper.
S1: Yeah same as the last one.
S2: Right. And then to that we have to add the bases [points to bases of prism] which are now different.
S3: The bases are….2.75?
S2: Yeah. So 7.5…now you got to multiple that by 2…15.
S3: What was the area of one of them?
S2: One of them is 7.56. So the total is 108.425, which is bigger.
S1: Okay, so similarities and differences between the surface area calculations…the lateral surfaces were the same, but the bases were different and therefore the total surface area…
S1: Okay, are we supposed to keep going?
S3: Well he said till 8.

In this discussion, the group focuses on making correct calculations of prism Y's total surface area. S1 asks S2 for the lateral surface area of prism Y (93.5), after which S3 asks S2 what 93.5 represents. As S2 begins to articulate the next step in the procedure for calculating total surface area, S3 asks her for the area of the base of prism Y. The only discussion surrounding mathematical concepts occurs at the end, when S1 states that the difference in surface areas is due to the difference in base areas. None of the other participants follows up on this claim at all.

We rated this small group discussion at a level 2 in cognitive demand using the IQA-AR rubric for implementation of the task. The purpose of this group's talk is to make sure that all group members arrive at the same numerical results for the calculations of total surface areas of prism X and prism Y. Since the group as a whole does not engage in any discussion around S1's statement, it is not apparent that the other group members agree with this statement or understand why it is true. Throughout their discussion, participants follow a well-known procedure for calculating surface areas; they are not engaged in any complex thinking or meaning making.

We rated this small group discussion at a level 1 using the *Levels of Math Talk* framework. Participants ask each other questions, but they do not listen attentively since questions are repeated (S3 asks for the lateral surface area immediately after S1 asks the same question). S1 is the only participant who describes her non-computational thinking, but her claim is not explored any further by the other students. In fact, small group discussion focuses solely on procedures for finding total surface areas, rather than the concepts underlying the problem.

When comparing Instructor F's small group interactions to Instructor C's small group interactions, clear differences appear. In Instructor F's class, group members maintain the task's high level of cognitive demand during task implementation. They do this by engaging in thoughtful discussion about the key mathematical ideas of the task, making sure to provide reasoning when appropriate. In Instructor C's class, however, group members are focused on getting the correct answer to the problem and neglect the last part of the question that asks for an explanation of the similarities and differences between calculations.

Differences in both group's level of math talk are also evident. Instructor F's group is at the highest level of math talk because they make repeated efforts to explain their thinking. In fact, when analyzing classroom video of these interactions, one notices a sense of urgency, among the group members, to make sure everyone understands the concepts under investigation. They are not afraid to interject their own ideas into a conversation because they know their ideas will be valued. On the other hand, Instructor C's group members exhibited a low level of math talk. Since participants were focused on getting the correct answer instead of making sense of their answers, questions were short and only elicited superficial responses. Also, since S1's claim is not explored by other group members during the small group discussion, one might conclude that the group uses another source of mathematical ideas, such as the instructor or whole class discussion, instead of each other.

Discussion

In this article, we provided examples of how differences between two small groups of elementary preservice teachers working on the same task lead to maintaining or lowering the task's cognitive demands. In Instructor F's small group discussions, participants maintained the cognitive demands of the task by fully answering the questions posed and justifying their answers. In Instructor C's small group discussions, participant discussion resulted in lowered cognitive demands because this group only answered the computational portion of the questions posed and neglected to provide explanations of why they performed their computations or reached their conceptual conclusions.

We also evaluated the two small group discussions using a rubric for levels of math talk (Hufferd-Ackles et al., 2004). We found that Instructor F's small group discussions were rated at a higher level of math talk than Instructor C's small group discussions. Participants in Instructor F's class were actively involved in asking each other questions and defending their own ideas, while participants in Instructor C's class rarely asked each other to explain their thoughts and were hesitant to pose clarifying questions.

Based on our analysis, we believe that the focus of preservice teachers' attention during small group discussion can impact whether tasks' cognitive demands are maintained or not. Small groups who focus on providing explanations, justifying procedures, and making generalizations appear to maintain a task's high level of cognitive demand. We observed a shared desire among all group members in Instructor F's class to make sense of the task. Participants were consistently asking each other for explanations and were often dissatisfied with correct solutions that they did not understand clearly. In contrast, small groups who focus solely on finding correct answers, do not justify their procedures, and do not attempt to generalize their ideas beyond specific cases risk lowering the cognitive demands of a task. In Instructor C's small group, there did not appear to be a shared need to develop an understanding of the mathematics of the task. Participants seemed satisfied when they arrived at the same numerical answer, and chose not to push for meaning or clarification.

Although it is unclear why one group developed a shared need to make sense of the task while the other did not, it seems that a small group working together in a preservice Instructor Course can develop its own culture that helps to determine how the group functions. Future research should explore the source of small group cultures. Do small groups adopt the culture of their classroom? Does what the instructor of the course value – respectful discourse and focus on meaning – dictate how small groups operate? In our study, Instructor F focused whole-class discussion on sense making while Instructor C focused his discussions on answer checking.

It is also possible that maintaining high levels of cognitive demand is associated with high levels of math talk during small group discussions. A future study could investigate the interplay between a task's cognitive demands and the levels of math talk used to solve the task: does a small group's success in solving cognitively challenging problems relate to the degree to which they use productive math talk during discussions? Our study suggests that math talk can help maintain high levels of cognitive demand, and that using contrasting cases might be a useful method for investigating this further.

PRESERVICE ELEMENTARY TEACHERS DEVELOPING UNDERSTANDINGS OF SELF AS MATHEMATICS TEACHER AND TEACHING IN CONTEXT

Jill Neumayer DePiper
University of Maryland, College Park
jillmariedepiper@gmail.com

As preservice elementary teachers (PSTs) examine their personal readiness, instructional practices, and their agency in enacting those practices, a ubiquitous question is "What can I do?" to support all students in learning mathematics amidst social, political and institutional dynamics present in today's classrooms. This paper explores how PSTs are developing understandings of self as mathematics teacher and of teaching through participation in a seminar designed to support critical examination of themselves as mathematics teachers, and if and how this self-examination is consequential for their understandings of teaching, particularly as within complex realities of schooling and attention to equity and access.

> I think I am experiencing an identity crisis as a teacher. …As far as me as a math teacher, I am not sure where I see myself. I want to believe that I will be using problematic tasks and encouraging my students to explore and to question. And I *hope* that I won't be skilling and drilling my students. I *hope* I won't be using mind numbing workbooks and textbooks. I *hope* my students are learning and growing in my classroom. I *hope* I continue to see them as unique individuals, not just as test takers. I *hope* I am still reflective and responsive to my students' needs. I *hope* that I am flexible and constantly strive to improve my teaching. I *hope* I am not stuck in a rut. I *hope* I haven't succumbed to the pressures of high stakes testing. And, I *hope* that I will think of the administrators and other teachers at my school as allies, not adversaries. (Sarah, March 29, 2010)

Sarah wrote this vision statement during the last semester of an intensive elementary master's certification program after completing over two semesters of coursework toward her degree and interning for seven months in a third-grade classroom. Sarah's writing highlights the complexity of teaching mathematics in the realities of her classroom context. Sarah essentially asked, "What can I do?" a complex question heard in preservice teacher education as preservice elementary teachers (PSTs), such as Sarah, question their personal readiness to engage in instructional best practices, their understanding of what those practices are, and their agency in enacting those practices in school contexts. As she discussed in other writings, for example, Sarah remained uncertain about how to actually work towards equity in mathematics by employing teaching practices such as engaging students in conceptually rich mathematics in this era of high-stakes testing. While it is generally accepted that teacher preparation needs to include an emphasis on best practices (Ball & Forzani, 2009) and classroom analysis (Hiebert, Morris, Berk, & Jansen, 2007), it also must prepare PSTs to navigate the many social, political, and institutional dynamics in classrooms so they can enact equitable teaching practices that best support *all* students in learning with understanding. Successful negotiation of these dynamics requires that teachers have an examined vision of their goals of mathematics teaching, the social and political contexts of schooling, and the realities of their school contexts, that is, understanding of themselves as mathematics teachers. The paper explores how PSTs develop understandings of themselves as mathematics teachers, and if and how this self-knowledge is consequential for their understandings of mathematics teaching, particularly as situated within the complex realities of schooling and with attention to equity and access.

Elementary teacher preparation is further complicated by elementary teachers' positioning as generalists (Brown & McNamara, 2005), such that they may not identify as mathematics teachers or attend specifically to creating rich mathematical experiences. Elementary teachers' existing beliefs and their personal, perhaps damaging, mathematical experiences also influence their interpretations of curricula and reform (e.g., Drake, 2006) and conceptualizations of mathematics (Gellert, 2000). In the complexity of their mathematics teaching environments and their complex positioning, PSTs highlight different tensions through three iterations of the question, "What can I do?": a) What can *I* do?, with emphasis on personal readiness; b) What can I *do*?, focusing on actionable steps; and c) What *can* I do?, attending to personal agency (Pollock et al., 2010)? In response, teacher preparation needs to emphasize dispositions and knowledge that relate specifically to mathematics and mathematics teaching for understanding, while also supporting elementary PSTs in understanding themselves, their students, and the social, cultural, and intellectual contexts of teaching.

Without approaches in mathematics teacher education that address the complex situations or multiple dynamics with which PSTs will contend as novice teachers, PSTs are unprepared for the realities of public schooling. In particular, PSTs need approaches that attend to issues of equity, self-understanding, and the social and political contexts of teaching within content-specific teacher education (Crockett & Buckley, 2009). The consequences of leaving teachers unprepared for the realities of schooling are damaging, not only for those teachers, but also for students, as teachers who are unprepared may be unable to provide all students opportunity to learn or to enact equitable mathematics teaching practices. Developing an understanding of self as mathematics teacher, which for Sarah means examining her own relation to the complexities in her context, may build capacity for making sense of one's relation to these dynamics and the realities of schooling and critically analyzing teaching decisions. This understanding of self as mathematics teacher is related to what the research literature frames as teacher identity. The theoretical perspective of this study extends current perspectives of identity, as simultaneously personal and social and in constant negotiation (e.g., Wenger, 1998; Holland, Lachicotte, Skinner, & Cain, 1998), but emphasizes the importance of individual's awareness of the construction of identity and active engagement in its negotiation (Butler, 1999).

I contend that engaging PSTs in understanding that *mathematics teacher* is a complex construction supports them in making sense of their relation to the multiple dynamics and forces present in their mathematics classrooms, or in understanding themselves as mathematics teachers. This understanding should be framed by prevailing discourses of teaching, mathematics, and students, and by local discourses within their teaching contexts. Further, it builds PSTs' capacity for navigating their contexts and taking up particular mathematics teaching practices that support access to mathematics and equitable learning environments, such as teaching students through methods of inquiry and problem solving (NCTM, 2000). As Butler (1999) argues, understanding how identity is situated and negotiated—simultaneously, asserted and threatened—may open possibilities for PSTs to reconstitute mathematics teacher identity with a different set of attributes and engagements.

In applying Butler's (1999) perspective of gender identity to elementary PSTs, the following questions guide this research: 1) How does the seminar support PSTs to critically examine their understandings of themselves as mathematics teachers and the discourses that shape those understandings?, and 2) How are PSTs' understandings of themselves as mathematics teachers and of related social and political discourses consequential for whether and how they take up new understandings of self as mathematics teacher and teaching in context?

Begin your paper here. All text is to be in Times New Roman 12-point, 1-inch margins, and single spacing. You should use the ruler tool or the style sheet to indent the first line of each paragraph one-fourth of an inch. DO NOT use the space bar or tab key to indent.

To begin your second paragraph, do not leave a blank line. Be sure to indent again. Indenting should happen automatically if you are using the style sheet or the ruler bar correctly.

It is suggested that authors make two copies of this Template and work directly in one of the copies, or copy an existing file into one copy and format using styles.

Theoretical Framework

Conceptions of teacher identity assume that identity is dependent on and formed within contexts, and is relational, shifting, and multiple (Rodgers & Scott, 2008). Becoming a teacher is not developing *an* identity, but is developing *identity* as a continuous process of constructing and deconstructing understandings within the complexities of social practice, beliefs, experiences, and social norms. This is similar to Butler's (1999) description of the process of becoming a woman: "If there is something right in Beauvoir's claim that one is not born, but rather one *becomes* a woman, it follows that *woman* itself is a term in process, a becoming.… As an ongoing discursive practice, it is open to intervention and resignification" (p. 45). Being and becoming a teacher also should be seen as open to continuous identification and reidentification. For example, Sarah engaged in this ongoing process during her internship, identifying how her mentor's actions were shaping her interactions with her students, and, thus, how she saw herself as a teacher in relation to her mentor:

> I find myself yelling at my students and I'm like, "Why am I yelling at them? They just don't get long division yet!" But … I feel my mentor, her voice, and it's like, "Is that me?" because I used to not be a yeller. Have I become *that* teacher? …Have I turned into my mentor? (April 27, 2010)

What Sarah is doing—struggling with the internal and external forces that are shaping her understandings of herself as a mathematics teacher—is identity work. Understanding of self as mathematics teacher is situated within and shaped by historical, political, and social contexts, and also influenced by other individuals and imposed constraints. Prevailing discourses about mathematics teaching and learning and local discourses within their teaching contexts influence PSTs' understandings of mathematics teaching (e.g., de Freitas, 2008) and may shape their engagement with teaching and learning to teach. These may include: institutional discourses around curriculum and testing (e.g., Brown & McNamara, 2005); social discourses around race, class, and student abilities (e.g., de Freitas & Zolkower, 2009; Sleeter, 2008); or, discourses of teacher as "savior" (e.g., Britzman & Pitt, 1996).

My theoretical premise is that deconstructing these contexts, expectations, and constraints and challenging PSTs to question them and the dominant discourses that frame mathematics teaching—the "culturally established lines of coherence" (Butler, 1999, p. 33)—is encouraging PSTs to be actively involved in the process of identity work. Developing awareness of these dynamics means "unpacking the invisible knapsack" (McIntosh, 2001, p. 180) of the implicit discourses that have shaped and are shaping their understandings of being mathematics teachers and making these discourses explicit. For Sarah, that may include thinking about *why* she may "succumb to the pressures of standardized testing" or otherwise lose the flexibility or responsiveness she aspires to demonstrate in her mathematics teaching. According to Butler (1999), deconstruction, as a process of critically examining the meaning and "substantive appearance of gender", identifying "its constitutive acts, and locat[ing] and account[ing] for those acts within the compulsory frames set by the various forces that police the social appearance of gender" (p. 45), can support resignification. As PSTs question these discourses and *deconstruct* (Butler, 1999) what it means to be mathematics teachers in context, they are examining themselves as mathematics teachers. Making sense of one's relations to the multiple dynamics in the mathematics classroom and developing understanding of self as mathematics teacher builds capacity for navigating these dynamics, attending to issues of equity, and being critical analytic about teaching decisions. Thus, this critical examination may lead PSTs to take up new understandings of being a mathematics teacher and of mathematics teaching.

Methods

Data collection took place during a seminar in the final semester of a 15-month elementary master's certification program and the required school-based fieldwork. Ten female PSTs, 23- to 34-years old, volunteered to participate in the eight 2-hour group sessions of the seminar and the study. One PST self-identified as African-American, one as an immigrant from Argentina, and eight as White.

Seminar Design

Seminar sessions engaged the participating PSTs in *deconstruction*, a process of critical examination of their understanding of themselves as mathematics teachers, teaching, and the political and social discourses that shape their understandings. The seminar design situated critical pedagogy (e.g., Ellsworth, 1989; Freire, 1970/2000; Kumashiro, 2000) in mathematics teacher education. Although PST education has attended to metaphors (e.g., Fenstermacher & Soltis, 1986) and the construction of a professional identity (e.g., Peressini et al., 2004), this seminar engaged theories of deconstruction and wove issues of self-understanding into content and context. PSTs analyzed case studies, transcripts, and videos, which provided opportunities for them to name and complexify prevailing discourses and positionings in relation to mathematics teaching and learning and to examine their own and others' practices. PSTs also completed writing assignments to relate these activities to their own positioning as mathematics teachers. Rather than reaching a predetermined understanding of certain content, the goal was for PST's self-understanding, where the PST asks how he or she is positioned and how others are positioned within discourses and "brings this knowledge to bear on his or her own sense of self" (Kumashiro, 2000, p. 45). That is, sessions served to open possibilities for PSTs to position themselves differently. Meeting as a group generated a sense of common cause and created a space for PSTs to voice their concerns as well as strategize; sessions, thus, became legitimate and valued spaces where PSTs could speak and others would listen.

Data and Data Analysis

I collected data from the seminar to examine: a) how PSTs develop understanding of themselves as mathematics teachers, b) how this is consequential for whether they take up new understandings of mathematics teacher and teaching; and, c) how the seminar supported PSTs' self-examination. Data include interviews, discussion transcripts, and PSTs' written work from the seminar.

Attention to PSTs' understandings of themselves and their take up of new understandings was analyzed through the particular discursive practices of "working difference" (Ellsworth & Miller, 1996). How PSTs are engaging in the particular discursive practices of working difference that attend to context, their positioning, and the positioning of others around an issue that emerges as salient speaks to how the seminar is supporting critical self-examination. If understandings of self are conceptualized as positioning, then repositioning and negotiating positions suggests new understandings of self and personal readiness. How PSTs are taking up *new* understanding of mathematics teacher is operationalized through how PSTs are engaged in the particular discursive practice of showing the active labor of working difference (Ellsworth & Miller, 1996), that is, how they are repositioning themselves.

To understand how PSTs are taking up new understandings of mathematics teaching, I followed how individuals are problematizing one emergent issue through the sessions, attending to content of their conversations about teaching and the processes they engaged in their conversations. Problematizing teaching includes how PSTs are attending to the work of teaching and how they are negotiating three specific levels of attention— attention to core principles of teaching, strategies for instruction, and actions specifically for tomorrow's classroom (Pollock, 2008)—and using particular discursive practices in taking up and engaging in problems of practice (Horn & Little, 2010). Pollock's (2008) three levels of talk serve to structure the analysis of the content of the conversation, while attention the discursive practices of normalizing, specifying, revising, and generalizing (Horn & Little, 2010) are the processes of the conversation that the analysis follows.

Results

The following analysis focuses on two PSTs' understandings of self as mathematics teacher and how the seminar was consequential for their new understandings of mathematics teacher or teaching. The analysis continues the case of Sarah and presents a contrasting case of Brooke. Issues of assessment emerged as salient to both Sarah and Brooke; Sarah engaged in particular discursive practices that suggest her taking up new understandings of mathematics teacher and mathematics teaching, while, in contrast, Brooke did not. That is, the seminar did not support Brooke's new understandings of mathematics teachers or teaching in the same way.

Sarah's initial vision statement presented her "hopes" for herself as a mathematics teacher and her teaching. She presented the complexity of mathematics teaching and tensions with standardized testing and how testing frames students and their achievement: "I *hope* I continue to see them as unique individuals, not just as test takers." In Session 2, Sarah also shared how she was uncomfortable in hearing her mentor's voice in her own teaching, asking herself, "Is that me?" when she yelled at her students because of their difficulties with long division. My analysis suggests how Sarah felt uncomfortable with how her mentor was positioning students and their abilities and with how she was also positioning her students when they were having difficulties with long division. Sarah's discursive practices suggest that she struggled with concurrently supporting her students' learning and assessing them, either in mathematics class or in relation to standardized testing. Sarah engaged in unpacking her positioning by attending to institutional pressures of testing and pressures in her context.

Issues of assessment also emerged as salient to Brooke's understanding of herself as a teacher. In the following excerpt, Brooke emphasized, but resisted her positioning by issues of assessment, even minimizing its influence on her teaching:

> But see, I don't feel like [curriculum pacing] influences me all that much because like I'm spending five days on this stupid volume lesson, which really doesn't have the huge practicality of counting these imperfect block shapes, but I'm doing it because it is going to be on their unit assessment. But the majority of the stuff I teach is all beyond what is being assessed on those tests. So I feel like the test doesn't necessarily, like I make sure that I hit

> those things but it is only like, you know, a couple of things that I need to do and I have a lot more time that I get to do a lot more enriching things with my kids.

Brooke attended to how she is teaching “a stupid volume lesson” because the content is on the assessment but also emphasized that she is not positioned by assessment: “It doesn’t influence me all that much.” In this way, Brooke seems to resist how she is positioned by district-mandated assessments, although she is spending a week of instructional time on a topic that she does not value. Brooke did not attend to these tensions or to the political contexts of her teaching or immediately engage in discursive practices of working difference (Ellsworth & Miller).

As the sessions continue, Sarah and Brooke engaged in different discursive practices with working difference, that is, in understandings themselves as mathematics teachers in relation to discourses about assessment. In a particular conversation in Session 4, PSTs highlighted challenges and tensions with engaging students in rich tasks and assessments while grading students in line with institutional constraints on teachers’ flexibility with assigning grades. In response to these tensions, PSTs began to complain and share categorical advice, which are discursive practices that Horn and Little (2010) suggest are not conducive to the taking up of problems of practice. Sarah, however, took up the tensions of assessment and shared a practice in her classroom that aligned with principles of seeing assessment as an ongoing practice of actively attending to student thinking in the context of her test-driven school culture:

> You have to give them opportunity. What I do a lot of times, as part of the morning routine, I don't give them morning work sometimes if I'm handing back like a big writing assignment or something. I'll leave it on the reading group table. Come and pick up your paper, read my comments, raise your hand if you have questions, and that's their morning work for the day. And you know, if you're monitoring and you're making sure they're not chit-chatting and they're, you know, staying on task, I've found that that's helpful. My mentor thinks it's a waste of time, she thinks it's stupid. I did [this] when I was in takeover, and I thought it was really helpful because I actually did have some kids come up to me and say, “What do you mean I'm not specific?” and like, “What does that mean?” I'm like, “You've got to give details.” You explain it them, like so, “Oh, this is what you wanted.” So I had like, you know, a couple of little writing conferences, and did it make big difference for everyone in the class? I don't know, but I do know it made a difference for two students in particular.

In attending to student thinking and supporting her students’ continued reflection on their work, Sarah presented assessment as a complicated process that she engaged in with students and within her school context. Sarah engaged in discursive practices of problematizing practice by specifying the problem through adding details of how she enacted this practice in her classroom and by generalizing: “You have to give them opportunity.” Additionally, Sarah wove together attention to different levels of Pollock (2008) through presenting principles of assessment, a strategy of how to enact this in her classroom, and the particular actionable steps she took. This conversation was significant for how Sarah demonstrated her developing positioning in relation to assessment, and it also created an opportunity for other PSTs to think about assessment, as evidenced by further conversation.

Other PSTs followed by asking Sarah questions. Then, the conversation shifted to discuss practices in mathematics assessment in primary grades as Candice asked about how to grade first-grade students on their understanding of place value when they are just learning how to count. Brooke interjected and shared how she graded second grade students’ homework:

> I'll be honest sometimes that it really kind of depends on my mood. Like, sometimes I'll be like, you know [shrugs shoulders], it's just that kind of day that I'm willing to be harsh on everybody. Which is bad. I know that we should be really consistent, but some days—

Brooke presented a solution grounded in her local context to the exclusion of attending to the complexity of assessing students. This is similar to her earlier comment about her volume lesson, where she did not attend to the prevailing discourses of testing, but focused on her current students. While assessment emerged as an issue that was salient to her understandings of herself and her teaching, analysis does not suggest that Brooke took up new understandings of assessment as situated within prevailing institutional discourses or problematized assessment or her current practices in this session or subsequent sessions in relation to these prevailing issues.

In her final presentation, Sarah, however, situated discourses of assessment into her mentor's current teaching context and its test-drive culture. Sarah emphasized how she did not appreciate her mentor's classroom management style or her mentor's strict and even negative interactions with students: "I struggled with [her mentor's style] throughout the year. She was too heavy handed with the kids. She relied on humiliation and fear." She ended her presentation, however, by presenting her understanding of assessment and her mentor in context:

> Even though my presentation probably started very critical of her, she's an amazing teacher. She's just operating within this Title 1 environment, where there is all this pressure on teachers to maintain pace with the curriculum guides and FAST test. … I actually calculated the amount of hours and amount of days [of testing]. I think that it was something like over a month of school days were disrupted by testing. So, overall, I think that kind of informs my critique of her. I had a really good year, and I look forward to next year. (June 21, 2010)

Sarah noted how her mentor operates within particular institutional discourses and is positioned in specific ways by the curriculum guides, testing, and her students' high test scores, which made her an "amazing teacher" by the administration's standards. In response to her initial criticism of her mentor's management style, Sarah related her mentor's positioning and the pressures she felt, as brought on by testing and the Title 1 environment, to how her mentor positioned and responded to students. In this way, Sarah presented awareness of the complexity of the assessment and the work of mathematics teaching in challenging contexts and how being a mathematics teacher is contingent on and in response to contexts.

In addition to her new awareness of the complexity of being a mathematics teacher, Sarah demonstrates awareness of the value in the process of deconstruction and critical self-examination. Her deconstruction supports her in understanding the complexity of the particular interactions in her classroom, her mentor's positioning and how this positioning influences her expectations, her students and their learning. That is, Sarah's presentation suggests that she valued the process of deconstruction, as it allowed her—and will continue to allow her—to explore and question how students and teachers are positioned and navigate the social and political dynamics in schools and classrooms. Deconstruction is now a tool that she can use to inform future decision-making, supporting her agency in reidentifying with particular discourses, repositioning herself, and redefining herself as mathematics teacher.

Discussion

As a seminar for mathematics teacher education, analysis suggests that opportunities for PSTs to analyze discourses and positioning and discuss their implications on students and teachers may support PSTs' critical examination of their understandings of themselves as mathematics teachers and their teaching *when* there are continued opportunities to connect to their own contexts and experiences, such as in seminar discussion prompts and writing assignments. Critical self-examination supported Sarah in taking up new understandings of mathematics teacher and mathematics teaching. Brooke characterized her positioning as *localized*, or in relation only to her particular field placement and current practices under her mentor, to the exclusion of how she positions herself towards or is positioned by broader social and political discourses. This suggests how some PSTs are strongly attending to their local contexts to make sense of how they are being positioned as mathematics teachers and more work with attending to the social and political discourses in her *specific* context may have supported her in attending to her complex positioning. Facilitating PSTs in connecting these discourses and positionings to their teaching contexts may empower PSTs, such as Brooke, to understand how they are positioned, a question of personal readiness, and to exercise agency—that is, what *can* I do?—in responding to prevailing discourses by taking up or rejecting certain positions. That is, deconstruction can become a practice used in mathematics teacher education for engaging PSTs in thinking critically about teaching and themselves and also a tool for supporting PSTs' own critical analysis of teaching practices.

Embedded in a conception of teacher identity as fluid and negotiated is "the implicit charge that teachers should work towards awareness of their identity" (Rodgers & Scott, 2008, p. 733). Teacher education has a responsibility to support PSTs in this identity work, that is, in navigating the social, political, and historical forces that are shaping their identity and the multiple demands in schools and mathematics classrooms, as this work is necessary for teachers to have the capacity to address issues of equity and access in teaching mathematics. By operationalizing identity and critical pedagogy in mathematics teacher education, this study contributes to research in mathematics teacher education by providing new tools for mathematics teacher education and attending to enduring questions of how to prepare teachers to enact equitable teaching practices in the complexity of today's classroom contexts.

TRUE OR FALSE? PRE-SERVICE SECONDARY MATHEMATICS TEACHERS' STRATEGIES FOR EVALUATING STATEMENTS

Yi-Yin Ko
Tufts University
winnie.ko@tufts.edu

To implement current reforms regarding proof and reasoning in secondary school mathematics successfully, pre-service secondary mathematics teachers must have adequate understandings of concepts across mathematical domains for their future teaching. This paper examined the strategies that pre-service secondary mathematics teachers had for evaluating statements in the domains of algebra, analysis, geometry, and number theory. The results suggest that most pre-service teachers rely on examples and their (partially) correct understandings of mathematical facts when determining the statement's veracity. The results also suggest that the majority of pre-service teachers accurately evaluate the validity of statements.

Introduction

Reasoning and proof have been receiving an increasing level of attention in mathematics because they are considered important components of understanding concepts mathematically. Recent reform documents from the National Council of Teachers of Mathematics (NCTM, 2000) and the Mathematical Association of America (MAA, 2004) have placed emphasis on teaching and learning about verifying statements in secondary school mathematics and undergraduate mathematics. The *Principles and Standards for School Mathematics* (NCTM, 2000) suggests that students should be able to evaluate conjectures by the end of secondary school. The *Undergraduate Programs and Courses in the Mathematical Sciences: CUPM Curriculum Guide* (MAA, 2004) recommends that undergraduate students need to "learn a variety of ways to determine the truth or falsity of conjectures" (p. 45). Research investigating secondary students' and pre-service secondary mathematics teachers' abilities to decide the truth and falsity of statements, however, suggests that many students and teachers have difficulty doing such tasks (Hoyles & Kuchemann, 2002; Ko & Knuth, 2009; Riley, 2003). Hoyles and Kuchemann (2002) found that 40% of 1,984 eight-grade students inaccurately determined the geometric conjecture's veracity. Riley's (2003) result indicated that roughly 57% of 23 prospective secondary mathematics teachers believed that a false statement in geometry was true. Ko and Knuth (2009) reached a similar finding, reporting that 20% of 35 pre-service secondary mathematics teachers who answered believed one false statement about differentiation to be true.

The aforementioned findings should come as no surprise because students are usually asked to prove a true statement rather than to disprove a false one in the mathematics classroom (Buchbinder & Zaslavsky, 2007). Under such a learning environment, it is likely that most students are easily convinced that mathematical propositions are true (Smith, 2006). Limited research has documented evidence that undergraduate students might rely on examples, deductive reasoning, both example-based reasoning and deductive reasoning, or their familiarity with content when asked to evaluate the statement to be true or false (Gibson, 1998; Goetting, 1995; Weber, 2009). No studies to date have investigated the mathematical thinking behind the strategies pre-service secondary mathematics teachers use to determine the validity of statements in different mathematical domains. Such practices are particularly important for secondary mathematics education majors, as they need to understand the conventions of proving in a variety of domains to implement current reform recommendations about reasoning and proving in secondary school mathematics. Thus, the main purpose of this study was to examine strategies pre-service secondary mathematics teachers had for evaluating various statements in the domains of algebra, analysis, geometry, and number theory. This study was guided by two research questions: (1) In what ways did pre-service secondary mathematics teachers verify each given conjecture to be true or false? and (2) Which strategy did lead pre-service secondary mathematics teachers to make a correct determination of the statement's veracity?

Theoretical Framework

Evaluating the truth and falsity of statements accurately is a complex problem-solving process, as individuals should have adequate understandings of mathematical concepts related to problems and be able to apply such knowledge flexibly. Although individuals need to be able to correctly decide the truth or falsity of a given proposition before constructing a proof or generating a counterexample, such a decision really depends on whether or not individuals believe the statement to be true or false. When evaluating purported statements, some individuals are inclined to base their determination on example-based reasoning strategies. Moreover, they tend to use random, general, or specific examples related to statements during the processes of verifying the statement's validity (Alcock & Inglis, 2008; Gibson, 1998; Goetting, 1995; Harel & Sowder, 1998).

When asked to evaluate the validity of statements, others use their understandings of true known definitions, theorems, or axioms involved in problems (Alcock & Inglis, 2008) or start constructing a proof and then find a counterexample if they get stuck in the proof (Weber, 2009). Still others make judgments based on their past memories of similar conjectures, so they begin producing a proof, looking for a counterexample, or testing a couple of numbers and then making an attempt at a proof (Goetting, 1995). Indeed, verifying statements across mathematical domains is a vital practice for pre-service teachers to foster their reasoning and comprehend the concepts. Particularly, undergraduate mathematics is an important period for pre-service teachers to build knowledge to advance mathematical reasoning for learning more advanced mathematics in secondary-school teaching. The goal of the paper reported here is to shed light upon the processes of evaluating practices associated with conjectures.

Methods

Eight secondary mathematics education majors from a large Midwestern university in the United States participated in this study. One was a third-year, five were fourth-year, and two were fifth-year undergraduate students. All of the participants had taken a number of upper-level, non-proof intensive mathematics courses that included the topics of analysis, combinatorics, differential equations, linear algebra, modern algebra, number theory, probability, or statistics. They had also taken at least two courses involving mathematical proofs about the topics of analysis, linear algebra, geometry, modern algebra, or transition to proofs. Since number theory, geometry, continuous functions, differentiation, and one-to-one functions were addressed in undergraduate mathematics courses as well as in pre-calculus and calculus courses in high school, all of the pre-service teachers participating in this study had some relevant domain knowledge.

The primary source of data was one-on-one semi-structured interviews. Interviews were audio-recorded, lasted approximately 90-120 minutes, and included a focus on the evaluation of the statement being true or false and the productions of proof and counterexample. Because the focus of this article is on pre-service teachers' strategies for verifying the validity of statements, the results presented and the subsequent discussion focus exclusively on data about their proof and counterexample productions. During the interview, the pre-service teachers were handed each statement (see Table 1), one at a time, and were asked to think aloud how to determine each statement to be true or false. The instrument, comprised of six mathematical statements that were adapted from existing literature and textbooks, was designed to assess pre-service teachers' abilities to evaluate the veracity of statements about algebra, analysis, geometry, and number theory. The instrument was finalized after receiving feedback from three mathematics professors as well as one mathematics education professor and pilot testing with engineering and mathematics graduate students.

The interview transcripts and participants' written responses were summarized initial impressions and highlighted interesting issues regarding the participants' statement verifications. Coding of the data began with a set of external codes that were derived from the theoretical framework. By examining the data and reviewing the transcripts, themes emerged in participants' statement verifications. After proposing these internal (data-grounded) codes, each transcribed interview was reexamined and recoded to incorporate these new codes.

Table 1. The instrument.

Question	Statement	Domain	True or False
1.	If $n \in N$, then GCD(n, $6n-5$) $=1$.	Number Theory	False
2.	If $\overline{AB}$ and $\overline{CD}$ intersect at the point M, $\overline{AM} \cong \overline{BM}$ and $\overline{CM} \cong \overline{DM}$, then $\overline{AC} // \overline{DB}$.  (Adapted from Yang & Lin, 2008, p.65)	Geometry	True
3.	Let $f: D \to R$ be a function and $x_0 \in D$. If $\lim_{x \to x_0^+} f(x) = \lim_{x \to x_0^-} f(x)$, then f is continuous at x_0.	Analysis	False
4.	If $n \in N$, then $n^3 + 44n$ is divisible by 3. (Adapted from Smith, Eggen, & St. Andre, 2006, p. 109)	Number Theory	True
5.	If $h: A \to C$ and $g: B \to D$ are both 1-1 functions, $A \cap B = \phi$, and $C \cap D = \phi$, then $h \cup g: A \cup B \to C \cup D$ is a 1-1 function. (Adopted from Smith et al., 2006, p. 204)	Algebra	True
6.	Let $f: D \to R$ be a function and $a \in D$. If $f: D \to R$ is differentiable at a, then f is continuous at a.	Analysis	True

Results

The results reported in this section are organized by two research questions concerning pre-service teachers' strategies for evaluating various conjectures.

Pre-Service Teachers' Strategies for Evaluating the Statement

Based on the theoretical framework regarding strategies for verifying conjectures, four specific categories—the example-based strategy, the mixed reasoning strategy, the naïve reasoning strategy, and the sophisticated reasoning strategy, as listed in Table 2, were proposed through the coding process to access the participants' responses to the ways they used for doing these tasks.

Table 2. Strategies for evaluating statements.

Strategies	Description
Example-Based Reasoning	● Individuals rely on numbers or diagrams to verify the statement.
Mixed Reasoning	● Individuals both use examples to identify relevant patterns and structures, and manipulate (partially) correct properties, definitions, and/or theorems to identify a reasonable example to attempt to prove or disprove the statement.
Naïve Reasoning	● Individuals manipulate partially correct properties, definitions, and/or theorems from their intuitive understanding or past experience to verify the statement.
Sophisticated Reasoning	● Individuals manipulate relevant true properties, definitions, and/or theorems to attempt to prove or disprove the statement.

Table 3 displays the distribution of strategies the pre-service teachers had for deciding each statement to be true or false. As shown in the table, the mixed reasoning strategies (33 cases out of 46) were used more often than the other three strategies (5 example-based reasoning strategies, 4 sophisticated reasoning strategies, and 4 naïve reasoning strategies) by prospective teachers when determining the validity of statements.

Table 3. Pre-service teachers' strategies for evaluating the statement.

Strategy	True								False				Frequency Count*
	Question 2 (Geom-etry)		Question 4 (Number Theory)		Question 5 (Algebra)		Question 6 (Analysis)		Question 1 (Number Theory)		Question 3 (Analysis)		
	n	%	n	%	n	%	n	%	n	%	n	%	n
Example-based	0	0	1	13	0	0	0	0	3	38	1	13	5 (4)
Mixed	8	100	7	88	6	86	5	71	5	63	2	25	33 (8)
Naïve	0	0	0	0	0	0	2	29	0	0	2	25	4 (3)
Sophisticated	0	0	0	0	1	14	0	0	0	0	3	38	4 (4)

Note. Pre-service secondary mathematics teacher 8 did not decide Questions 5 and 6 to be true or false.

*The frequency count is the number of each strategy that each participant used for evaluating the validity of six given statements.

Due to decimal rounding, the total percentage of Questions 1, 3, and 4 is greater than 100.

Data described in Table 3 also illustrates that each pre-service teacher used the mixed reasoning strategies at least once when evaluating the statement's veracity. Although the mixed reasoning strategies was the most commonly strategies used for verifying the validity of Questions 1, 2, 4, 5, and 6, substantially fewer pre-service teachers used the example-based reasoning, naïve reasoning, or sophisticated reasoning strategies for evaluating Questions 1, 3, 4, 5, and 6. Considering the statements across different domains, it is interesting to note that the false question in Number Theory was the most likely to be verified by examples-based reasoning strategies. Also, all pre-service teachers tended to employ the mixed reasoning strategies for determining the true geometric statement. The section that follows describes each strategy used by pre-service teachers when deciding the statement's veracity.

Example-based reasoning strategies. Four pre-service teachers based their determination of the statement's validity merely on numbers or diagrams related to the problem. One pre-service teacher stated what he did when determining a statement's (Question 1) veracity: "I went through a few possibilities, […], and I got up to five. […] Six times five is twenty five, so the greatest common divisor between twenty five and five is five" (PSMT1). Another participant used diagrams to evaluate a statement's (Question 3) veracity: "I was thinking like x, and it would be continuous. And then I was thinking about x^2, and it would be continuous as well" (PSMT5). Thus, these pre-service teachers tested a few numbers or diagrams to evaluate the statement's validity.

Mixed reasoning strategies. In general, every pre-service teacher used the mixed reasoning strategies at least once when determining the veracity of statements. Moreover, these teachers decided the statement's validity on the basis of examples and their (partially) correct understandings of definitions or theorems involved in the problem. One teacher labeled the figure first and said, "Angle *AMS* and angle *BMD* are equal because they are vertical angles, so [triangle *AMC* and triangle *BMD* are] congruent triangles, [so the] corresponding angles [angle *CAM* and angle *DBM*] are congruent, and they are alternative interior angles which make line *AC* and line *DB* be parallel." (PSMT3, Question 2). In explaining why he determined the statement to be true, one teacher said, "I plug in a couple of numbers just to see if the statement works. […] When I factor out n, I can see that any natural number that is a multiple of 3 means that is also divisible by 3" (PSMT2, Question 4). Still another teacher drew a picture and explained why she agreed with the statement to be true, "Continuous functions mean that you have a graph, it is a smooth line, and there is no hole on the graph. [T]he limit from the left and the limit from the right is the same that gonna be continuous" (PSMT8, Question 3). In summary, these pre-service teachers who applied the mixed reasoning strategies for verifying the validity of statements either relied on examples to identify the structure of the statement or based on their (partially) correct understandings of mathematical properties along with examples related to the problem.

