As has been exemplified, reducing abstraction in teaching, in some cases, proved to be an effective teaching strategy (mostly in category 1). However, in other cases, it does not seem to be supportive of the development of mathematical knowledge for the students (mostly in category 2 and 3). One important question then, is: what are the reasons behind reducing abstraction in teaching that do not promote learning with understanding (as in category 2 and 3)? Because this study was based on the TIMMS video lessons, and interview with the teachers was not possible, it is hard to infer why the teachers reduce abstraction in the categories that do not appear to promote learning with understanding. Further research will address this issue. Finally, the results emphasize the importance of paying attention to the nature of students' understandings that may arise as a consequence of reducing abstraction of the concepts they are attempting to teaching.

VOICES FROM THE TRENCHES: TEACHERS' VIEWS ON TEACHING MATHEMATICS TO GIFTED AND TALENTED STUDENTS

Abraham Ayebo
Purdue University Calumet
abraham.ayebo@purduecal.edu

This study reports the views of teachers of gifted and talented students on perceived characteristics of mathematical giftedness as well as well as what current instructional strategies are being used with mathematically gifted and talented students in the general education classrooms. Interviews were conducted with five teachers who teach mathematics to gifted students. Some of the findings include distinction between gifts and talents, student subgroups, and instructional needs of mathematically gifted students.

Introduction

Mathematically gifted students learn differently from their peers. They require special attention and differentiated curriculum to meet their specific needs (Greenes, 1981; Jolley, 2005). When these students do not receive the learning experiences that are appropriate for their unique abilities, they can become bored and frustrated and eventually become underachievers (Croft, 2003; Hoeflinger, 1998). Requiring mathematically gifted students to participate while concepts are repeated for the rest of the class is not a good approach for the gifted student. Studies have shown that curricula in general education classrooms are frequently inappropriate for gifted students. For example, a national study by Heacox (2002) found that an average of 35 to 50 percent of the regular curriculum at the elementary level could be eliminated for gifted students. Krutetskii (1995) also cites research showing that mathematically gifted students can complete a year of grade-level mathematics in three to six months. Mathematically gifted students are more likely to retain mathematics content accurately when taught two to three times faster than the average student (Krutetskii, 1995). Thus, schools need to make curricular changes to account for the learning needs of mathematically gifted students. This study was therefore designed to examine teachers' perceptions of mathematically gifted students and how to meet the instructional needs of such students.

Theoretical Framework

Tomlinson's (1999) work on differentiation informs this study because differentiation is frequently recommended as a strategy to meet the needs of gifted and talented students in the general education classroom. Modifications can be made to differentiate instruction for the gifted learner in the general education classroom according to the interests of the child, the pace of the curriculum, or the depth of the curriculum. Tomlinson (1999) offered four characteristics of the effective differentiated classroom. The first characteristic is that instruction is concept-focused and principle-driven. The next characteristic is that ongoing assessment of student readiness and growth is built into the curriculum. A third characteristic of the effective differentiated classroom is that flexible grouping is consistently used. Tomlinson (2003) defined flexible grouping as "students consistently working in a variety of groups based on readiness, interest, and learning profile, and both homogeneous and heterogeneous in regard to those three elements" (p. 84). A final characteristic of the effective differentiated classroom is that students are active explorers with teachers guiding the exploration.

According to Tomlinson (2003), differentiation is "responsive teaching, [that] stems from a teacher's solid (and growing) understanding of how teaching and learning occur, and responds to varied learners' needs for more practice or greater challenge, a more active or less active approach to learning, and so on" (p.2). Tomlinson explains differentiation of instruction as a teacher's response to students' needs, guided by general principles of differentiation. The principles of differentiation include the following: focusing on essentials; attending to student difference; aligning assessment and instruction; modifying content, process, and products; working and learning together; respectful tasks; flexible grouping; and ongoing assessment and adjustment. Tomlinson recommends that teachers differentiate content, process, or products based on student readiness, interests, or learning profile. Readiness refers to a student's knowledge, understanding, and skill that designate their entry point within a particular sequence of learning. It can be influenced by factors such as prior experience, attitudes, and habits of mind. Interest refers to topics that are of interest and are a passion for the learner. The learning profile refers to how students learn best and includes learning style, intelligence preference, culture, and even gender. Tomlinson adds that differentiation can occur through various instructional and management strategies. Some of the more critical strategies she suggests for differentiation include literature circles, tiered lessons, learning contracts, independent study, varied questioning strategies, compacting, and varied homework.

Method

Design and Theoretical Framework

The aim of this study was to examine teachers' views on teaching mathematics to gifted/talented students. More specifically, the study addressed the following questions: a) What student characteristics make a student gifted/talented in mathematics? b) What instructional approaches are important for teaching mathematics to gifted/talented students? The methodological orientation of the study was phenomenological. This means that teachers' accounts of their experiences may be understood as descriptions of the essential features of pedagogical interaction, allowing us to comprehend the phenomenon in a new way (Van Manen, 1990).

Participant

Five research participants, Julia, Janet, Jane, Joel and James (pseudonyms), were selected on a voluntary basis. The group of participants was fairly heterogeneous in terms of their discipline, age, and experience as a teacher. Three of the participants were female; two were over fifty years of age, two were between thirty and fifty, and one less than thirty years. All five participants were Caucasian. In order to protect the participant's identity, more specific demographic information cannot be provided.

Face-to-face, semi-structured interviews were conducted with each participant. The interviews lasted from thirty to forty-five minutes. The questions were open ended to allow participants to tell their stories freely. A typical question, for example, went as follows: "What teaching techniques do you believe are especially important for teaching mathematics to gifted and talented students?" The interviews took place at a mutually agreeable, private place and time. Interviews were audio taped and transcribed.

Limitations

The limitation of the current study is the representativeness of the participants. Thus, the findings and conclusions from this study might not necessarily reflect the views of all teachers of mathematically gifted and talented students.

Data analysis

After the data were transcribed, the transcripts were read while listening to the tapes, and initial codes were developed. The participant's story was the real guide to coding the data, and codes were developed as necessary to reflect the themes that appeared in the interview transcript. Once the coding scheme reached a point where it seemed to capture the relevant parts of the participant's story, the interview were re-coded.

Results

The main themes that were constructed in the data were characteristics of gifted students, distinction between gifts and talents, struggles/challenges for gifted students, instructional needs, and student subgroups.

Characteristics of Mathematically Gifted Students

The characteristics of mathematically gifted students mentioned by participants were understanding of numbers and patterns, communication difficulties, and lack of organization. Sample comments are as follows:

- Some of the characteristics include their understanding of numbers and patterns; their ability to think about mathematics in a variety of ways, so that mathematics comes naturally to them. They don't struggle at all. They just seem to understand the patterns. Now, sometimes, that doesn't translate, they are not able to show how they understand it. They just understand it, but then they struggle with showing how they got their answer and explaining their thoughts (Janet).
- I think that when we hear the word 'gifted', it means they are exceptional. They have a depth of understanding of the mathematical concepts, rather than the mathematical tasks. So you can give them application problems and they jump on it right away. Or they see a clever way or a much more convenient way of proving something, or just analyzing something. So they are operating at those really high levels of understanding and they always do very well on the application problems, extra-credit problems, things like that (James).
- I find that mathematically gifted students tend to do very well on math tests and quizzes. They tend to be lousy and disorganized. Some of them have find it difficult paying attention in class, especially if the lesson is not challenging enough (Julia).

Distinction Between Gifts and Talents

On whether mathematical giftedness and mathematical talent were the same or different, participants' responses were again inconsistent:

- I always assumed mathematical giftedness and mathematical talent were interchangeable.
  I would say gift is what you have naturally and talent is what you do with that gift (Julia)
- Gift is when you visualize math without having to be trained; talent is when you can learn and be efficient at it. (Janet)
- Talent is innate; talented students communicate well, write out their solutions. Gifted

> students on the other hand are bad at process and communication though functioning at high level in relation to concept understanding (Joel).

Struggles/Challenges for Gifted Students

All three participants noted that mathematically gifted children do in fact have areas of struggle that tend to hinder them from reaching their full potential. These difficulties include difficulty in showing/explaining solution processes, answers, and concepts; tendency to become bored more quickly and thus be unmotivated; reduced confidence with general education students due to being with intellectual peers, and fear of failure. Here are sample participants' responses:

- Showing their understanding and going through the little steps to get the solutions seems to be a huge problems for most mathematically gifted students. They are used to getting the right answers with less effort, and so they struggle with: How did you get that answer? And when they get the answer wrong, they get easily frustrated because they never did the 'baby' steps to get it (Jane).
- One of the biggest challenges facing mathematically gifted students is speaking the language of mathematics. They have been so good at math that they are kind of able to bully their way through a math class. They understand the concepts, especially at the lower levels. Once you start getting into the higher-level concepts and higher level thinking, they ran into trouble because they can't communicate in mathematics. And that has to do with symbols, for instance being able to tell the difference between an equal sign and an implied sign. You have to teach them how to express their ideas on a piece of paper. Otherwise, they are just ideas inside their heads. The other challenge is being organized. In my classes, I force them to keep a three-ring binder, where they keep their assignments, homework, exams, syllabi, schedules, calculators, pencils, and so forth. (Joel)
- They are often are unmotivated and need to be pushed a bit. It is difficult to keep them motivated in a linear fashion. You have to always keep them motivated and interested else, they lose focus entirely. Also, they tend to be perfectionists and fear to attempt a problem that presents a risk of failure (Janet)

Instructional needs

Participants noted that mathematically gifted students should be taught in separate classes from general education students. They further contended that the gifted students must be taught at an appropriate level of challenge - neither too low nor too high. This would require pre-assessing to see what they need to learn and compacting accordingly. Participants also mentioned that teachers should teach mathematics in varied ways to keep students creative; use real-world applications; and learn to think in a different way that values process and problem solving. Sample participants' comments follow:

- The teacher of the mathematically gifted needs to be organized. You need to have a clear path. You need to have assessment ahead of time. Pretest students to know where they are, what they understand and what they don't understand. I also think it is important to use questioning strategies to build student understanding (Julia)
- Generally, I think it is best to teach them in their own classroom. The teacher needs to keep them at the appropriate level of challenge (neither too much nor too little; don't want to bore or frustrate them) (Janet)

- The teacher needs to compact materials to suit their needs after pre-assessing to only address what they don't know. This would help eliminate unnecessary repetitions (James).

Student Subgroups

Participants noted that actual ability differences were not noted by gender or race/ethnicity. They said performance differences could occur based on background factors such as linguistic background (for English Language Learners) or what students have been exposed to and encouraged in. Here are some typical responses from participants:

- There is this general notion that somehow boys are better than girls at mathematics. But I think once you get all of them together, you realize that it is not necessarily true. One of my most gifted and talented students that I have ever taught was a Black female, so that breaks the stereotype right away. So I think with the gifted kids, you start seeing those stereotypes fall apart (Joel).
- I think race/ethnicity does not necessarily have an direct impact on the mathematically gifted student. It depends on the student. And I think that if their first language is not English, that could hold them back a little bit. With African-Americans, I don't think there is anything holding them back. I have several gifted and talented students that I taught who were African-Americans, and several who were Latinos. I noticed with the Latino students that if their first language is not English and they are still acquiring the language, they might be hesitant because they are afraid of coming our perfect in the way they say their answer (Julia).

Discussion and Implications

The teachers in this study mentioned many of the characteristics that are associated with mathematical giftedness. Many of these characteristics are described in the literature by Diezmann and Watters (2000), Hoeflinger, 1998, and Sriranam (2003). Straker (1983) also describes many of the same characteristics and suggests that one should look for indicators such as "a liking fnumbers including use of them in stories and rhymes; an ability to argue, question and reason using logical connectives: if, then, so, because, either, or…, and patter making" (p. 17)

Many scholars have noted that the way giftedness is defined and perceived affects how parents, teachers, or school administrators handle the gifted child (Assouline, 2003; Callahan, Cooper & Glasscock, 2003; Roedell, 1984; Rotigel, 2004; Sternberg, 2003; Van Tassel-Baska & Johnsen, 2007;). The teachers in this study did not have a comprehensive, articulated concept of mathematical giftedness. Their knowledge about some of the characteristics was based primarily on teaching experience and observation of their students' behavior. Potentially, it means that many students could be overlooked in the identification process if teachers do not have knowledge about these types of mathematical giftedness.

Participants from this study mentioned that mathematically gifted students should be presented with materials that are rich in content and that can arouse their natural curiosity. Teaching them material that is below their level causes them to feel bored and disengaged in class. This is consistent with the assertion of Leder (1991) that teachers who teach mathematically gifted children should ensure that their content is problem based, and rich in content.

The findings from this study provide intriguing initial insights into teachers' views on teaching mathematics to gifted/talented students. These findings also point to the fact that stakeholders still have an unfinished business of shedding more light on what constitutes giftedness and how to identify a gifted child

PRE-SERVICE TEACHER CONCEPTIONS OF REAL NUMBER

Robert Michael Baldwin
Virginia Tech
rbaldwin@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

This study examines pre-service teacher conceptions of real numbers within three contexts: distance, a point on the real line, and set membership. The study involved 25 pre-service mathematics teachers, in various stages of education, at a large university in the southeastern United States. Participants were administered a survey to assess their understanding and notions of real numbers. Analysis of participant responses from six survey items (two per context) revealed ten distinct conceptions of real number. Implications of these findings as they relate to nonstandard infinitesimals are also discussed.

Research has shown that many students struggle with the notions of real numbers (Tall & Schwarzenberger, 1978; Fischbein, Jehiam, & Cohen, 1995; Peled & Hershkovitz, 1999; Sirotic & Zazkis 2007). According to Olive (2001) a child's number sequence is a dynamic structure progressing as the child develops. Although Olive is addressing only part of the real numbers (i.e., the counting numbers), it is not farfetched to imagine that the same is true for the reals. But how do learners think about and work with real numbers? What types of concepts do they use and within what contexts do they use them? The purpose of this study is to investigate and document pre-service teacher conceptions of real number within three contexts: distance, a point on the real line, and set membership. For the purpose of this study conceptions of real numbers are not limited to the classical standard construction of the reals, but also include non-standard constructions involving infinitesimals.

The Real Numbers

Standard Analysis

To describe the real numbers in great detail would involve one or more textbooks. For the purpose of this study, the standard real numbers are defined in the classical sense, axiomatically, as a Cauchy Archimedean ordered field (Rudin, 1976). Casually, the reals refer to the set of rational numbers (i.e. numbers that are the ratio of two integers excluding zero from the denominator) and the set of irrational numbers (i.e., Archimedean numbers that cannot be represented as a ratio of integers). Informally, the Archimedean property of the real numbers implies that there can be no largest number and no smallest number.

It is noteworthy to mention that standard analysis as we know it today began to take shape in the early 1800's with the introduction of Weierstrass' epsilon-delta proofs of limit and continuity. These notions found favor among the formalists and their quest for formal mathematical foundations (Nunez & Lakoff, 1998; Tall, 1980; Keisler, 1976). Original notions of the calculus, up to that time, involved infinitesimals (i.e., a small unmeasureable cloud around a number, smaller than any real number) which were done away with because mathematicians had not yet developed a proper treatment for infinitesimals (Keisler, 1976).