Naïve reasoning strategies. With this strategy, three per-service teachers determined the statement's veracity based on their partially correct understandings of mathematical facts related to the problem. When evaluating a statement's (Question 3) veracity, one teacher stated, "[The continuous function] was defined at some point x on the function, or x_0 on the function. […] [T]he limit from the left is the same as the limit from the right, so since it's defined at that point and those limits are the same, then it has to be continuous" (PSMT1). Another teacher explained, "What I can remember, if a function is differentiable at a, then that means that the corresponding y value exists at a, so it doesn't necessarily mean the function to be continuous" (PSMT7, Question 6). Thus, these pre-service teachers seemed to possess fragile mathematical knowledge to verify the statement's validity.

Sophisticated reasoning strategies. Four pre-service teachers decided the validity of statements on the basis of true mathematical definitions, theorems, or properties. For example, one teacher explained his strategy for evaluating a statement's (Question 5) validity:

I know the definition of one-to-one function means that for exactly one, there is one x value for only one y value, so from the domain to the range. Umm, since both of those are one-to-one *functions and since, umm, the domains of each function h and g, respectively, are mutually exclusive as well as the range of mutually exclusive, the intersection is the no set, and the union between the two, umm, will still be one-to-one. (PSMT1).*

In responding to what he did when verifying the validity of a statement (Question 3), one teacher stated, “The statement is false because the definition of the continuity is the limit of the function at a point is also equal to the value of the function at that point” (PSMT2). In short, these pre-service teachers attempted to employ relevant mathematical facts logically when determining the statement’s veracity.

Pre-Service Teachers’ Strategies for Evaluating the Statement and Their Determination of its Validity

Table 4 presents the frequency count of strategies for verifying statements used by pre-service teachers along with their correct and incorrect decisions on the validity of statements.

Table 4. Frequency count of pre-service teachers’ strategies for verifying the statement and their decisions on its validity.

Strategy	True								False				Frequency Count*	
	Question 2		Question 4		Question 5		Question 6		Question 1		Question 3			
	Co	In	Co	In	Co	In	Co	In	Co	In	Co	In	Co	In
Example-based	0	0	1	0	0	0	0	0	3	0	0	1	4(3)	1(1)
Mixed	8	0	7	0	5	1	4	1	4	1	1	1	29(8)	4(3)
Naïve	0	0	0	0	0	0	1	1	0	0	0	2	1(1)	3(3)
Sophisticated	0	0	0	0	1	0	0	0	0	0	3	0	4 (4)	0(0)

Note. Pre-service secondary mathematics teacher 8 did not decide Questions 5 and 6 to be true or false.
Co indicated that the correct decision regarding a statement’s validity made by pre-service teachers.
In indicated that the incorrect decision regarding a statement’s validity made by pre-service teachers.

[a]The frequency count is the number of occurrences that a particular strategy was used. Totals may include multiple counts for a single pre-service teacher (i.e., a teacher may have used the example-based reasoning strategy for verifying the validity of more than one statement). The number of different teachers citing a particular strategy is provided in the parenthesis.

As seen in Table 4, the participants who used the sophisticated reasoning strategies accurately made a decision on the statement’s veracity. It is clear from the table that the pre-service teachers were more likely to make an incorrect determination of the statement’s validity by employing the naïve reasoning strategies. If we consider the most effective strategy used in allowing a correct decision on a statement’s validity, then the mixed reasoning strategies (29 cases out of 46) far out-numbered the other three strategies (4 sophisticated reasoning strategies, 4 example-based reasoning strategies, and 1 naïve reasoning strategy). These findings show that most pre-service teachers did not solely rely on examples when testing the proposition to be true or false. These findings also show that only a few pre-service teachers were able to employ true mathematical properties and theorems to decide the validity of statements correctly. Considering the statements across various domains, it is interesting to note that all participants accurately evaluated the geometric statement (Question 2) by using the mixed reasoning strategies. Perhaps relying on pictures serves as a helpful means for pre-service teachers to identify the structure of the given statement in Geometry.

Discussion

This study examined the processes through which pre-service secondary mathematics teachers evaluated the truth and falsity of given statements across domains. The overall findings indicate that all participants employed the mixed reasoning strategies—using both examples and their (partially) correct understandings of mathematical concepts—for determining the statement's veracity at least once. The fact that the pre-service teachers in this study overwhelmingly used examples when asked to verify the validity of statements is not surprising considering the literature on undergraduate students' tendencies to rely on example-based reasoning strategies (Gibson, 1998; Goetting, 1995; Harel & Sowder, 1998). This study, however, shows that the participants used examples to identify patterns and structures rather than conclusively determined the truth of statements. Considering the strategy used in allowing a correct decision on the statement's validity, the mixed reasoning strategies were more effective ways (29 cases out of 46) than the other three strategies (4 sophisticated reasoning strategies, 4 example-based reasoning strategies, and 1 naïve reasoning strategy). There were a few cases in which the pre-service teachers inaccurately made a decision on the validity of statements by employing the example-based reasoning strategy (1 cases out of 46), the mixed reasoning strategies (4 cases out of 46), or the naïve reasoning strategies (3 cases out of 46). These teachers seemed to use their partially correct understandings of limits, continuous functions, one-to-one functions, and the greatest common divisor to determine the statement's veracity. This result is reminiscent of Weber and Alcock's (2004) suggestion that "students' [concept] images of mathematical concepts are often inconsistent with the corresponding formal definitions" p. 232). In order to help individuals develop concept images—defined as mental pictures—to be consistent with mathematical definitions, mathematics instructors need to draw attention to pre-service teachers' misconceptions of concepts and seek ways to refine their content understanding.

Another feature of the results is that the majority of participants determined the validity of statements accurately (38 cases out of 46). Yet, the wealth of existing studies investigating pre-service secondary teachers' conceptions of proof show that many teachers have considerable difficulty understanding and producing proofs and counterexamples (e.g., Goetting, 1995; Harel & Sowder, 1998; Weber, 2001). The results of this study suggest that providing pre-service teachers with opportunities to experience determining the validity of statements across domains might be a way to enhance their development with proof and counterexample. Such practices can help pre-service teachers not only see the logic behind a statement (Tall, 1992) and explain why something is true or false, but also foster their mathematical reasoning and understanding (Buchbinder & Zaslavsky, 2007). If engaging learners in verifying the truth and falsity of statements can illuminate underlying concepts of propositions as well as promote learners' mathematical reasoning, more research is needed on what curricular tasks can better develop pre-service secondary school mathematics teachers' conceptions of proof and counterexample.

In summary, four strategies—example-based reasoning, mixed reasoning, naïve reasoning, and sophisticated reasoning—used by pre-service teachers to evaluate the validity of statements in different domains cannot make generalizations due to the small number of participants in this study. While most pre-service teachers relied on examples to test Question 1 (Algebra), the majority of participants were inclined to use numbers or diagrams along with their (partially) correct understandings of mathematical facts when verifying various statements across domains. These findings suggest a need to help pre-service teachers apply example-based and deductive reasoning strategies flexibly to evaluate the statement's veracity. These findings also suggest that designing instructional approaches by drawing from individuals' strategies for evaluating statements to help pre-service secondary mathematics teachers learn mathematics meaningfully and foster their mathematical reasoning is needed.

MATHEMATICAL KNOWLEDGE FOR TEACHING OF STUDENT TEACHERS AND ITS ENHANCEMENT THROUGH A SPECIAL FINAL COURSE

Simón Mochón

In this article we describe the results of a special final course, at the main teachers' college in Mexico, which had two related main objectives: one was to find out the Mathematical Knowledge for Teaching (MKT) held by student teachers (ST) at the end of their instructional preparation. The other was to discern ways to improve this knowledge and to document the changes observed. In teachers' colleges in Mexico, math contents and pedagogical ideas are taught separately, so we aimed to help student teachers to integrate these. The analysis showed that their knowledge is mainly instrumental but that through discussions and reflection about the main issues, they were able fairly quickly to attain a significant improvement in all the contents included. Moreover, they also showed changes on some of their views about math and its teaching.

Introduction and Theoretical Framework

For two decades in Mexico, great effort had been placed on improving education at the basic levels. Study programs have been changed, text books have been replaced and computers have been brought to help out, but internal and external evaluations have shown at best very small improvements in students' achievements. The most likely explanation, supported by research in math education (Adler et al., 2005) is that a very important element has been overlooked: teachers' professional development. With new principles, standards and approaches brought everyday into education, the preparation of teachers had become even more crucial.

A very important sector of teachers, which also has to be taken into account, are the future teachers being prepared in the different pedagogical schools and colleges. Ponte and Chapman (2008) give an overview of the studies carried out with student teachers (ST) about their math knowledge, their teaching knowledge and their development.

A common practice in teachers' instruction in Mexico is to separate content and pedagogy in different courses, with the assumption that the future teachers will be able to integrate them in their practice. However, this and the formal procedural orientation of their math courses, leave the ST with limited skills and inadequate conceptual understanding. Thus, in the main teachers' college in Mexico for secondary education (Escuela Normal Superior de Mexico), it was felt necessary to introduce a special course at the end of their training that would give the ST an opportunity to build on their previous knowledge and to restructure their conceptions through group discussions and reflection. Within this context we initiated a research study to find out the general knowledge held by ST at the end of their instructional preparation and to assess to what extent their pedagogical content knowledge in several topics was modified by this didactical intervention. We also recognized the importance and close relationship between conceptions, beliefs and practice (Thompson, 1984; Leder, et al. 2002) and although it won't be described in here, another portion of this project looked into these issues.

Pedagogical Content Knowledge (Shulman, 1987) refers to a complex mixture with many components like content, pedagogy, organization of topics and problems, student conceptions, models, representations, activities, curriculum, etc. Some facets of this teachers' knowledge are more closely related to the mathematical content, like knowing the structure and connections of mathematical concepts and procedures, deconstructing one's own knowledge or understanding students' methods of solution. Ball and Bass (2000) associated this special knowledge with the term: Mathematical Knowledge for Teaching (MKT). Hill and Ball (2004) continue developing the concept of MKT and describe another of its components: profound math knowledge, which is a specialized knowledge that helps teachers understand and plan their classroom activities.

Professional development programs seek, in various ways, to enhance teachers' practices and therefore students' competence. Some are centered on pedagogical ideas, others on mathematical content and some others on the mix, Pedagogical Content Knowledge (PCK). Our orientation is along this last line, with an emphasis on MKT and following the view of many researchers (Ponte and Chapman, 2006) who stress that teachers' training should be connected to their practices, using the same tasks, materials and techniques that could be used in their classrooms.

Based on different frameworks and methods of inquiry, there have been a number of research studies connected to teachers' professional development projects in different countries. Amato (2006), within a mathematics teaching course for student teachers, conducted a study to improve their relational understanding (Skemp, 1976) of fractions, by playing games. In a study investigating the Pedagogical Content Knowledge (PCK) of elementary school teachers in the topic of decimals, Chick, et al. (2006) proposed a framework with three categories for their analysis: 1. *Clearly PCK*; 2. *Content Knowledge in a Pedagogical Context* and 3. *Pedagogical Knowledge in a Content Context*. Like several other authors, Seago and Goldsmith (2006) studied the possibility of using classroom artifacts like students' work and classroom videos to assess and promote MKT. Also, in a collaborative action research, Cooper, et al. (2006) uncovered some characteristics of instructional interactions that lead to positive results in students' learning.

In an article about cognitively guided instruction, Carpenter, et al. (2000) stressed the importance of teachers' knowledge about the mathematical thinking of children. The authors identified four levels of teachers' beliefs that correlate with their mode of instruction: I. They believe that math has to be taught explicitly and therefore they show procedures and ask the students to practice them. II. They start to question this explicit mode and therefore they give to the students some opportunity to solve problems by themselves. III. They believe that students can have their own strategies so they provide problems and the students report their solutions. IV. Teaching becomes more flexible, with the teacher learning from his students' productions and adapting his instruction to this knowledge.

Since we were interested in assessing the MKT, we based our analysis on the framework given by Ball, et al. (2008), who divides this knowledge into three main domains:

A. *Specialized content knowledge* is the math knowledge and skill needed almost exclusively for teaching. The teacher requires supplementary math knowledge in the multiple activities of his practice. Among other things, he must have a profound understanding of the fundamental concepts of each of the topics, knowing not only 'how' but also 'why'. In addition, he should be able to unpack math ideas to make them more visible to others. Moreover, he should know the connections of different concepts and topics and relations with other subjects.

B. *Knowledge of content and teaching* consists of knowing about teaching math. This knowledge is required in the planning, design and instruction in the classroom work to answer questions like: What would be an appropriate sequence of teaching? What example would illustrate this or that? What classroom methods should be followed? What representations are adequate? Each of these tasks requires a combination of specific math understanding and pedagogical ideas.

C. *Knowledge of content and students* combines knowing about students and math. This knowledge is related to students' thinking, strategies, difficulties and misconceptions. It is needed to infer and evaluate what the students say or do, their methods, their solutions, etc. These tasks require a blend of a specific math understanding and a familiarity with students' thinking.

Methodology

The special course was given during the last semester of formal courses to a group of 21 students in a teacher's college in Mexico City (ENSM – Escuela Normal Superior de Mexico), preparing them for teaching at the secondary school level. Each six hour session of the 16 given was divided into two thirds of selected contents and one third of additional pedagogical elements. In this article we will describe only the selected contents section of the course.

Before the course, we asked the ST to mention math topics from their previous courses which they found difficult or they think to be a source of conflict to students. Among the most cited answers were: fractions, decimals, mental calculation, algebra, variables, functions, probability… Thus, we decided to form three sequential blocks for discussion in the course: 1) Fractions and decimals, 2) Mental calculation and estimation and 3) Variables and functions.

Professional development programs use a variety of resources to make teachers reflect on the ideas involved. For example, Borko and collaborators (2008) suggested video analysis to motivate discussions between teachers and Chamberlin (2003) employed written students' productions. In our study however, our instruments for analysis and means of motivating reflection were a series of questionnaires and further inquiries during the sessions.

All the 16 sessions were audio taped for their analysis. At the beginning of each of the three blocks and also in most of the sessions, a questionnaire or a worksheet was handed out (or previously given to answer at home) with the objective of making the ST reflect about some important ideas and concepts of that particular content. This also had the purpose of steering their thinking about the three main domains of MKT described above. From the research point of view, their written answers gave us a small window of their knowledge. Then a full class discussion took place to argue their own ideas and to hear and evaluate the others'. Because of the dual character of the course, for the most part, we let them express their ideas and encourage interaction between them. In the latter sessions of each block, we gave them notes (taken home to read) synthesizing some important ideas of the topic being covered and then the ST discussed those ideas further. This second phase gave us another window of their knowledge and of the possible changes brought about. The main sources for these notes were research papers on mathematics education in each subject. The pedagogical support for the course was taken also from the research literature, for example Schwartz, et al. (2006), Chick and Baker (2005) and McDonough and Clarke (2003).

Results

To illustrate the two ways data was collected, here we will describe 1) the results of the questionnaire applied before and after the six sessions of the block of fractions and decimals and

2) the results of the observations of the four sessions of the block of mental calculation and estimation (the other block not discussed shared similar conclusions).

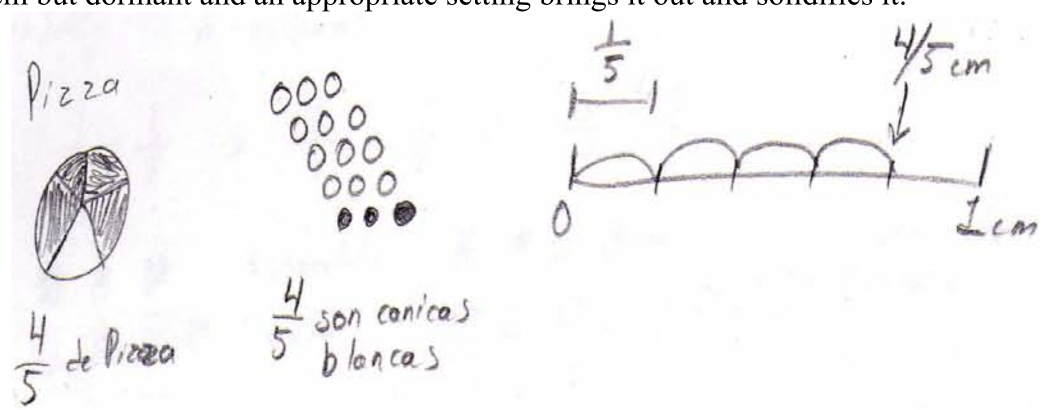
Results of the Questionnaire Applied Before and After the Block of Fractions and Decimals

The questionnaire consisted of 6 items (some with two parts). Here we show three of the six questions which seem representative (from the 21 ST, 18 took the initial questionnaire and 19 took the final).

Item 2. Consider the fraction 4/5. a) Describe some of its different meanings. b) Represent it in different ways.

Part a): *In the initial questionnaire*, 16 of the ST wrote only one or two meanings, without explanations: For example, "Four parts of five.", "Four over five.", "4/5 = .8", "Four of five.", "Four is to five. Four fifths." This exhibited a poorly established knowledge, extracted from what they vaguely remembered. *In the final questionnaire,* 15 of the ST gave much more complete answers, adding also the associated meaning. One short answer was: "As quotient → four over five; as ratio → four to five; as part-whole → four fifths…" Of course, this means that they learnt something, but the value we see in it is that, by briefly exposing them and letting them reflect on these ideas, the ST were able to demonstrate a more sound knowledge.

Part b): This is an important question that shows the amplitude and flexibility with different representations. *In the initial questionnaire*, 10 of the ST represented the fraction only as part-whole of continuous sets like rectangles and circles; 7 others used also part-whole in both types of sets (three of them include a third representation: an equivalent fraction, the numerical line or as a ratio). *In the final questionnaire,* we observed a multiplicity of answers. All of the ST employed at least three different representations like the one shown below in the figure. Five of them supported their answers with well elaborated explanations. Here we observe a richer *knowledge of content and teaching.* Again, this shows that much of this knowledge is held by them but dormant and an appropriate setting brings it out and solidifies it.



Item 4. a) Give a problem illustrating the operation: 1 ½ divided by 3. Explain its solution. b) Give a problem illustrating the operation: 1 ½ divided by ½. Explain its solution.

Part a): *In the initial questionnaire*, most of the ST gave a partitive context when posing the problem: "Juan wants to divide 1 ½ chocolate bars in equal parts for his 3 children. ¿How much would each one gets?" *In the final questionnaire,* we observed basically the same, but their symbolic solutions are more frequently supported with graphical representations and with more congruent explanations.

Part b): This obviously was more revealing than the first part. *In the initial questionnaire*, only 5 of the ST posed a correct problem, based on the interpretation "how many times it fits." For example: "I have a soda with 1 ½ liters and a glass of a ½ a liter. How many times will I be able to fill the glass without any leftover?" Another 6 ST posed an incorrect problem, either forcing the result of 3 of the original operation, not even using the numbers contained in it: "A car need gas every 50 km. How many times we have to stop for a trip of 150 km?" or posing instead the operation 1 ½ divided by 2: "If you have a chocolate bar and half of another, and we want to divide it between 2 people, how much does each one get?" The other 7 ST didn't answer. We can characterize this as a deficient *specialized content knowledge. In the final questionnaire,* more than half of the ST gave a correct problem, although we still observe the same two incorrect thinking mentioned. This seems to be a hard notion for them.

Item 6. Consider the numbers, 0.245, 0.2 and 0.1089. a) If a student says that 0.1089 is the biggest, what do you believe he is thinking? b) How would you show him which is bigger?

Part a): *In the initial questionnaire*, there were two types of similar but not equivalent answers; 11 of the ST mentioned that the decimal point was ignored and 7 others write that the student looks at the number of digits. This shows some *knowledge of content and students. The final questionnaire* showed similar results.

Part b): *In the initial questionnaire*, 7 of the ST drew a diagram showing the position value of each digit, 5 only proposed the use of the numeric line, another showed sequences of numbers without explanation and the rest didn't answer. This demonstrates a reduced *knowledge of content and teaching.* The main difference between the two questionnaires is that in the initial one, we observe mainly technical explanations based on the separation of the numbers into its digits, but in the *final questionnaire* there was an attempt to give semantic descriptions and more extended explanations. For example, one of them wrote: "In a table of positional values indicating integers, tenths, hundredths…" Shows the table and continues "We observe in the tenths, which is bigger, and see that in two numbers they are the same, so we compare the hundredths…" In general, they revealed afterwards a greater capacity for instruction.

Observations of the Sessions of the Block of Mental Calculation and Estimation

In the four sessions of mental calculation and estimation, the three issues addressed through diverse activities were: i) characteristics; ii) strategies; iii) comparison with the traditional algorithms. In the next subsections we will described the knowledge observed from the ST and their changes, according to the three main domains of the MKT proposed in the theoretical framework.

A. Specialized content knowledge. At the beginning of this block the ST were given three questions about mental calculation and then they argued their answers with the whole group. To the question "*Give two examples that show how people use mental calculation in real life."* the great majority had difficulties identifying situations. There was a clear confusion between mental calculation and estimation since most of the examples were calling for estimations like: "In the kitchen mental calculation is used to estimate portions…" "Time is a factor that we estimate constantly…" "When we go shopping we perform estimations…" When they were told that in mental calculation we expect an exact answer, they gave very vague examples related to some operation and frequently mistaken like "When you multiply by 99 you add 1 to be 100 and then you subtract the result by 1." or "Rounding quantities, for example $25.65 × 4, can be converted to 25.50." Thus we observed a very small *specialized content knowledge*. The ST claimed that "In our classes they don't develop abilities for these subjects." and pointed out that the only strategies they know, they learnt as rules of memorization.

To the next question formulated to the ST "*Which strategies do you know of mental calculation?*" their responses were only a list of names like: "counting", "rounding", "basic operations", decomposition", "chopping" and "multiples of 10". In the follow up discussion, we requested an example illustrating the strategies, but the ST claimed they didn't know how to apply them. Only two ST gave an example: One was: "Decomposition: For 35 + 48 =, first add 30 and 40 to get 70 and the 5 and 8 to get 13. To finish we make the operation 70 + 13 = 83." and the other was, according to him about "counting", but was in effect another example of decomposition. We can appreciate again a very limited knowledge of this subject, with one single strategy known (decomposition) which is the closest in form to the conventional algorithms.

Later on, we applied a worksheet with 10 simple operations where the ST were asked to describe the procedures that they could follow to solve them. More than half of the responses were mental applications of the conventional algorithms. Another 35% were answered by applying a decomposition strategy (the way to differentiate between this one and the algorithms is that in the former the value of the quantities are preserved but in the later, only the digits are handled). Another strategy appearing in approximately 10% of the cases, it is called "by steps". To give an example, for the division 400÷25, one of the ST wrote "4×25=100; 100×4=400; 4×4=16". Rounding appeared only in 4% of the responses although a few operations were designed explicitly to apply this strategy. For example, for 37+46, one ST wrote "40+46=86, 86-3=83"; for 87÷3, another ST wrote "90÷3=30, 3÷3=1, 30-1=29" and for 693÷7, yet another ST wrote "700÷7=100, 7÷7=1, 100-1=99". So not only the ST didn't have a clear set of concepts but their familiarity with strategies was very poor.

Before the second session on mental calculation, the ST were given reading materials on the subject. With this new information, they were able to bring out many strategies during the oral exercises proposed. For example, for the subtraction 56–18, one proposed: "To 18, I take away 2 and to 56 I take away 16 to get me 40. Then I take away the other 2 to give 38" (although hard to follow, this is a correct strategy, using compatible numbers); another followed rounding of the 56 with compensation: "I add 56+4 to get 60 and add 4 to 18 to get to 22. Subtracting these we get 38" and a third one also used rounding but of the 18 with compensation: "I would add 2 to both to get 58–20 = 38". In this same exercise, we observed also decomposition and "by steps" strategies. We see once again here that the ST were capable of applying very rapidly the different strategies shown in the readings and developing their knowledge with the interactions with others. So what was hindering them was a lack of knowledge. As one of them expressed, "Now we have the strategies and know how to use them. We only need to direct them to each exercise."

On to the sessions on estimation, we observed too that the ST' initial conceptions were quite vague. They describe estimation as "It is something approximated." "It is what we use to approximate large quantities." Afterwards, the ST were given a worksheet consisting of 5 exercises related to this topic (which we will refer below as I, II, III, IV and V.)

In items I and II an operation (374 + 421 + 339 + 472 and 1797.50 – 635.10) was given to the ST to estimate the result and give an appropriate context of estimation. In items III and IV, the ST were given a problem (one of addition and one of multiplication) to estimate the result and to explain their solution. In the discussion that followed, they heard others' responses and learned from them. We observed, in general, a significant growth in the variety of their strategies, applying rounding of various types (with one or two significant figures or to units, tenths…) and translations like 400×4 for the first sum.

B. Knowledge of content and teaching. Another question posed in the initial session was: "*How would you teach mental calculation?*" The ST' answers were all along these lines "With a lot of exercises so the students practice their calculations." "Through fast operations without using paper." We observed several misconceptions and inappropriate approaches to the teaching of mental calculation like repetition and memory as opposed to reasoning and the construction of strategies. Furthermore, two of the ST indicated that mental calculation is something that cannot be taught: "It is something used outside the classroom and there is no way to instruct it." In general this shows a poorly founded knowledge for teaching.

In the next session, after reading the materials given, they were requested to think of advantages and disadvantages of mental calculation and the conventional algorithms. Here we observed that their initial views changed considerably. For the algorithms they mentioned: "They are not used in higher courses because the calculator is used, not to lose time." "The numbers lose their meaning." "They are general, but we don't have a feeling if it is right or not." "About mental calculation they stated that: "An advantage is that each one looks for his strategy and applies it." "It develops a numerical sense, for their studies and their life." The progress of the ST illustrated here is in their motivation to teach mental calculation and in knowing a reasonable approach for teaching it. As one of them stated "The development of mental calculations is not only to give the steps to follow but we should base our instruction on strategies so they can decide which to follow."

After this, we questioned the ST about the differences of mental calculation and estimation. Two of their answers were: "there is only one exact answer but many reasonable estimations." "In estimation we should use much bigger numbers." We can appreciate that they showed an increased understanding of these subjects for teaching.

C. Knowledge of content and students. In exercises III and IV mentioned before, we added in each, a possible student's solution. We requested the ST that they would explain the solution and also evaluate it. For example, question III "*For the construction of a special classroom, the school has to collect $6,274 pesos. a) About how much does each of the 28 groups have to contribute? b) If a student writes: 6000÷20=300, explain and evaluate his answer."* Some of their explanations were "The student chopped. He didn't care if the last digits were 6, 7, 8 or 9." "He must take into account a smaller quantity to drop it." We appreciate here some dislike for the 'radical' way to carry out the estimation given. They showed in general very little tolerance for approximations. This is also shown in their evaluations of the estimation given: "this is correct although the error is very big." "It is right although his approximations were very far off."

Conclusions

The knowledge that a teacher should hold is very extensive and it has been characterized by what it is call MKT, which is the mathematical knowledge useful in the teacher practice, strongly conceptual in nature.

However, in many teachers' schools, math and pedagogy are separated in different compartments. ST in their last year of formal learning have a knowledge of mathematics and mathematics teaching, but our observations showed that the former is somewhat limited and forgotten, based mostly on procedural understanding. The latter is composed of conceptions formed through their own experiences.

In general, we observe important deficiencies in the three domains of the MKT. In the *specialized knowledge*, there was a lack of a variety of strategies of solution and the ability to unfold procedures. With respect to *knowledge for teaching*, they had a very small array of representations and illustrations. Their *knowledge of students* was based on their intuitions.

In this paper we described two rather different situations. In the case of fractions and decimals, the ST already received in previous courses, the same topics we covered in our sessions. In the case of mental calculation and estimation, although it is included in their programs of study, many times it was overlooked or the approach given is very mechanical without looking at strategies. In both cases, we observed a weak knowledge of the subjects. However, in the case of fractions and decimals, the six sessions given were able to bring back and solidify the main concepts and in the case of mental calculation and estimation the four sessions were able to provide a good background for further development. Furthermore, the ST learnt to ask themselves the proper questions about their practices within the three domains of MKT.

These results strongly suggest that it would be a very favorable strategy in teachers' colleges to implement a short special course at the end of the formal learning like the one described here, with the objective of ST discussing and reflecting about their strengths and weaknesses in some core subject matter. Currently in Mexico, training of ST is done in classrooms with in-service teachers. However this does not recuperate and refresh their knowledge and practices are often perpetuated by the same traditional ideas.

aokoca@wayne.edu

Reports on a research project designed to implement an adapted Lesson Study cycle whereby preservice mathematics teachers co-create a lesson with a Master Teacher and observe the Master Teacher teach the lesson. Results show the preservice teachers' shift, when designing a lesson, from a 'teacher presenting the task' perspective to a 'student engaging in the task' perspective and the importance of seeing their own *lesson taught.*

Introduction

This paper reports on a study designed to show how an adapted Lesson Study (Isoda, 2007) can enhance preservice teachers' early experiences in constructing mathematical tasks for use in the classroom. For the purposes of this study, the term Lesson Study refers to an improvement cycle in which teachers collaborate to discuss learning goals and plan one or more actual classroom lessons. Teachers engaged in lesson study assume shared responsibility for the teaching lessons they create, observe the effectiveness of these materials as they are taught, and then work to revise lessons for future use (Lewis, 2002).

Specifically we studied a community of planning and practice (Wenger, 1999) by implementing and studying a cycle of preservice teachers designing lessons which promote inquiry and learning for understanding; the implementation of those lessons by a Master Teacher (observed by the preservice teachers); and co-reflection on the lesson by the inservice and preservice teachers. We call this the CRAFTeD (Call for lesson; Referendum, Advising session; Fine-tune; Teach-Experience; Debrief) cycle. The key component of this cycle is that preservice teachers see *their own* Lesson Plan implemented by a Master Teacher which gives them a different level of investment in the lesson than if they watched exemplary lessons, and they see their Lesson Plan implemented without having the pressure of teaching the lesson themselves whereby their concentration may be such aspects as classroom management, teaching style and their interactions with the students.

In pilot studies undertaken in the past (Meagher, Edwards & Koca, 2009) we have seen the importance of exemplary field placements for the consolidation of issues about inquiry learning addressed in the university classroom. The use of video technology in our most recent work has shown how the school-university partnership has the possibility be scaled up to impact far more preservice teachers than are able to attend a field placement site.

The research questions guiding the research and the analysis are:

(a) How do preservice teachers engage in creating lessons with a Master Teacher?

(b) What is the impact on preservice teachers of seeing *their own* lesson being taught?

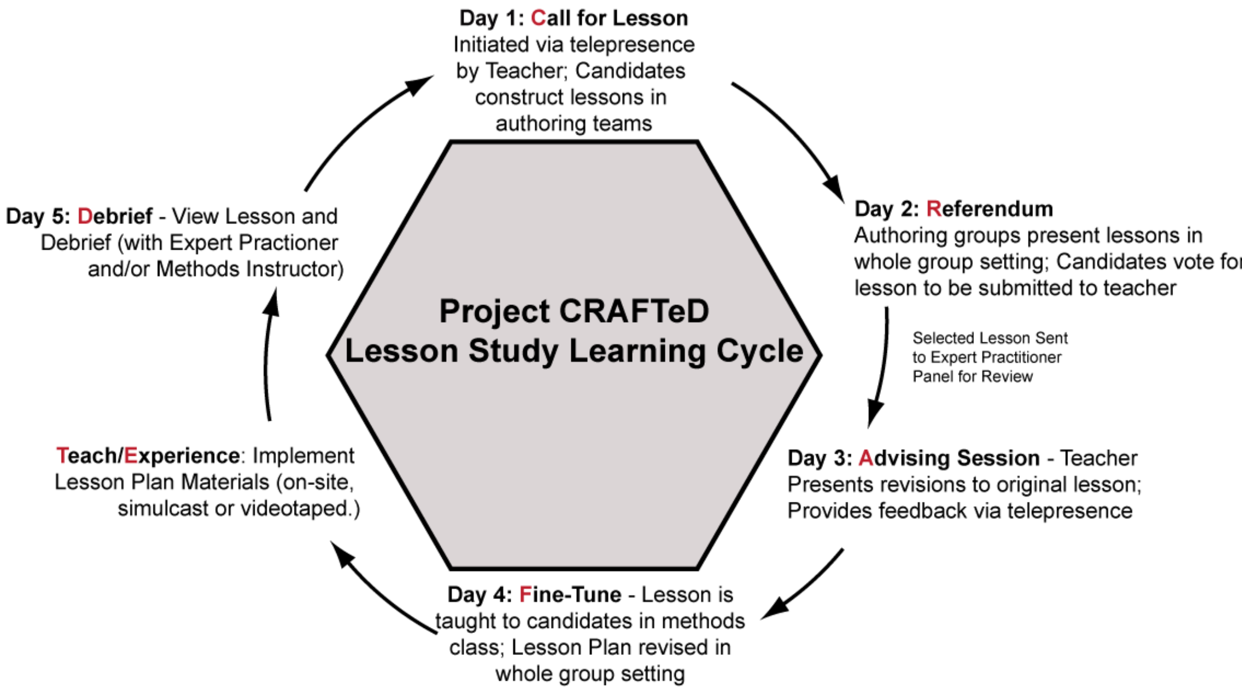
Literature Review and Relationship to Research

There is now a large body of literature (Conference on Learning Study, 2006; Fernandez, Cannon & Chokshi, 2003; Fernandez & Yoshida, 2004; Isoda, 2007; Lewis, Perry, & Murata, 2006) on the importance and effectiveness of Lesson Study approaches in improving teaching, curricular content, and instructional sequences. Hart, Alston & Murata (2009) draw on a plethora of research studies to argue that while many Professional Development models such as action research or teacher place teachers at the centre of the research, Lesson Study is unique in focus that is brought to bear on a "live lesson." They assert that "teachers notice certain aspects of teaching and learning, and this implicit and organic noticing does not happen in artificially replicated professional development settings." (p.1) Lesson Study approaches can also provide for more focused professional development than many traditional professional development models (Lewis, 2002). Furthermore, developing communities of practice (Wenger, 1999) and lesson study groups (Fernandez, 2002) can help teachers to adopt a more research-based focus in their lesson planning and to develop a shared repertoire of communal resources which can transcend individual contributions. Most research thus far has focused on inservice teachers: our research involves implementing an adaption of the Lesson Study approach for pre-service teaches.

Our research employs lessons learned from Lesson Study approaches to address the problem that the teaching methodologies advocated by methods instructors in teacher preparation programs are not readily observed in actual classroom settings, a disconnect that has become more pronounced in the age of high-stakes standardized testing. While university methods instructors laud the merits of student-led inquiry, exploration, and discovery-based teaching methods, secondary mathematics teachers in too many schools "set aside" such teaching in favor of instruction directly focused on student preparation for high-stakes, multiple choice state tests (Seeley, 2006). In an age in which testing dominates the landscape of too many classrooms, it becomes increasingly difficult to provide teachers-in-training with models of high-quality mathematics instruction in secondary school environments. The proposed study looks to explore an answer to this situation by providing preservice teachers with opportunities to collaborate with exemplary high school mathematics teachers by means of inexpensive, readily available web-based conferencing services and strategic face-to-face visits throughout the semester.

Methods and Methodologies

This research is designed to implement the following CRAFTeD cycle:



The cycle emerged from our previous work where the decisive influence of the field placement in terms of the mentorship/exemplars students experienced became apparent.

(i) A class of preservice high school teachers wrote Lesson Plans on a given topic and then worked together to develop improved lessons/short units designed often for technology-rich environments; (ii) an experienced inservice teacher reviewed the lessons/short units and presented an initial redesign; (iii) the inservice teacher taught the lesson, observed on video by the preservice teachers; (iv) the preservice teachers and inservice teachers met together to reflect on and redesign the lesson based on their experiences in the classroom

The purpose of the cycle is to examine (i) how pre-service teachers co-create a lesson and (ii) to examine the particular impact of ownership of the lesson on preservice teachers learning.

The preservice teachers

The pre-service teachers (n=15) were engaged in routine activities that comprise a mathematics teaching methods course, which met for two 75 minute sessions a week for 15 weeks, at a small Midwestern university. The course was the second in a two-course Methods sequence, these courses being the pre-service teachers' only Methods courses in the program. Prior to taking the Methods courses the pre-service teachers take Foundations and Mathematics Content courses. The course was designed specifically for pre-service secondary school mathematics teachers, with the subjects engaging in activities focused primarily on pedagogical issues (e.g. constructing lesson plans and grading rubrics, creating technology-oriented math activities) and content issues (solving mathematics problems, assessing student work). As part of the course the preservice teachers engaged in two iterations of the CRAFTeD cycle.

The inservice teachers

The inservice teacher was a Master Teacher at a local partnering school. The inservice teacher has been a co-operating teacher with the university for many years and is a teacher leader in the district with particular expertise in the use of technology in teaching mathematics.

Data Collection

The data collected during each cycle, as described above was

- A Skype-based discussion between the class and the inservice teacher initiating the cycle
- Lesson Plans created by small groups of the preservice teachers
- The Lesson Plan voted on as the best from the 8 created
- The revisions suggested by the inservice teacher
- Reflections from the inservice teacher and the preservice teachers on the revised lesson
- The final implemented Lesson Plan
- Videotape and fieldnotes from the lesson as taught by the inservice teacher
- Videotape and fieldnotes of the debriefing between the preservice and inservice teacher.
- Interviews with inservice and preservice teachers on the entire cycle.
- A revised Lesson Plan after the teaching of the Lesson.

The data coded for direct answers to the research questions with two basic codes: "co-creation" (CC) and "*their own* lesson" (TOL). The data was then re-analysed using the constant comparative method (Cresswell, 1998) to examine emerging patterns that were not revealed at the first round of coding. Sub codes such as Modifications to the Lessons, Classroom Management, Student Learning emerged at this stage. Quotes exemplifying the quotes were organised and exemplary quotes for each of the codes chosen to support the analysis. The analysis is presented in the order of the cycle.

Results

Call for Lesson

The cycle was implemented on two occasions in the semester. On each occasion there was a Skype teleconference with the experienced teacher. In the first iteration of the cycle the Call was for a lesson introducing right angle trigonometry in a manner that would allow the students experiencing the lesson to "make a connection to the 'sin' button on their calculator." For the second lesson the Call was for a lesson connecting the unit circle and the sine curve.

Referendum

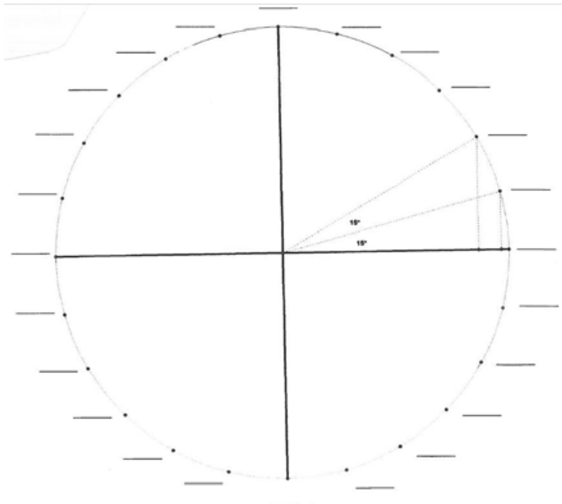
At the Referendum stage in the first iteration the preservice teachers decided to take elements from each of the group's lessons to make what they ended up calling the 'Frankenstein' lesson. The consensus was that the 'Frankenstein' lesson didn't work as well as it could have so, for the second iteration of the cycle the preservice teachers decided to pick one lesson and then work together to strengthen that lesson.

Advising Session

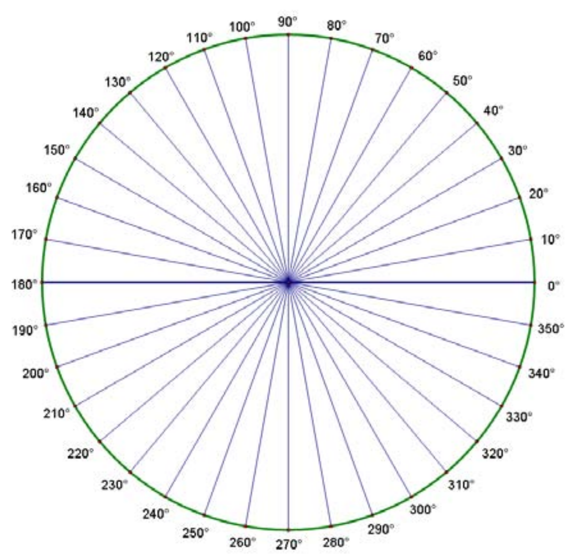
Two candidate lesson's were sent to the inservice teacher who reviewed both and then chose on commenting "I will use A's lesson. The other is good, but too algebraic. I really wanted something visual and kinesthetic, and A's fit the bill." (Inservice Teacher Interview)

The core of the Lesson chosen is a fairly standard use of pieces of dry strands spaghetti placed on a unit circle to create a physical measurement of the y-coordinate associated with a chosen x-coordinate. Students then paste these pieces onto an axis at the relevant place to create the outline of a sine curve.

The students sent a complete lesson, including worksheets to the inservice teacher who then return the lesson with several comments. It is interesting to note that many of the modifications made by the inservice teacher at this point showed his experience in thinking about the lesson from a students' point of view. To use the language of Stein and Schwab Smith (1998) he is thinking about "Tasks as implemented by students" rather than "Tasks as set up by teachers." Many of the modifications are simply practical elements which the inservice teacher recognises as crucial to allowing the students to concentrate on the substance of the task. For example, in the original lesson the students constructed a story about the bug's journey which involved taking measurements every 15 seconds which should then be equated to degrees (the journey having been set up to take 6 minutes so each degree would be a second) resulting in the following unit circle on their worksheet:



with just two indicators each showing 15 degrees. The inservice teacher judged the time issue to be a distraction and also recognised the ambiguity in this set up: Will students recognise that the two 15 degrees indicated are supposed to total to the 30 degrees required for the second measurement? Might students get confused about what happened when you get passed 90 degrees? There are some valuable mathematical discussions possible around those two questions but the inservice teacher wanted the students to concentrate on getting the correct measurements and not be distracted at his point of the lesson and so proposed the following unit circle for the worksheet:



The preservice teachers recognised this as having the advantage of focusing on the degree measurements of the unit circle and therefore being more focused on the substance of the mathematics.

Fine-tune:

The preservice teachers moved to the fine-tune part of the cycle wherein the authors of the original lesson plan formally taught the lesson to the other preservice teachers. This stage of the process turned out to be surprisingly powerful. It furthered the preservice teachers' development in taking the crucial step of thinking about the lesson from a students' perspective rather than from a teacher's perspective (students' tasks vs teachers' tasks again). Suddenly a plethora of practical issues were brought to light and modifications were made to the lesson as the preservice teachers realised that they had not thought carefully enough about many practical issues such as: "The blank graph also had a suggested location to place tape, which we discovered was problematic because the tape being placed over the x-axis made it difficult to determine the exact location of the x-axis." (Preservice teacher 14). The importance of this fine-tuning stage was discussed at length by most of the preservice teachers in their reflections resulted in statements such as "I think the debugging effort demonstrated the importance of "piloting" one's lesson. It is easy to imagine how smoothly things will be, but until you actually put yourself in the role of the student and follow the instructions and complete the activity, it is difficult to identify potential problems." (Preservice teacher 15).

As we have mentioned before this sort of realisation may read as something that should be obvious to teacher candidates but it was an important lesson for them to learn and a lesson that was only learned because their lesson was actually going to be taught not simply produced as an exercise for a class.

Teach/Experience

The Lessons were taught by the inservice teacher and videotaped so that the preservice candidates could spend adequate time watching and reflecting on the implementation of their lesson.

Debrief

The other stage of the cycle where the benefit to the students was greatest was in the debrief on the Lesson. The debrief was conducted through in class discussion and by having the preservice teachers write reflection papers.

In this part of the cycle we again saw the importance of the lesson being *their own* lesson coming through strongly. The level of investment and, therefore, the level of attention the preservice teachers paid to the lesson seemed to be a direct result of this ownership.

Modifications

The preservice teachers noticed straight away that the inservice teacher modified their lesson by including an introduction on families of graphs such as |x| and x^2. He then spent some time using a SmartBoard to animate the journey of the bug walking around the circle. He then challenged the students to think about what the graph of the height of the bug relative to the x-axis over time would look like. This introduction and conjecture setting may seem, to any experienced reader, an obvious aspect of any lesson and it may indeed seem like even novice teachers should know to do this but it is interesting to read in the student reflections how powerfully this aspect impacted them. The impact had two aspects (i) the conviction that it improved the lesson and (ii) this gave them an example, in a context, that they were familiar with and of which they had ownership, of how a teacher can draw on students' previous learning, connect to the current topic and force students to think through what the outcome may be to create a *student* investment in the outcome of the lesson. (Will the graph turn out to be a parabola as suggested by one of the students in the class?). In their reflections almost every preservice teacher wrote about these modifications and the impact they had on the lesson. As one preservice teacher reflected: "In the Spaghetti Sine lesson, the inservice teacher had to include a warm-up since we did not provide one with the lesson. The warm-up he presented was excellent in that it helped students to recall previously learned families of functions as a precursor to the introduction of a new family function, the sine curve. This modification significantly improved the lesson's effectiveness from a constructivist point of view. Students were asked to incorporate new information by layering it upon former knowledge." (Preservice Teacher 2). The idea of the conjecture also resonated strongly with the preservice as exemplified in the following comment: "Most students predicted that the graph of the bug's height above the x-axis would take the shape of a parabola. Having students predict what this graph would look like was a good idea because it forced students to really contemplate the problem before actually investigating it." (Preservice Teacher 5).

Classroom Management

As the lesson progressed the preservice teachers had an opportunity to closely observe a Master Teacher at work and see an exemplary implementation of the lesson without having to worry about classroom management let alone implementation. In fact, it gave the students an opportunity to observe how a skilled and experienced teacher used classroom management to further the goals of the lesson and engage with the students. As one preservice teacher noted "One small thing that he did to increase the quality of the lesson was going around and handing out tape to the students as they needed it. This small gesture allowed the inservice teacher to roam the room, checking student progress and answering questions while keeping the order by keeping them seated. Otherwise, the activity would be more chaotic if students were constantly getting up to get more tape. This is a management detail that I am now aware of as I begin my teaching career." (Preservice Teacher 5). The preservice teachers also observed that the inservice teacher was experienced enough to head off some potential difficulties before they could cause a problem "[He] took care of the issue we were concerned about with having the calculators in the correct mode right away at the beginning of class. By taking care of this before getting into the activity, he prevented the possible disaster that could have occurred later and disrupted the entire class." (Preservice Teacher 9).

Student Learning

The videotaping of the lesson also allowed the preservice teachers the opportunity to observe the students working on the materials they had created. The ownership here provided a real investment in student learning and the tone of excitement in the reflections as the preservice teachers wrote about how they observed student engagement and learning shows the impact of the cycle on their development as novice teachers.

> It was pretty cool to watch kids make connections as they were working. After the slope of their sine graph turned negative, many of them began to see the symmetry in the curve they were constructing. Then when the graph slipped below the x-axis many of them realized they were going to make the same curve but upside down from the first. The coolest connection students began to make though was that they could have cut out multiple pieces at the same time. We could literally hear students coming to this conclusion as we watched the video. As connections were being made we could see the students were adding meaning to what they were doing and that this lesson would be one that they would remember. (Preservice Teacher 1)

This observation of connections the students were able to make was frequently remarked upon. Others were encouraged by seeing that the kind of hands-on lesson advocated for by NCTM (2000) and most professors can work in a real class: "I found the level of student engagement heartening. We have been encouraged to find hands on activities when creating lessons. We are taught that students learn in stages and that abstraction is the last phase. At the secondary level, I believe teachers expect students to leap to abstraction far too quickly. When this happens, the students do not enjoy the process, and often feel left behind in their thinking. Lessons like the Spaghetti Sine lesson remind me to make the leap more of a step. I hope I never forget this pedagogical reality." (Preservice Teacher 2).

Discussion

This study was designed to implement the six stage CRAFTeD cycle we developed to provide preservice teachers enrolled in a Mathematics Methods class a rich and meaningful experience in writing lesson plans and to answer the following research questions: (a) How do preservice teachers engage in creating lessons with a Master Teacher? (b) What is the impact on preservice teachers of seeing *their own* lesson being taught?

The study was not on a large scale and was exploratory in nature but the data presented above provides evidence that there is a trajectory of development in understanding Lesson Plans as well as many basic and more nuanced issues of teaching when the CRAFTeD cycle is implemented. The fact of the lesson being taught provides extra motivation "These experiences have made something I wouldn't have cared about as much more worthwhile. If we had been doing lessons for this class and I knew that all they were going to be: all that was going to happen is that they were going to get graded and I was going to get them back I wouldn't be as prone to put as much time and effort into it as I am now knowing that this is actually being taught to actual students." (Preservice Teacher 6). The preservice teachers not only had an investment in what was happening but were able to follow every detail of the lesson closely. "I really appreciate having the extra time to create, get feedback, edit, and then give a final version of our lesson to him before he taught it. This made watching the lesson easier since I *knew* what was happening." (Preservice Teacher 10). The process can also encourage students to be innovative "being able to think outside the box and come up with these things and have a veteran who has outstanding classroom management skills to implement it helps you feel a little more at ease about thinking outside the box." (Preservice Teacher 8).

The investment in the lesson the preservice teachers had designed and worked on with an experienced teacher made this a very different experience from creating lessons which will never be taught and a very different experience from simply watching an exemplary lesson on video. We believe the CRAFTeD cycle has considerable potential to provide a variant model on traditional Lesson Study that can be very effective the development of preservice teachers.

Toward Common Ground: A Framework for the INVESTIGATION of Mathematics Methods Courses

Helena P. Osana
Concordia University
osana@education.concordia.ca

Anna Sierpinska
Concordia University
sierpins@mathstat.concordia.ca

We present an analysis of the practices of one mathematics teacher educator in the context of an elementary methods course. Our analysis of the 51 tasks used in the course revealed a content structure characterized by four components: mathematical knowledge, psychology of mathematics learning, teachers' didactic actions, and reflection. The epistemic nature of the tasks in these content areas is described. We also observed a number of structuring frameworks, largely informed by theory, that were presented to the students as tools for completing course tasks. We conclude with a general framework for the investigation of other methods courses.

Objectives

Teachers have a number of ways to check the degree to which their practice is aligned with local and national objectives set out for elementary mathematics teaching. Aside from assessing their students' understanding in the classroom, there are a number of standards documents that can assist them to stay "on track," such as the NCTM *Standards* (NCTM, 2000), which provides teachers a comprehensive vision of elementary mathematics instruction in terms of content and process objectives. The same cannot be said of mathematics teacher educators (MTEs), those who prepare future elementary teachers of mathematics in the context of teacher education programs. Few, if any, guidelines exist with respect to content, curriculum, or pedagogical approach for the MTE, and as a result, MTEs engage in widely different practices, with virtually no communication among them (Osana, Sierpinska, Bobos, & Kelecsenyi, 2010). Furthermore, while the research on the practices of MTEs has grown over the last decade (e.g., Even & Ball, 2009), it provides at the same time analyses that are at a large and small grain size. For example, cross-cultural comparisons of the mathematics components of teacher training programs are available (e.g., Pope & Mewborn, 2009) as well as psychological descriptions of individual preservice teachers' thinking (Newton, 2008; Tirosh, 2000), and detailed, narrative accounts of single MTEs engaging preservice teachers in specific tasks (see Chapman, 2009). Other studies have examined the practices of MTEs by using their syllabi as data (Taylor & Ronau, 2006), but the limitation of this approach lies in the challenge of determining the types of knowledge their tasks actually or intend to generate, resulting in a superficial or disconnected analysis that often generates more questions than answers.

Such varying perspectives and levels of analysis make it difficult to compare the practices of MTEs in their methods courses, which is the objective of our current research. Little is known about what MTEs do as they prepare future teachers of mathematics, including the reasons for what they do and the effects of their practices. Before one can even determine the effects of their specific practices, however, one needs a common language and organizing framework to analyze and document them. Thus, the objectives of the current study is twofold: (a) to present a detailed analysis of the practices of one MTE, and (b) to present a framework that can be used to document the practices of other MTEs in the context of their own methods courses.

The present study is part of a larger, ongoing project in which we are analyzing the data from five other university sites. We are currently using the framework presented in this paper, called the Mathematics Teacher Educator Framework (MTEF), to document the practices of the other five MTEs from whom we collected data. In so doing, we are refining, and may possibly expand, the framework so that it is general enough to examine the practices of any other MTE in the context of an elementary methods course. This will lead the way for more meaningful dialogue to take place among MTEs and allow for common ground on which to conduct future research in the area. While the findings presented in this paper are the beginnings of a work in progress, we nevertheless believe that our insights at this stage may prompt other MTEs, as well as scholars in the field, to think about adopting the common language we propose through the MTEF to communicate more productively about the preparation of mathematics teachers.

Theoretical Framework

The approach we take in our analysis of MTEs' practices is through an examination of the tasks they use with preservice teachers, those that are required of them in class as well as assignments that are to be completed outside of class. A theoretical framework that we have found particularly useful in our examination of tasks is derived from Chevellard's (2002) "praxeology theory." A praxeology is a theoretical model of a practice, and as such, a praxeology of a practice describes it using four dimensions: tasks, techniques, technology, and theory. One can begin talking about the existence of a "practice" in the execution of a class of tasks if (a) the *tasks* have been divided into types; (b) there are *techniques* for tackling each type of task; (c) there is a conceptual framework and *technological* tools to justify the purposes of the tasks and the validity of the techniques; and (d) there is a discourse that systematizes and brings theoretical coherence into the previous elements of the practice. The discourses in (c) and (d) are necessary for the practitioners to communicate their practice to others and to assess whether a task has been satisfactorily completed.

So far, the Chevellard's (2002) framework of "praxeology" has been usefully applied primarily in the study of practices in mathematics teaching (e.g., Barbé et al., 2005; Sierpinska, Bobos, & Knipping, 2008). We argue, however, that the same theory can be used to analyze our observations of MTEs' practices in their methods courses. In this paper, we show how we used Chevellard's model of Anthropological Theory of the Didactic (ATD) to analyze the tasks collected from one MTE in an elementary teacher-training program at a Canadian university.

Method

Participant and Settings

The mathematics teacher educator in the present study (referred to in this paper as MJ) was a full-time, tenured faculty member in education at a large university in Canada. For the 10 years prior to our data collection at this institution, MJ was responsible for teaching two required elementary mathematics methods courses, each offered during 13-week semesters. The first of these courses, offered every fall, provides the context for the present study. MJ's research background was in educational psychology, which included a minor in mathematics education.

Data Collection and Analysis

The primary source of data for the present study was 51 tasks used in MJ's methods course. We created a rubric based on the ATD model, and used it to code each task as we made a first pass through the data. The rubric contained two major categories: (a) the institutional status of the task, which contained the subcategories of in-class activity, take home assignment, and in-class test, and (b) ATD analysis, which contained the four subcategories specified by

Chevellard's (2002) ATD model, namely task type, technique, technology, and theory.

We also interviewed MJ to obtain more detail about each task and to tap into her justifications for including the tasks in her course. We conducted a total of 15 interviews with MJ over the course of one year, with the duration of each ranging from half an hour to two hours. The interviews were semi-structured, and included questions such as, "Why did you choose this task in particular? Why did you design it this way? What do you intend for the students to learn by engaging in this task? How was it implemented in the class?" Four of the interviews were audio recorded; detailed notes were taken during the remaining interviews. Finally, a third source of data used in our analyses was the collection of documents provided to students in the course, which included the syllabus, all handouts and tests, and lecture slides.

The transcriptions of the audio recorded interviews and the interview notes were analyzed using grounded theory techniques (Strauss & Corbin, 1998). These analyses were used to supplement the initial coding of the tasks to generate further categories in the rubric, which, through several passes through the interview transcripts and careful examinations of course documents, allowed us to describe the course and to create the MTEF in its current state. More specifically, when coding for task type, we coded the data for the content that was targeted by each task (e.g., psychological principles underlying children's thinking). This allowed us to address the structure of the course content. When coding for techniques, we searched for ways suggested by MJ to go about working through the task (e.g., "use your knowledge of problem types and apply it to extend the given third-grade activity"). We also coded the data for the techniques associated with each task, which directed us to search for tools suggested by MJ that justified the use of the techniques (e.g., a set of principles for analyzing a classroom lesson). Finally, we coded the data for evidence of any discourse that was intended to systematize and bring together theoretical coherence to the technologies recommended for each task.

Results and Discussion

In this section, we illustrate MJ's practice by presenting the content structure of the course (*task type*), the *techniques* suggested by MJ to tackle the tasks, the *technologies* MJ required her students to use as tools in their use of techniques, and finally, the *theories* used to justify the technologies. Our analysis of the tasks using the ATD framework allowed for an additional theme to emerge, called *epistemic actions*, which describes the kinds of knowledge that MJ intended to foster using the tasks she chose. Note that in this section, we refer to the preservice teachers in MJ's course as "students."

Task Types and Techniques

The content structure of MJ's course consisted of four content categories: (1) mathematical knowledge for teaching, (2) psychology of mathematics learning, (3) the teacher's didactic actions, and (4) reflection. We describe each of these categories below.

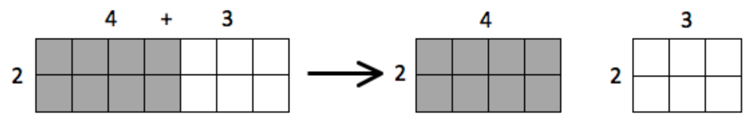
Mathematical knowledge for teaching. The first category – mathematical knowledge for teaching (MKT) – is defined here as knowledge of the concepts and principles of school mathematics (1). In MJ's course, MKT included knowledge of numbers and their properties, models of mathematical operations, and the ability to solve the problems in the elementary mathematics curriculum. There were 17 MKT tasks in MJ's course, which constituted 33% of all the tasks analyzed. A sample MKT task is presented in Figure 1.

Psychology of mathematics learning. We defined the category of Psychology of Mathematics Learning (PML) as knowledge of how children learn mathematics, which included, in MJ's course, (a) how children learn to count and understand number, and (b) the types of strategies children acquire as they learn to solve problems with whole numbers. The same number of PML tasks was assigned by MJ as MKT tasks – that is, we coded 17 PML tasks, which made up 33% of all tasks in the data set. A sample PML task is presented in Figure 2.

Is the statement below true or false? Justify.

On one of Mr. Barr's lessons on multiplication in his fifth-grade classroom, he writes the following on the board: $2 \times 7 = (2 \times 4) + (2 \times 3)$

One of his students raises his hand and asks, "Where does the extra 2 on the right hand side come from?" Mr. Barr then draws the following picture and says, "See? It was there all along!"



Statement: Mr. Barr is using a picture to illustrate the associative property.

Figure 1. Sample MKT task (adapted from Sowder, Sowder, & Nickerson, 2011).

Is the statement below true or false? Justify.

Jonathan used the following method to solve 234 ÷ 3 = □.

What is 234 divided by 3?
70 + 70 + 70 = 210
20 ÷ 3 = 6 R2
4 ÷ 3 = 1 R1
So, 234 ÷ 3 = 77 R3 = 78

Statement: This method will work for any division problem with whole numbers (divisor ≠ 0).

Figure 2. Sample PML task.

Teacher's didactic actions. There were 11 tasks (22% of all the tasks) that we placed in the category of Teacher's Didactic Actions (TDA), which we defined as the knowledge and skills needed to perform pedagogical actions, such as identifying the didactic objective of an activity, using a pictorial representation to explain an algorithm, and producing tasks intended to mobilize a specific mathematical concept. We present a sample TDA task in Figure 3.

Reflection. In the fourth category of task type, Reflection, we placed 6 of MJ's tasks, which constituted 12% of all 51 tasks. Reflection tasks were those that targeted the students' beliefs about the goals and objectives of the course in relation to their development as teachers. More specifically, MJ required her students to think about why subject matter knowledge is important for elementary mathematics teachers, how a "good" teacher uses mathematics in the classroom, and to identify a new kind of knowledge (namely, the professional body of mathematical knowledge that is "pedagogically useful," Ball & Bass, 2000) and distinguish it from the "plain old math," a term used by MJ to describe what she believed reflected her students' conceptions of the subject-matter. One such task assigned by MJ was to write a brief "journal entry" on the first day of class describing her students' thoughts about various aspects of a teacher's subject-matter knowledge, including their beliefs about the types of mathematical knowledge necessary for elementary school teachers. Subsequently, MJ required her students to read a non-technical article (Ball, Hill, & Bass, 2005) on the topic of mathematical knowledge for teaching and to compare Ball et al.'s account to the beliefs expressed in the journals of their peers, which were anonymously posted on the course's website.

Printing Pages

Book pages are printed on large sheets of paper called *forms*. Each form contains the same number of pages, so the number of pages in a book will always divide by that number with no remainder. After the forms are printed, they are cut apart so the pages can be bound.

? How many pages can be on a form? Explain your answer.

Book	Pages
1. How Come the Best Clues Are Always in the Garbage?	176
2. How Can I Be a Detective if I Have To Babysit?	160
3. Who's Got Gertie? And How Can We Get Her Back!	176
4. How Can a Frozen Detective Stay Hot on the Trail?	168
5. What's a Daring Detective Like Me Doing in the Doghouse?	192
6. How Can a Brilliant Detective Shine in the Dark?	200
7. What's a Serious Detective Like Me Doing in Such a Silly Movie?	192

As a teacher, you want to use the context of the problem to extend students' knowledge of multiplication and division – that is, to see how they think about other problem types. Write one word problem, in the context of this situational problem, that you might use with your students to meet this objective.

Figure 3. Sample TDA task (situational problem from Kestell & Small, 2004).

Across all the tasks in the four content categories, we observed MJ specifying a number of techniques for her students in the course. These techniques included using a checklist; recalling a definition; applying a principle or property; reading a text; describing observations; and comparing actions, tasks, and strategies; and were made explicit in all the tasks MJ assigned.

Technologies and Theories

Technologies can involve terminology, number facts, mathematical definitions, types of strategies used by children to solve problems, and didactic principles. Some technologies are loose collections of facts or principles, and others cohere as comprehensive frameworks. In classifying the technologies in MJ's course, we observed that they fell into two categories: (1) related to the mathematics itself (e.g., principles and properties of involving operations with whole numbers), and (2) related to teaching actions and children's learning. The majority of the technologies in MJ's course took the form of "structuring frameworks"; they were collections of principles, tightly bound together, to be used as tools for completing tasks.

To illustrate, MJ presented a number of mathematical properties, such as commutativity, associativity, and distributivity, as tools for thinking about a teacher's actions. The task provided in Figure 1 shows how MJ required her students to use their knowledge of the distributive property of multiplication over addition to interpret a teacher's actions during a lesson. In addition, a large component of MJ's course centered on frameworks of problem types and children's thinking taken from Cognitively Guided Instruction (CGI; Carpenter et al., 1996), a mathematics professional development program for elementary teachers. In several of her tasks, MJ required students to use the CGI taxonomy of children's strategies to interpret and evaluate their mathematical work. Another task MJ asked her students to complete was to use the taxonomy to evaluate the relative difficulty of two division word problems – one measurement division and one partitive division – while taking into account a specific strategy to be used in each case. As a final example, MJ required her students to use a framework presented by Hiebert et al. (2007) on the dimensions of effective learning environments in mathematics. In one task, she required her students to analyze a videoclip of a fourth-grade lesson on area and perimeter and to analyze the teacher's actions using Hiebert's framework. In the assignment, MJ states: "This is not necessarily a perfect lesson... Use the Hiebert reading to point out, where applicable, ways the teacher creates an effective environment and ways he can improve his teaching."

Our analysis revealed that MJ's technologies were informed by a deep theoretical understanding of teaching and learning in mathematics, but were left unjustified by theory. In particular, MJ noted specific reasons for not including theory in the course, such as a lack of time and pressure from the students themselves to know "the answer" and the one "right" way to teach. MJ was sensitive to the many "layers of complexity" in teaching mathematics, and as such, there were some tasks in her course that were left open to her students' interpretation. More specifically, MJ expected her students to use the structuring frameworks in completing the course tasks, but was less concerned with their analyses or creations *per se* – as long as they engaged in analytical thinking (in her case, used the frameworks consistently, applied the correct definitions, and attended to the information provided in the task), the task was left open to the students' interpretation of it. This relatively open-ended nature of many of her tasks caused, in her experience, great discomfort and uncertainty in her students. As such, MJ indicated to us that she was unwilling to add to the uncertainty by also requiring them to use theory to justify their actions in the context of the course tasks.

Epistemic Actions

We used our analysis of the 51 tasks to discern their epistemic nature – that is, from the results of our examination of the types of tasks emerged a picture of the type of knowledge MJ was intending to impart to the students in her course. Across all four content categories (MKT, PML, TDA, and Reflection), we observed seven epistemic actions intended by the tasks. These epistemic actions were: identify, produce, discuss/reflect, assess, model, solve, and explain. The actions differed according to the content with which they were associated. For MKT tasks, for example, students were required to *produce* a representation of a number with base-ten blocks; *identify* which property of an operation, among those they learned in class, was used in a teacher's didactic action or a student's solution; *identify* the type of a given problem based on a list of types of problems presented in class; and *solve* a mathematics problem. In the PML category, sample actions were to *identify* a child's strategy; *produce* an example of a given problem; use knowledge of children's thinking *reflect* on parents' false beliefs about mathematics learning and to *produce* an argument to convince them otherwise; *discuss* the relative difficulty of a problem; and *assess* the counting skills of a child. With respect to tasks of type TDA, for instance, students were asked to *produce* a problem of a given type; *explain* a standard algorithm to a child; and *identify* the didactic objective of a given curricular activity. Finally, in the Reflection category of task type, students were asked to *reflect* on why teachers need to know mathematics and how they use their knowledge during teaching; and to *identify* a new category of mathematical knowledge, namely "mathematical knowledge for teaching," of which they should have become aware by reading an article by Ball et al (2005).

The most frequently occurring action observed in the data was "identify," which accounted for 33% of all the epistemic actions found in the 51 tasks. This was nearly twice as many as the number of actions in the next frequent category, "produce," which made up 17% of all actions. "Discuss/reflect" and "assess" were actions accounted for 16% and 14% of all epistemic actions, respectively, followed by the final three (i.e., model, solve, and explain) which together constituted 20% of all actions. An additional epistemic action emerged from our analysis, and that was of justification, which was systemic throughout the course and was required of students in almost all tasks. Indeed, 18 of the 51 tasks (35% of the total) required the students to provide a written justification of their claims – oral justifications were required in almost all other cases. MJ expected the students' justifications to be systemic, or in other words, based on a system of concepts, properties, and principles in the areas of MKT, TDA, and PML, which were, in MJ's course, accepted as true. The choice of the concepts and the truth of these properties, principles, and statements was not questioned or debated.

Contributions: The Mathematics Teacher Educator Framework

Cochran-Smith (2003) argued that the responsibility of preparing qualified teachers rests primarily with teacher educators, who are becoming increasingly active in studying their own practices. Because of this, she continues, one sees, "the emergence of new terminology and new contexts for doing and making public the work of teacher education" (p. 9). We present here what we call the Mathematics Teacher Educator Framework (MTEF), an organizing model that we believe provides a common discourse to describe and communicate the work of the MTE. The MTEF emerged from our analysis of the tasks used in MJ's methods course and, while it is relatively restrictive because it is based on only one site, we present it here as a first of its kind.

The MTEF is anchored in a task analysis informed by the ATD model (i.e., task, technique, technology, and theory), through which one can describe the content structure of a methods course. Currently, the model contains four content areas (i.e., MKT, PML, TDA, and Reflection), but as our data analysis on the larger project unfolds, additions and reconfigurations to this content structure are inevitable. From the present task analysis, we were able to discern the epistemic nature of the tasks used in MJ's course, which provides a view into the knowledge that she was trying to impart to her students. Given that uncovering the knowledge objectives of MTEs is by no means straightforward, we consider this aspect of the MTEF to a be a particularly important contribution to the literature in mathematics teacher preparation.

Once the epistemic actions in any given methods course are determined, one can begin to classify them according to the degree to which they call for higher level thinking. In MJ's course, the tasks that called for "identification" were of lower level than those that called for "reflection" (Vygotsky, 1987). Indeed, in one of our interviews with MJ, we noticed that she was surprised that she had given so much weight to relatively low-level tasks. We used this opportunity to discuss with her how to increase the presence of reflection, generalization, and abstraction in her tasks. Reflective practice and adopting an inquiry stance toward teaching have been identified as key areas of growth for the developing mathematics teacher (Doerr et al., 2010; van Es & Sherin, 2008). The epistemic nature of tasks gleaned from the MTEF can itself be used as a tool for reflection, as MTEs may not be aware of the effects their own practices may have on the development of preservice teachers (cf. Torff & Sternberg, 2001).

Endnotes

1. We note that our conceptualization of MKT is more restrictive than that offered by Ball et al. (2008), who defined MKT as a combination of subject matter and pedagogical content knowledge (Shulman, 1987). We restrict our characterization of MKT to knowledge of school mathematics and the "specialized content knowledge" described by Ball et al. as the mathematical knowledge unique to teaching.

HELPING STUDENT TEACHERS LEARN TO NOTICE: A PRELIMINARY REPORT

Shari L. Stockero
Michigan Technological University
stockero@mtu.edu

Noticing is important to skilled teaching, as it enables teachers to modify instruction in response to students' mathematical thinking and understanding. Novice teachers, however, often fail to notice important student ideas. A study was conducted with two secondary-level student teachers that focused on using research-like video analysis to help them learn to notice and assess the mathematical potential of important moments during instruction. Preliminary results of this work, as well as participants' perspectives on their learning, are discussed. This use of video analysis holds promise for helping novice teachers use their classroom as a site for inquiry and learning.

Objectives and Purposes of the Study

The vision of mathematics instruction advocated in documents such as the National Council of Teachers of Mathematics' [NCTM] *Standards* (e.g., 2000)—one in which teachers listen to and make sense of student ideas in order to build on them during instruction—requires a very different set of skills, dispositions and competencies than the traditional, teacher-centered model of instruction (Feiman-Nemser, 2001). It requires that teachers use the classroom as a site for inquiry and continued learning. Given the recognition that completing a teacher education program is not sufficient to develop all of the finished competencies of an effective teacher (Feiman-Nemser, 2001; Hiebert, Morris, & Glass, 2003), it has been suggested that it may be more productive to conceptualize teacher education as a venue for helping teachers acquire tools that enable them to learn from practice over time (Ebby, 2000), rather than as a site for producing a fully-formed teacher.

Tools to learn from practice can be developed through engaging with student thinking (Feiman-Nemser, 2001; Philipp, et al., 2007), but many opportunities to do so within teacher preparation programs are not capitalized upon. Traditional field experiences, for example, have been criticized for helping prospective teachers learn what is currently being done, rather helping them rethink the possibilities for instruction (e.g., Philipp, et al., 2007). Even when placed in exemplary classrooms, prospective teachers often do not have the knowledge or dispositions to meaningfully observe classroom interactions (Masingila & Doerr, 2002). Adding to the problem is the fact that the goals of field experiences are often not well-articulated, leaving school-based mentors to develop their own goals for the field experience that often have little connection to mathematical content or students' understanding of it (Leatham & Peterson, 2010). Thus, it is becoming recognized that intentional and substantial teacher educator involvement—visiting school sites and engaging teacher candidates in discussions about what is observed—is critical to supporting meaningful learning from field experiences (Grossman, et al., 2009; Masingila & Doerr, 2002).

The use of video is another promising method of positioning prospective teachers to continue to learn from practice as it grounds learning in practice. In fact, studies have found that video cases can support the development of teachers' analytical skills by helping them learn to make sense of students' mathematical ideas and use classroom-based evidence to support analyses of teaching and learning (Sherin & van Es, 2005; Author reference). Much of the current work with video, however, has used classroom video clips that have been selected and edited by experienced teacher educators, eliminating the opportunity for teachers to determine what instances might be worthy of analysis. This is problematic because in order to learn from teaching practice, teachers first need to *notice* (Sherin & van Es, 2005) important instructional events. In fact, a major difference between expert and novice teachers' practices is their ability to notice and respond to important instances during instruction (Hogan, Rabinowitz, & Craven, 2003), with novices failing to notice or act upon many instructional instances that experienced educators intuitively recognize and productively respond to (Peterson & Leatham, 2009). Thus, to position teachers to learn from practice, teacher educators need to not only develop prospective teachers' ability to analyze classroom events, but also their ability to notice the events that are worthy of analysis because of their potential to support students' mathematical learning.

Ongoing work has led to an initial conceptualization of important mathematical moments that teachers should attend to during instruction (e.g., Leatham, Peterson, Stockero, & Van Zoest, in press) and a characterization of circumstances likely to lead to such moments (e.g., Stockero, Van Zoest, & Taylor, 2010). This work is an important first step in making such moments visible to teachers, as it provides frameworks that can be used to scaffold teacher noticing by focusing their attention on characteristics of potentially fruitful mathematical moments that could be capitalized on during instruction. The study reported here aimed to develop a preliminary understanding of how such frameworks might be used in practice. In particular, the frameworks developed as part of related projects were used to inform the development and implementation of instructional activities aimed to help two prospective secondary school mathematics teachers learn to recognize and analyze important mathematical moments in instruction during their student teaching experience. In this paper, the teacher learning activities, data collection, and analysis are described, and the results of initial data analysis are shared. The paper concludes with a discussion of the potential implications of this work for teacher education and future directions of the work.

Theoretical Perspectives

Consistent with current thinking in mathematics education (i.e., NCTM, 2000), this research is based on the view that the use of student thinking is central to effective mathematics instruction. Thus, it follows that noticing important student mathematical thinking is an essential skill of effective mathematics teachers, since teachers cannot intentionally act upon that which they do not notice (Sherin & van Es, 2005). The definition of noticing used in this work draws on that of Sherin and van Es (e.g., Sherin & van Es, 2005; van Es & Sherin, 2002), who define noticing as comprised of three interrelated skills: identifying important events during instruction, reasoning about them, and making connections between the events and broader educational principles. The conceptualization of the act of noticing during instruction underlying the research is shown in Figure 1; the first two components are the focus of the part of the work reported here.

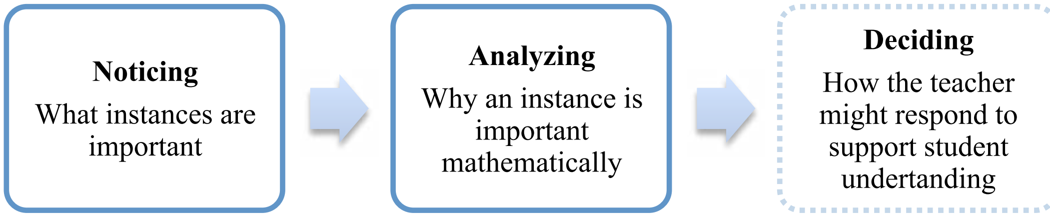

Figure 1. Components of teacher noticing.

The idea that student thinking is central to effective mathematics instruction does not imply that all student thinking is equally useful. Some student ideas, for example, are only tangentially related to the goals of the lesson or do not have the potential to add to students' understanding of important mathematical ideas. These ideas are probably not worthwhile to pursue during a lesson, as the benefit they would bring would not outweigh the time taken from the lesson. Other student ideas, however, are mathematically rich and provide an opportunity for the teacher to use the student thinking to develop important mathematical ideas (Author reference). These are the instances that were the focus of this study. The central component of noticing as used in this work was helping novice teachers learn to notice student thinking that has the potential to advance student understanding of important mathematical ideas, while not expending time and energy on that which does not.

Methodology

Participants

Two prospective secondary school teachers enrolled in the same teacher education program participated in the study during an 11-week student teaching experience. Both participants had been enrolled in a mathematics methods course taught by the researcher during the previous semester; an explicit focus of this course was on listening to and making sense of students' mathematical thinking in order to build on it during instruction. Both participants were working with two cooperating classroom teachers, one in their major content area and one in their minor; this is typical of students in the program. Mary was completing her student teaching in high school chemistry (major) and mathematics (minor) classrooms and Audrey in middle school mathematics (major) and science (biology minor) classrooms. Project activities focused only on the participants' mathematics classes. A graduate student research assistant (RA), an experienced teacher and Audrey's cooperating teacher for mathematics, assisted on the project. The RA had no previous experience with the type of research-like analysis of instruction that was the focus of the study and was explicitly asked not to discuss the project activities with Audrey outside of project meetings.

Context

To help them learn to notice and make sense of important mathematical instances during instruction, the participants used the Studiocode video analysis software (SportsTec, 1997-2011) as a tool to analyze video recordings of classroom instruction. This software was selected because it allows multiple users to individually code and annotate a video segment and then merge and compare coding among users. It was hypothesized that engaging participants in research-like video analysis, rather than in more open discussions of classroom video that have been typical in past video case research (e.g., Author reference), would enhance their ability to notice important mathematical moments during classroom instruction, as it required them to individually code the video and justify their coding before they engaged in discussions about it.

The participants coded a total of eight classroom videos during the project. The first was of the RA's instruction during the second week of the student teaching experience when the participants were just beginning to take on teaching responsibilities. The remaining videos were recorded in Mary's and Audrey's classrooms, alternating between classrooms each week. After recording, the researcher prepared each video for analysis by editing out portions where audio could not be heard or that were not related to the lesson content; this was done to reduce the participants' video analysis time. It is important to note that the researcher did not edit any portion of the video where the teacher or students were talking about mathematics. The only portions what were edited were those where the teacher was taking care of administrative tasks or where students were working quietly.

The participants were instructed to code each video for *mathematically important moments* that would be important for a teacher to notice during instruction and to annotate each coded segment to indicate its perceived mathematical importance. The phrase *mathematically important moment* was intentionally left undefined by the researcher so that the group could refine the definition during project meetings. The participants first coded and annotated each video individually, after which they sent their Studiocode coding timeline to the researcher via email. The researcher and RA also individually coded the same video and then met to discuss their coding and agree upon the mathematically important moments in the video that a teacher could capitalize on during instruction. The researcher then compared these agreed-upon instances to those coded by the participants to determine which instances would be discussed in the next project meeting. The instances that were agreed upon by the researchers and both participants were always discussed during the meetings, with an emphasis on making sense of the mathematical importance of these moments. Instances that were coded by only one participant, or only by the researchers, were sometimes chosen to help distinguish instances that were mathematically important from those that were less important, or to highlight important mathematics embedded in student thinking.

The participants and the researcher met weekly for 60 to 90 minutes to view and discuss the coded video segments; the RA attended the first four meetings. During each meeting, the researcher pushed the participants to articulate the mathematical importance of instances they had identified and to consider whether there were characteristics common among mathematically important moments during instruction. For instance, the participants came to agree that student involvement seemed central to mathematically important moments, and thus, it was unlikely for such a moment to occur if students were not actively participating in the lesson.

During the last two weeks of the project, each participant taught a lesson in which she was asked to indicate her real-time noticing during instruction. This was done via a self-mounted camera that could be activated by the participant. The researcher also recorded the entire lesson. Following the lesson, each participant engaged in an interview that focused on the mathematically important moments that she had noticed during the lesson. The interview also included questions aimed at understanding participants' perspectives on the project activities and how these activities supported their learning during the student teaching experience.

Data Collection and Analysis

Data included participants' individual and merged Studiocode coding timelines and the accompanying video, the researchers' Studiocode timelines, and video recordings of each project meeting. In addition, video snapshots from the real-time noticing experience, the corresponding complete classroom video, and a recording of the post-interview were also included in the data.

The first phase of data analysis focused on summarizing the instances in each video that participants coded as a mathematically important moment and making comparisons both between the two participants' coding and between the researchers' and the participants' coding. This analysis focused on documenting the segments that were coded as mathematically important, as well as the participants' reason for identifying them as such. In many cases, the participants did not give a complete explanation of the importance of an instance in their annotation, so were pushed for a more complete explanation during the project meeting. In these cases, information from both the Studiocode timeline and the project meeting video was used to develop a complete explanation of the perceived importance of the moment. The outcome of this phase of analysis was an account of participants' noticing and their explanations of the importance of the coded moments in each video. This gave preliminary information about how each changed over time.

The participant interviews were analyzed to understand the participants' perspectives on the learning activities themselves, the value of specific activities in terms of supporting their learning during student teaching, and what they perceived to have learned by engaging in the project activities.