Non-standard Analysis

In the early 1960's Abraham Robinson showed that infinitesimals were valid mathematical objects using methods from model theory developed in the 1950's. Robinson referred to his infinitesimal analysis as a non-standard analysis due to its use of non-standard methods (Keisler, 1976). In doing so, Robinson established a rigorous foundation for the infinitesimal notions that had proved useful to Newton, Leibniz, Euler, Hilbert and others (Robinson, 1966; Goldblatt, 1998; Nunez & Lakoff, 1998; Tall, 1980; Keisler, 1976).

The Hyperreals

Succinctly stated, Robinson, operating from the notions of Leibniz, formally defined infinitesimal numbers and extended the set of real numbers to include them, thus forming the hyperreal system. According to Keisler (1976), “one can form the hyperreal number system by adding infinitesimals to the real number system and obtain a powerful new tool in analysis” (p. iii). Goldblatt (1998) defines an infinitesimal number as follows: “a nonzero number ε is defined to be infinitely small, or infinitesimal, if,

$$|\varepsilon| < \frac{1}{n} \text{ for all } n = 1,2,3 \ldots$$

Conversely, 1/ |ε| is considered to be infinitely large or infinite. In this way the hyperreals form an ordered field *R containing R as a subfield” (p. 3).

Real Number Conceptions

Real number conceptions in this study are not limited to the classical standard construction of the reals, but take into consideration the notions of non-standard analysis as well. From this expanded perspective, the context of distance (a variation of the measure context; Fischbein, Jehiam, & Cohen, 1995), the context of set membership, (Peled & Hershkovitz, 1999), and the context of a point on the real line (Peled & Hershkovitz, 1999; Sirotic & Zazkis, 2007) were examined. Below we review the literature related to different conceptions of real number.

Fischbein, Jehiam, and Cohen (1995) conducted a study involving 30 ninth-grade students, 32 tenth grade students and 29 pre-service teachers. The researchers administered a questionnaire that examined formal knowledge of mathematics, real number hierarchy, and intuitive knowledge regarding continuity, infinity, and measure. According to the study, several pre-service teachers struggled with rational and irrationals in terms of set membership and some equated the term irrational with non-whole numbers. Results also indicated that participants in general did not have a problem with intuitive notions involving incommensurable segments (segments that cannot be divided evenly by a common unit), an infinity of rational numbers over a segment, or an infinity of irrational points over a segment. This study did not overtly investigate or involve intuitive notions related to infinitesimals.

Peled and Hershkovitz (1999) conducted a study involving a group of 55 students in their 2nd and 3rd years of college working toward mathematics teaching certification. Their study investigated student’s knowledge of irrational numbers, including location of irrational numbers on the real line and set membership. According to Peled and Hershkovitz, of the 55 students surveyed, 22 students were not able to locate $\sqrt{5}$ on the real number line. Several students believed that a measurement involving $\sqrt{5}$ could not be made because of the never ending decimal. It was hypothesized that students held a belief that numbers such as $\sqrt{5}$ cannot be reached because of the non-periodical never ending decimal expansion. Peled and Hershkovitz’s study (1999) was geared toward the exploration of pre-service teacher knowledge of irrational numbers within the system of standard analysis.

Building on the work of Peled and Hershkovitz (1999), Sirotic and Zazkis (2007) administered a questionnaire to 46 pre-service teachers as part of a course designed for professional development in the area of secondary mathematics. The study included an analysis of follow-up interviews with 16 of the 46 participants. With regard to the location of $\sqrt{5}$ on the real line, Sirotic and Zazkis (2007) found that the participant's answers fell into five categories. In the first category were those who made use of the Pythagorean Theorem to identify the exact location of the point. The second category consisted of those who used at least some precision in a decimal approximation. The third category included those using somewhat rougher decimal approximations to identify the point (e.g. somewhere between 2 and 3). The fourth category included those who used the graph of a function or a similar graphical aid to locate the number on the real line. Finally those who claimed that the task was not possible comprised the fifth category. Much of their analysis was qualitative and based on participant interviews. These five pre-service teacher conceptions emerged within the context of locating a point on the real line. Like Peled and Hershkovitz (1999), these researchers found that participants conceptualized a number as not being able to be reached or as having an approximate location on the real line. This study did not take into consideration infinitesimals or a non-standard approach.

Tall and Schwarzenberger (1978) describes learner conflicts involving the idea that $1 = 0.99\overline{9}$. According to Tall and Schwarzenberger, learner conflicts may result from a lack of understanding of the concept of limit, and the "intrusion of infinitesimals" (p. 6). They suggest that learners often feel that there "should be a one-one correspondence between infinite decimals and real numbers. They are confused when they see that two different decimals can correspond to the same real number" (p. 6). Confusion between decimal representation and other types of number representation has been noted by several researchers since this study (Oehrtman, 2009; Sirotic & Zazkis, 2007; Peled & Hershkovitz, 1999; Richman, 1999).

Oehrtman (2009) conducted a study involving 120 students from an introductory calculus class. Sixty-four of the students had taken calculus in high school. Oehrtman found that mathematical metaphors significantly influenced the way in which students justified certain claims. In terms of inconsistent responses regarding the standard definition of real numbers, Oehrtman points out that several students used what he refers to as an "approximation metaphor." For example, when talking about the equality $1 = 0.99\overline{9}$ several students described an "arbitrarily small," "infinitely small," "infinitesimal" difference or that 0.9 was the "next number" or that it "would touch one" (p. 417). These findings suggest a relationship between human intuitions of infinitesimals. For instance the number next to the number 1 makes sense in non-standard analysis whereas in standard analysis it cannot exist due to the Archimedean property.

Considering participant conceptions from both standard and non-standard analysis, Ely (2010) conducted a case study involving one college student selected from a larger group of 233 college-level calculus students. The larger study involved a questionnaire regarding conceptions of calculus, limits, functions, continuity, and the real number line. From the original sample of 233, six students were chosen for follow-up interviews. From these six, one female student was selected for the case study due to the interesting nature of her responses given during a follow-up interview. Based on this study Ely suggests that some misconceptions about real numbers and infinity may not be a misconception, but instead may be thought of as intuitive conceptions that are consistent with the non-standard system. Ely found that 31% of the participants in the larger study held non-standard views.

Richman (1999) suggests that two different conceptions of infinity form the basis for two distinct interpretations of the statement $1 = 0.99\overline{9}$. The two notions of infinity are related to what Aristotle described as potential infinity and actual infinity. According to Richman potential infinity conveys a sense of a process, as if the number $0.99\overline{9}$ were somehow on its way to the number 1 or in the process of getting there. Actual infinity suggests a completed process, that is, 1 is the same as $0.99\overline{9}$. Richman makes the point that if two numbers are considered the same in terms of limits, a distinction should be made between equality of numbers and convergence at a limit point. In this way, learners might learn why and under what conditions their intuitions are supported.

From the literature it is clear that people struggle with various concepts of the real number system. Much of the research has been conducted from the point of view of standard analysis. Recent research has suggested that some intuitions leading to misconceptions in standard analysis may be valid conceptions when considering nonstandard analysis. The Sirotic and Zaskis (2007) study revealed five conceptions of the standard real numbers within the context of locating a number as a point on the real line. The Peled and Hershkovitz, (1999) study revealed similar findings. Several of the studies revealed issues related to irrational numbers and their non-periodic never ending decimal representations. Nowhere in the literature is there a study investigating knowledge of real numbers from both the standard and non-standard perspectives over several contexts. This paper reports on both standard and non-standard conceptions within three contexts: distance, a point on the real line, and set membership.

Methods

Participants

This study involved 25 pre-service mathematics teachers in various stages of their education. All were juniors or seniors or graduate students at a large university in the southeastern part of the United States.

Procedures

The participants were given a survey including 25 items related to the real numbers. From this survey six items were selected for further analysis: two items related to distance, two related to location of a number as a point on the real line, and two related to set membership (see Table 1). D1 and D2 are related to distance and were presented in a True/False format requesting an explanation for the given answer. The two location items L1 and L2 and one of the set membership items, S1, were also presented in this format with L2 requiring a yes/no answer with explanation. For set membership item S2, participants were asked to circle all the irrational numbers in the given set and asked to explain the reason for their selection.

The first phase of the analysis involved the coding of participants' answers and explanations within the context of real number conceptions. We were not interested in the idea of participant misconceptions and focused solely on participant conceptions, in particular, we recognized that conceptions of real number may appear in both standard and non-standard ways. Although we did not intentionally marginalize concepts that did not fit either one of these constructions, our focus was centered on conceptions that were consistent with one or the other. As a result there may have been other conceptions that were not categorized within this analysis. Since two of the items in this study were closely related to the question posed by Sirotic and Zaskis (2007), we expected to find similar conceptions within the context of locating a number as a point on the real line. We were also interested in learning whether or not any of the five conceptions cited in their study would emerge from within the other two contexts. For these reasons, the five conceptions revealed in Sirotic and Zaskis (2007) were considered as a "start list" as discussed in (Miles & Huberman, 1994, p. 58).

Context	**Label**	**Item**
Distance	D1	The distance between two points is necessarily rational.
Distance	D2	To express a distance in terms of an irrational number makes no sense.
Location of a point	L1	The $\sqrt{5}$ has a precise location on the real number line.
Location of a point	L2	Can the exact location of $\sqrt{7}$ be found on the real number line?
Set membership	S1	The number $0.33\overline{3}\ /5$ is a rational number.
Set membership	S2	Circle all irrational numbers in the given set of numbers: $\{\ 0,\ \ \sqrt{5},\ \ \frac{3\frac{1}{2}}{7},\ \ 0.123152687943,\ \ \sqrt{\frac{1}{16}},\ \ 3i+5,\ \ 13,\ \ \frac{\frac{1}{2}}{\frac{2}{3}}\ \}$ Explain briefly why you believe these numbers are irrational.

Table 1. Items by context

Results and Discussion

Within the context of locating a number as a point on the real line, this study confirmed two of the Sirotic and Zaskis (2007) conception categories: a) use of the Pyhtagorean Theorem and b) Impossible situation. However, during the early stages of analysis it became necessary to expand the conception categories to accommodate the three different contexts as well as non-standard conceptions. Modifying the categories was also necessary due to the difference in focus between this study and the Sirotic and Zaskis (2007) study. For example, we did not ask participants to show "how" they would locate the $\sqrt{5}$ on the real line and therefore graphing or use of a function was not a conception documented in this study. Our items were focused more on pre-service teacher beliefs about its location and "why" they believed what they believed. As a result, several of the conceptions that we found, although related to the Sirotic et al. categories, were differentiated from 4 of their 5 categories. From our perspective, the Sirotic et al. categories represented conflations of conceptions. One example of this idea can be observed in the pre-service teacher response to L2: "yes, but not its decimal approximation." In this example, the pre-service teacher conceived of the $\sqrt{5}$ as having a precise location but believed its decimal approximation did not. Ultimately, in our study, five conceptions emerged from the location of a point on the real line context, a) precise location, b) approximate location, c) dynamic location, d) non-standard conception, and e) formal conception. The analysis of all six items, spanning the three contexts, revealed additional conceptions for a total of ten conceptions. These conceptions are listed in Table 2. In the following sections we present some of the participants' explanations of their answers and a discussion of the nature of the conceptions that seem to be represented by their responses.

Precise location
Dynamic location
Approximate location
Use of irrationals other than Pythagorean irrationals
Decimal representations
Ratio of integers
Use of the Pythagorean theorem
Impossible situation
Non standard conception
Formal conception

Table 2. Participant conceptions

Location of a Number as a Point on the Real Line

The following are examples of students' explanations associated with items L1 and L2 with associated category in parentheses:

> *Every real number has a precise location on the real line.* (precise location)
>
> *Yes. Between 2 and 3 closer to 3.* (approximate location)
>
> *Not exact but close.* (not able to locate)
>
> *Yes, through properties of triangles.* (Pythagorean Theorem)
>
> *It is the limit point of a sequence of rationals.* (formal conception)

In addition to these conceptions, some participants were found to use dynamic conceptions and non-standard conceptions of real number. The following two responses to item L1 are examples of these conceptions:

> *No it only theoretically exists. Because it is irrational it is impossible to pin down.*
>
> *We can never actually get there. We get infinitely close.*

We considered "impossible to pin down" to mean that the participant saw the point as moving. For this reason this response and others like it were categorized as a dynamic conception. The phrase "never actually get there" is a notion referred to in the Richman (1999) study dealing with potential infinity. Following this phrase was the phrase "we get infinitely close." Any explanation that used the term "infinitesimal" or "infinitely close" was considered a non-standard conception.

Distance

In response to items D1 and D2, several participants used the Pythagorean Theorem, drawing graphs and constructing right triangles in an effort to demonstrate an irrational distance.

In addition to the use of Pythagorean irrationals (e.g., $\sqrt{5}$), several students used irrationals other than Pythagorean irrationals. This conception was employed by participants who chose to use an irrational number such as π or a description not explicitly based upon the Pythagorean Theorem. For instance two participants described irrational distance this way:

> *Two numbers can be π distance apart.*
>
> *The distance between 4 and π is irrational.*

Within the context of distance the most common conception of real numbers involved the use of the Pythagorean Theorem; however, the use of irrationals other than Pythagorean irrationals was also common.

Set Membership

One participant's response to S1 suggested a perturbation involving the equality of 1/3 and $0.33\bar{3}$. She clearly had doubts about whether or not 1/3 = $0.33\bar{3}$ and as a result she answered that she was not sure. Her response was as follows:

> *We had this crazy long debate in [math] class. I'm not sure who won...1/3 =* $0.33\bar{3}$

Based on a discussion with the instructor (A. Norton, personal communication, January 17, 2010), the debate was between those who took the position of standard analysis, (i.e. that the two numbers are equal) and those who took the position of non-standard analysis, (i.e. the use of infinitesimals) suggesting that the numbers were not equal. This participant did not specify set membership related to the number $0.33\bar{3}\ /5$ possibly because she was unsure about what the number represented. Her response was nevertheless considered as a non-standard conception since she was on the fence as to whether or not 1/3 = $0.33\bar{3}$. Her response was the only non-standard response to item S1. The majority of participants simply confirmed that the number was rational.

When asked to "Circle all irrational numbers in the given set of numbers" (see S2, Table 1), of those participants who correctly identified $\sqrt{5}$ as an irrational number, many used a "ratio of integers" conception. What this means is that in the process of explaining why they thought $\sqrt{5}$ was irrational, several participants stated that $\sqrt{5}$ was irrational because it could not be written as a ratio of integers. For instance three responses were as follows:

> $\sqrt{5}$ *cannot be expressed as a ratio of integers.*
>
> *Cannot be written in rational form.*

Because you cannot express it as p/q a fraction.

Participants also employed a "decimal representation" conception to explain their reasoning for their choice of the $\sqrt{5}$. The following three responses are typical of this type of conception:

You cannot represent this number as a terminating decimal.