Results

Evidence of Learning in Coding and Project Meetings

Preliminary data analysis indicates that there was a change in participants' abilities to notice and analyze mathematically important moments during the study. In the first video, both participants focused mainly on identifying "good teacher moves." For example, both coded instances in which the teacher used a good visual representation of a problem, asked a series of questions to ensure that students understood the rules of a probability game, and summarized the lesson at the end. In addition, Audrey noted several instances where the teacher clearly defined mathematical terms. Although these were all productive teacher moves, they were each part of the teacher's plan for the lesson, and thus, are not the types of instances that are important for a teacher to notice during instruction. During the project meetings, instances such as these were used to discuss the difference between good planned teacher moves and moments that require a teacher response during a lesson.

On the other hand, in the same video, the researchers noted a mathematically important moment while students were playing a dice-rolling game related to probability that the participants did not. In the game, students placed 18 chips in columns numbered zero through six and then removed a chip each time the difference of two rolled dice was equal to the column number; the winner was the first to remove all 18 chips. After playing the game and recording the differences of the dice on each roll in a frequency table, the teacher told his students that they would play again. A number of students placed their chips by copying the outcomes in the frequency table in hopes of winning the game the next time, not realizing that the same outcome was unlikely. Although this moment had the potential to be used to highlight important ideas about theoretical and experimental probability, neither participant noticed its mathematical importance.

By the eighth video, both participants had shifted their primary focus from the teacher's actions to the thinking of students in the classroom, although Mary was generally better able to discern important student thinking from that which was less important than was Audrey. For example, both participants coded an instance in which a student used the distance formula to find the distance between some pairs of coordinate points, but used simple subtraction of coordinates for other pairs that were located vertically or horizontally from one another on the coordinate plane. Most students in the class had used the distance formula for all pairs of points. Both participants recognized this as an opportunity to highlight when the distance formula needed to be used, and when other methods were appropriate. Similarly, both coded an instance in which a student had included an unnecessary step in a geometric proof and another student explained why the step was not needed. Audrey, however, also coded an instance in which students were guessing which angles in a figure were supplementary to one another. Although supplementary angles are an important topic in geometry, there was no mathematical basis for their guesses, so it would be difficult to use the guessing to support student understanding.

Participant Perspectives on Learning

In the post-interviews, both participants agreed that the project activities were a valuable addition to their student teaching experience, despite the extra time they required. Both stated that coding the videos and then using the merged Studiocode timelines as a basis for project meeting discussions helped them really think about what moments during the lesson were mathematically important; instances on which they agreed confirmed their thinking, and those about which they disagreed pushed them to explain their thinking and continually refine their definition of what moments were mathematically important. Both participants also agreed that leaving *mathematically important moment* ill-defined at the start and then developing and refining the definition together made them think hard about what moments might meet the mathematically important criteria and which might not. They both stated that introducing the researcher's conceptualization of the construct via a reading (Author reference) mid-way through the project was helpful in that it gave them a framework to use to make sense of the work they had already done.

When asked to discuss how they felt the project activities affected their teaching, both participants noted that it shifted their focus from themselves to their students. Audrey said that, "It was good because it helped me key in onto the student a little bit more than I would have otherwise. Cause I would have been just trying to get, like, the content out there." Mary said that analyzing the videos helped her become more objective about her teaching, noting that it was important that the focus wasn't on "am I a good teacher, am I a bad teacher" but was on the mathematically important moments and how they could be used in the lesson. This, she said, helped her focus "on what [students] are learning rather than on 'Oh shoot, I should have done that.'" Mary also noted that she often thought about how to set up mathematically important moments when planning lessons. She said that she focuses on "trying get them to come up with things and asking them why more. I want to put a lot on them. And like, I already wanted to do that as a teacher, but I think this helped me think about it more, like, when I'm in class." Later in the interview she added, "You can, like, set [a moment] up and it might not happen, but it's more likely to happen if you if you set it up than if you don't."

Interestingly, both participants also noted that the activities helped them to think about the other non-mathematics classes they were teaching. Mary said that it helped her ask better questions in her chemistry class, where she noted that she had started out asking mainly lower-level questions. Audrey said, "I think [coding and discussing the video] helped me respond to those moments [in math], but then I feel like, why aren't we doing this in science, cause I don't know what those moments are in science. You know what I mean, the scientifically important moments. It's like, in science, I'm like what, I think I'm kind of struggling a bit with what is the big picture." Although not an expected outcome of the activities, this type of transfer is particularly encouraging to improving instruction more broadly.

Discussion and Conclusion

Preliminary findings suggest the value of engaging prospective teachers in detailed, focused analysis of practice as part of the student teaching experience. Both the participants' video coding and their interviews indicate that engaging in the project activities helped keep them focused on what matters the most during instruction—listening to student thinking and assessing the mathematical potential of that thinking in order to determine whether it might be worthwhile to incorporate. This is a very different focus than what has been documented in many student teaching experiences, where prospective teachers' primary focus is on issues, such as classroom management, that have little connection to mathematical content or to students' understanding of it (Leatham & Peterson, 2010).

The use of video analysis software seemed to support teacher learning by forcing them to identify specific moments and their reasons for selecting them as mathematically important prior to discussing them with others. Although the coding could have been done in other ways—for instance, on paper by noting video time stamps—Studiocode allowed the researcher to merge the participants' timelines in order to display their coding together and also to quickly select a coded moment and replay the instance in the video during a project meeting. These features of the software allowed for focused discussion of particular coded moments in ways that other modes of coding and reflection could not.

The discussions in which the researcher and participants engaged seemed critical to helping the participants learn to differentiate between moments that had significant mathematical potential and those that did not. In the discussions, the researcher pushed the participants to clearly articulate the mathematical importance of coded moments; when they could not, they were engaged in discussions about whether the moment was, in fact, mathematically important. Discussing instances that the participants had not coded provided an opportunity to help them better understand secondary school mathematics and to begin to make connections among mathematical ideas. Thus, although time-consuming, the sustained interactions with the researcher/teacher educator seemed critical to supporting participant learning. This study suggests, as have others (e.g., Grossman, et al., 2009), that teacher educators need to find ways to keep field experiences, particularly extended experiences such as student teaching, focused on students' learning of mathematics. Understanding what facilitator moves and tools are most productive in doing so will help teacher educators plan activities that most effectively and efficiently advance teacher learning.

Although the results of this work appear promising, there is much work to be done. Thus far, the data indicates that the activities supported learning, but does not illuminate the specifics of how that learning occurred. Subsequent data analysis will aim to draw connections between changes in participants' noticing and specific learning activities. This will entail detailed analysis of the questions the researcher asked to push participant thinking during project meetings, questions the participants raised during the meetings, and how specific tools and frameworks may have supported participant noticing. It is expected that this analysis will lead to hypotheses about teachers' learning-to-notice trajectories and specific learning events that might trigger advances in teachers' noticing. In future projects, the teacher education model will be refined and tested with larger groups of student teachers in a range of mathematics classrooms, and additional data will be collected to understand how the noticing skills that teachers develop affect their classroom instruction.

The preliminary results of this study provide support for including research-like video analysis in teacher education programs as a means of advancing teachers' ability to learn from practice. Developing teachers' abilities to notice and capitalize on important instructional events holds great promise in positioning teachers to become life-long learners in their own classrooms, and thus, improve their instruction over time.

PRESERVICE ELEMENTARY TEACHERS' LEARNING FROM VIDEOCASES: RESULTS FROM THE VPEM PROJECT

Alison Castro Superfine
University of Illinois at Chicago
amcastro@uic.edu

Wenjuan Li
University of Illinois at Chicago
wli26@uic.edu

While understanding children's mathematical thinking is an important part of what teachers need to know in order to be effective in the classroom, preservice coursework often fails to provide learning opportunities focused on this aspect of teaching. Using a videocase curriculum focused on children's mathematical thinking, the authors examined changes in preservice elementary teachers' knowledge of, beliefs about, and ability to analyze children's thinking. Results from a quasi-experimental study indicate that the videocase curriculum had little effect on participants' knowledge and ability to analyze children's thinking, yet a moderate effect on participants' beliefs about mathematics teaching and learning.

Research points to the importance of attending to children's mathematical thinking as an important aspect of what teachers need to know (Carpenter et al., 1989). Despite the centrality of children's thinking to teachers' mathematical knowledge, there exists little research involving preservice teachers' (PSTs) learning about children's mathematical thinking, with few exceptions (e.g., Philipp et al., 2007). Such research provides evidence that PSTs, if given opportunities to closely study children's mathematical thinking in the form of video clips, can further their own mathematical knowledge in relation to children's thinking (e.g., Philipp et al., 2007).

This study builds on and extends the extant research by examining how the design and implementation of a videocase curriculum supported PSTs' ability to analyze children's mathematical thinking. Specifically, the authors discuss findings from a quasi-experimental study of PSTs' engagement with the videocases in a required mathematics content course across two semesters, focusing on changes in PSTs' knowledge of, beliefs about, and ability to analyze children's mathematical thinking. The authors administered in both semesters a pre- and post-test using a mathematics content knowledge assessment instrument developed to measure mathematical knowledge for teaching, a pre- and post-test using the Integrating Mathematics and Pedagogy (IMAP) Beliefs survey, and a pre- and post-test video activity developed by the authors.

Theoretical Framework

Although most scholars and educators agree that mathematics teachers at all levels need to have a thorough knowledge of the content they teach (e.g., Kilpatrick et al., 2001), there is less agreement about the precise nature of the mathematics content that teachers should learn in preservice education programs. Some researchers have reconceptualized mathematics content knowledge, arguing that teachers need to not only know mathematics content, or common content knowledge, but that they need to know mathematics in ways needed for teaching, or specialized content knowledge (Ball et al., 2008). While common content knowledge refers to the knowledge that bankers or retailers, for example, have to know (e.g., computing percentages), specialized content knowledge refers to the mathematics knowledge that is specific to teaching (e.g., analyzing children's errors), and more closely resembles what teachers have to know and do with children in the classroom. If they are expected to support children as they investigate mathematical concepts, PSTs need to have a strong understanding of mathematical knowledge for teaching, which includes both common and specialized content knowledge.

Preservice mathematics coursework, however, often fails to adequately prepare PSTs for the work of teaching, as such courses focus solely on the learning of content with limited attention given to how such knowledge is used in actual teaching practice (RAND, 2003). In addition to knowing the content of the mathematics problems they use with children, teachers also have to analyze unusual solution methods that children may pose, appraise children's explanations, and ask mathematical questions that further children's thinking, teaching tasks for which PSTs are often ill prepared. These kinds of mathematical tasks of teaching (Ball et al., 2008), however, often receive scant attention in preservice mathematics coursework. Given what we know about the mathematics knowledge teachers need to be effective in the classroom (Hill, Rowan & Ball, 2005), mathematics content courses need to include opportunities for PSTs to develop mathematical knowledge for teaching.

Recent research has demonstrated that preservice coursework can provide opportunities for PSTs to develop their abilities to analyze children's thinking in ways needed for teaching. For example, in their experimental study involving PSTs in content courses, Philipp et al. (2007) argue that PSTs' content knowledge and beliefs about mathematics teaching practice can be enhanced if they have opportunities to learn about children's thinking while simultaneously learning mathematics needed for teaching. Assigning PSTs to four different treatment groups, the authors found that PSTs in the two treatment groups that involved the close study of children's mathematical thinking through the use of videos and interviews demonstrated more changes in their beliefs about mathematics teaching and learning as compared to the PSTs in the other treatment groups that involved more traditional field experiences. These findings are particularly important because they demonstrate that although PSTs may begin a content course with beliefs that stand in contrast to reform-oriented mathematics practice, content courses that connect content knowledge with the analysis of children's thinking can foster changes in PSTs' beliefs.

Project Background

Content Course

The content course in question is the first of two required content courses PSTs take during their freshman or sophomore years at the university, and precedes the mathematics methods course that PSTs typically take during their senior year. The content course is designed around developing PSTs' mathematical knowledge for teaching, and includes a focus on whole and rational numbers and operations, place value, proportional reasoning and aspects of number theory. The course also provides PSTs with opportunities to develop their abilities to engage in explaining, representing, and understanding and reacting to mathematical thinking that is different from their own.

Videocase Curriculum

As part of the Videocases for Preservice Elementary Mathematics (VPEM) Project, the authors developed 9 videocases and accompanying facilitator guides to be used in mathematics content courses for PSTs. These materials were designed to support the development of PSTs' understanding of the mathematical knowledge needed for teaching whole and rational number concepts and proportional reasoning by providing PSTs with opportunities to examine children's mathematical thinking in the context of actual classroom lessons. The videocases were implemented at regular intervals across the semester. Each videocase included a video clip(s) - focused on children's discussions of certain content and taken from actual classrooms - and a facilitator's guide - designed to support instructors in facilitating PSTs' discussion of the videocase, including focus questions. During the content course, PSTs first worked on the mathematics problems discussed in the video, and then viewed the videos through the lens of the focus questions. Table 1 below includes descriptions of the 9 videocases, including mathematical topic and mathematical tasks of teaching foci.

Videocase Title	Mathematics Topics	Mathematical Tasks of Teaching
Finding Patterns	Algebra	Evaluating the plausibility of children's claims Asking productive mathematical questions
Counting Strategies	Meaning of addition, subtraction; Addition, subtraction problem types	Evaluating children's mathematical explanations Asking productive mathematical questions
Understanding Place Value	Counting; Place value	Analyzing children's thinking
Modeling Double-Digit Subtraction	Subtraction algorithm	Linking representations to underlying mathematical ideas
Debating Remainders	Division; Remainder interpretation	Evaluating children's mathematical arguments Asking productive mathematical questions
Student Errors with Multiplication & Division Algorithms	Place value; Standard, alternative multiplication & division algorithms	Analyzing children's errors
Pattern Block Fractions	Relationship between improper fractions and mixed numbers	Analyzing children's thinking Analyzing children's errors
Why is 1/20 not equal to 20%?	Relationship between percentages and decimals	Analyzing children's errors Linking representations to underlying mathematical ideas
Making Predictions Using Multiple Solution Strategies	Fractions; Liner functions	Evaluating children's mathematical explanations

Table 1. Videocase design overview

Methods

The authors employed a quasi-experimental design to the study of changes in PSTs' knowledge of, beliefs about, and ability to analyze children's mathematical thinking to understand the overall effectiveness of the videocase curriculum.

Participants

Participants were recruited from PSTs who enrolled in two sections of a required mathematics content course for PSTs at a large midwestern university during the Spring 2010 and Fall 2010 semesters. PSTs from the sections of the course taught by the first author served as the treatment group (i.e., videocases), while PSTs from the other section of the course served as the control group (i.e., no videocases). 22 PSTs were in the treatment group and 17 PSTs were in the control group during the Spring 2010 semester; 30 PSTs were in the treatment group and 24 PSTs were in the control group during the Fall 2010 semester.

For both semesters, in the treatment course, PSTs viewed the videocases, answered focus questions related to the videocases, engaged in small group and then whole group discussions of the focus questions, all facilitated by the instructor. For both semesters, in the control course, PSTs worked on tasks similar in content focus to the tasks in the videocases in lieu of watching the videocases. However, in the Fall 2010 semester, the implementation of the videocases was modified in order to improve the quality and duration of videocase discussions, and PSTs' responses to the focus questions. These changes included the following: 1) PSTs watched videocases from the course website as part of homework assignments; 2) focus questions were revised to be more succinct; 3) guidelines for responding to the focus questions and a rubric for evaluating responses were developed to scaffold PSTs' written responses to the focus questions; and 4) PSTs' written responses were graded using the rubric in order to provide feedback for improvement.

Measures

As the study focused on changes in PSTs' knowledge of, beliefs about, and ability to analyze children's mathematical thinking, we administered the following measures pre-post in both semesters. First, we used a mathematics content knowledge assessment instrument developed by the Learning Mathematics for Teaching Project. Items not only capture whether teachers can answer the problems they use with children, but also how teachers solve the special mathematical tasks that arise during teaching (e.g., given 3 different multiplication strategies, determine which method can be used to multiply any two numbers). Second, as teachers can have differing conceptions of mathematics and mathematics learning which may or may not align with ideas about teaching and learning underlying recent reform efforts, we administered the IMAP Beliefs survey that was specifically designed to capture the characteristics of beliefs most closely related to understanding children's mathematical thinking: beliefs about mathematics as a discipline, beliefs about learning and knowing mathematics, and beliefs about children's learning and doing mathematics. Finally, we administered a video activity developed by the authors designed to analyze PSTs' ability to analyze children's thinking as depicted in video format.

Results

Mathematics Content Knowledge Assessment

Identical content knowledge assessments were administered in the first and last weeks of classes in both the treatment and control courses. The authors conducted a one-sample T-test to examine the gains from pre- to post-course on the assessment. Table 2 shows the results of a one-sample T-test for each group.

Semester	Group	N	Mean	SD	T	Df	Sig. (2-tailed)	Cohen
Spring	Treatment	22	.60	.58	4.82	21	.000	1.03
2010	Control	15	.70	.67	4.07	14	.001	1.05
Fall	Treatment	28	.85	.70	6.38	27	.000	1.20
2010	Control	25	.91	.58	7.89	24	.000	1.58

Table 2. One-sample T-test on content assessment gain scores by group

These results indicate that for the treatment group in Spring 2010, for example, the equated average IRT change score or the gain score from pre- to post-test was 0.60 logits with SD = 0.67. A one-sample T-test indicates that PSTs' content knowledge increased significantly during this semester, $t(21) = 4.82$, $p < 0.05$, $d = 1.03$. As displayed in Table 2, both treatment and control groups in both semesters demonstrated significant development in their mathematical knowledge for teaching. An independent T-test was conducted to examine the differences between treatment and control groups for each semester. However, we found no significant difference between treatment and control groups. One reason for no difference between treatment and control groups may be that the overall content course design and materials used in both courses were well aligned with the goals of learning mathematical knowledge for teaching. Indeed, both instructors were members of a planning group around the two content courses who collaboratively plan and design the course (Castro Superfine, 2010), thus making the two courses almost identical with the exception of the videocases.

IMAP Beliefs Survey

Identical online IMAP belief surveys were assigned as homework assignments for the first and the last weeks of classes in both courses. All PST responses were collected with the exception of the pre-test IMAP survey from the control group in Spring 2010. All responses were double coded blind using the IMAP belief rubrics in Ambrose et al. (2004). The survey data were then analyzed using the methods reported in Philipp et al's. (2007) work. Table 3 shows the distribution of beliefs score changes for the treatment and control groups in Spring and Fall 2010 by belief. Table 4 shows the percentage of PSTs in the treatment and control groups that demonstrated large increases, small increases, or no increase in terms of changes in their average belief scores across the seven beliefs.

Group		Large Increase	Small Increase	No Change or Decrease
1. Mathematics is a web of interrelated concepts and procedures (and school mathematics should be too).				
Spring	Treatment (n=22)	32%	18%	50%
Fall	Treatment (n=30)	17%	37%	47%
	Control (n=24)	21%	29%	50%
2. One's knowledge of how to apply mathematical procedures does not necessarily go with understanding of the underlying concepts.				
Spring	Treatment (n=22)	0%	19%	81%
Fall	Treatment (n=30)	7%	7%	87%
	Control (n=24)	4%	21%	75%
3. Understanding mathematical concepts is more powerful and more generative than remembering mathematical procedures.				
Spring	Treatment (n=22)	18%	27%	54%
Fall	Treatment (n=30)	33%	20%	47%
	Control (n=24)	25%	29%	46%
4. If students learn mathematical concepts before they learn procedures, they are more likely to understand the procedures when they learn them. If they learn the procedures first, they are less likely ever to learn the concepts.				
Spring	Treatment (n=21)	27%	27%	46%
Fall	Treatment (n=30)	13%	23%	63%
	Control (n=24)	17%	21%	63%
5. Children can solve problems in novel ways before being taught ho to solve such problems. Children in primary grades generally understand more mathematics and have more flexible solution strategies than adults expected.				
Spring	Treatment (n=21)	14%	23%	64%
Fall	Treatment (n=30)	14%	31%	55%
	Control (n=24)	13%	13%	75%
6. The ways children think about mathematics are generally different from the ways adults would expect them to think about mathematics. For example, real-world contexts support children's initial thinking whereas symbols do not.				
Spring	Treatment (n=21)	18%	14%	68%
Fall	Treatment (n=30)	27%	17%	57%
	Control (n=24)	13%	38%	50%
7. During interactions related to the learning of mathematics, the teacher should allow the children to do as much of the thinking as possible.				
Spring	Treatment (n=21)	18%	14%	68%
Fall	Treatment (n=30)	37%	27%	37%
	Control (n=24)	17%	8%	75%

Table 3. Beliefs-score-change percentages by belief, group and score-change category

We found the following patterns from the distribution shown in Table 3. First, treatment groups, in both Spring and Fall 2010, had the greatest percentage of PSTs with large increases on every belief. Second, for Beliefs 2, 3, 6, and 7, the treatment group in Fall 2010 had a large percentage of PSTs with large increases as compared to the treatment group in Spring 2010. Finally, for Belief 7, there is a relatively large percentage (i.e., 63%) of PSTs with large and small increases in the Fall 2010 treatment group, compared to PSTs (i.e., 25%) in the control group for the same semester.

	Spring	Fall	
	Treatment	Treatment	Control
Large Increase	18%	21%	16%
Small Increase	20%	23%	23%
No Change or Decrease	62%	56%	62%
Ratio Large/No	29%	38%	26%

Table 4. Average percentages of PSTs in each beliefs change-score category (with ratio of percentage with large change to percentage with no change) by group

As Table 4 indicates, the treatment group in Fall 2010 had the largest ratio of large increase to no increase in the average belief scores. Taken together, the IMAP beliefs survey data seem to indicate that engagement with the videocases influence PSTs' beliefs about mathematics teaching and learning, and reflect findings from previous research (Philipp et al., 2007).

Video Activity

A video activity assessment based on a video clip from an actual classroom was designed to assess PSTs' ability to attend to and analyze children's mathematical thinking in video format. As part of the video activity, PSTs were asked to watch a video clip and then to respond, in writing, to prompts about children's thinking: (1) What do you notice about student's mathematical thinking in the video? (2) Identify the different strategies used by students in the video, and (3) How are students' strategies different? Identical pre- and post-video activities were administrated in the first and the last weeks of class in both courses. All responses were double coded blind using a rubric developed by the authors, and focused on differentiating between the level of sophistication of PSTs' analysis of children's thinking. Level 1 indicates a general statement about the strategies was given (e.g., the child used addition). Level 2 indicates that a response included a mathematical focus, but yet was not specific enough to explore the underlying concepts. Level 3 indicates that a response included a mathematical focus and specifically unpacked the mathematics in the different strategies. Level 4 indicates that, in addition to the criteria for Level 3, the response also included the use of critical words (e.g., repeated addition, repeated subtraction, evenly distributed). Codes of G, U, and B denote responses focused on general aspects of the video, children's understanding, or children's behavior, respectively.

		Fall				Spring			
		Treatment		Control		Treatment		Control	
		Pre	Post	Pre	Post	Pre	Post	Pre	Post
Question 1	3SS-1	11	7	16	6	9	7	10	8
	3SS-2	8	11	5	5	9	9	1	0
	3SS-3	5	5	2	2	2	3	0	1
	3SS-4	0	0	1	0	0	0	0	0
	3S-G	10	9	8	15	5	9	6	3
	3S-U	6	8	0	1	6	5	6	10
	3S-B	2	0	1	0	0	0	0	0
Question 2	6-1	0	1	0	0	1	1	0	0
	6-2	2	1	0	3	2	3	1	1
	6-3	6	5	5	3	2	6	7	7
	6-4	20	23	23	17	17	11	9	9
Question 3	7-1	4	3	3	5	3	8	5	5
	7-2	19	20	23	17	15	11	7	9
	7-3	5	7	2	1	4	3	4	2

Table 5. Frequencies of PSTs' video activity responses by question and by level

As Table 5 indicates, while there were small shifts from pre- to post-course on certain questions, overall there were minimal differences between the treatment and control groups for the three questions on the pre-post video activity.

Conclusion

A primary aim of this study is to explore the potential of a videocase curriculum for supporting PSTs' learning about children's mathematical thinking as part of a required mathematics content course. Overall, results of the study indicate that, besides differences on the pre-post belief survey, there were no marked differences between the treatment and control groups. In other words, use of the videocase curriculum seemed to have a minimal effect on PSTs' knowledge of and ability to analyze children's mathematical thinking, yet the videocases did have a moderate effect on PSTs' beliefs about mathematics teaching and learning. We posit that one reason for such results may be that the content courses in the study were collaboratively designed and implemented by a group of mathematics educators and mathematicians around the idea of developing PSTs' mathematical knowledge for teaching (see Castro Superfine, 2010). Thus, the treatment and control courses were essentially the same course using the same tasks, in-class activities, homework assignments, and exams, with the exception of the videocases. In this particular course context, one would not expect the videocases to have a significant effect. As the videocases did have an effect on PSTs' beliefs about mathematics teaching and learning, there seems to be some potential for effecting change. However, the collection of videocases needs to be implemented in different course contexts in order to fully test the potential of the videocase curriculum.

This multiple-case study explored the experiences of two groups of elementary prospective teachers (n=12) completing distinct mathematics content courses. Individual interviews revealed perspectives on knowing, learning, and teaching mathematics as experienced by the two groups; the quantitative findings indicated differences in mathematical beliefs. One group characterized mathematics as a record of knowledge, difficult to understand and lacking in relevance; learning occurred through rote memorization and via external expertise, with teaching typified as explaining. The other group portrayed mathematics as process-focused, internally constructed, and relevant; learning took place through a focus on children's thinking, with teaching characterized as guiding and questioning.

The context for this study was an elementary teacher preparation program that was evolving in response to university system mandates requiring more courses in mathematics content for elementary teachers. Specifically, programs had to include a particular 3-hour course in elementary mathematics during the sophomore year in addition to 9 hours of upper-division mathematics courses. Throughout this period, mathematics department faculty members developed and taught the required courses for elementary teachers in Number and Operations, Algebra, Geometry, and Statistics.

Many prospective teachers failed or withdrew from these courses and consequently had to defer student teaching. Over one 4-semester period (Fall 2004-Spring 2006), 24.8% of prospective teachers did not complete or pass one or more of these mathematics courses. In response to this troubling trend, an experimental group of prospective teachers enrolled as a cohort in a one-time sequence of four content courses having specific foci on the perspectives of the National Council of Teachers of Mathematics (NCTM, 2000) and the development of the *specialized content knowledge* (SCK) needed for teaching elementary mathematics. This experimental sequence is referred to here as the "alternative courses" and was taught by an instructor in the elementary education department (grades PreK-5). The other group of prospective teachers in this study participated in what is referred to here as the "traditional courses" taught by instructors in the mathematics department.

This study explored these two groups of teacher candidates' (n=12) perspectives on knowing, learning, and teaching mathematics in the context of these experiences, as well as their mathematical beliefs and affect. More specifically, this study used a multiple-case design that applied mixed methods to explore the following research questions: (1) What are the perspectives on knowing, teaching, and learning mathematics of two groups of elementary prospective teachers' in the context of distinct mathematics courses? and (2) What are the mathematical beliefs and affect of these prospective teachers?

Theoretical Perspectives and Related Research

Perspectives on Teacher Knowledge in Mathematics

A pressing concern for elementary teacher preparation programs is the development of adequate and appropriate mathematical content knowledge. The precise nature of this knowledge has prompted significant debate in the mathematics education community (Ball, Hill, & Bass, 2005; Hill, 2010; Rowland, Huckstep, & Thwaites, 2005). In recent years, researchers (Ball, Hill, & Bass, 2005; Ball, Thames, & Phelps, 2008; Hill 2010) have proposed a *specialized content knowledge* (SCK) described as "the mathematical knowledge 'entailed by teaching' - in other words, mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" (Ball et al., 2008, p. 399). Examples of SCK include teachers' abilities to: (a) analyze and interpret students' mathematical thinking and ideas, (b) use multiple representations of mathematical concepts, and (c) define terms in mathematically correct and accessible ways.

Teacher Beliefs and Affect

Prospective teachers come to the teaching profession with deep-rooted mathematical beliefs and affect formed during their seminal years as students in K-12 classrooms (Lortie, 1975); they resist changing these beliefs and affect as they move through teacher preparation programs (Phillip, 2007). Three teacher belief constructs are relevant to this study including: efficacy beliefs, pedagogical beliefs, and beliefs about the nature of mathematics. The first belief construct, teacher efficacy, has been defined as teachers' beliefs in their skills and abilities to teach mathematics effectively and influence student learning (Hoy, 2004). The second belief construct, pedagogical beliefs, includes teachers' beliefs related to how they should teach and how students should learn; these beliefs can be viewed as grounded in theories of learning. Lastly, beliefs about the nature of mathematics include what mathematics is as a subject or what it means to know and do mathematics, ranging from mathematics as unrelated facts, rules, and skills to mathematics as problem solving, fluid and expanding in nature (Handal, 2003; Wilkins, 2008).

Elementary Prospective Teachers' Experiences in Mathematics Content Courses

Studies of elementary prospective teachers' experiences in mathematics content courses have focused on efforts to align the curriculum and instructors' practices with current reform recommendations (Lubinski & Otto, 2004; Philipp et al., 2007; Royster, Harris, & Schoeps, 1999). Royster et al. found that elementary education majors showed the greatest positive changes in mathematical dispositions when compared to other majors upon completion of a mathematics course that had been revised for congruence with reform recommendations. In another study, Phillip et al. concluded that prospective teachers in a mathematics course studying children's mathematical thinking developed more sophisticated beliefs about mathematics and improved their mathematical content knowledge than prospective teachers who did not have children's thinking as a focus.

Studies have also examined college students' perceptions of effective mathematics teaching and learning (Harkness, D'Ambrosio, & Morrone, 2006; Powell-Mikle, 2003; Schulze & Tomal, 2006). For example, Powell-Mikle reported certain classroom characteristics that support student learning in mathematics: adequate instructor availability, clear instructor explanations, prevalent classroom discourse, and a caring classroom environment. Schulze and Tomal's sizeable study of 2,042 college students examined factors contributing to a "chilly" mathematics classroom climate, which include: difficulty level of course content, teaching style/personality of the professor, and personality styles of classmates.

Methodology

The design of this study included a descriptive, holistic multiple-case approach (Yin, 2003). A case study methodology was applied as it was "impossible to separate the phenomenon's variables from the context," (Merriam, 1998, p. 29) and two bounded units were investigated. The two cases, which were the units of study and analyses, were the distinct mathematics course experiences, and the purpose of the study was to provide a "thick description" (Merriam, 1998, p. 29) of each. Further, this rich description provided opportunities to compare and contrast across the two mathematics course experiences in the interpretation of the findings.

Within this multiple-case design, mixed methods were applied. More specifically, a "concurrent triangulation" (Creswell, Clark, Gutmann, & Hanson, 2003, p. 224) approach to mixed methods was used, with data collection occurring via individual interviews and surveys. In this present study, the concurrent triangulation approach implies: (a) quantitative and qualitative data were collected concurrently, (b) qualitative data were given priority, and (c) integration occurred in the interpretation phase.

Participants and Setting

The participants were 12 randomly selected prospective teachers enrolled in an elementary teacher preparation program at a large, urban university in the southeastern U.S. The gender of the participants included 11 females and 1 male. At the time of this study, the participants were in the student teaching semester of the program. The program was two years in duration and included three semesters of courses with concurrent two-day-per-week field placements, followed by a full semester of student teaching.

The participants had completed one mathematics methods course and the four required mathematics content courses for elementary teachers. The mathematics methods course was taken during the second semester of the program and taught by instructors in the elementary education department. The content courses were Number and Operations (lower level), Geometry, Algebra, and Statistics (all upper level). As an admittance requirement, all 12 of the prospective teachers completed the Number and Operations course prior to entering the teacher preparation program. The other content courses were completed at different times during the program but were finished prior to the student teaching semester.

Six of the prospective teachers experienced the "traditional courses" (see introduction) taught by various instructors in the mathematics department, and six prospective teachers experienced the "alternative courses" taught by an instructor from the elementary education department. The nature of the course experiences is best viewed from the responses of the participants who experienced the courses firsthand; however, a syllabi analysis revealed that in general the two sets of courses focused on the same mathematics content with considerable differences in the nature of this knowledge as well as the ways in which this content was taught and learned. One major difference in these approaches was that the alternative courses included a significant amount of time studying children's development of mathematical thinking, problem solving, and understanding, whereas the traditional courses focused primarily on memorization of formal definitions and proficiency with standard algorithms.

Instruments and Data Collection

This mixed methods study included qualitative data collected via individual interviews and quantitative data collected via two belief surveys. Data collection occurred during the student teaching semester of the teacher preparation program.

The interview protocol included six multi-part questions such as: (a) What are your overall impressions of the math courses? What was easy and hard? What did you like and dislike? (b) After taking the math courses, do you feel confident that your content knowledge is sufficient to understand PreK-5 math? Why or why not? and (c) After taking the math courses, do you feel prepared to analyze children's math strategies in grades PreK-5? Why or why not? The semi-structured interviews were conducted at the convenience of the prospective teachers at the researchers' offices or the student teaching schools.

Two belief surveys were completed by the prospective teachers on campus: the Mathematics Beliefs Instrument (MBI) and the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI). The MBI is a 48-item Likert scale instrument designed to assess teachers' beliefs about the teaching and learning of mathematics and the degree to which these beliefs are cognitively aligned (Peterson, Fennema, Carpenter, & Loef, 1989, as modified by the Cognitively Guided Instruction Project). The three subscales include: (b) role of the learner (Learner), (b) relationship between skills and understanding (Curriculum), and (c) role of the teacher (Teacher). The Learner subscale contains 15 items that assess the degree to which teachers believe that children can construct their own mathematical knowledge. The 16-item Curriculum subscale examines the degree to which teachers believe that mathematics skills should be taught in relation to understanding and problem solving. The 17 items on the Teacher subscale address the extent to which teachers believe that mathematics instruction should be organized to facilitate children's construction of knowledge. The instrument uses a Likert scale with five response categories (strongly agree, agree, uncertain, disagree, and strongly disagree), with higher scores indicating beliefs that are more cognitively aligned. These subscales have high reliability (Chronbach's alpha =.89 for Learner, .80 for Curriculum, and .90 for Teacher) and represent independent constructs based on confirmatory factor analysis.

The MTEBI consists of 21 items, 13 on the Personal Mathematics Teaching Efficacy (PMTE) subscale and 8 on the Mathematics Teaching Outcome Expectancy (MTOE) subscale (Enochs, Smith, & Huinker, 2000). The two subscales are consistent with the two-dimensional aspect of teacher efficacy. The PMTE subscale addresses the prospective teachers' beliefs in their individual capabilities to be effective mathematics teachers. The MTOE subscale addresses the prospective teachers' beliefs that effective teaching of mathematics can bring about student learning regardless of external factors. The instrument uses a Likert scale with five response categories, with higher scores indicating greater teaching efficacy. Possible scores on the PMTE subscale range from 13 to 65; MTOE subscale scores range from 8 to 40. These subscales have high reliability (Chronbach's alpha = .88 for PMTE and .81 for MTOE) and represent independent constructs based on confirmatory analysis.

Data Analysis

This multiple-case design included analysis of the data within each case. Audiotapes of the interviews were transcribed and analysis of the data began by applying the *a priori* codes of knowing, learning, and teaching mathematics as experienced by the two groups of prospective teachers in the mathematics courses. Through this process an additional code emerged: beliefs and affect. Researchers used constant comparative methods (Lincoln & Guba, 1985) to generate more refined categories within these codes. Specifically, researchers individually analyzed the qualitative data through open coding, which generated numerous categories and subcategories that represented observed phenomenon found in the data (Strauss & Corbin, 1998). Researchers periodically met and discussed the subcategories to reach consensus on their meanings related to the categories. This recursive process of discussion and analysis of all interview data initiated development of a coding manual that was used in subsequent analyses. The researchers then engaged in data reduction by recoding data using the coding manual for guidance in comparing and refining categories. Coded categories were collapsed and renamed related to the themes of knowing, teaching, and learning mathematics, as well as beliefs and affect. Data from the belief surveys were considered at the case level by subscale and overall scale. The quantitative data were used for descriptive purposes.

Results

Quantitative Findings

Mean scores, including differences in mean scores, and standard deviations for the two groups of prospective teachers on the MBI and MTEBI (subscales and overall scale) are shown in Table 1. When comparing the two sets of scores, all subscale and overall mean scores have at least half-point differences in the Likert scale value. These findings suggest the prospective teachers in the alternative courses had stronger mathematics teaching efficacy beliefs and pedagogical beliefs that were more cognitively aligned. Two subscales, Teacher and Learner, evidenced the largest differences in mean scores, .77 and .76 respectively. It seems the prospective teachers in the alternative courses, more so than those in the traditional courses, believed that children can construct their own mathematical knowledge and that instruction in mathematics should be organized to facilitate this construction. Interesting, the subscale that revealed the next largest difference in mean score (.70) was the MTOE. When comparing the two groups of prospective teachers, those completing the alternative courses seem to have stronger beliefs that their teaching of mathematics positively influences student learning.

Table 1

Means and Standard Deviations for Mathematics Pedagogical and Teaching Efficacy Beliefs as Likert Scale Values

	Traditional Courses		Alternative Courses		Both Courses
Subscale and Overall Scores*	Means	Standard Deviations	Means	Standard Deviations	Differences in Mean Scores
Learner	3.70	.60	4.46	.49	.76
Curriculum	3.61	.55	4.15	.47	.54
Teacher	3.78	.49	4.55	.32	.77
Overall MBI	3.70	.50	4.39	.31	.69
PMTE	4.08	.23	4.68	.34	.60
MTOE	3.61	.28	4.31	.74	.70
Overall MTEBI	3.90	.13	4.54	.44	.64

*MBI = Mathematics Beliefs Instrument; PMTE = Personal Mathematics Teaching Efficacy; MTOE = Mathematics Teaching Outcome Expectancy; MTEBI = Mathematics Teaching Efficacy Beliefs Instrument.

Qualitative Findings

Traditional courses. The data analysis reveals the prospective teachers characterized the mathematics in the traditional courses as: procedural knowledge, lacking relevance, and difficult. More specifically, mathematics as procedural knowledge included descriptors such as "formulas," "step-by-step," "right and wrong," "abstract," "information," and "definitions," with little attention to processes in mathematics. Mathematics was typified as a *record of knowledge.* Further, the prospective teachers frequently spoke of the irrelevance of the mathematics, describing the mathematics as "high school" or "college" level, with little connection to the elementary classroom. Interestingly, before completing the courses, the prospective teachers believed they already had the mathematics knowledge needed for the elementary classroom; the courses did not challenge the prospective teachers' paradigm about the SCK needed for teaching elementary mathematics. Additionally, the prospective teachers described the difficulty of the mathematics in the courses, particularly as "hard" and "unattainable."

In considering the learning and teaching of mathematics in the context of the traditional courses, it is noteworthy there was little mention of the learning and teaching of mathematics for elementary students. Learning mathematics was characterized as: rote memorization, a process that occurs via experts, and "passing the course." The prospective teachers described their learning through rote memorization as "time-consuming, extensive practice," "note-taking", "homework," and "repetition and regurgitation." Further, this learning took place via receipt from external expert sources, and this expertise included the course instructors, tutors, textbooks, and class notes. Learning was also typified as "passing the course." The prospective teachers spoke of "passing the test" and "getting in and getting out."

The teaching of mathematics in the traditional courses was typified as explaining, and the prospective teachers experienced teaching as "lecturing," "showing," "step-by-step explanations," "Power Points," and "covering content." Further, teaching in the courses was characterized as teacher-centered and content-centered rather than attentive to the needs of the prospective teachers. The teaching was frequently described as "fast-paced," and instructor dispositions, such as differing levels of helpfulness, responsiveness, and availability, were a factor.

The prospective teachers' experiences with knowing, teaching, and learning mathematics were linked with their affective responses in the courses. They described emotional reactions to the courses, including "terrifying" and "frustrating." They also portrayed their experiences as having negative influences on their mathematics teaching efficacy (i.e., beliefs in their capabilities to be an effective mathematics teacher and influence student learning) and mathematics self-efficacy (i.e., beliefs in their capabilities to do mathematics).

Alternative courses. The analysis of the data indicates the prospective teachers portrayed mathematics in the alternative courses as process-focused, useful, challenging, and internally constructed. The process focus included an emphasis on "problem solving" and "understanding," which contributed to flexibility in their mathematical knowledge. The mathematics was also described as "useful" or "relevant," with explicit connections to the mathematics in the elementary classroom. Further, the mathematics was typified as "challenging;" it was a "struggle" for the prospective teachers to "unlearn" mathematics as being simply procedures. Mathematics in the courses was also portrayed as internally constructed (i.e., "in my head") rather than received from other external expert sources. Further, in describing the mathematics in the courses, the prospective teachers frequently contrasted it with the mathematics learned in other content courses.

The learning of mathematics in the courses was typified in several ways by the prospective teachers. They described learning as occurring through a community of learners, with an emphasis on discourse. Further, learning took place through mathematical processes such as "problem solving," which were portrayed as "engaging" and perceived as "okay to be wrong." Learning mathematics also took place through a focus on children's learning and thinking. The courses built the mathematical knowledge of the prospective teachers by studying how children think about mathematical concepts and ideas; this focus and course assignments led to learning as being perceived as directly applicable to the elementary classroom.

Teaching in the context of the alternative courses was typified by the prospective teachers as "guiding" and "questioning." The instructor promoted discourse, created a safe learning environment, and used tools (e.g., manipulatives) relevant to the elementary classroom. Interestingly, the prospective teachers described a "struggle" or tension in connecting what they were learning in the courses to their teaching in their field placement classrooms, which were often characterized as "traditional." Further, the dispositions of the instructor, such as "helpfulness" and "accessibility," were described as important to teaching in the course.

The prospective teachers' characterizations of knowing, learning, and teaching mathematics were linked with their affective responses in the courses. The prospective teachers described the courses as positively influencing their mathematics teaching efficacy and mathematics self-efficacy.

Concluding Thoughts

More than two decades have passed since Ball and Wilson (1990) challenged the assumptions that: (a) the development of elementary prospective teachers' mathematical content knowledge should occur within the context of traditional undergraduate mathematics courses, and (b) that content knowledge is the only professional knowledge necessary for teaching. These beliefs continue to be espoused by some policy makers and faculty members at institutions of higher education, who believe that prospective teachers need only take additional advanced mathematics courses to acquire content knowledge in mathematics, while disregarding SCK (Sowder, 2007). The prospective teachers' experiences related to knowing, learning, and teaching mathematics, as well as the differential outcomes in beliefs, suggest several benefits of alternative ways of thinking about elementary teacher preparation. Further, the findings provide insights into the issues and challenges of building the SCK needed for teaching elementary mathematics.

It is evident the prospective teachers in this study learned what they had the *opportunity to learn* (OTL) (Hiebert & Grouws, 2007), as revealed in their characterizations of knowing, learning, and teaching mathematics in the distinct course experiences. The Introduction to the original National Council of Teachers of Mathematics (NCTM) *Standards* (1989) states "*what* a student learns depends to a great degree on *how* he or she has learned it" (p. 5, italics in original). OTL is considered a complex process and product of both the curricular emphasis and the quality of instruction (Hiebert & Grouws, 2007). Teacher competencies developed in teacher preparation programs, including SCK needed for teaching mathematics, clearly depend upon how this knowledge is acquired.

STATICICAL PREPARATION OF TEACHERS: PRESERVICE ELEMENTARY TEACHERS (PSTS) CONCEPTIONS OF DISTRIBUTIONS OF DATA – THINKING ABOUT MEASURE OF CENTER AND VARIAIBLITY

Prior research investigating PSTs' statistical thinking is sparse, yet teacher educators need to know how best to prepare future teachers for their work and given the increasing importance of STEM education we need teachers who are capable of preparing students at an early age to think about data. In this paper we share the results from a study investigating pre-service teachers' (PSTs') initial thinking about distributions of data in four different contexts. In particular we investigated how PSTs reasoned about different distributions of data - including how they consider measures of center and measures of variability. Data was collected through surveys and interviews conducted prior to their beginning a statistical unit in their elementary teachers mathematics content course.

Without basic statistical literacy adults are unlikely to have the knowledge base to make informed personal decisions and, on a professional level, the door to many higher paying jobs closes. (Cobb & Moore, 1997; Garfield & Ben-Zvi, 2008).

Why Focus on PSTs' Conceptions?

Recent research on teacher knowledge has shown that the knowledge needed for teaching mathematics/statistics is complex and multifaceted (i.e. Hill, Ball, & Schilling, 2008; Ma, 1999; Shulman, 1986) and goes beyond content knowledge including such aspects as knowledge of how students think about the mathematical/statistical content. Hill, Ball, and Schilling (2008) introduced a framework for *mathematical knowledge for teaching* listing six different types of knowledge needed to teach mathematics, three in the realm of subject matter knowledge and three in the realm of pedagogical content knowledge (see Figure 1). In addition, teachers' mathematical knowledge for teaching has been empirically linked to instruction (Borko & et al., 1992; Fennema & Franke, 1992); and student achievement gains (Hill, Rowan, & Ball, 2005).

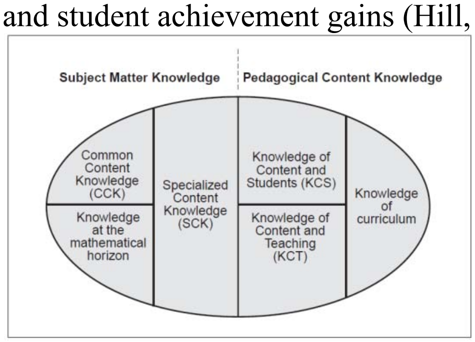

Figure 1: Domain map of mathematical knowledge for teaching (Hill et al., 2008).

New mathematical ideas are built on currently held conceptions. In order to help PSTs

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

develop such multifaceted knowledge of mathematics/statistics for teaching, teacher educators need to build on PSTs incoming conceptions. The conceptions we examine in this paper fall beyond common content knowledge (i.e. how to calculate the mean for example) and are situated in the realm of specialized content knowledge (i.e. knowledge of center and distribution specifically used for teaching). Mathematics teacher educators need to understand PSTs' initial conceptions when they enter our classrooms (Bransford, Brown, & Cocking, 1999) as these types of understandings underpin and inform the pedagogical decisions made when teaching.

Why Focus on PSTs' Conceptions of Statistics?

The importance of statistics for all citizens living in a democratic society is reflected by the Guidelines and Assessment in Statistics Education (GAISE) report (Franklin et al., 2007). GAISE highlights the important role of statistics education in preparing students to navigate our current society (reading newspapers, understanding political implications etc.). In particular, understanding distributions of data is a unifying theme in the study of statistics and one of the foci of the elementary math curriculum as laid out by NCTM and Common Core Standards (National Governors Association & Council of Chief State School Officers, 2010). Bakker and Gravemeijer (2004) suggest that distribution is an "organizing structure or conceptual entity" for looking at data (p. 149) and they argue that without a notion of distribution it is not possible to reasonably summarize a data set and make appropriate choices between different measures of center. While substantial efforts have been made to better understand students' statistical reasoning and how they think about distributions of data, there is a paucity of empirical research investigating teachers' statistical reasoning (Shaughnessy, 2007b). What little empirical research has been conducted (Groth & Bergner, 2006; Jaccobe, under review; Leavy & O'Loughlin, 2006) indicates that PSTs do not have the knowledge needed to teach statistics at the level endorsed by GAISE. It is not sufficient to know that teachers do not have adequate statistical knowledge for teaching statistics, teacher educators need to better understand teachers' statistical knowledge when they enter our classrooms so we can build on those conceptions when working with teachers.

In this study we examined PSTs' conceptions of distributions of data in four different contexts. In particular, we investigated: (a) how PSTs might compare two different distributions of data that had the same mean and median, but differed in variability; (b) the ways in which PSTs' construct a data set for a given mean (with a particular focus on the range of the data sets they created); (c) whether PSTs recognize the mean as an appropriate measure to compare two data sets of different size; and, (d) the ways in which PSTs' think about the median through a task that focuses on possible student interpretations of median. The results of this study provide a glimpse into U.S. PSTs' initial knowledge of distributions of data. We selected these particular tasks for two reasons. First, we wanted to build off the small body of prior research (see Leavy & O'Loughlin, 2006) and look for possible comparisons between U.S. PSTs and PSTs in Ireland. Second, the tasks used in this study align with Level A in the GAISE document and highlight components of statistical knowledge that PSTs need to be successful in their work. Thus, the strategies used by PSTs' when working on these tasks provides valuable insights into their specialized content knowledge; these insights inform the decisions that teacher educators make regarding the types of experiences we provide in our pedagogy of mathematics courses.

Methods

Twenty-seven PSTs enrolled in the 2nd of 3 mathematics-for-elementary-school-teachers courses completed a written survey followed by a brief interview. The survey items were drawn from various previous research studies (as cited below) to give an initial insight into PSTs' knowledge of distributions of data. We introduce the tasks in the results section. Data analysis was conducted by the first two authors and focused on the survey results. The authors independently categorized student responses to each item and then met to discuss the categories. Once common categories were established the data was coded using those common categories. Disagreements were resolved through discussion.

Results

What Measures Do PSTs Use When Comparing Distributions of Data?

To examine whether PSTs pay attention to distribution in a given data set we asked them to respond to the Movie Wait Time Task (Shaughnessy, 2007a). On this task PSTs are presented with a scenario involving the comparison of two distributions of data. In response to the task, 19 PSTs disagreed with Eddie, 4 PSTs agreed with Eddie; and 4 did not express agreement or disagreement. 25 of the PSTs mentioned the range or the variability of the wait times in their response. The 4 PSTs who agreed with Eddie agreed that the average is 10 but all 4 mentioned the variability in wait times. The two PSTs who did not mention variability performed calculations to find the mean. Thus at least in this task almost all PSTs recognized variability as a measure to take into account when comparing distributions of data.

Movie theaters show commercials along with previews before the movie begins. The *wait-time* for a movie is the difference between the ADVERTISED start time (like in the paper) and the ACTUAL start time for the movie. A class of 21 students investigated the wait-times at two popular movie theater chains: Maximum Movie Theaters and Royal Movie Theaters. Each student attended two movies, a different movie in each theater. The class's results are shown in the chart below. (Times were rounded to the nearest half-minute.) The students in the class found the median wait-time for both of the theaters to be 10 minutes. The students also calculated the mean wait-time for each theater to be 10 minutes.

Here's what Eddy, a 4th grader, concluded: There is no difference in wait-times for the theaters because they both were about 10 minutes.

Do you agree or disagree with Eddy? Explain all of your reasoning:

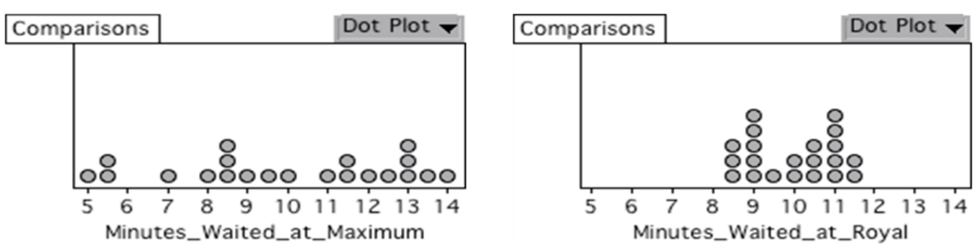

Figure 2: Movie Wait Time Task (Shaughnessy, 2007a)

Can PSTs Construct a Distribution of Data to Reflect a Given Mean? How Does Variability Factor in their Decisions?

To examine whether PSTs' can construct a distribution to reflect a given "average" the PSTs were asked to label prices on individual potato chip bags given that the average price is 27 cents. PSTs were asked to come up with a second labeling excluding 27 as a value (see Figure 3). In our analysis we focused on the PSTs' strategies and the range of the data set they provided.

Potato Chip Task A: The average price of a bag of chips is 27cents. We have seven bags of chips each of which has an empty price tag. Place prices on each of the bags so that the average price is 27 cents. □□□□□□□	*Potato Chip Task B:* The average price of a bag of chips is 27cents. We have seven bags of chips each of which has an empty price tag. Place prices on each of the bags so that the average price is 27 cents. *However, none of the bags of chips can cost 27 cents.* □□□□□□□

Figure 3: Potato Chip Tasks (see Leavy & O'Loughlin, 2006; Mokros & Russell, 1995)

For Part (A) of the Potato Chip Task our results showed that 14 PSTs (about 50% of the PSTs as opposed to 25% of PSTs in Leavy & O'Loughlin's study) put a 27 into each of the boxes on the first task (all listed results can be seen in Table 1). Seven PSTs (about 25% of the PSTs, similar to Leavy and O'Loughlin's study) started with 27 in the middle and then varied the numbers by +1/-1 as they moved outward resulting in the following prices: 24, 25, 26, 27, 28, 29, 30. Three PSTs used the mean algorithm, one selected numbers across a wide range summing to 189, two iteratively subtracted numbers from 189. One PST entered some 27s and then used balancing (i.e., adding and subtracting the same number from 27 in order to "balance" out to 27) to find the other prices in the data set. Two PSTs used what we call reasonable responses – using some type of reasoning that the bags combined have to be $1.89 the average price would have to be 27 thus the values would be *around* 27.

As expected, it seemed most PSTs understood the "average" as the "mean" rather than another measure of center. One PST used the mode in their reasoning for all 27s. Twenty-three PSTs chose numbers for the prices that stayed within a close range [24,30]. Four PSTs chose wide ranges for their data such as (100, 20, 20, 10, 10, 10, 19). These PSTs either gave no justification or used the mean algorithm (summing up to $1.89) as their explanation.

For Part (B) of the Potato Chip task all PSTs interpreted "average" as mean. Twenty-one PSTs gave values in between 20 and 35, while six PSTs gave wide ranges in value. Most PSTs used the mean algorithm some with guess and check, some with some basic balancing. Only four PSTs used a conceptual approach using balancing (pairs and one set of three) or a reasonable approach. Initially many of the responses in Part (A) looked like balancing approaches (i.e., balanced around the 27 like this response: 24, 25, 26, 27, 28, 29, 30), however, in Part B these PSTs seemed to focus more on the algorithm for finding mean. This indicated to us that just because their work "looks like" a balance approach does not mean it is. In fact, PSTs may be drawing on procedural rather than conceptual knowledge and using the mean algorithm to find pairs that average to 27.

Table 1: PSTs' responses to the Potato Chip Tasks

Responses to Part (A)	Reasoning for Part (A)	Counts
All 27s	No Justification	9
	Mean Algorithm	6
	Mode	1
27 & Values close to 27 (e.g., 26, 26, 27, 27, 27, 28, 28)	No Justification	3
	Mean Algorithm	1
	Balance	1
24, 25, 26, 27, 28, 29, 30	No Justification	1
	Mean Algorithm	1
	Mean Algorithm & Basic Balance	3
	Balance	2
Wide Ranges (e.g., 100, 20, 20, 10, 10, 10, 19)	No Justification	1
	Mean Algorithm	3

Responses to part (B)	Reasoning to Part (B) & Interview follow-up	Counts*
Range 20-35	Mean Algorithm / Guess & Check	6
	Mean Algorithm	3
	Mean Algorithm & Basic Balance (few over/few under)	8
	Algorithm & Balancing (pairs or triples)	1
	Reasonable	2
	Balance	1
Wide Ranges	Mean Algorithm	3
	Mean Algorithm / Guess & Check	3

Responses to Part (A)	Reasoning for Part (A)	Counts	Reasoning Part (B)
24, 25, 26, 27, 28, 29, 30	No Justification	1	Balance
	Mean Algorithm	1	Mean Algorithm
	Mean Algorithm & Basic Balance	3	Mean Algorithm (2) Mean Algorithm /Guess and check (1)
	Balance	2	Algorithm

All of the wide range responses appeared to use only the mean algorithm in order to justify their solutions – no evidence of average as balance or reasonable. Those PSTs who displayed balance type reasoning did so via general sense (some over, some under) or pair-balance. Only one PST displayed explicit knowledge of balancing three values; we argue that this may be an important first step in developing a more conceptual understanding of mean as point of balance.

Combining the results of the Movie Wait Time Task and the Potato Chip Task it seems that PSTs can recognize variability in the data but when asked to create a set of data may stay close to the mean value. Although our sample size is small and we only have evidence of this from two tasks, this finding is consistent with work done by Rubin, Bruce and Tenney (1991) with middle and high school students who seemed to recognize variability in some data contexts, but not in others. In particular, it seems that in tasks where students are asked to provide the data they may gravitate toward the expected value and not consider variability in the data; yet, in other contexts where students see different sets of data they may be more likely to focus on variability within the data or between data sets. However context is always an important consideration when dealing with data. In this case the actual context of the potato chip task (i.e. pricing bags of chips) may impact the variability of the distributions constructed by PSTs. Even though PSTs may recognize the 'possible/theoretical' variability in the distribution of prices, the context may limit the variability of the values they choose to represent the distribution of data. This raises an interesting issue for further research, would PSTs construct data sets with a wider variability if the context was not restrictive?

Do PSTs Recognize the Mean as a Way to Compare to Data Sets of Different Size?

A third task (see Figure 4) was given to examine whether PSTs would recognize the mean as a suitable measure to compare the data sets (Leavy & O'Loughlin, 2006). This recognition of the mean as a comparison measure falls into the realm of specialized content knowledge (SCK) and is an important component of the knowledge needed for teaching.

Basketball Task: Coach Andrews is selecting students to play on the All Star Team. He has decided to look at the scoring of each player during the last three weeks of the season. Below are the points scored by Bob and Deon. If Coach Andres can only select one of the two players, who would you recommend and why? [Note: The coach has not received scores for Deon's last two games played]

Bob	**21**	**16**	**23**	**21**	**20**	**17**	**16**	**22**
Deon	**24**	**18**	**21**	**25**	**22**	**28**		

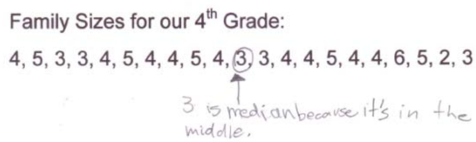
Figure 4: Basketball Task (developed by McGatha et al., 2002 and also used by Leavy & O'Loughlin, 2006)

In this task 15 PSTs (a little more than half of the PSTs in the US vs. 70% of the PSTs in Ireland) recognized the mean as an appropriate measure to compare scores. Thirteen PSTs compared group means while 2 PSTs made equal sized groups (putting in 0s or 23s for Deon's last scores – 23 is the average of Deon's first 6 scores). Eleven PSTs compared the scores without comparing the means. Seven PSTs compared pairs of games, one PST, for example, stated: "I would choose Deon because he has done better than Bob 5 out of the 6 games. Deon's avg. is higher than Bobs." One PST compared total points scored thus far as well as the differences in the first 6 games, one PST looked at consistently scoring above 18, one PST gave no response, and two PSTs wanted to await the last two scores before making a decision. This task illuminates that only about half of the PSTs recognized the appropriateness of the mean to compare data sets of different sizes.

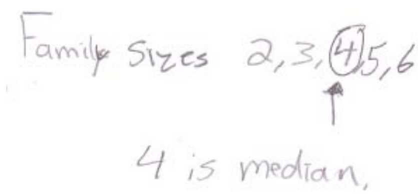
How Do PSTs' Think about the Median in Response to Children's Incorrect Interpretation of the Median?

A fourth task was constructed to examine whether PSTs would recognize children's misconceptions when responding to a task about the median (see Figure 5).

Family Size Problem: In a 4th grade class the students collected data on their family sizes (how many people are in their immediate family). The teacher put the data on the board and asked the students to find the median of the data. The students copied down the numbers and wrote their answers (See Figures 3a and 3b for Anna and Lisa's solutions). Please write a reaction to each of the solutions. In your reaction please include (a) whether you think the answer is correct/incorrect, and (b) what you might do next with that child if you were the teacher.



Anna's solution to identifying the median in the family size problem.



Lisa's solution to identifying the median in the family size problem

Figure 5: Two children's solution to a Family Size Problem**.**

The problem was designed to highlight two potential conceptual difficulties students may have understanding the median, the order of the data and the number of times each data point appears. Thus, the task was designed so that one student chose the middle number of the unordered data set, another the middle number of the various family sizes. The first of these solutions results in an incorrect answer the second in a correct answer, but based on an incorrect argument. Agreement with Anna's solution indicates a conception of median that may not include the notion of the importance of ordered data. Agreement with Lisa's solution, indicates that the frequencies of each family size do not matter. At Level A of the GAISE document students "should understand that the median describes the center of a numerical set in terms of how many data points are above it and below it" (p. 29). All but one PST identified the misconception in Anna's solution (i.e. that the data set needs to be ordered), however only 15 of 27 PSTs recognized that Lisa's argument was incorrect (see Table 2). This may be due to the fact that it resulted in the correct answer or due to the fact that the PSTs did not pay attention to the fact that each data point needs to be accounted for when calculating the median. One PST argued that Lisa's solution is correct because "each number only needs to be represented once to find the median" and another that Ana's is incorrect "Anna is … confused what the middle is in this situation… she should be considering the range of the numbers given (2-6) not the order in which they were written." Thus while most of the PSTs recognized that order mattered when all the data was presented about 44% of the PSTs did not recognize the need for all data points when they were not presented in the solution.

Table 2: PSTs responses to Family Size Problem:

	Identified misconception	Did not identify misconception
Anna's solution	26	1
Lisa's solution	15	12

Conclusions

The PSTs responses to these four tasks give a glimpse into U.S. PSTs' initial thinking about distributions of data. All PSTs, except one, displayed knowledge of the mean algorithm (Potato Chip Task), however, it can often be difficult to decipher procedural averaging of pairs from conceptual averaging through balancing (Potato Chip Task). What may look like balancing may be grounded in the algorithm. All but one of the PSTs interpreted average as "mean" – this is not surprising as the terms are often used interchangeably and PSTs often encounter the notion of average referring to all three measures of center for the first time in their mathematics/statistics for preservice teachers course. When given tasks like comparing two data sets of unequal size (Basketball task) only about half the PSTs recognized the mean as an appropriate measure of center and when confronted with a child's solution to the Family Size Problem about half the PSTs did not recognize the need for all data points to calculate the median. This shows that these PSTs conceptions of mean and median need to be further developed to be at the level recommended in GAISE. When we relate these findings back to the knowledge needed to teach mathematics, we can conclude that most PSTs possess common content knowledge (CCK) of the measures that index distribution, however performance on the tasks reveal problems with specialized content knowledge (SCK) of center and variability and understandings that extend beyond the ability to carry out procedures and manipulation of quantities. It is this specialized content knowledge of statistics that supports thinking and reasoning about distributions and that underpins the instructional decisions PSTs may make in classrooms when providing explanations for procedures, when selecting tasks and in recognizing sources of students errors.

PSTs seem to recognize variability in the data when presented with a a (Movie Wait Time Task) or already constructed data sets, but seem to provide responses close to the mean value when asked to construct data from a given mean (Potato Chip Task). Given that distributional reasoning entails the ability to simultaneously consider measures of center and measures of variability in data, more work needs to be done to understand how PSTs consider distributions of data and how they coordinate measures of center and variability when reasoning about data. Furthermore, we cannot ignore the potential influence of context on the decisions PSTs make when choosing values to represent a distribution of data. This area needs to be explored in future research.

To help PSTs develop their ability to reason coherently about distributions of data, we may need to explicate the relationship between the various measures of center and the data points from which they are created, as well as the role variability plays in statistics. In particular to help PSTs develop a conceptual understanding of the mean we may need to begin with balancing two numbers (pair) or fair share, then move to balancing 3 numbers or fair share among three, and then move to balancing more numbers or fair share. In addition we need to focus PSTs' attention to the range of values in a data set. The fact that one mean can originate from many different data sets is something that PSTs need to come to understand and they must begin to negotiate how context may play a role in the type of variability they expect to see in data.

ELEMENTARY PRESERVICE TEACHERS' CRITIQUES, COMPARISONS, AND PREFERENCES IN EXAMINING STANDARDS-BASED CURRICULAR MATERIALS

Andrew M. Tyminski

cdrake@iastate.edu

Shulman's (1986) curricular knowledge includes knowledge of the variety of curricular materials and the ability to evaluate, compare and justify curricular choices. To meet this need we have engaged our pre-service teachers (PSTs) in a comparison activity of two Standards-based lessons. We present PSTs' perceptions of the affordances and constraints within each lesson, interpret these results and present implications for further research.

Because *Standards*-based curriculum materials are becoming ubiquitous in schools (Archer, 2005; Remillard, 2005), there is a need for teacher education programs to prepare PSTs to be able to perceive the intended meaning of, mobilize the potential of, and continually develop their pedagogy through curricular resources. Our overarching research concerns the design of research-based activities for the elementary mathematics methods course that will allow pre-service teachers (PSTs) to learn about- and from- *Standards*-based curricular materials. We posit these types of activities can enable PSTs to move along a trajectory towards expert curriculum use. Our conceptualization of expert curriculum use can be associated with Taylor's (2010) notion of the "curriculum-proof teacher"; a teacher "who can use any given curriculum in highly-effective ways" (p. 152). This paper presents our findings related to PSTs' critiques and perceptions of two *Standards*-based lessons.

Theoretical Frame

Framing our examination of PSTs' perceptions and preferences in working with materials from *Everyday Mathematics* and *Investigations* is the research around teacher learning about and from curriculum materials and PSTs' capacities to evaluate curriculum materials. We also considered research that provides some insight into the relationship between teacher capacity, curricular use, and instruction involving *Standards*-based curriculum materials.

Learning about and from Curriculum Materials

To frame our use of curricular materials and to inform our examination of what PSTs learn about and from *Standards*-based curricular materials, we employ Shulman's (1986) construct of curricular knowledge:

> The curriculum is represented by the full range of programs designed for the teaching of particular subjects and topics at, a given level, the variety of instructional materials available in relation to those programs, and the set of characteristics that serve as both the indications and contraindications for the use of particular curriculum or program materials in particular circumstances. (p. 10)

The learning activity reported on in this study addresses PSTs' curricular knowledge by introducing examples of available materials and asking PSTs to evaluate, compare, consider and justify a curricular choice.

Several studies have examined how teachers use *Standards*-based curriculum materials and the impact those materials have had on teacher learning (e.g. Collopy, 2003; Nicol & Crespo, 2006; Remillard & Bryans, 2004). Some of those studies (e.g. Collopy, 2003; Remillard &

Bryans, 2004) have shown that external resources (e.g., curriculum materials, professional development) that have prompted some teachers to use and learn from curriculum materials in reform-oriented ways do not prompt *all* teachers with those same resources to learn or teach in similar ways. For example, Collopy (2003) reported the stark contrast between two teachers in their learning from the use of the same curriculum series with the same professional development opportunities. One teacher (Ms. Ross) developed a new teaching practice by using the materials as her primary source of professional development. Ms. Clark, however, did not change her practice and continued to emphasize memorization and the use of standard algorithms. Collopy (2003) contends that the two teachers differed in their "opportunities to learn" because of the ways in which they read and enacted the curriculum along with how they used the materials when collaborating with colleagues. We posit Collopy's (2003) findings on how teachers read curriculum may allow us to explain the PSTs' critiques and perceptions of the two lessons.

PSTs' Capacity to Evaluate Curriculum Materials

Studies in science and mathematics education (e.g. Beyer & Davis, 2009; Davis, 2006; Lloyd & Behm, 2005, and Nicol& Crepo, 2006) have found that 1) PSTs need continuous supports available in order to evaluate curriculum materials in reform-oriented ways, and that 2) PSTs can misinterpret lessons when they look for aspects of lessons that are familiar to them. In one study, PSTs were asked to complete three science lesson plan analyses using a narrative that provided a description and rationale for an important "principle of practice" (Beyer & Davis, 2009, p. 6). The majority of PSTs used the educative support in their analysis and made adaptations that better supported key principles in science teaching, but did not make similar analyses and adaptations when the support was not available (Beyer & Davis, 2009). Lloyd & Behm (2005) investigated the ways in which PSTs compared and contrasted two textbook lessons (one traditional and one reform-oriented). The researchers found that PSTs looked for aspects of the lessons that were familiar to them. Thus, the lessons they preferred were more traditional. Furthermore, the researchers concluded that PSTs' fondness for traditional lessons led the PSTs to misinterpret those lessons.

Capacity and Mobilization of Standards-based Curriculum

Stein and Kaufman (2010) investigated how teacher capacity and teachers' mobilizations of curriculum materials influenced instruction. They found that teachers implementing *Investigations in Number, Data, and Space* (*Investigations*) had higher-quality lessons (measured by maintaining high levels of cognitive demand, attending to student thinking and vesting intellectual authority in mathematical reasoning) than those implementing *Everyday Mathematics* (*EM*). The researchers attribute this finding to that fact that *Investigations* (TERC, 2008) provided more support to teachers for "locating and understanding the big mathematical ideas within lessons compared to *Everyday Mathematics*" (Stein & Kaufman, 2010, p. 663). After examining levels of cognitive demand and supports for teachers in both series however, the researchers branded *Everyday Mathematics* as a low demand/low support curriculum and *Investigations* as high demand/high support.

Methods

The Developing Addition Strategies module asks PSTs to examine and engage in two addition lessons from *Standards*-based curricula. "Addition Starter Sentences" is a third grade lesson from *Investigations* (TERC, 2008) and "A Shopping Activity" is a second grade lesson from *EM* (USCMP, 2007). Both lessons are designed to provide opportunities for children to develop alternate addition strategies for multi-digit addition. Over the course of two 75-minute class sessions, the first author used the Developing Addition Strategies Module within two sections of an elementary mathematics methods course. He engaged PSTs in the examination of the curricular materials and also in completing the learning tasks from each lesson. The researchers had several goals for this module, including affording PSTs an opportunity to develop knowledge of alternative addition strategies as well as how children develop, make sense of, and use alternative addition strategies (Tyminski, et al., 2010). Another aim, and the focus of this paper, was to give PSTs an opportunity to critique and compare the two lessons, culminating with the PSTs choosing and defending their preference for one of the two lessons. In order to support PSTs in critically examining curricular materials, the first author had introduced, implemented and discussed constructs and tools for analyzing tasks earlier in the semester. These supports included activities involving: levels of cognitive demand (Schwan-Smith & Stein, 1998); availability of multiple access points; whether solution strategies are teacher/textbook- or student-generated; the degree to which lessons support teaching through problem solving; and whether/how lessons address the essential skills and content in state Standards. The comparison activity was posed as follows:

> First, describe, in a bulleted list the strengths and weaknesses of these two lessons as written. Be sure to comment on:
>
> - What you think students will know or understand by the end of the lesson
> - Cognitive demand of the tasks
> - Whether strategies are teacher/textbook-generated or student-generated
> - Whether the tasks include multiple access points for different students
> - Whether/how this lesson reflects teaching through problem-solving
> - Whether/how this lesson addresses essential skills/content in your state Standards
> - Your overall impression of the lesson's strengths and weaknesses
>
> Second, write a short paragraph (4-6 sentences) telling which lesson materials you would rather teach from, why you feel that way, and what goals you would have for your students in using this lesson. Please use evidence from the materials and/or from your own experiences to support your choice.

This paper focuses on the results of the final paragraph in which PSTs selected the lesson they would prefer to teach from and justified their choice based on their perceived strengths and weaknesses of the curricular materials. We collected responses from 45 PSTs at a large, Midwestern university during the spring semester of 2010.

Addition Starter Sentences (TERC, 2008) begins by asking children to decide which of the following "addition starter problems" is easier for them to solve and why: 100 + 200 = ______, 136 + 200 = ______, 136 + 4 = ______. Next, children are asked to choose a starter sentence to solve 136 + 227 and explain why that would be a good start. After children solve 136 + 227, they share their solution paths. Children then complete a worksheet with five more "sets" of tasks, three starter problems matched to a final problem. In the methods course, we enact the lesson as written with PSTs participating as students. We then ask PSTs to read the curriculum materials and discuss the educative features (Davis & Krajcik, 2005). One educative feature we focus on is the information about alternate addition strategies that align with the starter problems: breaking apart by place; adding one number in parts; and changing a number, then adjusting (TERC, 2008). We then ask PSTs to analyze ten examples of children's mathematical thinking for the problem 249 + 175. The PSTs are to make sense of the strategies, determine if the approaches are mathematically valid, and categorize them according to the three strategies. We finish the module with a discussion of how teachers can support students in using these three strategies (see Tyminski, et al., 2010).

A Shopping Activity (UCSMP, 2007) also allows opportunity for students to develop invented strategies for multi-digit addition. According to the curriculum materials, “The main objective of this lesson is to develop and practice strategies for mental addition of 2-digit numbers” (UCSMP, 2007, p. 254). The lesson begins with some mental math exercises and a contextual task designed for students to use the “count up” strategy for subtraction. The lesson then moves into an activity in which the teacher selects two items from a list of eight, to “purchase”. Each of the prices for the items is less than $50. The teacher selects two items, for example a telephone ($46) and a toaster ($29) and asks the children how they might find the total cost. In discussing the students’ solutions the lesson reads:

> You or the children might suggest the following strategies:
> **Strategy 1:** Start with the larger addend, 46. To add 29, note that there are 2 tens in 29. Count up by 10s. Then add 9. The total cost is $75.
> **Strategy 2:** Think of $10 bills and $1 bills. Add the $10 bills. Add the $1 bills. Add the tens and the ones.
> **Strategy 3:** 29 is 1 less than 30. Add 30 to 46. Then subtract 1 to make up for the extra 1.
> **Strategy 4:** 29 is 1 less than 30 and 46 is 4 less than 50. Add 30 and 50. Then subtract the extra 1 and the extra 4. (UCSMP, 2007, p.253)

The lesson asks the teacher to pose more examples and discuss students’ solutions. It explicitly tells teachers not to introduce a traditional pencil and paper algorithm for addition at this point. The students are then put into pairs to complete the next activity, “Playing Shopping”, which uses the same eight items and prices. One child is the clerk and the other child the customer. The customer selects two items randomly and finds the total amount of the two items using a “part-part-total diagram”, but without using a calculator. The clerk then checks the total amount using a calculator. The children then switch roles. The lesson concludes with children completing a handout of shopping problems similar to the lesson tasks. In a similar manner to the Starter Sentences Lesson, we engage the PSTs in the main learning tasks as if they were students in the elementary classroom, followed by a reading of the materials and a discussion of its educative features (Davis & Krajcik, 2005).

Both lessons afford students opportunity to develop alternative addition strategies. The three strategies in both curricula are research-based student approaches to these types of problems. What differentiates the two lessons for us is in the amount of support given to students and the teacher in this process. The starter sentences are presented as a potential first step in a solution path and suggest one of the three solution strategies. The students however choose how to use the starter sentence to complete the problem and there are a myriad of ways to apply the strategies, especially within the “change the numbers” approach. Further, the Starter Sentences teaching materials include supports for the teacher in terms of student strategies (“Often the numbers in a problem will suggest one strategy more than another; for example, students may be more likely to add on to the next hundred if one number is close to a multiple of 100, such as 199” (TERC, 2008, p. 92)); questioning (“How did the Starter Problem you chose help you know what to do next?” (p. 92)); and for observation (“Do students choose one of the starts to solve the final problem? Which one? Can they follow though with the solution and keep track of the steps?” (p. 92).

Although the solutions included within the *EM* lesson are descriptions of the three strategies in *Investigations* (Strategy 1 is “add one number in parts”, Strategy 2 is “break apart by place”, Strategy 3 and 4 involve "changing the numbers"), similar scaffolds are not found within the *EM* lesson, leaving it up to the student to decide how to begin the task. In terms of teacher supports, the inclusion of the phrase "You or the students might suggest the following strategies" (UCSMP, 2007, p. 253) concerned us as it implicitly suggests to the teacher that it is acceptable to directly teach or introduce the strategies. We also identified a lack of teacher support in helping students begin to engage with the tasks. *EM* does include some instructions for supporting Strategy 2 with physical models, ("Use play money to illustrate Strategy 2. Put four \$10 bills and six \$1 bills on one stack and two \$10 bills and nine \$1 bills in a second stack. Combine the bills as indicated" (p. 253). This scaffold is more of a demonstration than an approach to help students think about the strategies, but at least it offers some pedagogical support. The lack of suggestions for the other strategies leaves it on the shoulders of the teacher to develop scaffolds for students.

Data Analysis

From two methods course sections, we collected 45 responses. These were first sorted according to their final curricular preference. Next, each justification paragraph was analyzed independently at the two university sites through a process of open and emergent coding (Strauss & Corbin, 1998), using a framework of PSTs' perceived affordances and constraints as a lens. Through an inductive analysis process, a series of codes for four categories: student affordance, student constraint, teacher affordance, teacher constraint, emerged from the data. As codes emerged from the PSTs' perceptions of the strengths and weaknesses of the materials, they were shared across university sites and refined. There were 18 codes established for student affordance, 5 for student constraint, 5 for teacher affordance, and 3 for teacher constraint.

Results

Of the 45 responses, 30 PSTs stated their preference for the *Everyday Mathematics* materials, while 13 PSTs selected *Investigations*. One PST did not include a final paragraph, and the other suggested using parts of both lessons in her teaching. We present data from the 43 responses in this section, broken down by the viewpoint of the student and the teacher.

Student Affordances and Constraints

In justifying their choice of lesson, many PSTs commented on features pertaining to the interactions and opportunities students would have in learning from the materials. A vast majority of the PSTs who preferred "A Shopping Activity" justified their choice with examples of student affordances (SA) of the materials. Twenty-seven of the 30 PSTs included an SA in their justification, and many students (22 of 27) included more than one SA in their justification. In all, 70 comments were coded as SA-EM (student affordance within *EM*). Table 1 presents the affordances that appeared in at least 15% of the PSTs' responses (N=30). None of the 30 responses included text coded as a student constraint (SC-EM) of the *EM* lesson. Three PSTs focused on student constraints within *Investigations* (SC-IN) as opposed to the affordances of *EM*. One PST felt that the *Investigations* lesson lacked student autonomy; two others described the solution strategies as being teacher/textbook generated. One of the PSTs who selected *EM* nonetheless mentioned that the *Investigations* lesson afforded students opportunities to make connections.

The majority of PSTs who had a preference for *EM* viewed "A Shopping Activity" as a familiar context, hands-on, and fun. These responses seem to focus on the interest of the activity rather than the interesting mathematics. Other, less reported reasons for preferring *EM* focused more on the mathematics – opportunities for practice, student-generated solutions, multiple solution strategies, student autonomy, and learning from peers.

Of the 13 PSTs who selected “Addition Starter Sentences” from *Investigations*, 7 included student affordances in their justification. Across these seven responses, twenty-two comments were coded as SA-IN. Table 2 presents the affordances appearing in at least 2 of the PSTs’ responses (N=13). One of the 13 PSTs who selected the *Investigations* lesson cited the lack of contextual tasks as a weakness of the materials; we coded this as a student constraint of *Investigations* (SC-IN). Three of the 13 PSTs focused on the student constraints of *EM*, two on “lack of student autonomy”, the other on a perceived “lack of goal”. Comparatively, the reasons PSTs gave for preferring *Investigations* tended to focus more on the mathematics: student autonomy, student generated solutions, and multiple solution paths.

SA Code	#	%
Contextual tasks	12	40%
Hands on tasks	9	30%
Fun	8	27%
Opportunities for practice	7	23%
Student generated solutions	7	23%
Multiple solution strategies	6	20%
Student autonomy	5	17%
Learn from peers	5	17%

Table 1: PSTs’ Perceptions of Student Affordances in EM Lesson

SA Code	#	%
Student autonomy	7	54%
Student generated solutions	4	31%
Multiple student strategies	2	15%
Scaffolding	2	15%

Table 2: PSTs’ Perceptions of Student Affordances in Investigations Lesson

Teacher Affordances and Constraints

PSTs also commented on their analysis of the curricular materials from a teacher’s perspective. Of the 30 who preferred the *EM* lesson, 13 used justifications we coded as TA-EM (teacher affordance within *EM*), 5 of these included more than one affordance for a total of 18 comments: 8 PSTs cited the materials for including “differentiation”; 7 comments indicated “ease of use (implementation)”, 2 PSTs noticed “possible student solutions” included in the materials; and 1 viewed the materials as giving the “teacher control” of the lesson. Only 1 PST who selected the *EM* lesson included a comment coded as TC-EM (teacher constraint within *EM*), it was coded as “difficult to understand”. We take this comment to mean the PST had difficulty in making sense of the organization of the curricular materials. A total of three PSTs included commentary from a teaching perspective on the *Investigations* materials within their *EM* justification. One commented on the “ease of use” of the *Investigations* materials (TA-IN: teacher affordance within *Investigations*). Two PSTs’ comments were coded TC-IN (teacher constraint within *Investigations*): one was coded “difficult to understand”; the other was coded as “difficult to use (implement)”. We specifically differentiated between difficulties PSTs perceived in *reading* the materials and *using* the materials, although we posit the two ideas are strongly connected.