Never ending decimal.

The number is a non-repeating decimal.

Within the context of set membership we documented participants' use of three conceptions: non-standard, ratio of integers, and decimal representation.

Conclusion

Recent research has suggested that many learners, even at the college level, struggle with different aspects of number, particularly with concepts related to the real numbers. The purpose of this study was to document pre-service teacher conceptions of real numbers within three contexts: distance, point on the real line, and set membership. The findings of this study established ten conceptions of real number within these three contexts. From location of a point on the real line this study confirmed two of the five conceptions found in Sirotic and Zaskis (2007) and found similarities relating to two other categories from their study. This study also found that participants described real numbers using irrationals other than Pythagorean irrationals, dynamic conceptions, and non-standard conceptions. From the set membership context, participants employed decimal representation, ratio of integers, and nonstandard conceptions. With respect to the context of distance participants employed the use of the Pythagorean Theorem and the use of irrationals other than Pythagorean irrationals.

Although this study illuminated ten conceptions of real numbers, many questions remain for further study. How and when do real number concepts begin to develop? How are the real numbers presented to learners in textbooks? What is the relationship between intuitive conceptions and the hyperreal system and does the nonstandard system enhance classical mathematics?

UNVEILING MATHEMATICS TEACHERS' PROFESSIONAL AND PERSONAL IDENTITIES USING PHOTO-ELICITATION INTERVIEWS

Theodore Chao
The University of Texas at Austin
theodorechao@austin.utexas.edu

How do mathematics teachers see themselves? For years, educational researchers have been correlating mathematics teaching with what a teacher knows or believes. But the construct of identity–how teachers see and position themselves–is equally important. This study investigates mathematics teachers' identity through the Photo-Elicitation Interview (PEI). Mathematics teachers choose photographs of the various parts of their lives, and then discuss them during an interview to elicit stories of who they are and how they see themselves. This paper details the use of this method to explore the mathematics teacher identity of two Algebra I teachers.

Once upon a time, Karla was the young teacher filled with potential. Karla routinely worked 70-hour weeks, cheered her students on at almost every single sporting event, facilitated an after-school mathematics tutoring club, and built relationships with local media outlets so that her students' class projects would be featured on the nightly news. She was even promoted to assistant principal in her second year of teaching.

At the time, Karla thought good mathematics teaching meant showing her students how much she cared. She positioned herself as an advocate for students who could not help themselves, chose to teach the low-track students in a low socioeconomic, Latino/a-dominant, urban school. On her lunch periods, students filled her classroom, not just because they wanted help on their math homework, but also because they liked talking to her about their lives.

Fourteen years later, Karla still teaches the low-track Algebra I course at a low socioeconomic, Latino/a-dominant, urban school. However, she has since changed schools twice and relinquished all administrative responsibilities. She leaves the campus shortly after students are dismissed, has not been to a single student sporting event, distances herself from extra-curricular activities, and has no plans to bring any news reporters into her classroom.

She sees her primary responsibility as a mathematics teacher to get as many of her students to pass the high-stakes standardized mathematics exam as possible. In order to be on pace with all the other teachers in the mathematics department, her teaching has become more predictable and structured. Her decisions for what content to teach hinges on whether she thinks it will appear on the high-stakes exams. She knows little about her students' lives, and readily admits that she purposely hides herself, her personality, and her background from her students. She even says she would be surprised if any of her students knew about her ethnicity; they all just assume that she is "Mexican too" even though she self-identifies as Indian-American.

Objective of the Research Study

While Karla does not represent every mathematics teacher, the struggle she has in merging her changing professional identity with her personal identity is an issue that affects all teachers (de Freitas, 2008; Enyedy, Goldberg, & Welsh, 2006; Gee, 2000; Van Zoest & Bohl, 2005; Walkington, 2005). While Karla's mathematics teaching practice looks very different today than it did fourteen years ago, she could be construed by some measures as being a better teacher since she is following a common scope and sequence and her students' scores on the high-stakes exams are consistently high. However, the part that makes her unique–her personal identity–is buried deeper and deeper beneath her professional identity.

In this study, I address the problem of the wavering relationship between personal and professional identities of mathematics teachers through the following research questions:

1. What makes an algebra teacher unique? Outside of defining themselves as mathematics teachers, what is it about where they come from, how they situate themselves, and how they see themselves that makes them special? And, how does this personal identity interact with their professional identity as a mathematics teacher?
2. How do algebra teachers' personal identities reveal how they see themselves in terms of power? In other words, within their own identity narratives, what role(s) do they see themselves playing? How do these role(s) unveil the amount of control they have in forging their own identities?

Theoretical Framework

Mathematics educational research generally splits influences to mathematics teachers into the constructs of knowledge (Ball, 2003; Hill, Rowan, & Ball, 2005; Hill, Sleep, Lewis, & Ball, 2007), beliefs (Leatham, 2006; Pajares, 1992; Philipp, 2007), or both (Simon & Tzur, 1999; Simon, Tzur, Heinz, Kinzel, & Smith, 2000). But beyond just what a teacher knows or believes, the construct of identity–how teachers see themselves–is an equally important component into understanding how people teach mathematics (Drake, 2006; Van Zoest & Bohl, 2005). Most of the existing work exploring the identity of mathematics teachers has been largely theoretical as it is has been a difficult construct to research until recent advancements in technology that allows cheap and easy ways to capture photo, video, and audio data (Clark-Ibanez, 2004; Enyedy, et al., 2006; Harper, 2002).

Teacher Identity

Teacher identity is defined in a number of ways within the educational research literature. Van Zoest and Bohl (2005) present a framework for *Mathematics Teaching Identity* as a way of understanding the various social spaces mathematics teachers encounter during their career, specifically in regards to supporting the development of 'reform-oriented' mathematics teachers. These social spaces emanate from Wenger's (1998) idea of *communities of practice*, in which identity is forged through multiple membership within these communities. Gee (2000) sees teacher identities as defined through power, and his four categories of *natural, institutional, discourse, and affinity-based teacher identities* intersect to unveil how much power teachers have in relation to the institutions they work within.

Other researchers see teacher identity as entrenched within the construct of narrative. Holland, Lachicotte, Skinner, and Cain's (1998) definition of identity involves self-authoring; identity is what teachers tell others about who they are, and the self-understanding that comes from acting to be this person. Sfard and Prusak (2005) use the idea of the narrative to frame identity as a collection of reifying, significant, and endorsable stories about a person. And de Freitas (2008) shows mathematics teacher identity as revealed in the spontaneous moments in which a mathematics teacher uses personal anecdotes during procedural moments in classroom instruction.

Listening to Mathematics Teachers' Narratives

Common to these narrative-based definitions of teacher identity is the idea that teachers only reveal their identities if someone is actually listening to what they have to say (de Freitas, 2008; Holland, et al., 1998; Sfard & Prusak, 2005). Within the work of Cognitively Guided Instruction, the simple act of listening to students is shown as a revolutionary teaching practice (Carpenter, Fennema, Franke, Levi, & Empson, 1999; Carpenter, Fennema, Peterson, Chiang, & Loef, 1989). Duckworth (2001) also argued that deep learning happens in the classroom when teachers stop viewing themselves as authorities of knowledge and instead position themselves as questioners and redirectors to listen to students.

This listening works with mathematics teachers as well. Drake (2006) found that listening to pre-service mathematics teachers write about their experiences as mathematics students led to deep reflections of how they taught mathematics. And de Freitas (2008) found that when teachers revealed their *vulnerable 'I'*–their personal identity–it forced her as a researcher to truly listen and form a relationship with the teacher. While most existing research listens to teachers through an analytic construal that emphasizes what a teacher knows or believes, a deeper listening comes through a narrative construal that emphasizes self-authorship and storytelling (Bruner, 1996; Gee, 2000; Hiebert, Gallimore, & Stigler, 2002).

The Photo-Elicitation Interview (PEI)

When researching such a broadly defined idea such as identity, specific anchoring structures are needed in order to unpack a teacher's notion of their own identity. Vygotsky (1978) wrote about the need for physical anchors, images or artifacts that helped situate the exploration of a child's development from an inner speech to a social speech. Using only observations and interviews with no anchoring structures, Van Zoest and Bohl (2002) were only able to use their construct of Mathematics Teacher Identity to analyze a single teacher because of the complexity of framing the teacher's multiple communities. The use of a structured math story/autobiography helped Drake (2006) unpack the identity of the pre-service teachers she worked with. And in their exploration of science teacher identity, Enyedy, Goldberg, and Welsh (2006) found that identity was best studied when analyzing *teaching dilemmas*–conflicts that come up in the classroom with no easy resolution. Therefore, any good study of mathematics teacher identity requires a formal anchoring structure.

The Photo-Elicitation Interview (PEI) is a structured research method that can anchor this exploration into identity through listening to teachers' narratives. The PEI is a qualitative research method in which researchers introduce photographs, either selected by the participant or the researcher, into the interview context (Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006; Harper, 2002). The PEI successfully elicits identity for a number of reasons. First, visual and creative methods like the PEI are especially useful for studying identities (Brown, Wiggins, & Secord, 2009; Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006). Second, visual and creative research methods open up authentic and socially imaginative spaces in a non-invasive way that honors teachers' busy schedules and responsibilities (Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006; Harper, 2002). Third, the PEI holds a strong history of studying identity within other social sciences, such as nursing and anthropology research (Hansen-Ketchum & Myrick, 2008), and is only recently being used within education research (Clark-Ibanez, 2004). Finally, the PEI excels in generating a narrative authored by the research participants themselves (Brown, et al., 2009; Clark-Ibanez, 2004; Gauntlett & Holzwarth, 2006).

This moment in time is perfect for utilizing the PEI as current technology has finally caught up to the theory–almost all teachers own mobile phones with attached digital cameras and have little issue in using them throughout their everyday teaching routine. In my own experience, I have found that PEI opens up narrative in ways that are respectful of teachers' time and responsibilities (Chao, 2010, 2011).

Methods and Procedures

To investigate mathematics' teacher identity, I gave two Algebra I teachers digital cameras and a loose prompt to "capture your world as a mathematics teacher" in at least 20 photographs. I then set a date three weeks later to sit for a formal Photo-Elicitation Interview. One teacher had taught for fourteen years and identified as female and Indian-American. The other teacher had taught for three years and identified as female and white. During the three weeks, I visited and observed each teacher's classroom to get a feel for her classroom teaching practice and to answer any questions they might have regarding the research protocol. The day before each interview, each teacher chose her ten most important photographs. I then sat with each teacher individually for a Photo-Elicitation Interview in which they shared their photographs one at a time while I asked non-judgmental and non-evaluative questions (Johnston, 2004).

Each interview was videotaped and transcribed for deeper analysis using a grounded theory coding structure to elicit emerging themes of mathematics teacher identity (Corbin & Strauss, 2007; Merriam, 2009). The main data source was this transcribed interview of each teacher, which I analyzed in Transana using a qualitative coding scheme built upon the emerging themes of narrative construction, self-authoring, power, positioning, and hegemony (Bruner, 1996; Corbin & Strauss, 2007; de Freitas, 2008; Gee, 2000; Hiebert, et al., 2002; Merriam, 2009). While the actual photographs that teachers captured as well as the notes I took during classroom observations helped to fill in my knowledge of each teacher, I did not use either of these data points as a source for direct analysis.

Both teachers were selected from a larger Academic Youth Development research project (Bush-Richards, et al., 2011). I had previously worked with both teachers through professional development workshops and classroom observations I helped facilitate, and selected them because they were interested in exploring and talking about their identities and mathematics teaching. Basically, I chose teachers who wanted to tell their story.

Results

Because of space limits, I will only show a snippet from the interview with Karla, the teacher from the introduction, and generalize the overall results from both teachers. The third photograph Karla presented was a school hallway display that showcased academic success, called the *Hall of Honor* (Figure 1). After pulling this photograph up, the dialogue over the next four minutes shifted quickly from a teacher talking about her pride in showcasing good academic work to her feelings of sadness that her career as a mathematics teacher had robbed her of an opportunity to start a family. During the following exchanges, I only asked non-judgmental and non-evaluative questions (Johnston, 2004), such as, "Tell me more about that," or, "How does this relate to your math teaching?"

Figure 1. **Photograph 3 in Karla's Interview. This photograph of a 'Hall of Honor' window display elicits a deep narrative that reveals feelings that the educational institution forced Karla to sacrifice personal happiness for her career, even threatening her ability to start a family. All identifying features of students or the school have been blurred out.**

In just four minutes, the discussion gets very personal and reflective of the way Karla is positioned within the various institutions she interacts within. She moves quickly from discussing the hard work and sacrifice it takes to be a "good" teacher, her feelings of society's expectation of mathematics teachers, to how her professional identity has negatively affected her ability to get married and become a mother.

[00:17:57] Karla: And bringing the news camera in my room and stuff. **But I don't want to work 18 hours a day anymore, and I just didn't feel like I wanted to change the system myself.** So, like that's a systemic issues. That's a cultural issue. That's . . .

. . .

[00:19:40] Karla: **I need a life. Otherwise, I'm going to regret like . . . I would spend a decent amount of hours here and do a pretty darn good job.**

[00:19:56] Me: Uh-huh <agree>.

[00:19:56] Karla: I would say I'm an above average teacher with the amount of hours I put in. But not an excellent teacher. **And I could be an excellent teacher, but then my personal life suffers so much.** That's why I started working at the gym.

[00:20:13] Me: Uh-huh <agree>.

[00:20:13] Karla: **That's why I started doing other stuff. Because I wasn't meeting men. I wasn't like . . . I was working, working, working. It got ridiculous.**

. . .

[00:20:32] Karla: **That's not fair for society to ask us to do that. You hear all the stories about "hero teachers" <finger quotes>, about this and that. You know what? I don't want to be the hero, because it's just sacrificing yourself. <laughs> I just want to be good. And that's it.** So . . .

. . .

[00:20:57] Karla: **I wanted to get married. I wanted to, you know. I feel like that's why I got married so late in life.** Like, because <laughs>

. . .

[00:21:29] Karla: Yeah. But, **there's a big difference in trying to have kid when you're 35 and when you're 30.**

This snippet showcases something that happened in both interviews, the elicitation of a deep identity narrative in a relatively short amount of time. First, the PEI opened up emotional wells quickly; both teachers cried during the interview and repeatedly stated that this was the most reflective and personal professional development they had ever encountered. Second, both teachers realized specific practices they would change immediately as a result of the interview. Third, the interview helped the teachers situate the frustrations they felt into a formal structure of power. They saw how they were positioned as mathematics teachers in society and started to explore the relationship between their personal and professional identities. Finally, the PEI drew me into each teacher's narrative through the opening up each teacher's *vulnerable 'I'* personal identity (de Freitas, 2008). I moved from the role of researcher into privileged observer of each teacher's life, listening and responding with authenticity and compassion as the teachers articulated their true feelings of powerlessness. The more room I gave teachers to talk about themselves and how they saw themselves, the more the teachers wanted to, and needed to, talk about who they were. I had to cut each interview off after two hours even though both teachers wished they could keep going.

In answering the first research question, this study showed how the PEI was able to quickly reveal each algebra teacher's uniqueness in her own personal identity. However, both teachers revealed that they felt that what made them special was rarely brought into their professional identity. Both teachers expressed how they felt locked into playing up their role of "mathematics teacher", leaving little room for their real selves to emerge. This outwardly defined role encouraged them to build an "anonymous" professional identity built not upon how they saw themselves, but false stereotypes of what it meant to be a mathematics teacher (de Freitas, 2008; Van Zoest & Bohl, 2005).

In answering the second research question, the PEI helped each teacher self-author their narrative and recognize their own access to power. In their narratives, they positioned themselves as having relatively little power through their profession. Even worse, both teachers revealed that the less they tried to incorporate unique attributes into their teaching, the easier it was for them to teach. Conformity is not only encouraged, but also rewarded with less stress and a more stable career. This reveals tremendous information about the amount of power these algebra teachers felt they held: none.

Discussion and Conclusion

This investigation help me realize that the idea of mathematics teacher identities, while highly theorized in the literature, is something that only fieldwork and a narrative-based, creative methodology can answer. I found that understanding teachers' identities came from allowing teachers to author their own narrative using their own words, ideas, and visual images. Additionally, it was important for me as a researcher to meet teachers within their space and to approach them as owners and authorities of this space, rather than asking them to come into my world and play by my rules. I cannot fully understand exactly what a teacher means when they tell me something. But when they create a visual glimpse into their world, something they can both define and describe, the interactions between teacher and researcher become real–we end up looking through the same window together. They are the tour-guide and I am the tourist. However, the fact that I worked with both teachers prior to this study complicates things. I selected each teacher personally, and my relationship with each teacher affected their openness and trust with me. During analysis, I could not help but use this prior knowledge to filter and add depth to their narrative.

I hope this study adds to the existing research on understanding mathematics teachers through the lens of identity. I have experimented with a tool that might help us better explore mathematics teacher identity in a minimally invasive and easily implementable way. I hope this paper spurs further exploration of the PEI method to help us better understand the conflicting personal versus professional identities of our mathematics teachers.

Teachers making sense of algebra problems:

"IT depends what the students did"

Joshua Chesler
California State University, Long Beach
jchesler@csulb.edu

How do teachers determine what a mathematics problem is about? Groups of teachers, mathematicians, and mathematics educators were separately tasked with categorizing a set of twelve algebra problems. Teachers appealed to student activity, real or hypothetical, as a means of making sense of and justifying claims about the problems. Both the scale and nature of the role of students in teachers' discussions contrasted with the discourse of the other professional groups. This has potential implications for cross-disciplinary interactions including teacher training and communication through curricular materials.

Introduction

A teacher's interactions with mathematics curricular materials are shaped by varied and complex factors such as her/his knowledge and beliefs as well as by often subtle features of the curricular materials. This paper reports on research which addresses questions about how teachers make sense of curricular materials. In particular, it examines the means by which algebra content was analyzed at two workshops in which algebra teachers, mathematicians, and mathematics educators were separately tasked with discussing and categorizing middle/high school algebra problems. The teachers, as compared to the other professional groups, made more frequent reference to students, real or hypothetical, as they negotiated the categorization. Furthermore, student actions served as justification for the teachers' claims about the nature and focus of specific algebra problems; this was not observed within the other two professional groups.

The sites for the present study were two 3-day workshops comprised of mathematicians, mathematics educators, and teachers from geographically diverse locations. The teachers were middle and high school teachers of algebra; the mathematicians and mathematics educators were university professors (See Table 1). The workshops were organized around a set of 12 algebra problems spanning content from pre-Algebra to Algebra II which were compiled by the workshop organizer Chris Norris, a mathematician, and administered in the participating teachers' classrooms. Norris was the only person who participated in both workshops. The data presented here is primarily drawn from a particular task in which the workshop participants, separated by professional group, analyzed and categorized the 12 algebra problems. This categorization task required each professional group to negotiate and justify categories for the set of 12 problems; the instructions for the task were summed up by Norris as, "So what do you think is the sort of mathematical content of the problems and do they fall naturally into different groups?"

Workshop	# of Teachers	# of Mathematicians	# of Math Educators	Total
1	4	6	4	14
2	8	5	0	13

Table 6. Number Workshop Participants and their Professional Groups.

Perspective

The categorization task can be thought of as mathematicians, mathematics educators, and mathematics teachers *interacting with* the workshop algebra problems. As such, there are three overlapping categories of research which comprise the theoretical framework of the study: (1) research on interactions with curricula, (2) research on the learning and teaching of school algebra, and (3) research on the beliefs, knowledge, and dispositions of the three professional groups. Herein, I use Remillard's (2005) definition of curricular materials as "printed, often published resources designed for use by teachers and students during instruction" (p. 213) and the present study is, in part, framed by Remillard's description of curriculum use as a participatory relationship between teacher and curriculum. This relationship is influenced by characteristics of the individual (beliefs, pedagogical content knowledge, etc.) and by features of the curriculum (voice, representation of concepts, etc.). Her framework acknowledges that teachers construct their understanding of curricular materials yet are also influenced by these materials.

The inclusion of research on school algebra is motivated by the acknowledgement that some view of school algebra influenced the workshop participants' interactions with these problems. Kieran (2007) described the content of school algebra as ranging between reform-oriented and traditional. Reform-minded algebra often is characterized by an emphasis on functions, real-world problems, and a value on multiplicity of techniques (such as the use of technology). Included in this the view of algebra are the multiple ways of representing functions including graphical, tabular, and symbolic representations. A traditional view conceptualizes algebra as generalized arithmetic and often focuses on symbolic manipulations, recognition of forms, simplification of expressions, solving equations, and factoring polynomials. The traditional view puts an emphasis on letter-symbolic and structural aspects of algebra whereas reformed algebra emphasizes a combination of mathematical representations.

Many factors influenced the workshop participants' interactions with the problem set. These factors include the features of the problems as well as less tangible characteristics of the workshop participants. Thus, the theoretical perspective which frames this study also includes research on these disciplinary groups' beliefs about and dispositions toward mathematics in general and algebra in particular. The few studies about mathematicians' and mathematics educators' beliefs about mathematics indicate a diversity of views (Mura,1993, 1995; Burton, 1999). Some mathematicians (e.g., Bass, 2006; Cuoco, 2001), however, have endorsed a more structure-oriented approach to algebra. Similarly, there is not much conclusive to say about teachers' beliefs about algebra. Doerr (2004) noted that "there has been little research about teachers' knowledge and practice and its development with respect to the teaching and learning of algebra" (p. 285). Doerr's survey of such research on teachers' algebraic knowledge revealed "no research evidence in the USA that would suggest that teachers see the concept of function as an integrating theme for algebra instruction across the curriculum despite this being envisioned in the curriculum standards of the National Council of Teachers of Mathematics" (p. 278).

The discussion which follows also draws upon the Mathematical Knowledge for Teaching (MKT) framework of Hill, Ball, and Schilling (2008). By distinguishing subject matter knowledge from pedagogical content knowledge (PCK) and then further unpacking each of these into smaller components, it provides a finer-tuned means for describing the knowledge which workshop participants drew from as they discussed the algebra problems. Of particular relevance is the notion of knowledge of content and students (KCS), a component of PCK, as "content knowledge intertwined with knowledge of how students think about, know, or learn this particular content" (p. 375).

Methods

Data included audio and video recordings from both workshops, audio recordings of interviews with all but one participant from the second workshop, and observational data/field notes from the second workshop. The open-ended interviews investigated participants' reactions to the workshop and their beliefs about algebra. Transcripts of the categorization task and the interviews were coding in three distinct phases as codes were refined. Codes were based both on the theoretical framework and on themes which emerged in the data. In general, I collected multiple data sources and subjected them to methodical, iterative analyses while simultaneously documenting my reflections and decisions. Member checks were conducted with three of the participants (one from each professional group).

Results

Analysis of the categorization task revealed that all three groups drew from diverse types of knowledge in order to justify claims or observations about the 12 algebra problems. However, in both workshops, teachers, more than members of the other two professional groups, used ideas about real students or their views of typical students to frame their discussion of the algebra problems and to justify their claims about the problems. During both workshops, the teachers referenced students during their discussions of every problem except for problem number one during the first workshop (they spoke about this problem for less than 30 seconds total). The teachers at times referred to their own students in their discussions of the algebra problems; for example, Nadya King, in discussing number four (See Figure 16), said, "So my kids didn't know what it meant 'for increasing values of *a*". Teachers also drew upon knowledge of content and students (KCS) to talk about students in general or about their own conceptions of typical students. Tom Luft, for example, said "I also think that kids don't understand that multiplying by one fifth is dividing by 5 very well" when discussing problem number five, a problem which the teachers subsequently categorized as being about "rational number operations" in the first workshop.

In the expressions below, *a* and *x* are positive numbers. For each expression explain the effect of increasing *a*: does the value of the expression increase, decrease, or remain unchanged?

	Increases	Decreases	Remains unchanged
$ax+1$			
$x+a$			
$x-a$			
$a+x-(2+a)$			

For each expression, explain why you made the choice you did.

Figure 16. Problem Number 4.

The mathematicians and mathematics educators also engaged in discourse related to students and student work. They, of course, were less familiar with the work which students did in the participating teachers' classrooms and they referenced these students or classroom experiences less frequently. Indeed, the data and coding revealed that teachers had a greater focus on students; this was particularly notable in pronoun usage across groups. The teachers would talk about what "they", the students, would or should or did do for a particular problem. Table 7 shows the frequency with which members of each professional group used certain words which reference the students. A caveat of this word-count pertains to the use of the words "they" and "them"; the word count was not sufficiently sophisticated to detect the noun which each instance of these words referenced, however sampling indicated that the overwhelming majority of the usages of these words referred to "the students". Likewise, there were instances where students were referred to but none of the four words included in the word-count were used; for instance, phrases like "mine did" or "a couple did" were not detected. The word count presented below is an imperfect metric but the scale of the difference in rates of usage of words referencing students is quite telling. Teachers used these words more than 500 times per hour. In contrast, mathematics educators used these words 205 times per hour and mathematicians used them 159 times per hour.

	they	them	student(s)	kid(s)	total
Teachers WS1	474	130	26	129	759
Teachers WS2	308	75	50	72	505
usage per hour	312.8	82	30.4	80.4	505.6
Math Educators WS1	119	79	73	37	308
usage per hour	79.3	52.7	48.7	24.7	205.3
Mathematicians WS1	103	51	58	10	222
Mathematicians WS2	79	46	51	0	176
usage per hour	72.8	38.8	43.6	4	159.2

Table 7. Word counts from the categorization tasks, 90 minutes in the 1st workshop (WS1), 60 minutes in the 2nd (WS2). "Usage per hour" is calculated for each professional group using totals from both workshops.

The difference in how professional groups referenced students was not limited to a difference in quantity. In contrast to the two other professional groups, there were instances amongst the teachers in which students were used as a means to justify claims about particular problems. An illustrative example is the teachers' discussion of problem number two (Figure 17 below) during the first workshop; Ursa Harper justifies her interpretation of the question by referring to the mistakes her students made. She is a bit dismissive of Sheila Eastman's claim that the problem is about the distributive law because that is not what Ursa perceived her students to have struggled with. It is worth noting that Sheila was the only person in the teachers' group who did not administer the problems to her own class.

Sheila Eastman	You know, with what [the question writers] did here truly it's just the distributive property because they wanted them to just come up with one [possible first step].
Ursa Harper	But what the kids made mistakes with were order of operations. They also made mistakes on like terms was the big one for my kids.
Sheila Eastman	Okay, order of operations, like terms, distributive property.
Ursa Harper	Bigger than distributive property was order of op, was the like terms.

Sheila Eastman	Oh, okay.
Ursa Harper	I was shocked when I looked at it [the student work]. I was like "excuse me".

This discussion lead directly to the categorization of number two as a problem about "properties of real numbers" which, for this group of teachers, included concepts such as order of operations and like terms.

You are simplifying *7-2(3-8x)*. Which of the expressions are possible results after the first step?

	Possible	Not Possible
5(3-8x)		
7-2(-5x)		
7-6-16x		
7-6+16x		

For each expression, explain why you made the choice you did.

Figure 17. Problem Number 2.

A similar discussion took place about problem number four (Figure 16 **Error! Reference source not found.**). Ursa cites student errors with the distributive law and number sense as the justification that the problem is about these properties. Tom Luft and Tammy Vonce contributed to the discussion by suggesting other ways in which students could approach the problem, namely ideas about graphing, functions, and signed numbers.

Tom Luft	I would, um, extend that to, um, the idea of a function because I think the way my kids approach it is more of an input-output style…
Tammy Vonce	Put in different inputs, look at the outputs.
Tom Luft	Input-output, they looked at in slope-intercept form. You know, they saw *ax+1* and they said, well, this slope's positive, it's going up, this slope's negative it's going down, that kind of thing. So I mean I think that's an underlying principle. Whether or not all kids would see it that way, depending on their experience and stuff, I would think that most kids would just plug in and just see what happens.
Tammy Vonce	Well, you know, my kids, now that you're saying that it reminds me, they looked at it as signed numbers.

This problem was ultimately categorized as being about "signed numbers". The categorization of this problem was negotiated largely through an examination of what students did with the problem.

Generally, the teachers discussed multiple ways in which students could and did solve each of the problems. This was, in part, what lead the teachers, in both workshops, to place individual problems in multiple categories (something which the other professional groups did not do). Their interactions with the workshop problem set were framed to a large extent by their experiences with the problems in their classrooms. This was not the sole influential factor but it was prominent in their discussions as they engaged in the categorization task.

Mathematicians and mathematics educators also referenced (real or imagined) students as they interacted with the problem set. However, this happened less frequently as indicated by

Table 7 and was rarely a sustained focus of their discourse. Perhaps it would have been a larger focus if they had administered the problem set in classrooms of students but this is unclear from the present data. The teachers based their analysis of the problems, in a large part, on what their students did.

Discussion

The present study is largely framed by Remillard's (2005) idea that teachers *interact with* curricular materials. This idea has been extended in the present analysis in order to view the workshop categorization task as mathematicians, mathematics educators, and teachers interacting with algebra problems. By framing these activities as interactions, my intention has been to highlight that the nature of the problems was determined by the participatory relationship (as Remillard calls it) between the workshop participants and the problem set. Her framework for teacher-curriculum relationship is intended as a framework for studies on curriculum use. It should be noted that the workshops were not exactly about curriculum use. Although the participating teachers had implemented the problem set in their classrooms, the decisions they made regarding implementation were neither the focus of the workshops nor of the research and analysis described herein. Furthermore, the problems were presented absent of the organizational structure (e.g., section or chapter headings) typical of classroom materials (though perhaps typical of standardized tests). However, the results described above are relevant to curriculum use; though the categorization task was removed from the typical environment and context in which teachers interact with curricular materials, the workshops provided insight into the ways in which teachers interact with curricular materials. For example, teachers made sense of the problem set through frequent reference to and guidance by their perceptions of students.