Seven of the 13 PSTs’ justifications that selected *Investigations* materials included comments coded as TA-IN (teacher affordance within *Investigations*); only 2 made more than one such comment in their paragraph. There were a total of 11 comments coded as teacher affordances: 7 indicated “ease of use”; 2 indicated the inclusion of “differentiation” for students; 1 PST cited the inclusion of “examples of teacher talk”; and 1 noticed “possible student solutions” included in the materials. Two PSTs indicated teacher constraints within the *Investigations* materials (TC-IN): 1 response was coded as “needs to be adapted”, the other as “difficult to use (implement)”. One PST, who commented on the ease of use of the *Investigations* lesson, also cited the *EM* lesson as “difficult to use” (TC-EM).

We were surprised by the marked difference in the number of comments coded as student affordance or constraint and the number of comments coded as teacher affordances or constraints. There were 99 comments that addressed the materials from a student point of view and 38 from a teaching point of view. One interpretation of these results is that PSTs were more attuned to the potential experience of learning from these materials, rather than teaching with the materials. The comments that were made however, provided interesting evidence of PSTs’ critiques of the lessons. The theme of differentiation was evident within many of the PSTs’ comments on both sets of curricular materials, demonstrating to us they were aware of the importance of addressing the needs of individual learners, and noticing the supports within the materials designed to aid teachers in doing so. What was interesting to us about these results is the assignment did not specifically ask them to comment on this facet of the lessons. Fourteen PST commented on the ease of use of the materials, 7 for *EM* and 7 for *Investigations*. This data raised a new question for us to consider as researchers, what was it specifically about the materials that PSTs were referring to when citing their ease of use?

Conclusions and Implications

We agree with Stein and Kaufman’s (2010) assessment that *Investigations* is stronger than *EM* in terms of cognitive demand, and in the amount and quality of teacher support. Yet, our PSTs overwhelmingly picked *EM* as the curricular materials they would rather teach from. Why was what was clear to us, not evident to the PSTs? We conclude with three possible explanations and implications for future research.

First, we agree with Collopy’s (2003) notion that the manner in which PSTs read the materials, with a viewpoint of a learner, may have caused them to miss out on some of the opportunities to learn *about* the curricular materials. We base this upon their comparative lack of attention to teacher affordances and supports; particularly lack of attention to supports within both curricular materials in terms of presenting possible student solutions. Our future research needs to specifically address how PSTs view teacher supports. Do PSTs believe they can learn from the curricular materials? Should we include a non-*Standards*-based example lesson in the comparison in order to help them notice when supports are not available?

A second explanation also pertains to PSTs’ tendency to evaluate the materials from a student’s point of view. By selecting the *EM* lesson and focusing on aspects of the lesson such as hands on materials, real world contexts and being “fun”, PSTs are trying to ensure that the *activity* involved in the lesson is interesting. From a teaching point of view, we would hope they would try to ensure that the *mathematics* involved in the lesson is interesting. Most PSTs perceive mathematics as a discipline of discrete facts and procedures to be memorized rather than a discipline of interconnected concepts (Thompson, 1992). In other words, mathematics is not meant to be interesting. To make mathematics interesting, the activity needs to be interesting. Thus, the “shopping activity” is preferred.

A third explanation is the PSTs were drawn to *EM* as a result of their teacher capacity. Teacher capacity, including a teacher’s education, experience, and mathematical knowledge is a measure of ability needed to implement curriculum (Stein & Kaufman, 2010). At the PSTs’ current stage of development (first semester seniors), it is fair to classify them as having comparably low teaching capacity in terms of education and experience. Although they did not clearly state this in their paragraphs, perhaps given their experience and knowledge, the PSTs perceived that *Investigations* could be difficult to teach from, leading them to prefer the lower demand in *EM*. Stein and Kaufman (2010) talked about this notion – some believe that "even among standards-based curricula, some are more difficult for teachers to implement than are others" (p. 664). Our PSTs, and others, are not noticing the supports provided in *Investigations* to help implement the high-demand tasks.

Finally, it is evident that through this activity, PSTs are learning about the curricular materials, developing curricular knowledge, and are able to use educative supports in their critique and analysis of *Standards*-based curricular materials. While many PSTs did not view the materials in the same manner an expert might, we are encouraged that with further experiences, PSTs will continue to develop in their ability to do so.

PROSPECTIVE ELEMENTARY TEACHERS DEVELOP IMPROVED NUMBER SENSE IN REASONING ABOUT FRACTION MAGNITUDE

Ian Whitacre

snickers@sciences.sdsu.edu

We report on results of a classroom teaching experiment in a mathematics content course for prospective elementary teachers. A local instruction theory for the development of number sense, which was previously applied to whole-number mental computation, was extended to inform instruction concerning reasoning about fraction magnitude. We found that students' reasoning in fraction comparison tasks improved in several ways. Their performance improved, they became more flexible in their reasoning, and they came to use less conventional and more sophisticated strategies. These changes parallel those that we previously saw around mental computation.

We report on results of the implementation of a local instruction theory (LIT) for number sense development in a mathematics content course for prospective elementary teachers. Our previous research showed that students involved in an earlier teaching experiment developed improved number sense, particularly in terms of flexible mental computation (Whitacre, 2007). The previous research was informed by a conjectured local instruction theory and informed the refinement and elaboration of that local instruction theory (Nickerson & Whitacre, 2010). In a recent iteration of the classroom teaching experiment (CTE), the local instruction theory was extended from the whole-number portion of the course to the rational-number portion. We found that interview participants' reasoning about fraction magnitude improved over the course of the semester. Their performance improved, they became more flexible in their reasoning, and they came to use less conventional and more sophisticated strategies. These changes parallel those that we previously saw around mental computation.

Background

This study represents the latest phase in an ongoing design research effort (Gravemeijer, 1999) concerning the number sense of prospective elementary teachers. Our previous research involved the design and elaboration of a local instruction theory for students' development of number sense with a focus on whole-number mental computation (Nickerson & Whitacre, 2010). In the recent CTE, the local instruction theory was applied to reasoning about fraction magnitude. Our research involves both documenting collective classroom activity and analyzing student learning. Our focus in this paper is on the analysis of interview data.

Previous Research

One area of focus in the number sense literature has been the computational strategies that students use. Good number sense is associated with flexibility, which is exhibited in the use of a variety of computational strategies. In mental computation, inflexibility often manifests in the use of the mental analogues of the standard paper-and-pencil algorithms. While the standard algorithms can be useful, skilled mental calculators tend to select a strategy for an operation based on the particular numbers at hand. Furthermore, the strategies that these individuals use often stray far from standard, as in reformulating computations or rounding and compensating (Carraher, Carraher, & Schlieman, 1987; Greeno, 1991; Hierdsfield & Cooper, 2002; 2004;

Hope & Sherrill, 1987; Markovits & Sowder, 1994; Reys, Rybolt, Bestgen, & Wyatt, 1982; Reys, Reys, Nohda, & Emori, 1995; Sowder, 1992; Yang, Reys, & Reys, 2009).

In order to teach mathematics effectively, elementary teachers need to understand elementary mathematics deeply (Ball, 1990). However, prospective and practicing elementary teachers often know the procedures of elementary mathematics, but do not understand the material conceptually (Ball, 1990; Ma, 1999). Studies of preservice elementary teachers have found that this population tends to exhibit poor number sense, even after having completed their required college mathematics courses (Tsao, 2005; Yang, 2007; Yang, Reys, & Reys, 2009). In light of these findings, we have focused on improving the number sense of prospective elementary teachers.

In 2005, we conducted a CTE in a mathematics course for prospective elementary teachers. In that study, we focused on mental computation as a microcosm of number sense. Thirteen students participated in pre/post interviews in which they were given story problems to be solved mentally. In addition to coding for the particular mental computation strategies that participants used, we coded these as belonging to more general categories of strategies. We used a scheme of Markovits and Sowder (1994) to categorize participants' strategies as *Standard*, *Transition*, *Nonstandard without Reformulation*, and *Nonstandard with Reformulation*. The essential criterion in this scheme is the extent to which the person's approach is tied to (or departs from) the standard algorithm for the operation. Nonstandard strategies are those that diverge substantially from the standard algorithms. The use of such strategies suggests an understanding of the operation that is not bound to any particular algorithm; these nonstandard strategies are associated with number sense (Markovits & Sowder, 1994; Yang, Reys, & Reys, 2009).

The Standard-to-Nonstandard framework revealed a rather dramatic shift in the strategies used by the 13 interview participants. Participants shifted from using the most standard to the least standard strategies, which suggests that their understanding of the operations moved from being bound to the standard algorithms to being unconstrained by these (Whitacre, 2007; Whitacre & Nickerson, 2006). These results were encouraging and led us to pursue further research concerning the number sense development of prospective elementary teachers.

Local Instruction Theory for Number Sense Development as Applied to Fraction Magnitude

The previous teaching experiment was reflexively related to the development of a local instruction theory. A *local instruction theory* (LIT) consists of "the description of, and rationale for, the envisioned learning route as it relates to a set of instructional activities for a specific topic" (Gravemeijer, 2004, p. 107). We have described elsewhere our local instruction theory for the development of number sense (Nickerson & Whitacre, 2010). Here, we briefly list the three major goals around which this LIT is organized: (1) Students capitalize on opportunities to use number-sensible strategies; (2) Students develop a repertoire of number-sensible strategies; (3) Students develop the ability to reason with models.

We sought to extend the LIT to the rational number domain, with a focus on reasoning about fraction magnitude. This area relates to mental computation in that a variety of strategies can be used, including traditional procedures, as well as nonstandard strategies. Behr, Wachsmuth, Post, and Lesh (1984) touted the importance of reasoning about fraction magnitude as a prerequisite to reasoning meaningfully about operations involving fractions. Fraction estimation and comparison tasks have been used in assessments of students' number sense (Hsu, Yang, & Li, 2001; Reys & Yang, 1998; Yang, 2007).

Our thinking concerning reasoning about fraction magnitude is informed by the framework of Smith (1995). Smith groups fraction comparison strategies into four categories, which he calls *perspectives*. These perspectives serve not only to categorize strategies but also to highlight commonalities in reasoning across groups of strategies. Strategies such as converting to a common denominator or converting to a decimal belong to the *Transform* perspective. They involve transforming one or both fractions in some way in order to facilitate the comparison. One can also compare fractions without performing any sort of transformation. One way to do this is to apply the *Parts* perspective, wherein the fractions are interpreted in terms of parts of a whole. This perspective alone is sufficient for relatively simple cases, such as comparing fractions that have the same numerator or same denominator.

The *Reference Point* perspective involves reasoning about fraction size on the basis of proximity to reference numbers, or *benchmarks* (Parker & Leinhardt, 1995). For example, using the *residual strategy* for comparing fractions, one compares the difference of each fraction from a common benchmark number, typically 1: To compare 7/8 and 6/7, we can notice that 7/8 is 1/8 away from 1, whereas 6/7 is 1/7 away from 1. Since 1/8 is less than 1/7, 7/8 is closer to 1, and therefore larger (Yang, 2007). (Smith refers to this as the *reference point* strategy, as do Behr, et al., 1984.) The *Components* perspective involves making comparisons within or between two fractions, as in coordinating multiplicative comparisons of numerators and denominators. For example, in order to compare 13/60 and 3/16, we can notice that 13 x 5 = 65 > 60, whereas 3 x 5 = 15 < 16. It follows that 13/60 is greater since its numerator-denominator ratio is less extreme.

In designing instruction, these perspectives informed our decisions relative to tasks, number choices, and anticipated student reasoning. We mapped out the envisioned learning routes described in our LIT in terms of the evolution of these perspectives and of particular strategies within each category.

Although Smith (1995) does not describe the perspectives or particular strategies belonging to his framework in a hierarchical way, we view the Reference Point and Components perspectives as generally more sophisticated categories of reasoning about fraction size. There is support for this in the literature. For example, Yang (2007) considers the residual strategy to be Number sense-based, as opposed to Rule-based. We posit that there is a general correspondence between Smith’s perspectives and the Standard-to-Nonstandard framework, described earlier. In particular, the Transform and Parts perspectives correspond more or less to the Standard and Transition categories of strategies, while the Reference Point and Components perspectives correspond to Nonstandard strategies (with or without reformulation). We do not intend by this a one-to-one mapping of categories, but a more general grouping into Standard (including Transition) and Nonstandard.

The general number sense literature, as well specific studies of researchers such as Yang (2007) and Newton (2008), suggested that prospective elementary teachers would come to the first course with limited number sense and would tend to apply standard algorithms for comparing fractions. Pilot interviews that we conducted with preservice elementary teachers who had completed their mathematics content courses confirmed this expectation. In our instructional sequence, we aimed for the more sophisticated strategies to eventually be used by students and established for the class by mathematical argumentation. In particular, we sought to engage students in reasoning about fraction size from Smith’s Reference Point and Components perspectives. Tasks were designed and sequenced so as to begin with students’ current ways of reasoning and to provide opportunities for reasoning about fraction size in new ways.

Instruction

Topics in the curriculum include quantitative reasoning, place value, meanings for operations, children’s thinking, standard and alternative algorithms, representations of rational numbers, and operations involving fractions. Our work in the CTE involved identifying in the curriculum particular opportunities to engage students in authentic mental computation and reasoning about fraction size, and to share and justify their strategies. Over time, a shared set of strategies was established via mathematical argumentation. These strategies were given agreed-upon names, and the class maintained a list of strategies with examples of each. Students came to the course with a Parts conception of fractions, and Parts reasoning served as a foundation upon which more sophisticated strategies came to be established. Students also engaged in activities involving placing fraction markers on a string representing a number line, and distance along the number line often featured prominently in students' arguments concerning fraction comparisons.

Methods

This study took place at a large, urban university in the Southwestern United States. The participants in the study were students enrolled in a first mathematics content course of a four-course sequence. There are multiple sections of the course, and a common final exam is used. The second author taught the section of the course in which data was collected.

Seven of the students participated in pre/post interviews concerning their rational number sense. The interview participants were female undergraduates. Participants were asked to evaluate the relative sizes of pairs of fractions, amongst other tasks. Nine pairs of fractions were presented, one at a time. The particular pairs of fractions that participants were asked to compare appear in Figure 1. The same pairs of fractions were used in both interviews. The fractions were presented visually, and participants were asked to read them aloud. Participants solved the tasks mentally and explained their reasoning verbally, as shown in Figure 2. Participants were not allowed to do any written work for this portion of the interviews.

Figure 1. Fraction comparison tasks

Figure 2. Maricela comparing 13/60 with 3/16 in her second interview

We modified the framework of Smith (1995) for use as a coding scheme in order to account for differences in student population, the particular set of tasks that we used, and the foci of our research. Certain strategies were removed from the scheme because they never occurred in our data set, and there were pairs of strategy codes that we collapsed into a single code. The refined scheme was used to code the pre/post data.

In addition to coding for strategies and perspectives, we coded responses as Valid or Invalid. This is a researcher's assessment of the mathematical validity of a participants' strategy. Fraction comparisons are multiple-choice tasks with only three options (one fraction is larger, the other fraction is larger, or the two are equal). As a result, it is not uncommon for students to give correct answers on the basis of invalid or unclear approaches. We were interested in identifying valid strategies that led to correct responses. Thus, we also coded responses for correctness. In analyzing the pre/post data, we focused on those responses that were Valid and Correct (VC). We also coded students' strategies as Standard or Nonstandard, as discussed earlier.

As an assessment of change in performance, we compared the number of VC responses pre and post for each student. To assess change in flexibility, we compared the number of distinct VC strategies used by each student pre and post. Finally, we compared the numbers of Standard and Nonstandard VC responses pre and post.

Results

A comparison of interview participants' pre/post responses reveals improved performance and increase flexibility. Furthermore, participants' reasoning shifted from predominantly employing Standard strategies to a more balanced range of Standard and Nonstandard strategies. We discuss the case of one particular participant in more detail.

For six of the seven interview participants, the numbers of VC responses increased from the first to the second interview. The mean VC score increased from 5.86 to 7.7 (of a total of 9 responses). The additional VC responses were often the result of new strategies used by the participants. The number of distinct VC strategies used also increased from the first to the second interview for six of the seven participants. The mean number of distinct strategies used increased from 4.86 to 7.57. Thus, the participants used VC strategies more often in the second interview, *and* they used a wider variety of VC strategies. These data appear in the tables below.

Student	**VC Pre**	**VC Post**
Angela	4	8
Brandy	4	7
Maricela	7	8
Nancy	8	9
Trina	7	8
Valerie	5	8
Zelda	6	6
Mean	*5.86*	*7.7*

Mean	*4.86*	*7.57*

Table 2. Numbers of Distinct Valid-Correct Strategies Pre and Post

Maricela's Transformation from Inflexible to Flexible

Maricela was particularly inflexible in her reasoning about fraction magnitude in the first interview. For seven of the nine comparisons, she attempted to solve by finding a common denominator. In some cases, this approach was manageable and led her to the correct answer. However, she also attempted this approach for comparisons for which it was extremely unwieldy, including to compare 35/832 and 37/834. Such conspicuous inflexibility suggests that her reasoning about fraction magnitude was bound to the standard algorithms for comparing fractions. Even though pencil and paper were unavailable to her, she entertained no alternative other than attempting to mentally compute and retain multiple multi-digit products.

In her second interview, Maricela used a different strategy for each of the nine comparison tasks, and eight of these were VC responses. In her first interview, she had compared 13/60 with 3/16 by converting to a common denominator. In her second interview, she compared these by comparing their distance from 1/4. We coded her primary strategy as *Distance Below* under the Reference Point perspective. She identified a benchmark fraction that would be useful for comparison. This required an initial estimation of the size of the fractions as being roughly close to that benchmark of 1/4. She then identified fractions equivalent to 1/4 but with denominators of 60 and 16, which facilitated her distance comparison by making it easy to find differences. She identified the distances from 1/4 as 2/60 and 1/16. She simplified 2/60 to a unit fraction, which then enabled her to compare the "gaps" of 1/16 and 1/30. She stated that 1/16 was the larger of these. She then correctly concluded that 13/60 was larger than 3/16 because it was closer to 1/4. The reasoning that Maricela displayed here contrasts starkly with her very procedural approach to this and other fraction comparison tasks in her first interview.

Shift from Standard to Nonstandard

Maricela's contrasting pre/post responses suggest a shift in perspectives. Her responses to eight of the nine comparison tasks in the first interview reflected a Transform perspective: She approached the tasks by attempting to apply a procedure for converting one or both fractions to an equivalent form in order to make the comparison. In her second interview, Maricela's responses reflected a range of perspectives. Four of her nine responses were coded as Parts, two as Reference Point, two as Components, and only one as Transform.

This shift in perspectives was also a trend across the interview participants. In the first interview, 30 of the 41 VC responses involved a Standard strategy, such as converting to a common denominator. In the second interview, there were 54 VC responses, and 30 of these involved Nonstandard strategies. (See Figure 3.) We note that the responses in the first interview were weighted largely toward Standard, which reflects a lack of flexibility. In the second interview, Nonstandard responses outnumbered Standard ones, but by a relatively small margin. We view this more balanced set of strategies used as a desirable picture. There is nothing wrong with the Standard strategies in principle. In fact, four of the nine comparison tasks that we used lend themselves well to Standard approaches. Thus, we would expect flexible, skilled individuals to use such approaches approximately as frequently as the interview participants did for the given set of tasks. In fact, exactly 24 of 54, or 4/9, of the VC responses were Standard.

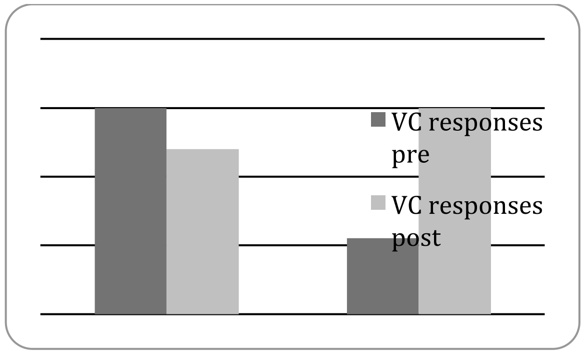

Figure 3. Shift from Standard to Nonstandard strategies

Figure 3 actually provides a concise summary of the interview results: We see the shift from Standard to Nonstandard, the increase in VC responses demonstrates improved performance, and the increase in Nonstandard VC responses coincides with improved flexibility.

Conclusion

We began this study with the idea of extending a local instruction theory for the development of number sense to the domain of rational numbers. Our focus shifted from whole-number mental computation to fraction comparison tasks. Smith's framework informed our thinking about strategies and perspectives involved in comparing fractions. The research literature, together with our pilot interviews, enabled us to anticipate prospective elementary teachers' initial reasoning about fraction magnitude. Our pre-instruction interviews enabled us to refine our expectations. We designed the instructional sequence in terms of students moving from the Transform and Parts perspectives toward the Reference Point and Components perspectives. Specific instructional activities were crafted with this envisioned learning route in mind.

Results from pre/post interviews with seven of the students show that the participants' performance and flexibility in comparing fractions improved, and that they shifted from using predominantly Standard strategies to a balance of both Standard and Nonstandard. These results provide evidence that the prospective elementary teachers developed improved rational number sense. The results also parallel those that we saw in a previous study in which the LIT was applied to mental computation. Taken together, these findings suggest to us that the LIT does serve its purpose in shaping instruction design in such a way that substantial number sense development occurs. The fact that these results have been achieved with prospective elementary teachers is especially significant since the literature tells us that this student population tends to have poor number sense, even after having completed their mathematics content courses.

Having found further evidence that the implementation of our local instruction theory supports number sense development, the current phase in our ongoing design research seeks to better understand *how* that development occurs by analyzing collective classroom activity.

A Mathematics course for elementary school teachers (MFET) is required in North America in most teacher education programs. Our study investigates the perceptions of prospective elementary school teachers with respect to the contributions of such a course to their teaching. The results show that acquiring an understanding of concepts from the elementary school curriculum is the main contribution. We conclude with two perspectives – a pessimistic one and an optimistic one – on this finding.

In many teacher education programs in North America a Mathematics course (or a sequence of Mathematics courses) for elementary teachers is either a requirement of, or a prerequisite for, entry to a teacher education program. Despite repeated calls for a "thorough rethinking of mathematics courses for prospective teachers of all grade levels" (CBMS, 2001, p.6), and an agreement about the need for integration of mathematics and pedagogy at the elementary level in order to develop profound knowledge of mathematics for teaching (Ball & Bass, 2000), in many programs there is still the traditional separation between the Mathematics-content courses and the Mathematics-methods courses for prospective elementary school teachers. This study investigates prospective teachers' views of the contributions, both actual and potential, of the Mathematics-content course, referred to as MFET – Mathematics for Elementary Teachers – to their teaching.

On Teachers' Knowledge

With the extensive emphasis on teacher education in recent mathematics education research, the primary foci have been on assessing the knowledge that teachers have and exploring what knowledge teachers should have (e.g. Hill, Sleep, Lewis & Ball, 2007; Davis & Simmt, 2006). Acknowledging that teachers' knowledge is multi-faceted, different attempt were made to categorize the components of such knowledge. Shulman's (1986) classical categories refer to subject matter knowledge (SMK), pedagogical content knowledge (PCK) and curricular knowledge. An extended categorization of teachers' knowledge was introduced by Deborah Ball and colleagues (Hill, Ball and Schilling, 2008). It was referred to as "mathematical knowledge for teaching" (MKT) and presented as an extension of Shulman's categorizations. The PCK refinement included Knowledge of Content and Students (KCS), Knowledge of Content and Teaching (KCT) and Knowledge of Curriculum. The SMK refinement contained the categories of Common Content Knowledge (CCK), Specialized Content Knowledge (SCK) and Knowledge at the Mathematical Horizon. As knowledge acquired in a Mathematics-content course is of interest in this study, we note that CCK was described as shared among individuals who use mathematics, while SCK was considered as the domain of teachers that allows them "to engage in particular teaching tasks" (ibid, p. 377).
In contrast to this categorization, Davis and Simmt (2006) argued against the traditional separation of content and pedagogy, and claimed that "mathematics-for-teaching" can be considered as a distinct branch of the discipline of mathematics. Extending the research of Davis and Simmt (2006) on what teachers need to know, Askew (2008) examined the research evidence for the mathematics discipline knowledge that primary teachers might need in order to

teach effectively. Askew suggested that attention of mathematics educators should be shifted from *what* mathematics primary teachers should know to *why* they should know this mathematics. He also supported the view that distinction between content knowledge and pedagogical content knowledge may no longer be helpful. However, despite the repeated claims against separation of content and pedagogy in teacher education and research, this long-established separation still exists within the coursework towards teachers' certification.

Our prior research investigated the perceptions of secondary school mathematics teachers on the use of their knowledge of 'advanced' mathematics – knowledge they acquired during their studies at colleges and universities – in their teaching practice (Zazkis & Leikin, 2010). The results varied significantly: some teachers claimed that they have never used what they learned in their university courses, while others claimed that they used it "all the time", but had difficulty in providing specific examples of this usage. The current focus on elementary school teachers, the mathematics they study in their University degrees and its perceived usefulness for teaching is a natural follow up.

Mathematics for Elementary Teachers (MFET) Course

While certification at the secondary level requires teachers to acquire a significant background in the subject matter, usually a degree or at least a minor, for elementary school teachers, as generalists, the mathematical subject matter requirements are limited. If such a requirement exists, it is usually for one or several mathematics-content courses designed specifically for this population.

A typical MFET course – and we infer what is 'typical' from a variety of textbooks with a similar tables of contents (e.g., Bassarear, 2007; Billstein, Libeskind & Lott, 2009; Musser, Burger & Paterson, 2006; Sowder, Sowder & Nickerson, 2010) and a variety of course outlines or course syllabi posted on the web – provides an overview of the underlying concepts of elementary mathematics. Typical topics include number systems and algorithms, patterns and introductory number theory, measurement and geometry, probability and data analysis. Different authors and publishers, in an attempt to satisfy the market, chose different perspectives on concepts and topics, such as problem solving, mathematical reasoning, the use of manipulatives, connection to the Standards, or the use of technology. The degree to which a certain perspective is implemented depends on the instructor's choice; however, the core topics remain the same.

The Study

Participants in this study were prospective elementary school teachers (PTs) enrolled in a one-year teacher certification program. All the PTs had some teaching experience in elementary school, having completed a 'practicum' of either 6 weeks or 5 months. All of the PTs had taken a MFET course, similar to a 'typical' course described above, as it is a required prerequisite in their teacher education program. However, they completed this course at various times, with various instructors and at various colleges or universities. As such, our study concerns the course, rather than its specific implementation.

Our study attempted to address the following question: How do prospective teachers describe the contribution of their MFET course to their teaching? Or, stated differently: What have prospective teachers learnt in their MFET course that they perceive as useful for their teaching?

Data Collection and Analysis

The data collection included a written response task and a clinical interview.

A written response task was administered to a group of 25 PTs. Initially, they were asked to provide examples of several teaching situations in which their mathematical knowledge from the MFET course could have been useful. The teaching situation could have been actual or imaginary. However, several students claimed that they "just knew things" and had difficulty identifying the source of their knowledge. Acknowledging this difficulty the task was modified. The task sought examples of usage, either actual or potential, of mathematical knowledge beyond the topic that was being taught.

The interviews were conducted with 14 PTs from a different group. The interviews initially attempted to solicit explicit examples of mathematical knowledge usage in teaching elementary school mathematics. However, the flexible structure of the interviews turned in part into a conversation about the MFET course and its contributions to teaching.

The data analysis was ongoing, using a qualitative approach based on grounded theory procedures and techniques (Strauss & Corbin, 1990). In the written responses that explicitly addressed mathematical knowledge from the MFET courses we identified the mathematical topic in each example and the setting in which the example was presented. We then identified several recurring themes in the provided responses. Then, in the analysis of the interviews we identified additional emerging themes. The themes that were identified in participants' responses serve as an organizing structure for the subsequent results and analysis.

Results and Analysis

To foreshadow our main observation, we start with an illustrative comment from Linda:

> *Linda*: I likely learned about […] in grade school. It was not until MFET course that I learned <u>the reasoning behind why this works</u> and fully <u>understood</u> […]. This was very helpful when teaching […] during my practicum.

Please note that we intentionally deleted the mathematical content that Linda mentioned, as similar comments were provided with respect to different topics and procedures. We return to the ideas of 'understanding' and "reasoning behind why this works" in our subsequent analysis. In what follows we attend to the recurring themes in the participants' responses as well as to their particular examples of knowledge usage.

Initial Hesitation

In the clinical interviews, among the initial 'warm-up' questions, the participants were asked about their MFET course. The questions were of general nature, such as, where did you take the course, how long ago was it, what did you think of it? A typical response is presented below.

> *Rita*: Actually when I enrolled in it I was so <u>freaked out</u> the first couple of days, because I'm so <u>terrified</u> of math that I was going to transfer out, but I really wanted my elementary school pre-req's. And so I was in the middle of transferring out and then I just really <u>started enjoying</u> it and I stuck with it and I ended up getting an A, so I was like, this wasn't so bad.

The words anxious, nervous, terrified, freaked out, intimidated, panicky and alike were common in participants' descriptions of their entry point to the course. However, many students reported a degree of confidence and satisfaction towards completing the course, as well as some joy and excitement. While a level of confidence with the mathematical content taught is essential for teaching, we were further interested in specific examples of what PTs believe they learned that were helpful for teaching.

Examples of Usage

In this section we summarize examples of usage from the written response task. The particular examples that were provided in the interviews appear further on, as illustrations of the recurring themes.

Out of 25 PTs who completed the written response task, 17 explicitly referred to the knowledge acquired in their MFET course, generating 42 examples of knowledge usage. Table 1 presents a distribution of the 42 examples by topics. Table 2 presents a distribution of the 42 examples by the intended usage.

Mathematical content	Number of examples
Computation (shortcut tricks, estimation, order of operations)	9
Elementary Number Theory (divisibility, prime numbers)	8
Fractions and Decimals	8
Geometry (area, perimeter, angles, π)	8
Algebra	5
Other (e.g., different bases, division by zero)	3
TOTAL	42

Table 1: Distribution of examples by topic

Method of usage	Number of examples
Evaluating correctness of a student's response	24
Helping a student, responding to a question	8
Creating examples/tasks/activities for students	5
Classroom management/grouping of students	5
TOTAL	42

Table 2: Distribution of examples by the intended usage

Computation

The most frequent category is that of computation, however the examples that we clustered there are very different. They include computational shortcuts and tricks, such as how to multiply a 2-digit number by 11, attending to compatible numbers by performing computation mentally while students learn algorithms, evaluating the potential correctness of a student's answer by estimation, and identifying a source of a student's error, such as disregard of the order of operations. In most cases the knowledge from MFET course was used in order to evaluate a response from a student by a method different from the one used by the student. Awareness and appreciation of different approaches is elaborated upon further in the analysis of the interviews.

Elementary Number Theory

As "Elementary Number Theory" we clustered examples that referred to divisibility rules, prime numbers and prime decomposition. Familiarity with divisibility rules served teachers in recognizing an error in a student's answer, such as when the difference of two odd numbers was not even, or when the sum of two numbers divisible by 9 was not divisible by 9. It further served when designing examples for student work, for example, when students are learning the long division algorithm, divisibility rules help the teacher to present students with exercises where division is without remainder, without carrying out the division. Moreover, some PTs reported that divisibility rules helped them when planning an activity that involved student work in small groups, that is, deciding on whether equal size groups were possible with a given student attendance.

Fractions and Decimals

Included in this category were examples related to introducing students to different models of representing fractions and equivalent fractions, to converting improper fractions to mixed numbers, comparing fractions and performing operations. These examples referred mostly to designing pedagogy for student understanding and, again, evaluating student answers, achieved by applying a standard procedure, by different means, such as comparing fractions by attending to units and not to a common denominator.

Geometry

Examples related to geometry mentioned the sum of the angles in a triangle and in a quadrilateral, the concepts of area and perimeter, and the meaning of π. Knowledge from the MFET course was helpful in assessing students' work, for example, when students measured all the angles of a quadrilateral and calculated their sum to 274 degrees, the teacher immediately recognized an error either in measurement or in addition. Examples in this category also referred to designing activities to introduce concepts. One such example replicated with elementary school students an activity previously experienced in the MFET course: It involved measuring the diameters and circumferences of different circular objects in order to introduce π as a ratio and not "as a strange appearance in some formulas".

Algebra

In this category PTs' examples mentioned their knowledge of solving equations in order to obtain the answer "quickly" and evaluating the work of students performed without algebraic means.

The repeating themes identified in the written responses of PTs were those of understanding and awareness of different ways to perform a mathematical task. We elaborate on these themes in further detail, and add other themes, as we turn now to the analysis of clinical interviews.

Understanding and Explaining

The most robust theme, which was mentioned in the written responses and which appeared in all of the interviews, was that of understanding. Only two participants mentioned that their MFET course helped with "revisiting" or "refreshing basic skills". The majority maintained that in their MFET course they understood mathematical ideas, in some cases for the first time, and this personal understanding was ultimately related to the ability to explain, that is, to teach. While Tanya (below) makes an explicit connection between understanding and teaching, Betty elaborates further, starting with a severe criticism of her elementary school experience and her desire to find out why certain rules exist.

> *Tanya*: I always struggled in math for myself and taking this course helped me <u>understand math better</u>. You definitely <u>need to understand</u> that to be able to teach that.

> *Betty*: She explained all of the things that we just were taught in elementary school as this is the way it is, like this is the rule. She'd explain why. I remember when I was a kid, I was like why? Why is this the rule? And then they'd be like, because it is. And I'm like well, OK, that doesn't help. So she explained why those rules were and I was just like, finally, I can understand it because it's true, if you understand why the rules exist your application of them will be more accurate but also you can figure out other rules. <u>You need to really understand why</u> the rules exist <u>in order for you to teach</u> this.

Once the connection between understanding and teaching was mentioned, the interviewer invited specific examples of concepts or ideas that were "really understood" or "understood better" as a result of the MFET course experience. The mathematical topics mentioned in the interviews echoed those from the written response task. These included measurement, algorithms, fractions, focusing on division of fractions, and multiplication tables. For limitations of space, we illustrate only the last topic in the following excerpt:

> *Lisa*: Multiplication tables – I thought that has to be a skill that's just memorization and drills and, actually, you can do a lot with understanding around that, like patterns and stuff.

Multiple Ways, Questions and Connections

Closely related to the theme of understanding is the theme of acquiring different ways to approach a mathematical task. Lisa makes this connection explicit, while Betty connects availability of different methods to understanding her students' thinking:

> *Lisa*: I have a deeper understanding for it and then I can see lots of different ways of doing it.
>
> *Betty*: I think that I've learned, and this is sort of intimidates me, is that I have to open my mind to understand how other people think […] to not underestimate the students and to try really hard to understand how they came up with, to say show me…

The connection here is obvious: personal awareness of multiple strategies is helpful in trying to understand students' strategies and approaches that may be different from the conventional ones (Leikin & Levav-Waynberg, 2009). Moreover, the ability to acknowledge different approaches in students' work was also connected to the ability to deal with students' questions.

> *Tanya*: I also think it helps when they have questions, you'll have other knowledge to draw from for questions they may have.
>
> *Betty*: I don't want to be the teacher who says that's the way it is. […] And I remember she told us why that works, I remember she did bring that up and I was like, oh, well that totally makes sense […] If they ask I'd like to be able to provide an answer, at least guide them in the direction of finding the answer, rather than just saying this is the way.

Note that Betty makes explicit reference to her Mathematics instructor, "she told us why that works", whereas she herself balances the ability "to provide an answer" with her pedagogical belief in the need to "guide them in the direction of finding the answer".

"Math today is different"

The idea that "Math today is different", that is, different from the mathematics they experienced as learners, was the second most prominent and unsolicited theme in the interviews, mentioned by nine participants. Several PTs mentioned that the course opened their minds, extended their horizons and influenced their views on what mathematics is about. This difference is contrasted with a description of prior experience, which is common among the participants.

> *Cara*: When I was going through math, it was just the numbers, not the problems.
>
> *Anne*: Math is completely different today. I asked my teacher, I don't understand this and he's like well can you do it, that's how I remember most of my math being, all I learned was equations and if you could do the equation, if you could use the equation then you didn't need to know anything else.

At first we considered the theme of mathematics being different, and the presented prior experiences of frustration, as not explicitly related to our research questions. However, on a second look, acknowledging and appreciating this difference – between mathematics of yesterday and that of today or tomorrow – can be considered as the main impact of a teacher education program in general and a MFET courses in particular. Participants implicitly or explicitly contrasted their experience of "doing" and being shown how to do, with the desired explanation and understanding, which was considered essential for teaching.

Discussion

Acquiring understanding is a declared purpose of the MFET courses. For example, Musser, Burger and Peterson (2006), authors of one of the popular textbooks for such a course, state explicitly in their introduction:

> "This book encourages prospective teachers to gain an understanding of the underlying concepts of elementary mathematics while maintaining an appropriate level of mathematical precision" (p. xi).

In the "Message to prospective and practicing teachers" on the first pages of their book, Sowder, Sowder and Nickerson (2010) mention different perspectives and contributions to teaching:

> "Some mathematics may be familiar to you, but you will explore it from new perspectives. […] Though the course is about mathematics rather than about methods of teaching mathematics, you will learn a great deal that will be helpful to you when you start teaching" (p. xiv).

As such, our findings suggest that the MFET course, or at least the offerings of the course that our participants were enrolled in at different times and at different places, achieved the set goal, at least from the perspective of participants in this study. However, this personal perspective of participants needs to be investigated further. It cannot be concluded from the participants' testimonies that they have indeed acquired a desirable level of what researchers referred to as PUFM - profound understanding of fundamental mathematics (Ma, 1999) or KDU – key developmental understanding (Simon, 2006), that is deemed as a prerequisite for MKT – mathematical knowledge for teaching (Silverman & Thompson, 2008). We further also note that the MFET course is only one step in the mathematics education of prospective teachers, and it is likely that ideas that developed in this course are reinforced and reexamined in courses that attend to "methods" of instruction, that is, to pedagogy and curriculum.

Taking a pessimistic view on our results, we note that the majority of participants entering a teacher education program for certification at the elementary level acknowledged that they did not sufficiently understand the concepts and procedures of elementary school mathematics. While this is consistent with prior research, our specific contribution, however, is in basing this finding on participants' testimonials related to their understanding (or lack of it) within particular concepts and topics of elementary school mathematics, rather than on researchers' observations.

Taking an optimistic perspective, we note that following a MFET course PTs reported that they "really understood it", whereas "it" referred to various concepts, such as place value or fractions, or algorithms, such as column addition or division by a fraction. However, what does it mean to "really understand" something? Betty summarized this as "knowing the reasons behind all the things that you teach the kids". Moreover, according to our participants, several related and further elaborated answers can be offered: For some PTs this means to know *why* and not only to know *how*, for others it means being able to provide an explanation to a student, and, furthermore, to be equipped with several different explanations. These views are in accord with the shift from *what* mathematics teachers should know to *why* they should know this mathematics, suggested by Askew (2008). The teachers' (partial) answer to "why" is the implementation of knowledge in teaching.

We mentioned above that self-report of acquired understanding does not necessarily mean that an appropriate level of understanding was achieved. Nevertheless, the personal acknowledgement of the importance of understanding and the ability to explain mathematics to students, rather than provide rules, is a valuable contributor to a teacher's comfort zone (Borba & Zulatto, 2010). Furthermore, the awareness that "math today is different", that is, that the desirable way of learning mathematics is different from the personal experience of participants, is an important step towards "teaching differently" or "teaching for understanding". We also suggest that the repeated reference to "different mathematics" may also signify a change in personal beliefs of what mathematics is about. That is to say, not that mathematics has changed, but rather the PTs' view of mathematics.

What can this imply for the teaching of mathematics? Anne's opinion is embedded in her question:

> *Anne*: And there were all those things that you learn that you're like, why didn't we just learn it like that from the beginning, because it would have helped me so much more.

In our optimistic perspective we would like to conclude with the hope that Anne's students will "learn it like that from the beginning".

Armando M. Martínez-Cruz
California State University, Fullerton
amartinez-cruz@exchange.fullerton.edu

This study investigates the extent to which pre-service elementary teachers (PETs) use their real-world knowledge to solve problems for which the result of the arithmetic operation is problematic, if one takes into consideration the reality of the context. A paper-and-pencil test was administered to 566 PETs enrolled in mathematics content courses. The test included 8 experimental items and 4 buffer items. The findings for a sample of 68 PETs are not very encouraging. The total number of realistic responses varied from 5 to 58 (out of 68 possible for each problem).

Word arithmetic word problems play an important role in learning mathematics at the elementary school level. There are several practical and theoretical reasons of the inclusion of arithmetic word problems in the elementary curriculum. First, they provide contexts in which students can use their mathematical knowledge so they can develop their problem-solving abilities, an important goal of learning mathematics. Second, word problems provide practice so students can develop their abilities to use their knowledge in real-life situations. Third, word problems serve as motivators so students can see the relevance of the procedures and algorithms learned in school. Fourth, word problems have the potential to provide students with rich contexts and realistic activities in which to ground mathematical concepts and, thus, facilitate the learning of more complex concepts. Finally, word problems provide students with experiences to learn how to use mathematical tools to model aspects of reality, that is, to describe, analyze, and predict the behavior of systems in the real world (Burkhardt, 1994; De Corte, Greer, & Verschaffel, 1996; Verschaffel, Greer, & De Corte, 2000; Verschaffel & De Corte, 1997).

Some critiques (e.g., Gerofsky, 1996; Lave, 1992; Nesher, 1980) argue, however, that the mathematics curriculum fails to achieve these lofty goals because traditional instructional tasks tend to focus on a straightforward application of procedures and computations to solve artificial problems unrelated to the real world. As a result, students tend to approach word problems, more often than desirable, in a superficial and mindless way with little, if any, disposition, to modeling and realistic interpretation. Several pieces of research provide empirical evidence to these claims

(Davis, 1989; De Corte & Verschaffel, 1989; Greer, 1993, 1997; Reusser, 1988; Reusser & Stebler, 1997; Schoenfeld, 1991; Silver, Shapiro, & Deutsch, 1993; Verschaffel, 1999; Verschaffel & De Corte, 1997; Verschaffel, De Corte, & Lasure, 1994).

Purpose of the Study

The purpose of the study was to examine prospective elementary teachers' (PETs) reactions and responses to problematic arithmetic word problems for which the solution is not the result of application of the most obvious arithmetic operation suggested by the two numbers given in the problem statement.

As suggested by the research literature, elementary school children tend to ignore the realistic constrains of the context embedded in the statement of the problem, a phenomenon that Schoenfeld (1991) coined "suspension of sense-making." Several critics and researchers argue that children' suspension of sense-making is the result of school practices (Davis, 1989; Greer, 1993; Nesher, 1980; Schoenfeld, 1991; Silver, Shapiro, & Deutsch, 1993). To develop children' disposition to realistic modeling, we must change curriculum and instructional tasks. Since the teacher has an important role in the construction or selection of learning tasks and opportunities, one may argue that researchers and curriculum developers need to understand teachers' reactions and responses to problematic problems.

Theoretical and Empirical Background

Mathematical modeling is the process of representing aspects of reality by mathematical means. In particular, the solution of some physical or real-world problems requires some form of mathematization. That is, the construction of a mathematical model. The complexity of the process of mathematization depends, of course, on the nature of the problem. There are several proposed models of representing reality by mathematical means (e.g., Silver, Shapiro, & Deutsch, 1993; Verschaffel, Greer, & De Corte, 2000), but Silver et al's model (Fig. 1) suffices for our purposes.

According to Silver, Shapiro, and Deutsch's model, a simplified version of the process of mathematical modeling consists of four different stages: understanding of the problem, construction of a model or selection of a mathematical procedure, the execution of the procedure, and the interpretation or evaluation of the outcomes of the procedure.

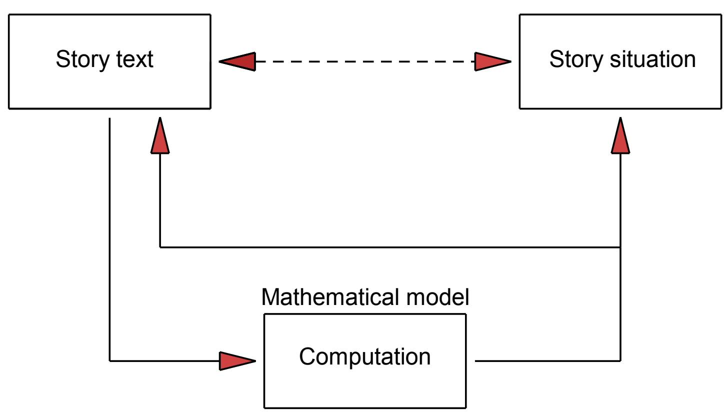

Fig. 1: Silver et al.'s (1993) referential-and-semantic-processing model for successful solutions

The first stage of the process of mathematical modeling involves understanding the problem

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

situation embedded in the story text. That is, we need to understand the given or known facts, the unknown information, the superfluous data, and missing information. The second phase involves the construction of a mathematical model or selection of a suitable procedure, operation, or algorithm whose outcome will lead us to the solution of the problem. To perform the second stage of the modeling process successfully, we must understand the mathematical structure of the problem. That is, we must understand the interconnections or relationships among the different types of information related to the solution of the word problem. The third stage of the problem involves mainly performing the computation, procedure, or algorithm either with paper and pencil or using a computational device. Finally, we should interpret and assess the outcome of the mathematical procedure in terms of the realistic context embedded in the story text of the word problem or in terms of the real-world story situation. It is during this step that we need to focus on the meaning of the result of the mathematical model so we can establish the connection between the outcome of the computation and the solution to the real-world story problem. It is during this stage that we need to assess whether our modeling assumptions are realistic or reasonable.

Silver, Shapiro, and Deutsch's model implies that there are three main potential sources of error when solving word problems: lack of understanding of the mathematical structure of the problem, which leads students to select an inappropriate procedure, executing the procedure incorrectly, and failing to interpret or assess the result of the procedure in terms of commonsense or everyday-life knowledge. Silver, Shapiro, and Deutsch (1993) examined 195 middle grade students' solution processes and their interpretation of solutions to the following problem:

The Clearview Little League is going to a Pirates game. There are 540 people, including players, coaches, and parents. They will travel by bus, and each bus holds 40 people. How many buses will they need to get to the game?

Their analysis revealed that 91% of the students selected an appropriate procedure (e.g., long division, repeated multiples, repeated additions, etc.), but only 61% of these students performed it flawlessly (about 56% of the total number of students). Overall, the researchers found that only 43% of the total number of students gave the correct answer (14) to the problem. However, some of these students provided inappropriate interpretations or justifications. For example, one student wrote "14 buses because there's leftover people and if you add a zero you will get 130 buses so you sort of had to estimate. Are we allowed to add zeros?" (p. 124-125). The researchers also reported that about 55% of the students did not get the correct answer because either they did not properly interpret the outcome of the computation or executed incorrectly the procedure. These computational mistakes could have been prevented if students had interpreted their solutions appropriately. Silver, Shapiro, and Deutsch proposed the model displayed in Figure 2 as a graphical representation of unsuccessful solutions that are due to a failure to connect the outcome of the procedure to the real-world context embedded in the story problem.

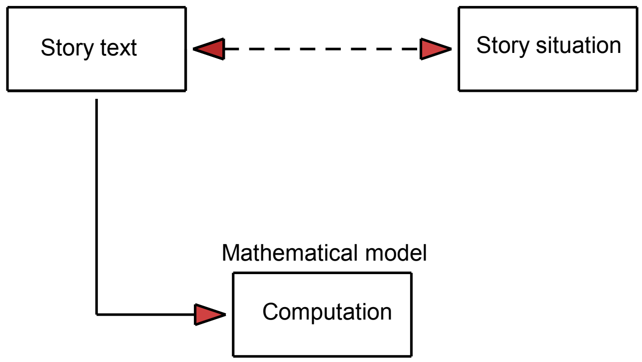

Figure 2: Silver et al.'s (1993) referential-and-semantic-processing model for unsuccessful solutions

Other pieces of research have amply documented elementary school children' improper modeling assumptions when solving arithmetic word problems. Some further examples of the word problems that students have been asked to solve are the following:

1) What will be the temperature of water in a container if you pour 1 liter of water at 80° and 1 liter of water of 40° into it? (Nesher, 1980)
2) John's best time to run 100 m is 17 sec. How long will it take to run 1 km? (Greer, 1993)
3) Lida is making muffins that require 3/8 of a cup of flour each. If she has 10 cups of flour, how many muffins can Lida make? (Contreras & Martínez, 2001)
4) In September 1995 the city's youth orchestra had its first concert. In what year will the orchestra have its fifth concert if it holds one concert every year? (Verschaffel, De Corte, & Vierstraete, 1999)

In their study with 75 fifth graders in Flanders, Verschaffel, De Corte, and Lasure (1994) reported that only 7 (9%) students provided a realistic and correct response to the temperature problem. Similarly, in the same study, these researchers found that only 2 (3%) responses included realistic answers or reactions to the running problem. In another study, Contreras and Martínez (2001) focused on prospective elementary teachers' solution processes and realistic reactions to the third problem. Their analysis revealed that only 19 (28%) of the participants' responses contained a realistic solution to the problem, but none of the participants made any comments about the problematic nature of the problem.

Verschaffel, De Corte, and Vierstraete (1999) addressed upper elementary school children' difficulties in modeling and solving nonstandard additive word problems involving ordinal numbers. The participants were administered a paper-and-pencil test consisting of 17 word problems, 9 of which were experimental items and 8 buffer items. The result of the straightforward arithmetic operation yields the correct answer for three of the nine experimental items. An example of such a problem is "In January 1995 a youth orchestra was set up in our city. In what year will the orchestra have its fifth anniversary? However, the solution of the remaining six experimental items is either 1 more or 1 less that the result of the straightforward arithmetic operation of the two given numbers. An example of such a problem is problem 4 stated above. Overall, the researchers found that the percentage of correct responses for each of the six problematic items was less that 25%. An error analysis revealed that 83% of the errors made on these problems were ± errors. In other words, most of the children' errors were due to their interpretation that the result of the addition or subtraction of the two given numbers yielded the correct answer.

Although research has convincingly documented elementary school children' strong tendency to model problematic problem unrealistically, the generalizability of the findings to more mature students, such as prospective elementary teachers, has not been established empirically. On one hand, since PETs have had even more experiences with traditional school problems, we may argue that there is no reason to expect that prospective elementary teachers would use their real-world knowledge and realistic considerations in their solution processes of problematic word problems. On the other hand, we may claim that PETs may have faced real-world problem situations outside school more often than young children and, having a more developed mathematical knowledge, have a stronger disposition to activate their real-world knowledge when confronted with problematic problems whose realistic solutions require taking into consideration contextual real-world knowledge. In the present study we focus on the extent to which the findings from previous research with pupils are generalizable to prospective elementary teachers.

Methods and Sources of Evidence

The total sample of participants consists of 566 PETs enrolled in different sections of mathematics content courses for elementary teachers at a Southern University in the United States. The present paper reports the results of two groups (68 PETs) for which the analysis has been completed. The PETs had not been previously engaged in any intentional or systematic modeling activities or tasks.

A paper-and-pencil test consisting of 8 experimental items and 4 buffer items was administered to the PETs during regular class instruction. The 8 experimental items (Table 1) were problematic in the sense that the outcomes of the arithmetic operations performed with the given numbers in the problem story does not provide the answer to the problem, if one takes into consideration the real-world situation embedded in the contextual problem story. The buffer items, on the other hand, were standard routine problems whose solution is the straightforward result of the operation performed with the given numbers. The experimental items were adapted from Verschaffel and De Corte's (1997) study. An example of a buffer item is "Joel is building a collection of 175 different stamps. He has already collected 107 different stamps. How many more stamps does he need to complete the collection?"

Table 1: The eight experimental items

1. 1175 supporters must be bused to the soccer stadium. Each bus can hold 40 supporters. How many buses are needed? (Carpenter, Lindquist, Matthews & Silver, 1983).
2. 228 tourists want to enjoy a panoramic view from the top of a high building that can be accessed by elevator only. The building has only one elevator with a maximum capacity of 16 persons. How many times must the elevator ascend to get all the tourists on the top of the building? Verschaffel, 1995)
3. At the end of the school year, 50 elementary school children try to obtain their athletics diploma. To receive the athletic diploma they have to succeed in two tests: running 400 m in less than 2 minutes and jumping 0.5 m high. All the children participated in both tests. Nine children failed the running test and 12 failed the jumping test. How many children did not receive their diplomas? (Verschaffel, 1995)
4. Carl and George are classmates. Carl has 9 friends that he wants to invite to his birthday party. On the other side, George has 12 friends that he wants to invite to his birthday party. Since Carl and George have the same birthday, they decide to give a party together. They invite all of their friends. All their friends come to the party. How many friends are there at the party? (Nelissen, 1987)
5. A man wants to have a rope long enough to stretch between two poles 12 m apart, but he has only pieces of rope 1.5 m long. How many of these pieces would he need to tie together to stretch between the poles? (Greer, 1993)
6. Steve has bought 12 planks of 2.5m each. How many 1 m planks can he saw out of these planks? (Kaalen, 1992)
7. Sven's best time to swim the 50 m breaststroke is 54 seconds. How long will it take him to swim the 200 m breaststroke? (Greer, 1993)
8. The flask is being filled from a tap at a constant rate. If the water is 4 cm deep after 10 seconds, how deep will it be after 30 seconds? (This problem was accompanied by a picture of a cone-shaped flask) (Greer, 1993)

After each problem, we have indicated its original source; however, in some cases the numbers were replaced by others.

Students' written responses to the problems were the source of data. Written directions asked students to show all their work to support each of their answers and to write down any questions or concerns they may have about each problem**.** We recognize that written responses have some intrinsic limitations when compared to verbal protocols. However, written protocols allow researchers to collect data from large samples. Moreover, some researchers (Hall, Kibler, Wenger, & Truxaw, 1989) have validated the use of written responses to infer cognitive processes.

Analysis and Results

Each response to problems 1 and 2 was coded as correct or incorrect. Each response to problems 3-8 was coded as correct, partially correct, or incorrect. Two independent raters judged every response. A response was judged as correct if it included a realistic numerical answer that estimated or indicated the range of possible solutions and took into account the contextual restraints of the real-world problem situation. A response was judged partially correct if it was incomplete or wrong but included a realistic comment suggesting that the student displayed awareness of the contextual restraints of the real-world problem situation. A response was judged incorrect when it did not suggest any awareness of the contextual restraints of the real-world problem situation. The inter-rater agreement was 99.6%. Table 2 summarizes the results of the analysis.

Table 2: The number and percentage of correct, partially correct, and correct responses for the 8 experimental items.

Problem	Number and percent of correct responses	Number and percent of partially correct responses	Number and percent of incorrect responses
1	55 (81%)	0 (0%)	13 (19%)
2	58 (85.5%)	0 (0%)	10 (14.5%)
3	3 (4.5%)	13 (19%)	52 (76.5%)
4	3 (4.5%	15 (22%)	50 (73.5%)
5	2 (3%)	4 (6%)	62 (91%)
6	14 (20.5%)	1 (1.5%)	53 (78%)
7	1 (1.5%)	4 (6%)	63 (92.5%)
8	0 (0%)	5 (7.5%)	63 (92.5%)

As shown in Table 2, PETs' performance on most items was alarmingly poor: The percentage of incorrect responses ranged from a high 92.5% for items 7 and 8 to 14.5% for item 2. Overall, the percentage of realistic responses (correct responses and partially correct responses) on the 8 problematic items was only 33%. We should notice, however, that the number of realistic responses was considerable greater for the division problems involving remainders, problems 1 and 2). If we exclude these two problems from our analysis, then the percentage of realistic responses for the remaining 6 problems is only 16%.

Discussion and Conclusion

The purpose of the present study was to collect systematically empirical data about the extent to which prospective elementary teachers activate their real-world knowledge when solving problems whose solution in not the direct result of an arithmetic operation. Using similar problems and methodology as previous studies (e.g., Verschaffel & De Corte, 1997; Verschaffel, De Corte, & Lasure, 1994), a test consisting of 8 problematic items and 4 standard problems was administered to a sample of 566 PETs. The analysis has been completed for 68 PETs (2 groups) and it is reported in the present article.

Although previous studies have convincingly demonstrated children' strong tendency to ignore the contextual realities embedded in the story of the problem situation, we were hoping that our findings with prospective elementary teachers would be much more encouraging. After all, prospective elementary teachers are part of a more mature and experienced population and it is reasonable to assume that they have an understanding of the contextual knowledge needed to realistically solve the problems. Therefore, the question of PETs' failure to activate this knowledge needs to be further discussed and investigated. We offer several tentative hypotheses to explain PETs' lack of disposition to model contextual word problems realistically.

First, children and PETs' lack of activation of their real-world knowledge may be due to their constant exposure to traditional and stereotypical school word problems. If this is the case, then this tendency may remain constant or get stronger with additional years of immersion in the mathematical culture of traditional classrooms. Future research is needed to better understand the effects of traditional learning environments on students', including PETs, failure to activate their real-world knowledge to solve problematic problems.

A second possible explanation to understand PETs' tendency to ignore the contextual realities of the situation embedded in the problem story is that they lack enough world-real knowledge of the situational context of the problematic problems. Even though this seems unlikely, follow-up studies should provide empirical data to confirm or refute this hypothesis.

A third explanation may be that PETs approached the problematic problems in an automatic way thinking that they were standard mathematical problems without reflecting on the contextual realities of the problem. Further research is needed to better understand PETs' suspension of sense-making when solving these types of problems.

In conclusion, this study provides, at the very least, some empirical evidence that PETs lack an initial disposition or reaction to consider the contextual restraints of problems grounded in the real world. Further research is needed to better understand PETs' apparent suspension of sense-making when engaged in solving problems that require realistic interpretations.

THE EFFECTS OF TEACHERS' UNDERSTANDING OF ADDITION AND SUBTRACTION WORD PROBLEMS ON STUDENT UNDERSTANDING

Jana Lunt
Southern Utah University
janalunt@suu.edu

This study investigates the influence of teacher understanding on student understanding through teacher practice. Three elementary school teachers participated in a university course that discussed mathematical and pedagogical knowledge regarding addition and subtraction word problems. The data from this study were analyzed qualitatively to describe the nature of the teachers' understandings, the ways teachers used their understandings in their practice, and the nature of their students' understandings. I hypothesize that teachers used their understanding to create and implement tasks at a high level of cognitive demand, maintaining that demand over time, which affected student understanding.

There is quantitative evidence that content knowledge and pedagogical content knowledge influence student understanding (Hill, Rowan, & Ball, 2005; Fennema & Franke, 1992), but how teacher knowledge affects student achievement needs to be explored. In this study I begin to uncover how teacher knowledge affects student understanding using a qualitative perspective. If we assume that teacher understanding affects practice and that teacher practice affects student understanding (Hurry, Nunes, Bryant, & Pretzlik, 2005; Smith & Baker, 2001), then we can begin investigating these relationships.

Objectives

In three cases, I describe the nature of a teacher's understanding of a particular mathematical topic and investigate how that understanding affects the teacher's practice while teaching that topic. In addition, I examine the link between teacher understanding and student understanding in order to hypothesize about the relationships between them.

My study is exploratory in nature and seeks out possible connections that will need to be further developed. Since teacher knowledge is so expansive and varied, I limited this study to investigating one mathematical topic in light of only a few aspects of teacher knowledge. In this study I examine the understanding of three teachers regarding the content knowledge and pedagogical content knowledge shown to be integral to teaching addition and subtraction word problems, according to the Cognitively Guided Instruction (CGI) program (Carpenter, Fennema, Franke, Levi, & Empson, 1999). I investigate how a teacher's understandings of the structure of addition and subtraction word problems and of how students typically solve addition and subtraction word problems affect her practice, and how her practices affect student understanding of addition and subtraction.

Framework

My research uses Deborah Ball's construct of the mathematical knowledge needed for teaching (Ball, Phelps, & Thames, 2008). According to Ball, Specialized Content Knowledge (SCK) is an important aspect of subject matter knowledge and Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT) are vital to pedagogical content knowledge. I have chosen to examine teacher and student understanding of addition and subtraction word problems due to the extensive research that has identified the content knowledge and pedagogical content knowledge for teachers in this area. I examine qualitatively how a teacher's understandings of the structure of addition and subtraction word problems, a substantial part of their SCK, affects students' understandings of addition and subtraction through its effects on teacher practice. I also examine how a teacher's understanding of the strategies students use to solve addition and subtraction word problems, part of their KCS as well as KCT, affects students' understandings of addition and subtraction through teacher practice.

I relied on research by Wiggins & McTighe and Sierpinska to establish when participants were exhibiting understanding. Understanding is "a family of interrelated abilities" that develops over time in an individual and involves "sophisticated insights and abilities, reflected in varied performances and contexts" (Wiggins & McTighe, 1998, p. 5). Wiggins and McTighe (1998) describe six indicators of understanding: *explanation, interpretation, application, perspective, empathy, and self-knowledge*. Sierpinska (1994) also identifies four indicators, which she calls mental operations, involved in understanding: *identification, discrimination, generalization,* and *synthesis.* There was some overlap in the two bodies of research, but each offered some valuable insight into indications of understanding. I referred to both Sierpinska's work and the work of Wiggins and McTighe to qualitatively describe the understandings of my participants.

Methodology

A pilot study indicated that the teachers in the local school district, unfortunately, did not have the type of content and pedagogical content knowledge I wanted to explore. Therefore, it was necessary to offer a course taught at a large university in the Mid-Atlantic region. The mathematics coordinator for the school district invited first-, second-, and third-grade teachers in the district to participate. Two first-grade and two second-grade teachers responded. The teachers in the study were selected from this course.

The course functioned as a discussion group with all four elementary school teachers, the mathematics coordinator, and myself. We met 10 times for a total of over 18 hours. The purpose of the course was to both improve and evaluate the teachers' understandings of how students think about addition and subtraction word problems, the classification of problems, the direct modeling of problems, the counting strategies used for solving problems, and the relationships among these topics, as researched by CGI. During the first half of the course I instructed the teachers. During the second half of the course the teachers decided how this knowledge could be used to change and enhance their own teaching. Throughout the last half of the course teachers were given the opportunity to evaluate their lesson plans that involved addition and subtraction word problems. The curriculum they used contained almost solely Join and Separate (Result Unknown) problems. They rewrote almost all the word problems in the curriculum, using each of the structure types identified by CGI.

Three teachers, Carmen, Pam, and Julie (all names used are pseudonyms), clearly exhibited understandings of the content and pedagogical content knowledge as described by current research, to observe in their classroom. I observed any class time during which the teachers taught addition and subtraction word problems. I audio-recorded the teaching sessions and took field notes, which included verbatim teacher and student interactions, writing on the board, or other relevant data not captured by the audio-recording. Copies of lesson plans and classwork were collected. The field notes, lesson plans, other additional documents such as student work, and transcribed audio-recordings were used to analyze the understandings teachers had, how this understanding affected the teachers' decision making, and how this understanding influenced student understanding. I also examined the students' understandings of the mathematics by listening to class discussions, teacher and student discussions, and by accessing student work.

During interviews, the elementary school teachers in the study were asked about why they made specific decisions before and during class time. Events that merited attention during interviews included the teacher making changes to lesson plans, claims she made about student understanding during class, the teacher intervening in student work, assessments she made about students' solution strategies, or just conversations the teacher had with a student. I concentrated on observing four or five students in each classroom. Students were interviewed using mathematics tasks similar to those they encountered during their regular class work. To evaluate teacher and student understanding, I investigated participants' ability to *identify, explain, interpret, discriminate, apply,* and *generalize* within the context of understanding addition and subtraction word problems.

The analysis was conducted qualitatively using the data I collected in classroom observations, field notes, documents from the teachers, and interviews. The manner in which teachers used the curriculum provided me with an important avenue for investigating their understandings and how they utilized their understandings in practices such as planning lessons, choosing tasks, and anticipating student responses. I reviewed the data points searching for indicators of understanding in which I found multiple pieces of evidence. I also searched the data for evidence that teachers or students did not exhibit a specific understanding to make sure the assertions were made with as little bias as possible. Once I gained a better understanding of the understandings, I organized the categories into subcategories, based on types of understanding repeated in the data.

Next, I determined how the teacher used her understandings and how those understandings may have influenced the students' understandings. I usually worked backwards from a particular student understanding, investigating the data to find possible instances when the teacher may have influenced that understanding through her practice. In addition, I hypothesized how the teacher's knowledge could have affected the teacher's practice. Multiple instances of a particular student understanding, coupled with multiple instances of a particular practice influencing that understanding, merited a connection worth noting.

Results

The following paragraphs suggest some aspects of student understanding influenced by teacher understanding as well as aspects of teacher practice that influenced student understanding.

Aspects of Student Understanding Influenced by Teacher Understanding

Student understanding of their written representations was one of the most notable items influenced by the teachers' understandings. Students understood that addition and subtraction word problems could be represented with devices such as equations, pictures, diagrams, or tally marks. Teachers influenced how the students were able to interpret the representations and how they used the representations to explain and interpret the problems given to them. For example, Pam asked students to write an equation to represent each problem they were asked to solve. She used equation writing as a tool for students to observe and articulate the differences in structures. Her consistent emphasis on where the question mark was in the equation enabled students to show what parts of the problem were given and what part of the problem was missing. Similarly, the teachers influenced the quality of students' verbal explanations of their thinking. All three teachers used written and verbal representations that described, as literally as possible, the thoughts and actions of a typical student when solving the problems (as described by CGI), which may have contributed to why the practices were relatively easily incorporated by their students.

There was an extensive amount of evidence in all three classrooms that teacher understanding can lead to an expanded student understanding of mathematical operations. I believe that the teachers' flexible understandings enabled the students to interpret the mathematical operation as a strategy used to solve the problem instead of a defining characteristic of the problem. The students could focus on the problems' structure, not relying on an operation to interpret problem. The operations were possible avenues for solving the problems. The teachers asked the students to solve problems in multiple ways, including by the use of different operations. Students showed an ability to interpret the operations as "opposites" of each other. They explained that the opposite operation could be used to check their work or to solve a problem using a second method.

Students in this study were able to learn about concepts such as recognizing invariance, generalizing, justifying, and focusing on the structure of the problem instead of just how to solve a problem. For example, when one student, Niki, solved a Join (Change Unknown) she wrote the equation 32 + ? = 50. Niki then wrote 30 + 20 = 50 and then 32 + 18 = 50. Her teacher asked her about her thinking. The student responded:

Niki: Because this [the number in the problem] is 32, this [the number in her equation] has to be 32. So I added 2 more. Then I took 2 less from the 20 because if I added 2 more to here [the first addend] I have to take away from there [the second addend].

Pam: How did you know the 50 would not change?

Niki: Because I added 2 more and took away 2 more so it would be the same thing.

Niki showed surprising mathematical insight with her generalization and her nascent understanding that she could add to one addend and subtract from the other addend and maintain the same sum. These young students were developing the building blocks for identifying and explaining these important mathematical practices and powerful mathematical concepts.

The ability of students to progress to more sophisticated levels of problem solving was also influenced by the teachers' mathematical and pedagogical understandings. The teachers understood the students' current ability levels and they also understood the more sophisticated strategies, so they developed tasks to build on the students' understanding. The teachers understood the importance of students developing their individual interpretations of the mathematical topic. Practices such as refraining from teaching a standard algorithm until the students were capable of understanding the algorithm allowed students to develop their own strategies as shortcuts for direct modeling and counting strategies. All three teachers encouraged their students to use less sophisticated methods for solving problems when they believed a student lacked the ability to interpret the nature of the problem, which the teachers hoped would lead to a deeper mathematical understanding for the student.

Aspects of Teacher Practice That Influenced Student Understanding

The first and most drastic change in the teacher's practice was the complete revamping of the problems given to the students. It is clear that the teachers' understandings affected their practice through the types of problems they chose to give to their students and through the sequencing of those problems. The teachers also used their understandings to comprehend and carry out the objectives for each of their lessons. They were able to make more specific lesson objectives and have those objectives guide their interactions with the students throughout their teaching. They could decide whether the purpose of their lessons was to introduce a certain type of problem, develop interpretations for problems, discriminate among different types of problems, or develop strategies to solve problems.

The teachers' understandings enabled them to better address the needs of their students, not only through the building of their lesson plans but also in daily interactions with students. Prior to this study, the teachers were unhappy with how they taught the lessons, but were unable to make changes because they did not understand the mathematics well enough. By their own admissions, their knowledge only enabled them to change the numbers in the problem to increase or decrease difficulty. Because of their increased mathematical understandings they were able to construct tasks that would build on student understandings. The teachers gained insight into students' weaknesses and strengths, and could modify their practice accordingly. For example, Julie noticed that a group of two higher achieving students answered all of their problems correctly except for the Compare (Referent Unknown) problems. She was able to design more problems of this type and target her verbal questions to address the relationships involved.

All three teachers identified that the questions they asked their students were more targeted than in previous years on the mathematics they wanted their students to understand, because they understood the mathematics better. For example, the teachers' understandings of structure were evident in their teaching when they continuously asked students to explain the relationships within the word problems. Carmen made a practice of asking students to explain the story without using any numbers. These teachers did not simply expect students initially to be able to explain the nature of the problem; they used scaffolding to press students to interpret the numbers in the problem, the objects to which those numbers refer, and the relationships among the referents within the problem, instead of focusing on getting an answer or which operation to use to solve the problem.

The teachers used multiple representations in their teaching, such as blocks, pictures, equations, and diagrams. Teachers asked students to model high-level performance with explanations for how they wrote their equations, including interpreting why they decided to represent the quantities in the manner they chose and where to place the quantities in the equation. The teachers encouraged the use of direct modeling to understand the nature of difficult problems. The teachers spent time not only showing examples of ways to solve problems but also explaining how the strategies worked and how the strategies were contingent upon the nature of the problems they were attempting to solve. Asking the students to solve problems in multiple ways increased the flexibility of their understanding (Star & Rittle-Johnson, 2008). It gave the students further incentive and avenues to develop their strategies and develop their ability to explain and interpret the mathematics they used.

Finally, teachers were able to find validity in the arguments students made that were different from their own, and encouraged students to continue in their thinking. For example, Pam found herself wanting to ask students to solve Separate (Change Unknown) problems using the missing addend approach, because that is how she conceptualizes those problems. But she allowed her students to develop their own strategies, based on their interpretation. She identified that there are many appropriate ways to think about mathematical problems, and decided not to instruct her students specifically how to solve them. Teachers can allow students to develop their correct interpretations, merely by knowing when to refrain from imposing their own ideas that might hinder productive student thinking.

Discussion

After analyzing the data, I hypothesize that teachers' mathematical knowledge for teaching determines the teacher's ability to design and implement a task at a high level of cognitive demand as well as their ability to maintain that level throughout implementation. The following figure adapted from Henningsen and Stein (1997) illustrates the three phases through which tasks pass; the task in the curriculum, the task set up by the teacher, and the task as implemented in the classroom. The way the task is implemented in the classroom directly affects students' learning outcomes.

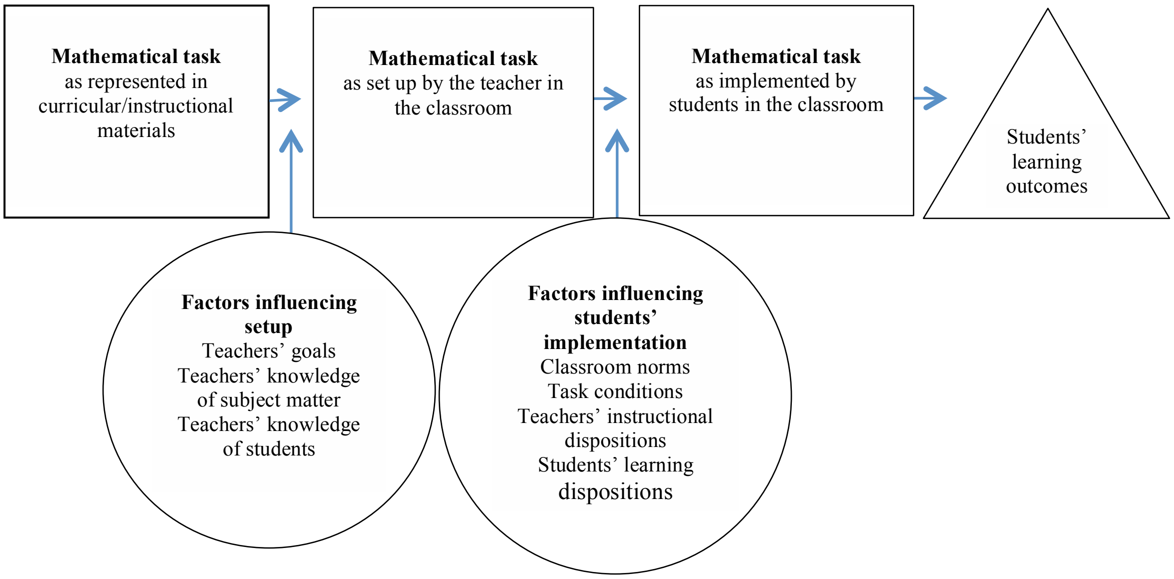

Figure 2. Framework for Mathematical Tasks (adapted from Henningsen & Stein, 1997, p. 528)

Research shows that the level of cognitive demand of a task tends to decrease as the task proceeds through the framework. In the framework, teacher knowledge of subject matter appears as a factor influencing the setup of the task, but it does not appear as a factor influencing the implementation of the task. I agree that teachers' instructional dispositions determine the way a teacher desires to implement a task, but, a cross-case analysis of the participants in my study showed that not only did they desire to implement tasks at a high level of cognitive demand – but they also used their understanding to create situations in which students were using tasks at a high level of cognitive demand and maintaining that demand throughout implementation.

The teachers used their understanding to create the two types of higher level cognitive demand tasks, "using procedures with connections" and "doing mathematics" indicated by Henningsen and Stein. Tasks that use procedures with connections were chosen to "focus students' attention on the use of procedures for the purpose of developing deeper levels of understanding of mathematical concepts and ideas" (Stein, Smith, Henningsen, & Silver, 2000, p. 16). For example, Carmen asked her students to use the procedure of answering a list of questions she constructed to encourage them to think about the relationships between the quantities in the word problems, such as "Who has more?" "What clue tells you this?" etc. The students followed this procedure trying to make connections among the numbers in the problem, the quantities they represented, and the relationship between those quantities. The teachers also used problems that asked students to represent the quantities and actions in the problem in multiple ways, such as with diagrams, manipulatives, symbols, and problem situations (Stein et al., 2000, p. 16). Because the teachers were aware of the connections they were able to incorporate those connections with procedures. Teachers consistently asked students to make connections among the representations to develop their meaning, such as when Pam asked students to write mathematical equations to lead students to understand the types of knowns and unknowns in the addition and subtraction word problems.

The teachers also used their understanding to create higher-level cognitive demand tasks called “doing mathematics.” Instead of giving students the same type of problem repeatedly and telling them how to solve it, students were given problems that required nonalgorithmic thinking. Students were purposefully not given algorithms so they could develop more complex thinking about the operations. Teachers thought flexibly about the problems–not defining them by a single operation,–allowing different operations, depending on the strategies students chose. All three teachers chose tasks that required considerable cognitive effort so that some level of anxiety was experienced by the students at some time during their work, which was a change from previous years when the students were described as “bored.”

The teachers were also able to use their understanding to maintain that demand level over time. According to Stein and colleagues there are seven factors associated with maintenance of high-level cognitive demands (Stein et al., 2000). These factors coincide with the aspects of teacher practice that I claimed to be influenced by teacher understanding. I will discuss four of the factors I saw evidenced by the teachers in this study.

Eighty-two percent of tasks that stayed at a high cognitive demand were tasks that built on students’ prior knowledge (Henningsen & Stein, 1997). The participants in my study decided to write a pretest for their students. Through this test the teachers realized the students were capable of much more than the teachers were previously expecting. The teachers knew the demand of the tasks in the current curriculum was too low, but they did not have the understanding necessary to change them. During this study they completely changed their curriculum, based on the results of the pretest they gave their students. The teachers also encouraged the students to use strategies to solve problems based on their understanding of the students’ ability levels. Using their increased mathematical understandings, teachers were better able to determine the students’ prior understandings and design activities that could improve those understandings—without their increased mathematical understanding they could only increase or decrease the size of the numbers.

Scaffolding of student thinking and reasoning is another significant factor to maintaining tasks’ high level of cognitive demand. With each teacher I witnessed situations in which students were unable to complete a task and the teacher provided assistance through questioning and comments that asked students to think about the structure of the problem without reducing the demand of the task. For example, when one student was unable to understand a Separate (Change Unknown) problem, Carmen helped her develop a strategy using tally marks to solve the problem. The student was eventually able to build off this interaction and solve these problems without Carmen’s assistance.

Carmen also demonstrated a fourth factor, giving students a means of monitoring their own progress. She gave the students a checklist to fill out for each problem to enable students to guide their own progress in problem solving. 1) Read the problem. 2) Look for clues in the problem, find the important information. 3) Think of some strategies. 4) Solve the problem. 5) See if it makes sense. Carmen reported that this type of list was unnecessary before because the students “didn’t have to think” about the problems. Now that her curriculum did contain problem solving that required students’ cognitive effort, she addressed the development of students’ ability to monitor each step toward solving the problem.

These teachers modeled high-level solution strategies, another tool for effective maintenance of high cognitive demand. They explained how solution strategies were appropriate based on the nature of the problems. They acknowledged that they were unable to do this successfully before learning more about addition and subtraction word problems. They were aware of the important relationships in problems and could therefore model these relationships in a variety of ways. Part of these demonstrations involved drawing conceptual connections, another important factor in maintaining the task demand level. For example, teachers could draw connections between addition and subtraction when demonstrating the use of both of the operations within one word problem.

I suggest that student understanding was affected by the teachers' maintenance of the level of cognitive demand. The students demonstrated the type of understandings fostered by tasks with higher cognitive demand level that focused on "procedures with connections" (Stein et al., 2000). Students were able to develop deeper levels of understanding of mathematical concepts, such as their expanded understanding of the operations of addition and subtraction, through their use of procedures. They represented problems in multiple ways, such as modeling, equation writing, and creating their own word problems. Students were able to develop meaning by making connections among multiple representations. For example, the students in Pam's class were able to use equation writing, picture drawing, and creating of problem situations to better understand the relationships between types of knowns and unknowns in an addition and subtraction word problem. There were many examples of students showing cognitive effort, not following procedures mindlessly, and engaging with underlying conceptual ideas. There is also evidence that students were able to demonstrate the type of understandings that "doing mathematics" tasks are intended to engender. Students showed nonalgorithmic thinking while solving the addition and subtraction problems in multiple ways. There is evidence of students beginning to explore aspects of mathematical concepts such as invariance, generalizing, justifying, and focusing on the structure of the problem instead of just how to solve a problem. There were countless examples of students accessing relevant knowledge and using it appropriately to work through a task.

The teachers each expressed that they knew they were not effectively teaching this topic prior to the study. They did not realize they were lacking the mathematical understanding necessary to enhance their practice. Within days of increasing their SCK, KCS, and KCT they were able to change their practice. Their teaching practices, affected by their deeper understanding, influenced the quality of their students' understandings.

CONNECTING PD TO PRACTICE: USING A TASK IN 7TH GRADE MATH[1]

Chandra Hawley Orrill
University of Massachusetts Dartmouth
corrill@umassd.edu

Julie M. Kittleson
University of Georgia
jkittl@uga.edu

In this study, we expand the Cohen and Ball triangle of interactions to explore the relationship of professional development to classroom practice. We consider a case study of one teacher's implementation of a task from professional development in her 7th grade classroom. We were specifically interested in how the content and pedagogy of the professional development would be adopted by the teacher. Our findings suggest that this teacher treated pedagogy and mathematical content as separable, which led to problematic implementation of PD practices.