This contrast between the professional groups in how they made sense of the algebra problems may have also manifested itself in the groups' differing emphases on graphs. As he revealed in his interview, Chris Norris, the compiler/author of the problem set, did not consider graphing to be a prominent theme in the 12 problems or an important piece of algebra in general, though he did acknowledge that graphs can be useful tools for doing algebra. However, both groups of teachers spoke about graphing in relation to five of the problems. For Chris, a major theme within the workshop problem set was the structure of expressions and equations. This theme was discussed amongst the mathematicians and mathematics educators but was generally not discussed amongst the teachers. It is perhaps necessary to clarify here that I do not present the opinions of Chris Norris in contrast to those of the teachers in order to make a statement about the correctness of the teachers' interpretations of and interactions with the problem set. On the contrary, I wish to highlight the inevitability that interactions with curricular materials are interpretative acts; an individual encounters curricular materials through her or his own subjective filter. In light of this, questions about fidelity or correctness of interpretation are not relevant to my analysis and are potentially inconsistent with my perspective that workshop participants *interacted with* the 12 problems.

The teachers' discussions of the 12 problems differed from Chris' intentions (and from the discussions by mathematicians and mathematics educators) as they pertained to graphing and to structure. Is it possible that this is connected to the prominence of the roles of students in their analyses of the problems? For instance, structure was a focus for both the mathematicians and the mathematics educators in the first workshop as they discussed and categorized problems 10 and 11. Teachers from both workshops discussed graphing in relation to these problems which they perceived as difficult for the students. The teachers often spoke about graphing in terms of its pedagogical efficacy and as a strategy for students to approach a problem. Tom Luft discussed how students "have to have a visual connection". Ursa Harper described number 11 as "straight-forward" for students who have experience with graphing calculators. Thus, it is possible that the prominence of teachers' perceptions of students in their interactions with the workshop problems was, in part, responsible for these differences in focus with the mathematicians and mathematics educators. That is, their greater emphasis on graphing and their lesser emphasis on structure may have been related to their focus on how students would or did approach the problems.

In the interviews of the second group of teachers (none were conducted with the first group), six out of seven described algebra in a traditional way (e.g., generalized arithmetic) as did Chris Norris and all of the interviewed mathematicians. However, graphs are generally associated with reformed approaches to algebra. By emphasizing graphs, were the teachers infusing the workshop problems with a view of algebra different from that intended by the problems' author? The answer to this is unclear especially since the interviews did not reveal particularly reformed views of algebra. There is little evidence that the teachers' emphasis on graphing was a sign of a reformed, function-oriented view of algebra; rather, it may have been motivated by a concern for how students did or should approach the problems. This is certainly consistent with Doerr's (2004) report that there is "no research evidence in the USA that would suggest that teachers see the concept of function as an integrating theme for algebra instruction across the curriculum" (p. 278). In categorizing these algebra problems, the teachers' perceptions of students, and their knowledge of content and students (KCS), may have played a larger role than their stated beliefs about algebra.

Chris' intentions to focus on structure and to deemphasize graphs were not acknowledged within the teachers' categorization tasks at both workshops. This, once again, highlights the interpretive nature of interactions with curricular materials. Furthermore, there are associated implications for developers of curricular materials. Chris' development of the problem set was guided by his opinions about the nature of algebra. The problems were distributed to the participating teachers with no explanation of his intentions or viewpoints and with no instructions for implementation. For the most part, his intended foci for the problem set were not implicitly communicated to the teachers through his presentation of the problems. In order to have successfully communicated his intentions *through* these curricular materials to the teachers it would have been advisable to have considered the role that student activity plays in teachers' appraisals of algebra problems. At least within the context of the workshop, a domain-centric lens was insufficient for consistently communicating ideas to teachers through curricular materials.

Of the three professional groups at the workshops, the teachers were the only group to have administered the problem set to students and were the most familiar with the student work. This surely was a factor in their greater emphasis on student activity during the categorization task. Perhaps the results of this study would have been different had the teachers not implemented the problem set. However, this potential caveat is not particularly relevant to the discussion herein; by the nature of their craft, teachers have access to information about student activity and are concerned with implementation of curricular materials. It is important for developers of curricular materials and for instructors of pre-service and in-service teachers to acknowledge that teachers' interactions with algebra content may be largely framed by their relationships with and perceptions of students; that is, they may draw heavily from their knowledge of content and students (KCS). It would be of use to study this idea further within the context of classroom curriculum use.

During the categorization tasks, perceptions of students played a larger role for teachers than for the other two professional groups. I hypothesized that this was at play in teachers' greater emphasis on graphing; this focus may have resulted from a perceived appreciation for the pedagogical efficacy of graphs more than from views of algebra which embrace functions and graphs as central themes. Furthermore, I have presented a view across professional groups which may inform collaborations and communication across professional groups. It may move us closer to the interdisciplinary cooperation which Bass called for in 1997:

> As mathematical scientists, as mathematics education researchers, and as teachers in universities, colleges, community colleges and schools, we must begin to see our concerns for graduate, undergraduate, and K–12 education as parts of an integrated educational enterprise in which we have to learn to communicate and collaborate across cultural, disciplinary, and institutional borders, just as we are called upon to do in mathematical sciences research. (p. 21)

This study reports on how the presenters at a conference sponsored by a state affiliate of the National Council of Teachers of Mathematics aligned with literature on reform mathematics. Nonparametric methods were used to compare conceptions on three domains: nature of mathematics, learning mathematics, and teaching mathematics. Significant differences in conceptions were found within groups factored by gender, institutional position, and number of years presenting at a state conference. The findings suggest that teacher educators align more with reform literature on conceptions of learning and the nature of mathematics, while female and male presenters differed in their conceptions of teaching.

The modern standards movement began with the National Council of Teachers of Mathematics' (NCTM, 1989) publication of the first curricular standards: *Curriculum and Evaluation Standards for School Mathematics*. Smith (2001) claimed the intent of the document was to develop students who could engage in complex mathematical problems, alone and with peers, and who could communicate convincing arguments and justifications for their work. To support the vision outlined in the standards, NCTM published the *Professional Standards for Teaching Mathematics* in 1991 and the *Assessment Standards for School Mathematics* in 1995 (NCTM, 2000). These standards documents have had a substantial impact on teacher preparation programs but have not impacted classroom teaching to the same degree (Price & Ball, 1997). Changing classroom practice to be more aligned with the reform movement in mathematics education remains problematic for teacher education faculty, professional developers, and school district personnel. To continue the conversation about reform-based teaching and standards, to respond to criticisms to the 1989 standards, and to address relevant research on teaching and learning since the original publication of the standards, NCTM published revisions of the documents: *Principles and Standards for School Mathematics* and *Mathematics Teaching Today* (Martin, 2007).

In order to move toward the vision of mathematics teaching outlined in the NCTM standards documents, teacher preparation and professional development opportunities must address not only the mathematics content to be taught, but also elements of effective teaching. But how do practicing teachers come to experience such professional development? One important source of professional development for mathematics teachers is conferences, especially the state and regional mathematics conferences sponsored by NCTM affiliates.

Other disciplines also hold state conferences affiliated with their national organizations. Koballa, Dias, and Atkinson (2009) questioned how the messages teachers receive at a conference sponsored by the state affiliate of the National Science Teachers' Association [NSTA] were aligned with national reform efforts. The researchers found that, even though the session leaders were members of the NSTA state affiliate and were likely considered leaders in their schools, most of their conceptualizations of inquiry did not align with the meaning of inquiry promoted by the NSTA.

After reading these results, we began to question how session leaders at a state mathematics conference, sponsored by the state affiliate of NCTM, conceptualize reform in mathematics education. The present study sought to investigate conference presenters' background knowledge about reform and how they relay their knowledge to session participants. A question of interest in considering such knowledge is how the presenters' beliefs align with those promoted by NCTM.

To this end, four research questions were developed for the study, two of which are addressed in this report:

1. What conceptions of reform-oriented mathematics teaching do presenters hold?
2. How are the presenters' conceptions of reform, modes of presentation, and intended impacts related to each other with respect to the mathematics education reform literature?

We will address some of the qualitative results in our presentation.

Conceptual Framework

Philosophers (e.g., Ernest, 1991; Lerman, 1998) discuss two major theories about the nature of mathematics: absolutist and fallibilist. Whereas absolutists attempt to provide an authoritative account of how mathematics should be understood, fallibilists attempt to describe the field and provide a means of growing the body of mathematical knowledge. Reflecting on the nature of mathematics advocated NCTM documents, Sfard (2003) explained that the documents promoted keeping both the student and the mathematics at the forefront, ensuring that "the needs of the learning child never disappear from the reformers' eyes" (p.353). Reformers promote a view of mathematics as relative, fallible, and expanding rather than a mathematics that is static and absolute. As such, mathematics is a human endeavor that children should actively construct during their school mathematics experiences.

Learning theories of mathematics are rooted in specific perspectives of the nature of mathematics. In mathematics education reform literature, learning mathematics is an active process in which students build knowledge through social interaction, discourse, conjecturing, problem-solving, and validating. NCTM (2000) identifies problem solving, reasoning and proof, communication, connections, and representation as processes for promoting the development of mathematical understanding. In their support of the NCTM Standards, Ball and Bass (2003) argue that mathematical reasoning is a basic skill necessary for learning mathematics with understanding. All students can learn mathematics when they are invited to investigate its nature in their own way, when it is situated in culture, and when it is scaffolded by individuals who understand the tacit and concrete dimension of mathematical knowledge (Lampert & Cobb, 2003; Martin, 2007; NCTM).

Because learning mathematics should be an active process wherein students build their own understanding, the teacher's role in helping students develop that understanding cannot be underemphasized. The teacher's role in reform-oriented teaching is active, reflective, and cognitive and must shift from the dispenser of pre-determined knowledge to a facilitator of creative and generative processes. The teacher must be active in managing the discourse in the classroom, which requires "planning that involves capitalizing on what students do and directing their activity toward important mathematical issues" (Lampert & Cobb, 2003, p. 244). Teaching should result in students learning mathematics with conceptual understanding and should be "centrally guided by students' ideas" (Ball & Bass, 2003, p. 30). Furthermore, student differences should be respected and valued; reform teachers modify their instruction based on the needs of the learners in their classrooms. They use worthwhile tasks that reflect a high level of cognitive demand on the part of students (Stein, Smith, Henningsen, & Silver, 2009) and should require students to engage in authentic problem solving. Reform teachers view teaching as problematic and reflect on their practice, often in systematic ways in communities of practice (Martin, 2007).

The NCTM's impact on standards-based reform in learning and teaching mathematics is profound and ongoing. Professional communities that provide discourse and professional development for mathematics educators also contribute to the changing landscape of reform-oriented mathematical content and instructional practices. Specifically, educational leaders who present reform-oriented practices to other practitioners help to form, model, and foster accepted truths of mathematical knowledge within such professional communities (Ernest, 1999). This study hopes to explore how such presenters at the state conference conceptualize and demonstrate reform-oriented mathematics during workshop presentations.

Methodology

To help us determine how presenters' beliefs align with reform literature, qualitative methods and a survey were used to collect data.

The study was conducted during fall of 2010 at a state mathematics conference which annually hosts approximately 1900 attendees. There were 188 sessions spanning grades P-16, held over three days. The conference program was used to identify lead presenters. Session descriptions were used to categorize presentations that addressed various aspects of the nature of mathematics, learning mathematics, or teaching mathematics. One hundred forty sessions met the categorization criteria, and the lead presenters of those sessions comprised the survey sampling frame. Sixty presenters completed the survey for the study. We verified that the sample proportionally represented the presenter demographic position (7 resource personnel = exhibitor or publisher; 12 support personnel = instructional leader, coach, or administrator; 13 teacher educators = professional developer or pre-service program faculty; and 28 active classroom teachers).

A 15-item survey was designed to measure conceptions about reform mathematics, based on findings from Raymond's (1997) study on teacher beliefs. Items contained phrases contrasting more traditional (choice *a*) statements, the negative pole of the scale, to more reform (choice *b*) statements, the positive pole, regarding dispositions on the nature of mathematics, and mathematics learning and teaching. Presenters responded to a five-point Likert-type scale (1 = *Agreement with (a)*, 2 = *Towards (a)*, 3 = *Equal agreement with (a) and (b)*, 4 = *Towards (b)*, 5 = *Agreement with (b)*). The survey was pilot tested with mathematics educators and teachers to determine the appropriateness and clarity of the items. It was then administered online, opening approximately one month prior to the conference. Consent for participation in the study was gained and assured by electronic signature using email addresses. To address non-response, follow up requests to participate were sent electronically, along with personal reminders to complete the survey during the conference.

We disaggregated the data by presenter's gender, institutional position, highest degree earned, and conference presentation experience because prior research revealed that the *type* of provider was not an adequate predictor of session quality; rather, "the skills, background, and preparation of professional development providers" (Banilower, Boyd, Pasley, & Weiss, 2006, p. 35) were greater determinants of effective professional development. Graphical displays, within each domain, were first examined holistically and then disaggregated by the above factors, to examine the overall alignment of survey takers with reform literature.

Results

Reliability for the conceptions of reform mathematics scale was measured by computing Cronbach's Alpha (0.602). Utilizing "Cronbach's Alpha if Item Excluded" analysis, Cronbach's Alpha (0.720) increased with the elimination of four items from the instrument. The adjusted coefficient demonstrated sufficient reliability for the scale. Questions (Q1-Q3) were related to the nature of mathematics, (Q6-Q8, Q10) comprised the domain on learning mathematics, and the teaching of mathematics was assessed using questions (Q10-Q13, Q15). The item means are presented in Table 1. Higher means for an item indicate a conception towards reform mathematics. For comparative analysis, nonparametric tests were used because these methods are better suited for ordinal data, they are appropriate for unequal or small groups, and they do not require the assumption of normality for the population distribution from which the sample was drawn. An alpha level of 0.05 was used for all Kruskal-Wallis Rank Sum Analysis of Variance test. Significant results are presented below.

Domain	**Nature of Math**			**Learning Math**				**Teaching Math**			
Question	Q1	Q2	Q3	Q6	Q7	Q8	Q10	Q11	Q12	Q13	Q15
Response Mean	3.68	2.97	2.95	4.05	3.23	4.19	4.24	4.66	3.64	3.14	3.78
No. of Responses	60	60	60	60	60	59	58	58	59	58	60

Table 1. Item Response Averages

Conceptions of the Nature of Mathematics

Rank orders pertaining to the nature of mathematics were found to be significantly different among groups when factored by number of years presenting at the state conference (see Table 2). For all groups, ranking tended towards mathematics as changing, fallible and relative, as opposed to fixed, absolute and predictable. A consistent trend across all items within the domain was a higher score mean for the group 2-3 years (M_{Q1} = 33.12, M_{Q2}= 34.08, M_{Q3} = 38.31) than that of the group First year (M_{Q1} = 30.4, M_{Q2} = 26.55, M_{Q3} = 23.40). One possible rationale for this finding relates to exposure to the conference settings and to others who discuss effective teaching and learning. Some presenters may have presented as a class requirement or as a way to get more involved in their state organization. After that first experience, presenters may express perturbations in their conceptions based on feedback from participants in their sessions or they may consider their practice in greater depth before they present at the conference in the future.

Level	Count	Score Sum	Score Mean	ChiSquare	DF	Prob>ChiSq
First	20	468.000	23.4000	8.0680	3	0.0446*
2 – 3	13	505.500	38.8846			
4 – 6	9	230.500	25.6111			
>6	17	566.000	33.2941			

Table 2. Kruskal-Wallis Test: Nature of Math by Years Presenting at Conference

The respondents struggled with the dichotomies provided that sought to tease out the conceptions of the nature of mathematics: “I struggled with the relative/absolute statement and the doubtful/certain statement. My faith has certainly swayed my opinions, but because I understand math, I tend to be in the middle about some of my answers.” Additionally, the responses were influenced by their classroom practices: “I think that mathematics had a definite body of knowledge...however, the way we teach and learn mathematics varies. Exploring mathematics can lead to new discoveries and understandings about how and why mathematics works the way it does.”

Conceptions about Learning Mathematics

The four items assessing conceptions of learning mathematics showed closer alignment with the reform literature. For the learning domain, a significant difference in score means by position (see Table 3) prompted an inspection of item means. On item Q6, which contrasts learning through skill and drill with learning through investigation, a significant difference was detected ($\chi 2 = 10.48$, $p = 0.015$), where the greatest differences was between teacher educators (M = 41.31) and teachers (M = 24.13). Although no other significant differences were found, on two of the remaining items, teacher educator score means ($M_{Q7} = 33.15$, $M_{Q8} = 35.38$) were greater than teacher ($M_{Q7} = 28.68$, $M_{Q8} = 24.72$). For teacher educators, conceptions of learning mathematics tended towards choice *b*, where learning by investigation, group work, with a good teacher, and by doing challenging tasks were ranked higher than learning by skill and drill, independent work, being a strong student, and memorizing. Teachers tended to rank items in this domain as being equally important for learning mathematics.

Level	Count	Score Sum	Score Mean	ChiSquare	DF	Prob>ChiSq
Resource	6	182.500	30.4167	9.1998	3	0.0267*
Support	10	273.000	27.3000			
Teacher	22	425.500	19.3409			
TEducator	13	445.000	34.2308			

Table 3. Kruskal-Wallis Test: Learning by Position

The following quotes highlight some of the differences in these two groups’ conceptions:

Teacher Educator: “I firmly believe that learning and understanding mathematics requires students to be actively engaged in mathematics. They need the opportunity to develop their conceptual understanding of mathematics. Drill, lecture, and practice don't work.”

Teacher: “Mathematics is a combination of memorization/ skill & drill to learn the basics and exploration once the basics are concrete.”

This finding seems contrary to those by Banilower et al. (2006) that type of presenter was not an indicator of quality; however, we did not analyze the backgrounds of each teacher educator, which is what Banilower et al.’s research claims is the greater determinant.

Conceptions about Teaching Mathematics

The results for conceptions about teaching mathematics were in the middle of the traditional-reform scale (see Table 1). The exception was the question that generated the most consistent results, Q11: “Good mathematics teaching is (a) guided primarily by a textbook and its supplemental materials or (b) by a variety of instructional materials from various sources.” Strong agreement with choice *(b)*, ($M_{Q11}= 4.66$) may be explained by the present curriculum and materials being used in the state in which the conference was being held. The state is rolling out an integrated curriculum based on the process standards for which quality texts were not readily available. Teachers saw this as a challenge to implementing the new curriculum: "one challenge was pulling together the materials; no textbooks exactly aligned to the standards and materials were *everywhere* on the internet; careful planning for the tasks is required" (Edenfield, 2010, p. 174).

The overall scale analysis showed a significant difference in score means by gender (see Table 4). Females ranked items as "towards *b*", while males tended to rank items as "equally both *a* and *b*". The greatest point of departure for the two groups was on the teaching domain. Although the score means in the domain were not significantly different, the most noticeable variations were on items Q11 ($M_{female} = 30.52$, $M_{male} = 26.81$) and Q15, which contrasts the importance of using multiple examples with using problem solving tasks in teaching, ($M_{female} = 32.76$, $M_{male} = 24.28$). The following quotes by gender illuminate some of the thoughts participants had about teaching:

> *Male1:* "Although the student has to choose to participate in the learning process, the teacher must also meet them halfway by doing their best to provoke them."
> *Male 2:* "Since students have different learning styles and readiness levels, there must be a balance of what they see and what they do. This usually changes with each content, so teachers must constantly assess their students to find the balance."
> *Female 1:* "When teaching mathematics the instruction should not be driven by any particular resource. It should be driven by the teacher. The teacher can plan for flexibility within the lesson and should make explicit any information that does not come up in the student work or classroom discussions."
> *Female 2:* "Problem solving tasks are most beneficial in the learning, practicing, retention, and mastering of math. I equate math problem solving to be quite parallel to life. It is in doing, making mistakes, and analyzing those mistakes that we truly learn."

Level	Count	Score Sum	Score Mean	ChiSquare	DF	Prob>ChiSq
Female	40	1234.00	30.8500	4.6818	1	0.0305*
Male	15	306.000	20.4000			

Table 4. Kruskal-Wallis Test: Overall by Gender

Discussion and Implications

Across all subgroups in the study, the means for the questions related to the nature of mathematics were centered around three on the five-point scale. The participants, therefore, viewed mathematics as balanced between absolute and fallible. Watson (2008) contrasted the discipline of mathematics with school mathematics:

> Mathematics as a discipline, by contrast to school mathematics, is concerned with thought, structure, alternatives, abstract ideas, deductive reasoning and an internal sense of validity and authority…. The concerns of school mathematics pull learners in directions that differ from these. The core activity in school mathematics is to learn to use mathematical tools and ways of working so that these can be used to learn more tools and ways of working later on. (p. 6)

These differences in mathematics as a discipline and mathematics in schools may partly explain our results. We posit that it is possible for a person to view school mathematics as absolute, while viewing the discipline of mathematics as fallible. Our questions did not address this difference, but it is an area for future research. While the mathematics education literature promotes a view of mathematics as fallible, none of the subgroups in the study showed a tendency toward viewing mathematics in this way. Raymond (1997) found that teachers' conceptions of the nature of mathematics are more influenced by their early learning experiences; as most mathematics teaching in the US is not considered standards-based (Stigler & Hiebert, 1999), it is not surprising that the presenters' conceptions of reform fail to align with the reform literature.

The findings on gender parallel similar findings in the field of workplace psychology (deMarrais & LeCompte, 1999). Men and women conceptualize the purpose and function of their jobs differently, and teaching is no exception. Boaler (1997, 2008) also identified gender differences in the students at Amber Hill and Phoenix Park that paralleled findings on brain research on gender differences: Male students valued separate knowledge involving logic and abstraction whereas females preferred making connections involving creativity, intuition and experience. Additionally, women preferred more cooperative environments that encourage sense making, while men preferred more competitive work or learning environments. Given that teachers' beliefs about teaching and their practice are highly influenced by their own learning experiences, their preferred methods of learning might influence their ideas of effective mathematics teaching. Because our sample size was small, we refrain from generalizing our results. Our purpose was not to privilege a particular conception of teaching but rather to describe presenters' conceptions of effective mathematics teaching. We will continue mining literature on gender differences, paying particular attention to studies conducted in STEM fields, to contribute to our understanding of this finding.

For the sample, those conference presenters who were teacher educators were more aligned with reform literature concerning the learning of mathematics than were the presenters who were classroom teachers. Battista (1999) explained that most educators (including teachers, professors of education, and administrators) hold faulty views of constructivism, not the research-based constructivist theory. Some

> conceive of constructivism as a pedagogical stance that entails a type of nonrigorous, intellectual anarchy that lets students pursue whatever interests them and invent and use any mathematical methods they wish, whether these methods are correct or not. Others take constructivism to be synonymous with "discovery learning" … others even see it as a way of teaching that focuses on using manipulatives or cooperative learning. (p. 429)

In mathematics education reform literature, learning mathematics is an active process in which students build knowledge through social interaction, discourse, conjecturing, problem-solving, and validating. One possible explanation for the differences between teachers and teacher educators is that the teachers were not as aware of research on how children learn mathematics or held misconceptions about those theories, as Battista described; whereas the teacher educators may have read more research literature as a function of their graduate work or their jobs as teacher educators. The teacher educators at the conference were probably mathematics teacher educators, and not generalists who teach foundations of education courses, and were hence likely to know more about learning theories specific to mathematics. Another possibility is that many teachers go through teacher preparation programs wherein they discuss student thinking as theoretical. They may not have the opportunities to engage in discussions about research on learning and actual student thinking and learning in the context of their practice. We see this finding as particularly relevant for professional development, including initial teacher development. If, through further research, we see a general trend that teachers' conceptions of reform are more aligned with research literature with respect to teaching than to learning, then professional development is needed.

We know that the conceptions revealed by presenters via the survey may not align with their actual practice or the messages they portray in their presentations. We are in the process of analyzing a subset of presentations and interviews with those presenters. We will search for confirming or disconfirming evidence about the conceptions communicated in the survey but we also expect to get a better understanding of the messages conference attendees receive. We hope to report on these extended findings at the conference. From our observations of sessions at the conference (not having yet completed the analysis), we noticed a lack of focus on worthwhile mathematics in the actual presentations, with the focus being more on using engaging activities with students. Most session presenters were not clear about what they wanted students to learn, and how they wanted that learning to occur when the activities presented in their sessions were used with students. As the findings unfold, we will be able to offer other implications for professional development. For example, in all professional development materials – including workshops and presentations – not only does the goal of the session need to be emphasized but also the mathematical goals for students.

The "Developing Investigations of Mathematical Experience" (DIME) research program is focused on building a research-based understanding of the interiorized experiential world of idiosyncratic mathematics. We seek to identify and relate expressed indicators of intended and actual mathematical experiences, as they appear to occur in the complex relationships of participants involved in mathematics teaching and learning. The goals of this case study are to characterize individual experiences in ways that acknowledge a person's active and reflective thinking efforts within problematic contexts linked to emotive dimensions of their lived and living mathematical experiences, in order to inform improved mathematics teaching practices. To probe these largely unexplored complex domains, we are using both phenomenological and constructivist theories and methods to build our investigations.

Today, there is surely an implicit and implied emphasis upon high quality mathematical experiences within the goals and expectations for a sound mathematical education. Yet, within our literature and advocacies for curriculum, for teaching, for learning and development, and for research knowledge there seems to be very little explicit attention to the phenomenal data of an individual's "lived/living mathematical experiences." This frames an important goal of our research efforts.

What is the nature of lived and living mathematical experiences? What are the particular qualities (essences) of human experience that make it a "mathematical experience?" Are these experiential qualities that are unique to mathematics, or are they also found more broadly in other human experiences? In what ways do "lived/living mathematical experiences" vary or differ among humans, and why? What factors related to the individual or the experiential context might frame or affect or impact upon the actual phenomenon of a high quality "lived mathematical experience?" In what ways do the experiences of individuals vary within mathematical contexts, such as classroom situations that are intended to engender the "same" kinds of experiences for all participants? How do "lived mathematical experiences" accumulate within differing individuals, and with what more general intellective and emotive consequences? In what ways do thinking and feeling aspects of "mathematical experience" interact within a lived experiential context, and with what kinds of impacts or outcomes? In what ways might a mathematics educator use what can be learned about "lived/living mathematical experiences" of students, parents, teacher educators, mathematicians, or others in society to improve educational practices?

These are some of the questions that serve as "starting points" for our research program. In addition, we are confronting many research methodological questions that are framing much of our initial struggles to conceptualize what we see as a largely undeveloped research domain for the field of mathematics education.

Purpose of the Study

This study is being conducted with four selected volunteer students enrolled (Spring semester 2011) in a third undergraduate mathematics course (Geometry and Measurement) in a sequence specifically designed to prepare future elementary teachers. These students are also participating with all of the enrolled students in a companion investigation of the impacts of differentiated course instructional approaches on students' mathematical understandings.

The primary research question for this study is: What is the nature and quality of self-reported and analyzed mathematical experiences of students in differentiated classroom situations and in individually presented supplementary geometry and measurement situations?

This individual case-study research will allow us to develop a deeper understanding of the ways that selected students perceive important elements of their course experiences, including their activities in learning mathematical concepts and processes, how the differentiation has impacted their experiences in learning and achieving the course objectives, and what ideas from the course will be useful in their future teaching of mathematics to children. In addition, a variety of geometric and measurement problematic situations will be posed for them to solve, with the purpose of investigating the nature and quality of their living mathematical experiences and their mathematical thinking and feeling within extensions to the content they are learning in the course.

Prior Research on Mathematical Experience

Brown (1996) described the mathematics classroom from the perspective of social phenomenology where it is seen as an environment of signs, comprising things and people, which impinge on the reality of the child. His framework sees mathematical ideas as contained and shaped by the child's personal phenomenology, which evolves through time. He introduces the notion of "personal space" as a model for describing how children proceed through a classroom environment of phenomenal experiences toward their idiosyncratic "sense making." The report provides interesting data from children solving symmetry tasks, and demonstrates how Brown uses his framework to interpret the child's functioning in experiential terms.

Roth (2001) critically questioned some of these views and approaches in his review of Brown's (1997) book, an extensive attempt to relate many important aspects of mathematics learning and teacher education to phenomenology, hermeneutics, post-structuralism, and semiotics. In particular, Roth's central concern is whether all mathematical activity and experience can be reduced to text, based upon Brown's unequivocal assertion that "There is no experience outside the text" (p. 226).

Among the few investigations we've found, Francisco (2005) involved the elicited reflections of five high school students in their 12th year of a longitudinal study in which their school mathematics from grade one had been developed in ways claimed to be consistent with a constructivist approach (called "Rutgers Math"). Maher (1987) had described these learning conditions to include: collaborating in work, exploring patterns, conjecturing, testing their own hypotheses, reflecting on extensions and applications of the concepts, and explaining and justifying their reasoning. Steffero's (2010) study of one female student's beliefs and mathematical activities that occurred over a seventeen-year period constitutes an enormous record of her mathematical experiences from grade four through graduate school. Handa (2006) examined ways of knowing and doing mathematics using phenomenological reflections to construct views of experiential relationships with the subject matter of mathematics.

Perhaps there are good reasons why so little explicit focal attention is given to "mathematical experience." Thompson (1991) observes that while the paper authors (in an ICME conference on epistemological foundations of mathematical experience) are concerned with mathematical experience, they offer no information about "what is a mathematical experience." Indeed, in DIME we fully acknowledge a serious lack of clarity of constructs in this domain of "mathematical experience," but through systematic efforts to study "lived mathematical experience," we will seek to build new, grounded clarities of meanings. Here again, we may easily fail.