Research and theory around the design of high-quality professional development suggests that using materials like those a teacher would use in her classroom is one particularly effective strategy for influencing teaching (e.g., Banilower, Heck, & Weiss, 2007; Hill, 2004) as is modeling the kind of learning environment that is desired for the K-12 classroom (e.g., Desimone, et al., 2002; Elmore, 2002; Hill, 2004). Further, an emerging body of research highlights the need for high-quality teaching practices to be implemented in ways that are grounded in the mathematics. For example, Wood, Williams, and McNeal (2006) found that teachers who asked questions that pushed students to engage in inquiry and argument led to higher levels of success among mathematics students than teachers who asked questions that only required the students to report their thinking. While both instances involve *questioning*, the first is necessarily grounded in the mathematics and students' reasoning while the latter can be used generically (e.g., 'How did you get your answer?'). Similarly, Kazemi and Stipek (2001) identified the characteristics of classrooms in which there was more push for conceptual learning. Their findings suggest that these classrooms include norms such as: explanations need to include mathematical arguments rather than descriptions; students are expected to understand connections among multiple problem-solving strategies; errors are treated as a means for enhancing learning, thereby serving a generative role; and collaboration features consensus building through mathematical argumentation. Like the Wood et al. study, this study demonstrates that the precise ways in which pedagogical moves are implemented fundamentally shapes the classroom environment. Given what is known about professional development and what is known about teacher practice, we sought to understand what aspects of professional development (PD) a teacher might carry into her classroom and what the movement between the PD and classroom environment might look like.

Theoretical Framework

We frame our effort by extending the triangle of interactions metaphor introduced by Cohen and Ball (1999, 2001). In their model, the classroom learning environment is shaped by the interactions of three primary elements: teachers, students, and content as embodied in materials. We extend this metaphor to include a second triangle, which represents the same elements interacting in professional development (see Figure 1). The two triangles are joined at the vertex representing the teacher/participant. This vertex is noteworthy because the teacher is not only present in both environments, but also because her interpretation of the PD fundamentally shapes both environments as she brings experiences from her classroom to the PD and experiences from the PD into her classroom. While it is true that the materials from the PD can be taken into the classroom, the teacher is responsible for turning the intended (written) curriculum into the enacted curriculum (Remillard, 2005).

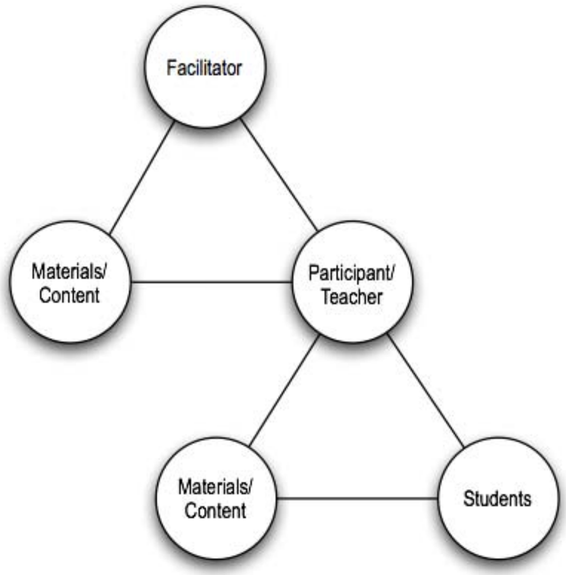

Figure 1. Double triangle of interactions representing the classroom (bottom) and PD environment (top).

The teacher is ultimately responsible for implementing ideas from PD in her classroom. This study, therefore, documents one teacher's experience in PD and the way this experience shaped her classroom. Since the teacher is the point joining the two triangles it is important to examine the teacher in the professional development context and her classroom context. To frame our analysis, we focused on a specific set of instructional moves as well as the teachers' content knowledge. Specifically, we were interested in the ways the teacher supported connection-making in her classroom as this had been a significant factor in her PD experience. We defined connection-making with a 4-facet framework for connection making. The four facets include:

- *Questioning & Communicating*: in this framework, these serve as tools for articulating, expanding, and refining mathematical ideas. Specific kinds of communication in which we were interested included that which supported exploring connections among representations, problematizing ideas, promoting conjecture-making and testing, and engaging with ideas in ways that move the learner to deeper levels of mathematical understanding.
- *Reasoning with Representations*: in the framework, reasoning with representations is seen as connection making. To reason with a representation, a person must draw on a set of mathematical understandings, embody them in the representation, and communicate to others about those ideas using language and the representation itself.
- *Embracing Multiple Approaches*: this framework builds from the perspective that different people have different solution paths. The path taken depends on knowledge invoked and the solver's knowledge. The value of highlighting these differences is in its effectiveness for introducing all of the learners to new perspectives and promoting their ability to create connections among ideas.
- *Scaffolding*: this framework is built from the perspective that facilitators make a number of moves that support learners in moving from their current levels of

> understanding to new understandings. Scaffolding moves include, but are not limited to, those consistent with the five practices for facilitating discourse around cognitively challenging tasks (Stein, Engle, Smith, & Hughes, 2008). These include anticipating responses, monitoring responses as learners work, select particular approaches to highlight during group discussion, sequence responses to highlight particular ideas, and support learners in making connections between different approaches.

These four facets of connection making formed the basis of our analysis of both the PD and classroom settings as we considered how the teacher translated the PD experience into her classroom practice.

Methods

Data were collected as part of a larger research project in which we used a mixed methods design to understand teacher learning in PD and the impact it has on classroom experiences and student performance. For this study, we considered one videotaped session of a 14-week mathematics PD experience and one videotaped session from one participant's 7th grade classroom. This teacher, Donna, was the only one in our study who invited us to videotape an implementation of a task taken directly from the PD course.

Professional Development

The PD workshop was a 14-week (total of 42 hours) experience for middle school teachers in which they specifically engaged in content knowledge development. The course engaged the 14 participants in exploring fraction multiplication and division as well as proportional reasoning. Each session, which was taught in the district office in a large, underachieving, urban school district, lasted three-hours and engaged the participants in hands-on, technology-supported engagement with the mathematics. The three stated goals of the PD were (1) understanding referent units (the *whole* to which a fraction refers) in a variety of situations; (2) using drawn representations; and (3) proportional reasoning. To meet these goals, participants were asked to engage with a number of open-middle tasks either as a group or in small groups. For the small group work, each teacher was responsible for preparing a *write-up* that documented the approach taken to solving the task, any dead-ends hit, and a fully discussed solution.

The facilitator, a member of the research team, had extensive experience as a professional developer and was a former high school teacher. Each session was videotaped using two cameras. One was focused on any written work being discussed, while the other focused on the people speaking. These two sources were combined into a single view using picture-in-picture technology to create a restored view (Hall, 2000).

7th Grade Class

As part of the larger research project, we asked several teachers representing a cross-section of abilities on our pre-course assessment to allow us into their classrooms so we could understand how the professional development impacted their teaching. We specifically asked to see examples of a typical lesson and a lesson the teacher felt was like the PD. For this analysis, we consider Donna's implementation of a task she thought was like the PD. The lesson was implemented approximately three months after the completion of the PD. As in the PD, the classroom was videotaped using two cameras and the sources were combined.

Data Analysis

Both the PD session and Donna's 7th grade lesson video were analyzed using memoing (Strauss & Corbin, 1998). Every instance of any of the four facets of connection making was noted. This included those instances that did not capture our full definition (e.g., the teacher may ask a closed question rather than a generative one). We chose this approach in place of grounded theory to help us focus on those aspects of classroom practice that have been demonstrated to be important for learning as well as those specifically built into the PD experience. Once we had memoed each lesson, we built a model of it to help us understand how the facets of connection making worked in that lesson.

Secondary data, including weekly telephone interviews with Donna completed during the 14-week PD, write-ups of her tasks, and reflections (e.g., specific questions about generalizing the mathematics) collected in the PD sessions were analyzed. We used the same facets of connection making and memoing technique as was used with the video data.

Results

In this section, we briefly present an overview of Donna's experience in the PD as well as some elaboration on her content knowledge. This is followed by a discussion of Donna's PD-inspired lesson. Data are summarized due to space limitations. Both the PD and the 7th grade lesson like the PD focused on a pair of mathematical tasks (shown in Figure 2).

Problem 2:

a) Joe the farmer drained his grain silo into a holding bin. The silo was full and held 300 cubic meters of grain. It drained at a rate of 5 cubic meters per hour. How fast would Joe have to drain a silo that held 420 cubic meters of grain so that it took the same amount of time? How fast would Joe have to drain a silo that held 210 cubic meters of grain so that it took the same amount of time? Is the relationship between volume and rate the same across these three examples? If so, describe the general relationship.

b) Grain elevators are large containers used to fill train cars with grain that farmers have harvested. If the elevator dispenses grain at 500 cubic feet per minute, it takes 12 minutes to fill a train car. If the elevator dispenses grain at 200 cubic feet per minute, how long will it take? If the grain elevator dispenses grain at 250 cubic feet per minute, how long will it take? Is the relationship between rate andtime the same across these three examples? If so, describe the general relationship.

Figure 2. Task used in both lessons. Discussion in this paper focuses on task (b).

Donna's PD Experience

A typical session of PD opened with the facilitator asking participants to work on a task for a short time that was then discussed in the whole group. Then, participants were introduced to the tasks from which they could select to complete a write-up. During the times in which the participants worked, they could choose to work alone or with a partner.

Donna, who was an 11-year veteran teacher, began the PD with a slightly above average mathematical knowledge in the areas of interest to us. On our pretest, her z-score was 0.2 but by the end of the PD, she scored a 1.4, showing much more than the 0.3 growth considered significant. In observations of the class from which these data are drawn, it was clear that she had some confusion about aspects of proportional reasoning and that her definitions for proportional relationships were superficial. For example, she spoke of direct proportions as being "up/up" relationships and inverse proportions as "up/down" relationships. In both whole class discussions and one-on-one discussions, the facilitator communicated the need for precision in defining the relationships by saying things like, "I think this speaks really nicely to what that is that we're talking about. I think just saying 'as one goes up the other goes up' and 'as one goes up the other goes down' — talking like that — additive and multiplicative — I don't think we're really being clear enough."

In the course of the PD class session, Donna developed a conjecture for herself about inverse variation. She asserted that if you multiply one value (e.g., *y*) by an amount, then you would need to multiply the other value (e.g., *y*) by the reciprocal of the amount. As shown in Figure 3, for example, to increase the 12 to 24 requires multiplying by 2, therefore, according to Donna's rule, the corresponding value to 24 would have to be ½ of 500. The facilitator worked one-on-one with Donna to explore this conjecture by asking questions about the situation in Figure 2B. The facilitator challenged Donna by asking questions about the t-chart Donna had made (Figure 3) such as, "So, if we take 500 to 200 and then we did 12 to 30, we should see the reciprocal?" Donna and the facilitator worked on this situation together for several minutes using the representations Donna had created and Donna's own conjectures. In the whole-class debriefing, she scaffolded the entire group's thinking by again emphasizing the need for more precision in defining proportional situations than simply describing them in terms of the idea of one value increasing or decreasing as the other increases. Through these conversations, we assert that Donna had an opportunity to begin thinking about proportional relationships as being multiplicative in nature.

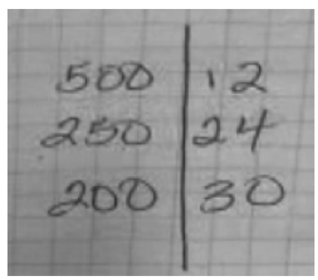

Figure 3: Donna's work for the situation in Figure 2, Question B.

At the end of the session, participants were asked in the reflection activity whether data shown in a table were directly proportional, inversely proportional, or neither. Donna showed evidence of both properly identifying the situations and providing mathematically grounded evidence for those. For example, her rationale for (appropriately) rejecting one table of data was that it "… is not a proportional relationship because there is not a constant pattern that fits either description (xy=k or y=kx). The multiplicative aspect is not there." She also provided a coherent definition for constant of proportionality that suggested she may be starting to think differently about direct and inverse relationships than she previously had: "A constant of proportionality is a number that can be multiplied by one term to get the other. Doesn't apply to inverse?"

Despite the promising evidence that Donna was beginning to sort out proportionality in November, by March when we recorded her classroom, she reported that she was still confused about how and why inverse and direct proportions were different. She said, "…I'm not even absolutely sure that's ever clearly defined for me…[in my own classroom] I recognized the difference… I'm not sure that it's defined. And I guess it's because the materials I work from don't define it clearly to me. I probably don't define it clearly to [my students]."

Donna's Classroom Lesson

Donna introduced the two tasks in Figure 2 (parts A and B) to her students by asking them to read aloud and using communication moves to ensure the students understood the problem. She encouraged them to work with "the mathematician next to you". She also used questioning to remind them of the representation they had been using with proportional situations (graphs) but also promoted other approaches saying, "… you can use the graph if you want to. But if you have an idea in your head of how you could visualize this in a different way, some other kind of model, then you can draw that." Donna circulated the room as the students worked asking them questions. Her questioning was largely confined to reporting questions (Wood et al, 2006) in which students explained *how* they did the problem but not *why* that had chosen an approach. For example, she asked one group, "What did you do when you did what you did?" We saw a few frequent questioning patterns in Donna's interactions with her students. One was to ask students to explain what the problem was asking if they were confused about what to do. Another pattern was her invitation to students to use their own strategies when solving a problem. However, this became problematic for Donna when she needed to evaluate students' approaches. Their approaches, at times, differed from what she expected and her only responses were either encouragement or to explain her own thinking—both without supporting students in connecting their understanding to her own. In one case, a student used a solution path Donna had not expected, so she explained her own to him. His response to her was to ask if he could have done it her way. When she said he could have, he commented on his own effort saying, "All that work for nothing." Communication was about evaluation and efficiency, not about engaging in mathematical discussions or pushing students thinking forward as Donna had experienced in the questioning she had in PD.

Donna had suggested to students that they should use representations in her launch of the problem, but as she circulated, she was clearly surprised by some of the representations she saw. In the spirit of supporting multiple approaches, Donna seemed hesitant as she tried to accept the ways students chose to approach the situation. For example, Donna encountered a group that created a bar graph for their inverse proportion. She asked the group, "Is this the kind of graph we've been doing with direct and inverse variation?" A student responded, "We've been doing line graphs, but I didn't feel like the line graph would be comfortable…" Donna responded, "If you think this is going to show you a better picture then go for it." Another student in the group commented, "I don't feel right about doing a bar graph." Donna articulated that students could use different approaches as long as they were comfortable with their answers, and she reminded them that the question asked them to determine which kind of variation (direct or inverse) was represented in the problem. Unlike the PD where mathematical discussions were had about the representations and their mathematical affordances, in Donna's class, the discussions focused on student comfort with no elaboration on that comfort or on aspects of the mathematics.

Analysis

In the PD, the framework of connection making was clearly present with all aspects of the class working together to scaffold learners. The facilitator used questioning to either understand participants' thinking or to push their understanding. She used precise communication in terms of not only incorporating mathematical terms but specifically discussing those terms and why she was focused on the precise use of them. She encouraged the use of representations and focused teachers on explaining them to her and to each other. The whole class debriefings of tasks always focused on connecting the various approaches together.

In contrast, when Donna implemented the task in her class questioning stopped at explaining how a problem was worked. Although multiple approaches were tolerated, they were not used to promote thinking and connection making among students. In fact, students saw Donna's approaches as being better than their own and, in the class we observed, they did not get to see any approaches other than their own or ones that Donna talked to them about in their partner work. Communication was not mathematically precise and, while not presented in the data due to space limitations, she pursued using the up/up and up/down explanations for the proportional relationships. She also emphasized the shape of the graph without pursuing any discussion about understanding the graphs in more detail. There was no sense of connecting ideas to each other and Donna did not seem to scaffold students' efforts so that the pieces fit together. In fact, she would give different pairs of students different directions without purpose—for example, one group was told to work the problem another way while another was asked about a different representation. But, there was no follow-up of any kind on these challenges.

Conclusions

Our goal in this study was to explore aspects of professional development a teacher might carry into her classroom and what the movement between the professional development and classroom environment might look like. In our case, we were offered the opportunity to observe a single teacher engage with a task taken from the PD. We assert that this analysis contributes to our understanding of how a teacher mediates the double triangle of interaction.

Donna was a good teacher in many respects. Her classroom was pleasant and her students clearly liked her. Her mathematics knowledge was clearly above average, despite some problematic understandings. According to her interviews, she enjoyed the PD and thought it was helpful to her teaching, though she could not provide examples of specific ways in which it was helpful.

From the perspective of the double triangle of interaction, however, we can see that the teacher mediation of the two environments plays an important role in the experience the students have. In PD, the task served as a conversation starter. It had been intentionally chosen by the facilitator to highlight particular relationships among the numbers (and the facilitator had discussed this intentionality in the PD). The focus of the task activities was on developing conceptual understanding that was mathematically precise. To do this, the facilitator used all four aspects of the framework for connection making in ways that were consistent with high press practices (Kazemi & Stipek, 2001).

Donna, having experienced this environment as a learner, chose to take the exact materials to her own students. She framed the task as a challenge for the students and used it to engage them in talking to each other and to problem solve. The focus of her interactions was often on correct calculations and the take-away was the shape of the graphs. There was no attention to precise use of mathematical terms nor was there any attention to the multiplicative relationship of the values in the task. Whereas the task had been used to engage participants with mathematical concepts to develop understanding in the PD, in the 7th grade classroom, the task was about doing hands-on mathematics with a goal of knowing that the graph shapes were different.

This suggests that while Donna was able to see the moves the facilitator made and take those into her classroom (e.g., she used questioning, supported multiple approaches and representations, etc.). Her lack of tying these to the mathematics in ways that supported a high press learning environment meant that the students missed out on opportunities for learning.

As suggested by the double triangle of interactions, in order for PD to impact classroom practice, it must be relevant and apparent to the teacher because she is the one who moves the opportunities from one environment to the other. While Donna valued her experiences as a learner, she did not take them, except in a superficial way, into her classroom practice. This suggests two things. First, the Donna viewed pedagogical moves and content knowledge as being separate from each other—thus her ability to use the same pedagogical moves as the facilitator but in less rigorous ways. Second, it suggests that the goals of PD may need to be reconceptualized from supporting the teacher in her personal development to providing support for developing the learning environment in which the teacher practices. This does not mean telling the teacher how to conduct her practice, rather it means focusing the PD so that the teacher's personal development is situated, for her, in the practice of teaching. For example, we wonder whether Donna's content knowledge development around the relationship of quantities in the inverse proportion would have been more salient to her teaching had we presented her with student reasoning similar to her own and let her think about how she would interpret and respond to that reasoning in her own practice. Pursuing opportunities to more fully integrate the two triangles of interaction may support teachers in better translating their own experience as learners into their practice as teachers.

Endnotes

1. The work reported here was supported by the National Science Foundation under grant number DRL-0633975 and DRL-1036083. The authors wish to thank the members of the research team as well as Donna and her 7th graders for their assistance with this research.

STUDYING ONLINE PARTICIPATION AND ITS IMPACT ON THE DEVELOPMENTOF MATHEMATICAL CONTENT KNOWLEDGE FOR TEACHING

Jason Silverman
Drexel University
silverman@drexel.edu

We report on our efforts to support teachers' development of mathematical knowledge for teaching through online professional development. In particular, we report on our investigation into the relationship between online interaction and teachers' development of mathematics content for teaching. Through the integration of content analysis and social network analysis, we identify underlying relationships between aspects of online interaction and teacher learning. Results indicate that while interaction, broadly speaking, was not correlated with teacher learning, particular combinations of content and the centrality of an individual in the interaction were. Implications of these significant correlations for mathematics teacher education are discussed.

For more then a decade, the importance of teachers' content knowledge has been a major focus in the literature (Ball, 1993; Ma, 1999; Shulman, 1986) and increasing teachers' mathematical knowledge continues to be a major focus in both education research and policy (Greenberg & Walsh, 2008; National Mathematics Advisory Panel, 2008). Despite these calls, a great number of elementary teachers continue to be underprepared and uncomfortable with the mathematics content they are expected to teach (Greenberg & Walsh, 2008). At the secondary level, studies have shown that students who have been successful in high school and university mathematics classes – even those with grades of A in calculus – often have weak or underdeveloped understandings of the concept of function, a core concept in the K-12 mathematics curriculum (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Monk, 1992; Thompson, 1994). With regards to the mathematics preparation of school teachers, Cuoco (2001) notes the solutions "will not come from rearranging the topics in a syllabus or by adding more topics to an already bloated undergraduate curriculum. Making lists of topics that teachers should know … won't do it either" (p. 170). He argues that teachers need experiences *doing* mathematics and to develop a "taste" and passion for it. Bass (2005) notes that regardless of their level mathematical preparation, evidence suggests that that teachers lack *Mathematical Knowledge for Teaching* (MKT): "the mathematical knowledge, skills, habits of mind, and sensibilities that are entailed by the actual work of teaching" (p 429).

Throughout the past two years, we have engaged in an extended research project focusing on supporting teachers' mathematical content knowledge and mathematical knowledge for teaching through online professional development. The overarching goal has been to support teachers' mathematical development through authentic engagement in collaborative mathematical problem solving and connecting that engagement with the teaching of school mathematics. In this paper, we report on the results of a subset of this project that sought to support teachers' developing a coherent view of the school algebra curriculum and mathematics content knowledge for teaching school algebra. The primary research question we explore is *What is the relationship between online participation in teacher development activities and teachers' development of MKT?*

Theoretical Background

The majority of online instruction emphasizes the importance of interaction and the affordances of the internet in supporting interaction at a distance, but pays little attention to the key features and functions of those interactions. We have found Lotman's (1988) characterizations of text as *univocal* or *dialogic* particularly useful in understanding the function of the individual posts that make up an online interaction and the interaction as a whole. Univocal discourse functions "to convey meaning adequately" (Lotman, 1988, p. 34). In contrast, dialogic discourse can be characterized as a "thinking device." Lotman describes dialogic function as generating new meaning: "In this respect a text ceases to be a passive link in conveying some constant information between input (sender) and output (receiver). … [I]n its second function a text is not a passive receptacle, or bearer of some content placed in it from without, but a generator" (Lotman, 1988, pp. 36-37). This dualism has guided both the design of our teacher development activities and our analysis of the online interactions.

In our work with teachers, we seek to provide environments that support the dialogic function of text, where teachers view and use each others posts as "thinking devices." We, then, attempt to understand these interactions in terms of their potential and success for catalyzing the generation of new mathematical knowledge and knowledge for teaching. This perspective is consistent with a variety of research in the learning sciences that emphasizes the importance of discourse and interaction in learning (Mercer, 2000; Paloff & Pratt, 1999; Ravenscroft, 2001; Shale & Garrison, 1990; Su, Bonk, Magjuka, Liu, & Lee, 2005). Previous results documenting the relationship between interaction and learning include that learning is promoted through dialogue (Cunningham, 1992) and that learning occurs online through social activity in communities (Haythornthwaite, 2002; Rovai, 2002).

Through a design research methodology, we have developed and explicated a model for Online Asynchronous Collaboration (OAC) in mathematics teacher education, which has at its core cycles of individual, small group, and whole class interaction (see Silverman & Clay, 2010 for a detailed discussion of OAC). OAC begins with participants drafting a solution, initial approach, or questions on a set of purposefully selected, open-ended mathematics tasks in a private online workspace. In these initial posts, we do not expect that each teacher will be able to complete each of these activities, but we do expect each participant to attempt the assigned task and either pose a solution method and solution or ask relevant questions or wonderings that reflect their current state of thinking about the task. After the individual work phase, each participant's initial postings are made public for small-group and dyadic interactions where participants add comments, respond to classmates' questions, or ask for clarifications. Finally, the instructors orchestrate a whole-class discussion that lies at the confluence of the participants' collective sense making and the sessions' instructional objectives.

We have had success documenting participants' mathematical development (Clay & Silverman, 2008; Silverman & Clay, 2009) and the role of the teacher in supporting that development (Clay & Silverman, 2009). Despite these successes, we have struggled to identify correlations between the online teacher development activity and teacher development. In this paper, we focus our attention explicitly on this relationship.

Setting and Participants

In this article, we focus on an online graduate class in mathematics education that focused specifically on proportional and algebraic reasoning. The course was designed to support teachers as they deepen and extend their mathematical understandings and develop schemas within which a variety of mathematical ideas are conceptually connected (Silverman & Clay, 2009). First, we began by exploring mathematical ideas that the teachers teach regularly and ostensibly know well. We then sought to problematize the teachers' current mathematical understandings through posing "changes" to the mathematical idea (for example the exclusion, replacement or addition of properties, generalization, application to a new setting, etc.). These new conceptualizations of school math concepts were then used to support instructional conversations that bridged teachers' developing understandings and the school mathematics curriculum and focused on how various mathematical ideas fit together.

The wholly online class took place in the winter term of 2008 at an urban research university in the Northeastern United States. The class consisted of 17 (13 women, 4 men) who were geographically distributed throughout the United States. The 10-week course was hosted in the Blackboard Learning Management System. Within Blackboard, participants accessed course materials (readings and activities) from their homes or workplaces and participated in both threaded discussion boards and blogs. Each week, participants were presented with prompts to consider when creating their posts, but were consistently reminded that the prompts were meant as guides and not as a list of questions that must be answered. For each discussion board, participants were required to post a minimum of one initial post by Tuesday evening and two replies by Saturday evening.

Data Sources and Analytical Procedures

The two primary sources of data for this study include online interaction data, taken from the participants' interaction in the online discussion forums, and teacher learning data. Teacher learning was measured using instruments developed and validated by the Learning Mathematics for Teaching Project (http://sitemaker.umich.edu/lmt) for measuring teachers *Mathematical Knowledge for Teaching.* For this paper, the two versions of the LMT instrument for patterns, functions, and algebra were administered and are used as a validated measure of participant learning of the relevant content. Teachers' gain scores were converted to Item Response Theory (IRT) scaled scores using conversion tables provided by the developers.

Coding and Content Analysis

While raw interaction data (who talked to whom) is relatively easy to generate and can provide us with useful information about the interactions between teachers, this information does not provide us with any information about the content of and function of those interactions. In essence, it neglects the basic question posed by Schlager, Farooq, Fusco, Schank & Dwyer (2009): "What constitutes a meaningful relation or tie between individuals?" (p. 87). In order to better understand this question, we employed a variant of content analysis to compare, contrast, and categorize the posts. Coding of interaction data began with Lowes, Lin & Lang's (2007)'s coding scheme for coding interactivity in an online class, which was adapted to meet the needs of this project through a recursive process. Ultimately, the following codes became stable for our data set:

Cheerleading/Affirming (C/A)

- Offering praise and encouragement
- Focus on ideas not related to mathematics or teaching (ie. use of learning management system, course logistics, personal issues, etc.)
- Affirmation of work without any evidence of reflection

-

Students, Teaching, and Schools (STS)
- New information about students and teaching from teachers' own classroom or classroom experience

Direct Instruction (DI)
- Providing direct instruction to classmates; telling how to do or solve a problem

Doing Mathematics (DM)
- Making mathematical activity (thinking, representing, conjecturing, etc.) public

Questioning/ Challenging (Q/C)
- Raise questions that extend previous post, or express disagreement with it

All posts were coded on each of the two dimensions by two researchers using the above scheme. In order to ensure the reliability of the coding process, the researchers coded the first 30 posts together and came to agreement on the codes, definitions, and examples. The researchers then coded the entire data set independently and approximately 77% of the items were coded similarly by both researchers. Each item that was coded differently was discussed and deliberated until agreement was reached on how to code the item in question.

Social Network Analysis

Social network analysis (SNA), a mathematical approach for analyzing interactions and the structure of social network and the strength of the ties between actors in the network (Wasserman & Faust, 1994), was used to quantify the interactions being studied. One primary use of social network analysis is to identify important actors in the interaction and we use these measures of importance to further parse the online interaction data and to quantify teachers' role in the online interaction. Within social network analysis, there are two primary ways of quantifying the "importance" of actors in an interaction: centrality and prestige. An actor's centrality, or the number of posts generated by the actor is a measure of his or her influence on others within the social environment. In particular, it is the actor's potential influence on the interaction. When one has a high centrality, he or she is in direct contact with many others: "this actor should then be recognized by others as a major channel of relational information … a crucial cog in the network, occupying a central location" (Wasserman & Faust, 1994, p. 179). An actor's degree prestige, or the number of posts received by the actor (the in-degree), is a measure of how he or she is potentially influenced by others in the social environment. In terms of online learning, an actor's prestige can be interpreted as the amount to which colleagues (other actors) seek out and support an individual (Russo & Koesten, 2005).

Analysis of Relationship Between Online Participation and Increases in Mathematical Knowledge for Teaching

In order to quantify participants' participation, each participant's centrality and prestige was calculated (both their overall centrality and prestige as well as centrality and prestige broken down by each of the codes discussed above). Finally, Pearson's correlation was used to identify statistically significant linear relationships between participants' centrality and prestige and gains in mathematical knowledge for teaching, as measured by the LMT instruments.

Results

Analysis of the relationship between individual participation and LMT gain scores was conducted on the twelve independent variables shown below in Table 1.

Table 1: Twelve Independent Variables

	Centrality	Prestige
Overall	[1]	[2]
Cheerleading/Affirming	[3]	[4]
Students, Teaching and Schools	[5]	[6]
Direct Instruction	[7]	[8]
Doing Mathematics	[9]*	[10]
Questioning/Challenging	[11]*	[12]

An analysis of the linear relationship between each of the independent variables for participants' content prestige and centrality and participant learning was conducted using Pearson's correlation coefficient. This analysis indicated the following positive relationships (indicated by * in Table 1 above):

- A positive relationship between participants' Doing Mathematics (DM) centrality and their LMT gain score, $r(15) = 0.624$, $p < 0.05$.
- A positive relationship between participants' Questioning and Challenging (Q/C) centrality and their LMT gain score, $r(15) = 0.631$, $p < 0.05$.

Conclusion and Discussion

In this study, we bring into question the common belief and research results that emphasize the importance of interaction in online learning (Paloff & Pratt, 1999; Shale & Garrison, 1990; Su et al., 2005). In particular, we present evidence for the claim that it is not *simply* interaction that is important for learning in an online context. We extend Schlager, Farooq, Fusco, Schank & Dwyer's (2009) question of "What constitutes a meaningful relation or tie between individuals?" (p. 87) in two key directions: the content of the contribution and the individuals' patterns of activity. Results indicate that while overall levels of activity in online interactions were not correlated with gains in mathematical knowledge for teaching, the centrality of individuals Doing Mathematics and Questioning/Challenging were. Put another way, teachers with high activity (ie. teachers who generated a large number of posts) coded as Doing Mathematics and Questioning/Challenging tended to have higher LMT gain scores.

We recognize that this result might seem counterintuitive: one of the benefits of social networks (like online classes – or schools, for that matter) is that individuals can learn and grow through individual interactions with group members. For example, research has shown that *who* a teacher "gets help from" and not *the amount* of help a teacher gets was related to changes in teaching practices (Penuel & Riel, 2007). In other words, it seems that the posts directed towards an individual should be an important predictor of teacher learning. This was not the case in this study: participants' learning was correlated with the centrality of an individual (the number of posts an individual directed towards others), provided the posts involved Doing Mathematics or Questioning/Challenging.

We reconcile this apparent contradiction by focusing on the nature of MKT. We have argued previously that the development of MKT starts with coherent mathematical understandings and involves personal reconstruction of one's mathematical understandings to include both (1) the variety of ways that individuals may understand the idea and (2) how particular ways of understanding can empower individuals to learn other, related mathematical ideas (Silverman & Thompson, 2008). We also argued that this personal reconstruction is necessarily the result of a *reflecting abstraction* (Steffe, 1991) and not easily developed through explanation or demonstration: “the transition requires a building up of the understanding through students’ activity and reflection and usually comes about over multiple experiences” (Simon, 2006, p. 362). Framed this way, it appears to make sense that our participants’ learning was not correlated with explanations and demonstrations directed towards the participant (others’ posts directed to the participant). Doing Mathematics and Questioning/Challenging centrality can be interpreted as a metric for the one’s level of personal engagement and reflection in interactions designed to support the development of MKT. We speculate that participants with a high Cheerleading or Direct Instruction are experiencing the same discussion board quite differently than those with high Doing Mathematics and Questioning/Challenging centrality: rather than “telling” they are “doing” and “wondering” and placing themselves in a state of cognitive disequilibrium, which has the possibility of stimulating equilibration (learning).

Implications for Mathematics Teacher Education

The primary implication for mathematics teacher education is that, while teachers need to be challenged and encouraged to engage with their colleagues as part of their professional development activities, efforts need to be made to increase the amount of Doing Mathematics and Questioning/Challenging that they engage in. One obvious method, which we have implemented with little success, is being more specific about the posting requirements (for example, requiring at least one Doing Mathematics or Questioning/ Challenging post). We believe that there are two reasons for our lack of significant results from more specific requirements: our past participants (1) want to talk about what they believe their current needs to be and doing or learning math is often not a current perceived need and (2) often believe that direct instruction *is* the essence of doing mathematics. With these two factors in mind, it is clear that the challenge is not one of imposing requirements but rather one of a cultural shift: teachers need to come to see the value of MKT for their teaching and that the more teachers engage in *doing* mathematics, the more effective they will be at supporting their students as they do mathematics. Thus, it seems that one way to increase the effectiveness of online implementations designed to foster MKT would be focused teacher development activities designed to support this cultural shift. Examples of such activities include the Math Forum’s Online Mentoring Project (Shumar, 2006) and dialogue games (Ravenscroft, 2007).

Future Work

We fully recognize that all of the emphasis cannot be placed on increasing participants’ Doing Mathematics and Questioning and Challenging centrality – these posts need not and do not happen in a vacuum. A great many Doing Mathematics posts were in response to others’ posts and it is necessary to have something (a post) to question or challenge. Further, we acknowledge that other types of posts (cheerleading, for example) may be useful in supporting generative discourse. We have begun to explore sequential analysis (Bakeman & Gottman, 1997; England, 1985; Jeong, 2003) to study group interactions. Sequential analysis involves using probability to study relationships between individual posts and predict the characteristics of interactions that support individual contributions with particular characteristics (for example, “Doing Mathematics” posts) and the conditions under which those posts are more likely. In addition to increasing the effectiveness of our online teacher development, we believe that this research can help us bridge our work and the current emphasis on online communities in teacher professional development.

We investigate the impact of integrating dynamic geometry environments with haptic devices, which allow users to not only see and manipulate geometric figures on a screen but also feel, through force-feedback, the result of interacting with such objects. The feedback loop can be assigned to varying attributes of objects, for example, the changing area of a deformable triangle, as well as invariant ones. We report preliminary findings from our work in informal settings. Our findings indicate that such experiences allow young children as well as undergraduates to yield expressive discourse that is intimately connected to the mathematical concepts being presented.

Introduction

Our project combines various technological ingredients to develop a new mathematical and scientific learning environment for allowing more students to access conceptually demanding ideas through various senses in K-5th grade classrooms. We are using a modified version of *The Geometer's Sketchpad®* software, the H3D Application Programming Interface and specific haptic devices.

Haptic literally means "ability to touch" or "ability to lay hold of" (Revesz, 1950) and has evolved in a technological era to be an interface for users to virtually touch, push, or manipulate objects created and/or displayed in a digital visual environment (McLaughlin, Hespanha, & Sukhatme, 2002). Haptic devices can provide force-feedback or tactile feedback. Haptic interfaces allow users simultaneous information regarding their input and reaction to that input as programmed within a computational environment.

The activities we are creating allow users to construct, interact and explore geometric figures and shapes, and so engage in model-eliciting activities in various mathematical topics. Our study is assessing and evaluating what new or enhanced learning experiences can be created by the synergistic integration of dynamic geometry with new haptic hardware, why this is necessary and how it can improve present practice.

We are designing new mathematical investigations that build on established curricular standards and frameworks, and assess the potential scalability of such an approach in the future given these intersecting research traditions. We can finally do this because of the availability of new affordable devices, but such technological advances are irrelevant without an aim to transform the mathematical and scientific activities of the classroom. The first stage of our project, which we report on here, investigates the educational potential for introducing such a multi-modal environment in different settings by investigating how it can engage different aged students to investigate mathematical ideas focused on change and variation. We particularly focused on features of *expressive discourse* that are elicited when students interact with our dynamic haptic geometry environment. We have analyzed whether the added modality of force-feedback can be engaging and rich for students in terms of how they can potentially discover new concepts, which has led to the emergence of design principles for future implementation in formal mathematics settings.

Theory

Haptic technology has evolved over the past 10 years, particularly out of a focus on virtual reality in the 90s, and has become more available in a variety of commercial and educational applications, including 3D design and modeling, medical, dental and industrial applications. However, research specifically examining haptics in relation to learning and education is scarce. A large proportion of the existing studies focus on "haptic perception" a major field in psychology focused on haptic sense, and the second main set was focused on multimodality. Multimodality reaches into education in various ways intersecting deeply with a multi-media approach. Recently, multimodal approaches have also focused on the role of gesture with increasing interest (Wagner Cook, Mitchell, Goldin-Meadow, 2008) with particular focus on this mode as a form of mathematical expressivity (Hegedus & Moreno-Armella, 2008).

Historically, this has been translated as a way to create multiple learning pathways for students to work within auditory and visual modalities. In fact, the audio/visual modality is still the predominant "multi-" media form. But, students can interpret visual, auditory and haptic displays to gather information, while using their proprioceptive system (making sense of the relative positions of one's own body parts) to navigate and control objects in their synthetic environment (Dede, Salzman, Loftin & Sprague, 1999). In this work, multiple sensory representations can offer mutually reinforcing information that a user can collect to develop an understanding of a mathematical or scientific model. In addition, haptics have been said to be superior to vision in the perception of properties of texture and microspatial properties of pattern (Zangaladze, Epstein, Grafton, & Sathian, 1999), while vision is more useful in the perception of macrogeometry particularly shape and color (Sathian, Zangaladze, Hoffman, & Grafton, 1997). Leveraging these relative strengths, our proposed activities will incorporate the need to investigate both shape and properties of construction (i.e., the mathematical structure of a figure or surface). We propose that it is relevant to integrate haptic technology with dynamic geometry software to offer multiple sources of information-feedback for students; it is not enough to offer a way for students to just see a mathematical object or a scientific model in a static way they must also engage with it dynamically, tactically and naturally.

Setup of Multi-Modal Technology Environments

Description of the haptic activity setup

The SenseAble PHANTOM Omni haptic device (See Figure 1) is capable of reading position and orientation data of a stylus in 3D space, which serves as the physical interface to the device. The device also provides force feedback to the user through the stylus. Users can grip the stylus and move it freely in 3D space with their choice of grip suitable to their intentions at any given time. We paired PHANTOM Omni with a laptop so that users are able to view a visual simulation as they simultaneously manipulate the device. Interviewers used the mouse and a separate keyboard to manage switching among activities and manipulating the parameters of activity variations.

Description of the Types of Simulations

We aimed to elicit student expressivity associated with two types of simulations: *breaking point* and *impact*. A *breaking point* is defined as a point of resistance against the haptic stylus, where the resistance is removed once a large enough force is exerted on the stylus. An *impact* is defined as bumping into, or being bumped by objects within the haptic environment. These simulations were embedded into activities in which the students were not initially presented with any visuals. This protocol gave us the opportunity to hear students draw heavily on their haptic experiences without the additional influence of the visual simulation. Later, visuals were revealed in order to examine ongoing expressive discourse in the presence of additional stimulus.

One activity we embedded the simulation of *breaking point* is called *Falling Off*. Haptic experience in this activity consists of a resistant force occurring from a user's contact with a visual surface using the haptic device. As the user moves off the edge of the surface, the resistance is removed, which results in a feeling of falling off. Another activity involving the simulation of breaking point is called *Break Through*, wherein users encounter an unavoidable barrier in the center of the haptic environment. When contacted by the user, the barrier provides a resistant force, which can be removed once the user exerts sufficient force on the barrier. Additional haptic experiences can be added to either side of the barrier through the exertion of forces that oppose a user's movements within the haptic environment.