It is the goal of this research program to begin to study intentionally the phenomena of "lived mathematical experiences." Why bother? Are not the traditional views emphasized in intended curriculum, instruction, learning, assessment, evaluation, and research on learning and teaching adequate? Indeed, it is exactly because the goals and strategies of a sound mathematical education today embody a major emphasis upon stimulating, nurturing, and demonstrating high quality thinking arising from particular kinds of intended experiences that we must now seek to understand more clearly the nature of what students and teachers are actually experiencing in their "math lives" (Csikszentmihalyi, 1990).

If we want educational outcomes that mirror the empowerment that a deep knowledge and proficiency of mathematics can afford, we must now seek to move beyond our current perspectives and approaches that still seem to produce (for too many of our students) much less than we seek. If we are to understand deeply why so many of our students still achieve very poor understandings of the mathematical ideas and processes that our reformed curricula and our improved teaching methods, materials, and tools seek, we must begin to penetrate beyond more superficial indicators, such as test scores or written work, or even observed classroom behaviors into the interior world of the student's actual "lived mathematical experiences" where we may be able to identify deeper explanatory aspects of the individual's progressive growth (or deficits) toward greater mathematical knowledge and proficiency.

There is one other rationale that seems increasingly important. Too many of our citizens bear negative feelings toward their own past mathematical education (Hersch & John-Steiner, 2011), but for us educators to help our current students avoid such debilitating beliefs, feelings and attitudes we must begin to understand the nature of their experienced emotions that occur and develop within the mathematical contexts we offer. That is, not only must we understand the intellective dimensions of a person's constructions and reconstructions of their mathematical knowledge and proficiency, but we must also understand the emotional dimensions of their experiences, and how the interplay of thinking and reasoning actually functions within their live experiential feelings, emotions and affective schemas. It is time to seek to understand the whole "mathematical life" of our clients.

The goal of such new understandings is the assumed promise or potential that from such knowledge we mathematics educators will all be helped to engage in improved forms of mathematical education in which enhanced qualities of "lived mathematical experiences" occur for all persons. We seek a pedagogy that understands and honors the experiences of the other (surely a primary intention of a constructivist epistemology).

Theoretical Perspectives: Lenses upon "Mathematical Experiences"

We each know the centrality of the "lived experiences" we have throughout our lives. Even modest personal reflection can lead an individual to a sense of realization that it is specific experiences that shape "who they are, what we know, how we think" in powerful and fundamental ways. This includes what is experienced "outside," in the so-called "real world" that involves interactions within our environment (our physical experiences) and within our interactions and relationships with other minds (our social experiences). But, this also includes interior experiences that occur in our mind within our "inside" constructed world, where our thinking and our feeling "being" (person) is shaped and functions.

In Project DIME, we acknowledge the significance of the typical "mathematical" environment that includes students, teachers, parents, discourse, textbooks, technology tools, classrooms in schools, tasks and tests, the structured contexts of lessons, local, state and national curriculum frameworks, professional preparation and development, mathematicians, societies and cultures, governance, politics---all of the usual cultural and social elements in and around a person's mathematical education today. In doing so, we also accept that the meaning structure for any or all of these elements is a totally idiosyncratic construction for any of the multitudes of persons attending to matters of mathematical education. Now, we seek to "look into" the interior phenomenal world of "lived experiences" where each individual dynamically encounters and processes their idiosyncratic "mathematical experiences" that lead to "who they are and become," mathematically.

Phenomenology begins in the lived world, and seeks to bring to reflective awareness the nature of the events of "lived experience" (Hegel, 1977; Husserl, 1970, 1982). The principle of intentionality acknowledges an inseparable connection to the world (in our focus, the world of mathematical education) wherein "…we question the world's very secrets and intimacies which are constitutive of the world, and which bring the world as world into being for us and in us" (van Manen, 1990, p. 5). We are choosing to study thematic meanings, adopting themes and conducting thematic analyses within our particular orientation to the phenomenon of "mathematical experience" as "people of mathematics:" all being teachers, teacher educators, students of learning and teaching, mathematically educated, and interested is pedagogic theories. In DIME, we are trying to be explicit about our individual and shared intentions and orientations as a preparatory anchoring step in our research process.

As such, phenomenology accepts the curriculum of being and becoming (paideia), pursuing understanding of the personal, the individual, set against the background of an understanding of the other, the whole, the communal, or the social. It seeks to explicate phenomena as they present themselves to consciousness---the only access humans have to the world. But, consciousness cannot be described directly (the fallacy of idealism); the world cannot be described directly either (the fallacy of realism); real things in the world are only meaningfully constituted by conscious human beings, and these constructed meanings can only be revealed by the constructing human as inferences.

In our formative research approaches we presume the nature of "lived experience" to be fundamentally an internal construction/re-construction that emphasizes a consciousness of "sense-making," attempted within the unique idiosyncratic mental operations, schemas and constructive mechanisms as they exist and function in the mind of the individual within that "lived experience." To emphasize Piaget's (Piaget & Inhelder, 1969) theoretical inclusions that both intellective and affective aspects are involved within experience leading to development, so we seek to study both as a seamless whole, even as we reject many other dichotomies as false (such as "thinking versus feeling") typical of a strictly modernist structuralism.

Among the constructivist focal constructs we want to consider in our study of "lived mathematical experience" are representation and re-presentation, reflection and reflective analysis and abstraction, intuition and intuitive reasoning, and perturbation and equilibration, and particularly to search for where and how they may be found to function in, impact upon, and in turn be affected by particular experiential contexts. For example, in today's curricular frameworks one sees a major attention given to "representations" and representational activities; students are expected to learn to understand, use, and make various canonical mathematical representations. Yet, what from a study of "lived mathematical experiences" can we find about a student's actual conceptions and views of representations, and especially how they experientially use such images in problem contexts to re-present the conceptual ideas they are presumed to represent? Moreover, von Glasersfeld's (1991) view of cognitive functioning sees representation, re-presentation, and reflective abstraction as inseparable aspects; can we find this exhibited in "lived mathematical experience?"

Methods

On the first day of class, both research projects were explained to all nineteen students; most agreed to participate fully in the course-based investigation. Additionally, nine students expressed interest in participating as one of four selected paid volunteers. Over the next several days, the Principal Investigator (Hatfield) met each prospect individually for about 45 minutes, to explain further details related to the conduct of the ten 90-minute weekly (extra out-of-class) interview sessions, and to engage in a sample geometric problematic situation that illustrated what might be expected in each interview. By the time these preliminary sessions were completed, two students had withdrawn from the course (due to personal circumstances); all others confirmed their interest to participate if selected. Four of the remaining volunteer prospects were then selected based upon PI perceptions of these factors: expressed interest in the research, personal goals for learning from the individual sessions, openness, qualities of "thinking aloud" during sample problem solving, qualities of reflective analysis about their past mathematical experiences, and survey profiles of views of mathematics, mathematics learning, mathematics teaching, and school mathematics. Two women and two men were chosen; one female and one male are both older ("non-traditional") students and both expressed greater insecurity (less confidence) in relation to their mathematical knowledge and prior experiences.

The constructivist/phenomenological research methodologies used in this study require dynamic spontaneous interactions with each subject, functioning within a specific task-oriented framework. Data used in analyses include interactions and observational field notes of the researcher-interviewer (Hatfield) and a researcher-observer (Belbase), written or computer-based productions of the student, and video-recorded behaviors and verbal responses constructed by the subject, prompted by a "thinking aloud" expectation and questioning and probing protocol. Additionally, both the researcher-interviewer and the researcher-observer constructed post-session written descriptions of their intended and lived session experiences, these to be used as further data for analyzing and interpreting the co-contextualized (collaborative intellective and social dynamic) experiences of the student participants.

In general, all 90-minute interviews are structured into the following sequence of events (with approximate time allocations to be completely flexible and determined by the real-time decisions of the researcher-interviewer to proceed forward in the sequence, or to dwell longer to pursue productive interactions on behalf of the research question).

Part 1. (~20 minutes) Experiences in the course activities---Reflective interactions first focus on the student's conceptions and perceptions of what they have been experiencing in the class sessions, and how those experiences (from their point-of- view) are shaping their mathematical knowledge, their views of "doing" mathematics, and their ideas related to their future teaching of geometry and measurement to elementary students. These are prompted by questions such as the following: "Talk to me about what you've been experiencing during class sessions. Which of these experiences have seemed especially significant to you? Why? How have you benefited from those experiences, and why do you think you did? Tell me what you thought about ______ (a particular activity or event). Have there been any course events that were not particularly helpful or useful to you? Do you see ways that your course activities might impact your future teaching? Why? How might that happen?"

Part 2. (~50 minutes) "Living/lived mathematical experiences"---A non-routine geometric problematic situation is posed to the student, with the request to try to solve it as they share what they are experiencing via a "thinking aloud" approach. These geometric situations are challenging applications beyond the course content, solvable by good precollege problem solvers, including upper elementary students. An example: "Three towns, A, B, and C, are all on the same road. Town A is 12 kilometers from town B, and town B is 6 kilometers from town C. There is an additional town X on the same road that is also twice as far from town A and from town C. How far is town X from town B?"

There is not an a priori interview protocol, but efforts of the student constructively develop within an approach that promotes solving efforts (in which the researcher-interviewer will encourage student questions, and may include carefully placed problem-related questions or suggestions he poses) while frequently asking that the student describe her current thinking. At appropriate points he may ask her to pause ("take time out") in her solving efforts to reflect upon and describe qualities of her ongoing "living/lived mathematical experiences" in the unfolding situation. The fundamental goal is to reveal and study mathematical experience in terms of a dynamic interplay among cognitive and emotive thinking and feeling represented in the interiorized events of another person.

Part 3. (~20 minutes) "Looking back" and "Looking ahead"---Near the end of the interview, the subject is asked to reflect upon the session and to ponder anticipations beyond the session. This "looking back" phase of discussion reflectively focuses on her reported experiences of the session, emphasizing the problem-solving episode. In this, attention is given to potential connections to the nature and quality of experiences occurring in the class sessions. The "looking ahead" aspects then requests the student to anticipate potential connections of what she has experienced in the interview to how she views her future teaching of elementary mathematics, and in particular geometry and measurement, with children. In this discussion one focus is upon how elements of her personal philosophy and epistemology for mathematics are possibly being transformed by the course and interview experiences.

In the final interview session, the student will be asked to collaborate to construct a reflective analysis of their lived mathematical experiences across all course sessions and interview problem-solving episodes. Their written productions will be used for stimulated recall and analysis; selected segments of video may also be used to stimulate and support their recall and analysis. They will be guided to discuss what they perceive as the essences of the mathematical experiences they have had across the sessions, and how these relate to the qualities of their other lived mathematical experiences.

Results

Data are currently being collected and formatively analyzed, and this will continue to the end of the scheduled individual interviews (late April 2011). Formative data analysis has been initiated, in part to reflect a "constructivist teaching experiment" in which ongoing analyses and interpretations yield idiosyncratic inputs to influence potentialities within the subsequent interview dynamics. Identified elements of expressed and observed "lived" and "living" experiences are used to inform the intentional questions and interactions of the researcher-interviewer with a particular student during a subsequent interview session, all framed within the contexts of the three-part dialogue.

Using discourse analysis supported by video reviews (Hurlburt & Akhter, 2006; Petitmengin, 2006; Wolcott, 1994), thick descriptions for each session for each student are being constructed independently by the researcher-interviewer and the researcher-observer; these will then be jointly analyzed and contrasted, leading to consensual descriptions. After the course ends (by research protocol agreement) the observational and analytical voices of the other two project researchers [Chamberln (course supervisor and collaborative investigator) and Schnorenberg (course instructor and collaborative investigator)] will be added to the detailed analysis of all data from the forty sessions. In particular, all consensual descriptions will be collaboratively reviewed and analyzed, leading to a written interpretation for each student to portray the composite essences and overall qualities and to characterize a phenomenological model of mathematical experience for each of the four students. Particular attention will be given to identifying ways their mathematical experiences may have changed or developed across the class sessions and interview episodes in terms of their understanding and reasoning for "sense making" in geometry and measurement, their emotions and feelings for learning and solving problems, and their conceptions and anticipations for their future teaching children mathematics.

Some very preliminary results from our mid-study analyses include:

- There are differences among the students in their lived mathematical experiences that deeply affect their beliefs and self-efficacy about mathematics.
- There are strong connections between, and mediations by, qualities of prior lived mathematical experiences and the ways they seem to be able to engage in, and benefit from, new living mathematical experiences.
- The qualities of their current mathematical experiences are strongly shaping their views about how they will engage elementary students in their future teaching.
- A developing idiosyncratic "theory" of a student's experiential relationship to doing mathematics provides an important meditational template for teaching interactions.

Final interviews (in the Fall) with each student will be conducted in which the written interpretation (characterizing model) of the student will be shared and discussed. In this context we will encourage the student to agree or disagree on particular elements of interpretation, to explain and elaborate differences, to offer alternative views and ideas, and express the degree of agreement they feel they have for the characterization of their lived mathematical experiences during the Spring studies. These interview discussions may lead to revisions in the written interpretation, and will be data also summarized and reported.

Discussion

Little theoretical or empirical research with explicit attention to "lived or living mathematical experience" has been reported to date. Yet, there is a pervasive and deep focus on implied or intended mathematical experience across the history of mathematics education. The DIME (Developing Investigations of Mathematical Experience) research team seeks to establish a research program that will begin to build toward a deeper understanding of what a variety of participants in mathematical education can reveal about their interiorized worlds of "lived and living mathematical experience."

The students (prospective elementary teachers) who participated in this study have been invited (and all have given preliminary commitments) to participate in follow-up investigations of mathematical experiences during their enrollments in two "methods of teaching elementary mathematics" courses, in "student teaching," and then into their first year of classroom teaching of mathematics. Through this sequence of studies with the same students, we will build accounts of the accumulated impacts and consequences of their idiosyncratic lived mathematical experiences upon their development and modifications of personal theories and practices for teaching children mathematics.

(RE)SHAPING ELEMENTARY PRESERVICE TEACHERS' ATTITUDES TOWARD MATHEMATICS

Cindy Jong
University of Kentucky

Thomas E. Hodges
Western Carolina University
tehodges@wcu.edu

The purpose of this study was to investigate how preservice elementary teachers' past schooling experiences and their participation in a mathematics methods course influenced their attitudes about the teaching and learning of mathematics. Pre- and post-surveys were administered to preservice teachers (n = 75) enrolled in mathematics methods courses at a university in the northeastern United States. Findings indicated that while prior schooling experiences influenced preservice teachers' initial attitudes about mathematics, the methods courses were conducive to shaping attitudes in a positive way, suggesting that experiences that build on preservice teachers' prior experience can, in fact, shift attitudes.

Introduction

Learning to teach mathematics is a multifaceted process beginning as K-12 students, continuing into teacher preparation programs, and extending into teachers' own classrooms (Wideen, Mayer-Smith, & Moon, 1998). Similar to K-12 students who enter the classroom, preservice teachers (PTs) enter teacher education programs with certain conceptions regarding the roles of teachers and students in mathematics classrooms. These conceptions are based upon particular forms of knowledge, resources, experiences, and conceptions of what it means to be a competent mathematics student and teacher (Ball, 1989; Ball, Lubienski, &Mewborn, 2001). Lortie (1975) suggested that the process of becoming a teacher involves an "apprenticeship of observation." From this perspective, teachers' socialization into teaching starts not when they enter teacher education programs, but as participants in K-12 school settings. Lortie claimed that the thousands of hours spent as a pupil in school create a "latent culture" that surfaces when one becomes a teacher. Additional research has shown that this apprenticeship of observation is influential in shaping preservice teachers' ideas about teaching and learning (Ball & Cohen, 1999; Feiman-Nemser, 1983; Wideen, et al., 1998). Once participating in teacher education programs, courses and field experiences typically expose PTs to multiple views that can help reshape their conceptions of teaching (Ball & Cohen, 1999; Ebby, 2000). However, the lenses through which preservice teachers make sense of these course and field experiences are developed by prior knowledge and experiences (Ball, 1989).In this paper we argue that just as teachers are encouraged to access students' prior knowledge and use their experiences as resources, teacher educators should take the same asset-based approach with preservice teachers.

Purpose of Study

Although several studies make the case that past schooling experiences are influential, few have specified how to build upon the existing attitudes and experiences preservice teachers bring with them to teacher education programs. A first step in building upon PTs' prior experiences is to understand the attitudes with which PTs enter mathematics education coursework, how those attitudes are a reflection of prior school experience, and how attitudes change through participation in a mathematics education course. Correspondingly, we asked, *How do preservice elementary teachers' past schooling and their mathematics methods course influence their attitudes about the teaching and learning of mathematics?* Regardless of the nature of teachers' prior experiences in mathematics, those experiences can provide an effective backdrop for developing attitudes towards mathematics teaching and learning aligned with reform recommendations in mathematics education (National Council of Teachers of Mathematics, 2000).

Perspectives

It has long been argued that teachers' affect is an important part of the way teachers understand mathematics (Ball, 1990). In Phillip's (2007) review of the literature on mathematics teachers' beliefs and affect, he argues that "for many students studying mathematics in school, the beliefs or feelings that they carry away *about* the subject are at least as important as the knowledge they learn *of* the subject" (p. 257). He defines "affect" as "[a] disposition or tendency or an emotion or feeling attached to an idea or object" (p. 259). He then goes on to explain that while "[a]ffect is comprised of emotions, attitudes, and beliefs….[a]ttitudes are more cognitive than emotion but less cognitive than beliefs" (p. 259). Much of the research on elementary teachers' affect has focused on the anxiety they have about mathematics; however not much, if any, has focused on teachers' affect and the relationship to their expected practice (Phillip, 2007).

Our study follows a well established line of research that has attempted to examine PTs' attitudes towards the teaching and learning of mathematics whether they adopt a more reformed view of teaching mathematics (Ebby, 2000; Eisenhart, Borko, Underhill, Brown, Jones, &Agard, 1993; McGinnis,and MacNab& Payne, 2003). Methods courses that expose teachers to reform practices tend to positively influence PTs' attitudes towards mathematics teaching and learning. However, Eisenhart et al (1993) found that while their participant had a desire to teach for in a reformed way, observations indicated that she rarely taught mathematics using approached aligned with reform documents in mathematics education. McNab and Payne (2003) had a similar finding with PTs in Scotland, where once they were out in the classrooms were "relatively unadventurous in their teaching" (p. 66). While field based experiences can contribute to PTs' attitudes towards mathematics, we chose not to include this factor in our analyses here. This was due to the varied field based experiences of participants included in this study; thus, we focus on the mathematics methods course.

Modes of Inquiry

Research was conducted at a private university in the northeastern United States. The teacher education program offered both a traditional four-year undergraduate degree and a graduate degree that could be completed in a twelve-month period. As part of the teacher education program, preservice teachers were required to take one mathematics methods course. This course was typically taken during the fall semester before student teaching.

All participants were undergraduate or graduate level preservice elementary school teachers enrolled in one of four sections of the mathematics methods course. Three professors taught the four sections of the elementary mathematics methods course. The mathematics methods courses at this university emphasized a reformed view of teaching mathematics. At least half of the class sessions used manipulative materials where the instructor emphasized links between concrete models and abstract mathematics concepts. Reflecting upon those experiences was an important part of connecting past experiences and prior knowledge to new ideas. The course was organized around the NCTM Standards (2000) where the instructors purposefully used process standards as a means for teaching content standards. Participating PTs completed both a pre-survey, which was administered the first week of the mathematics methods course, and a post-survey, which was administered during the last week of the course during the same semester.

Instrumentation

The pre-survey sought to capture participants' entering attitudes about mathematics and inquired about their experiences as K-12 students. The purpose of the post-survey was to examine preservice teachers' attitudes the teaching and learning of mathematics, field experience, and mathematics methods course experience. The population size was 102 and the total sample size for those who took both the pre- and post-survey was 75, a 73.5% response rate. The surveys, which were based on existing instruments, were first created and piloted in the first author's dissertation. Overall factor analyses indicated that approximately 67% of the variance was accounted for within seven scales. The sub-scales of each of the surveys had moderate to high reliability, with Cronbach's alpha levels from .612 to .921.

The pre-survey included the following four sections about mathematics: attitude and past experiences, teaching and learning, methods course expectations, and diverse learners. The post-survey included the following four sections about mathematics: attitudes and practicum experiences, teaching and learning, diverse learners, and future teaching. Most of the 48 items (per survey) were on a four-point Likert scale ranging from "strongly agree" to "strongly disagree." However, the section about the practicum experience included the fifth option, "not applicable."In addition to the pre- and post-surveys, which were administered during the first and last weeks of the course, observations of the mathematics methods courses were conducted and course artifacts (i.e. syllabi, assignments, and assessments) were collected to provide contextual information related to survey and interview data related to the mathematics methods courses. However, this paper solely focuses on the survey data.

Data Analysis

Multistage survey data analyses were carried out using SPSS. First, descriptive statistics were applied to analyze overall item response percentages and note any possible trends in responses. Second, we used correlations to examine the relationships among past experiences, the methods course, attitudes about mathematics education, and confidence to teach. Lastly, a multiple regression model was created to examine how past schooling and the mathematics methods course accounted for preservice teachers' attitudes towards mathematics and perceived level of preparation to teach mathematics.

Results

Considering the influence past experiences have on PTs conceptions of teaching and the desire of teacher education programs to help shape these conceptions (Ball, 1989; Lortie, 1975; and Scott, 2005), we became interested in responses on three unique items on the post-survey that directly asked preservice teachers about the perceived impact of their past K-8 schooling, practicum, and mathematics methods course on their future teaching practices (see Figure 1). The percentages were based on the total n of 75 to avoid an inflated percent due to missing data. The stem for the three items stated, "The following will have a major impact on the way I teach math in the future." The PTs were then asked to respond to this statement specifically about their past K-8, practicum, and methods course experiences. 85% percent either strongly agreed or agreed that past experiences would have a major impact on their future teaching practices. 81% percent strongly agreed or agreed that they believed their practicum experiences would be influential, and 96% thought that the mathematics methods course would have a major effect on their future teaching. Further analyses examined the relationships and influences of past experiences and the methods course.

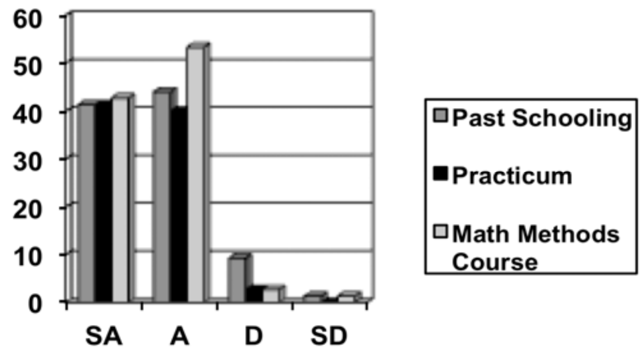

Figure 1. Elements influencing preservice teachers' anticipated practices by percentages

Results displayed in Table 1 indicate a positive relationship between PTs' attitude towards mathematics and positive prior schooling experiences in mathematics at the K-8 grade level (r= .599, p< .01). Participants' *positive math attitude* had an especially strong positive relationship to their perceived *proficiency* and positive high school experiences with mathematics (r= .719, p< .01). Undoubtedly, these constructs are all interrelated. If preservice teachers perceived themselves as highly proficient in mathematics, they were likely to be more confident (r= .585, p< .01), look forward to teaching mathematics (r= .563, p< .01), and have a higher positive attitude towards mathematics (r= .713, p< .01). Similarly, preservice teachers' attitudes and self-perceptions were related to their own experiences as students learning mathematics.

Table 1.Relationships among Attitudes and Prior Schooling Experiences in Mathematics

Pre-Survey Items	2	3	4	5	6
1. Positive math attitude	.599**	.719**	.713**	.661**	.553**
2. Positive K-8 math		.539**	.526**	.455**	.368**
3. Positive 9-12 math			.599**	.508**	.440**
4. Perceived Proficiency in math				.563**	.585**
5. Looking forward to teaching math					.504**
6. Confidence in ability					

** Correlation is significant at the 0.01 level (2-tailed)

To examine the relationships among preservice teachers' experiences in mathematics methods course, attitudes about mathematics, anticipated approaches to teaching mathematics, and perceived preparation, bivariate two-tailed Pearson's correlations were run at the .05 alpha level (see Table 2) among items pertaining to these topics on the post-survey. Results indicated a moderate positive relationship between participants who had a more positive attitude towards math and whether they learned a variety of strategies in the mathematics methods course (r= .273, p < .05), planned to teach mathematics in a conceptual manner (r= .326, p< .01), were going to require their students to memorize facts (r= .274, p < .05), and agreed that the mathematics methods course would have a major impact on their future teaching (r= .268, p < .05). Preservice teachers who indicated that they learned a variety of strategies in the methods course showed an increased desire to teach mathematics (r= .371, p< .01), confidence (r= .277, p

< .05), and believed that the course would have an impact on their teaching practice (r= .440, p< .01). An increased agreement that the mathematics methods course would have an impact on teaching practices was also significantly related to an increase in looking forward to teaching mathematics (r= .360, p< .01) and confidence (r= .291, p < .05). Participants' level of confidence was also associated with whether they would encourage students to use multiple strategies (r= .279, p< .05), a characteristic of teaching with a conceptual focus.

Table 2.Relationships Among Attitudes and the Mathematics Methods Course Experiences

Post-Survey Items	2	3	4	5	6	7	8	9	10
1. Positive math attitude	.273*	.306**	.794**	.566**	.326**	.168	.066	.274*	.268*
2. Learned a variety of strategies		.192	.371**	.277*	.149	.043	.142	-.013	.440**
3. Prepared to teach math			.397**	.438**	.139	-.149	.227*	.047	.210
4. Looking forward to teaching math				.711**	.311**	.011	.140	.061	.360**
5. Confident in ability					.412**	0.031	.279*	.137	.291*
6. Teach conceptual math						.275*	.382**	.155	.014
7. Teach procedural math							.051	.601**	-.083
8. Encourage multiple strategies								.016	.119
9. Require students to memorize facts									-.109
10. Methods course, major impact									

* Correlation is significant at the 0.05 level (2-tailed)
** Correlation is significant at the 0.01 level (2-tailed)

Following a confirmatory approach, we hypothesized that the variation found in preservice teachers' feelings of preparation and anticipation to teach mathematics after being in the mathematics methods course for one semester could be explained in terms of the variables listed above. In statistical terms, the hypotheses can be expressed as: $H_0 = \beta_{positiveK8math} = 0$, $H_a = \beta_{positiveK8math} \neq 0$ and $H_0 = \beta_{mathcoursestrats} = 0$, $H_a = \beta_{mathcoursestrats} \neq 0$. The significance level was set at the 0.05 two-tailed level.

The overall regression of *preplookfwd* on positive *K-8 math* and *math course strategies* was statistically significant [R^2 = .208, F (2, 75) = 9.441, p< .001]. Overall, the variance explained by the two predictors differed significantly from zero; thus, we rejected the null. Table 3 shows the overall model summary and significance levels. This model had a higher F-value and was statistically significant. The *positiveK-8 math*variable accounted for approximately 12.5% of the variance in *preplookfwd*, while *math course strategies* accounted for an additional 8.3% of the variance. Taken together, the predictor variables could explain approximately 20.8% of the variance of *preplookfwd*. Although the model was significant, nearly 80% of the variance was unaccounted for in *preplookfwd*, which supports the argument that a multitude of variables influence preservice teachers' attitudes and preparation to teach mathematics. The unstandardized coefficients of the model were .192 for *positive K-8 math* and .330 for *math course strategies*. The regression solution for this model was:

$\hat{Y}_{preplookfwd} = 0.942 + 0.192X_{positiveK8math} + 0.330X_{mathcoursestrats}$ .To evaluate the effect size of the regression model, we computed a post-hoc power analysis. The model with two predictors (see Table 5) had a very high level of power (1 - β = 0.97) with a medium effect size (f^2 = 0.26) at the alpha level of .05.

Table 5.Model Summary and Significance of Two Predictors

Predictors	R^2	ΔR^2	F	p	DW
1. Positive K-8 Math	.125	.125	10.447	.002	
2. Positive K-8 Math Math Course Strategies	.208	.083	9.441	.000	2.164

Note. Dependent Variable (constant): PrepLookfwd to teach Math

Discussion

Descriptive statistics from the post-survey clearly showed that more than 80% of participants perceived their prior schooling and the mathematics methods course experiences as having a major impact on their anticipated teaching practices. The multiple regression model confirmed that the two variables accounted for a significant proportion of preservice teachers' perceived level of preparation and their attitude towards teaching mathematics. Nevertheless, the two factors combined accounted for only 20.8% of the desired outcome variable including preservice teachers' looking forward to teach mathematics and viewing themselves as prepared. Thus, other factors beyond those in our model account for almost 80% of PTs' preparation to teach mathematics and attitudes about teaching mathematics. In this section we present an interpretive summary of the two main themes from our data.

Evolution of Attitudes

Findings indicated a strong relationship between PTs' attitudes about mathematics and their prior schooling experiences. A positive increase in participants' attitudes towards mathematics was related to positive experiences in K-8 prior schooling (r= .599, p< .01) and to high school (r= .719, p< .01). Similarly, an increased response to perceived proficiency in mathematics had a strong positive relationship with attitude towards mathematics (r= .713, p< .01). In addition, participants' perceived proficiency was related to both their prior K-8 (r= .526, p< .01) and high school (r= .599, p< .01) experiences in mathematics. Thus, correlation results indicated that those with more positive prior schooling experiences had more positive attitudes towards mathematics and considered themselves as more proficient. These findings support a qualitative study conducted by Ellsworth and Buss (2000), who examined preservice teachers' attitudes towards mathematics by analyzing their autobiographies. They found that past teaching models was the most salient theme because preservice teachers' commonly reported that their interest in or attitude towards mathematics was positively or negatively affected by past teachers. By bringing past experiences to the surface, preservice teachers may be more cognizant of how their own attitudes about mathematics are shaped.

Influential Factors

It is particularly important to acknowledge that preservice teachers enter teacher education programs with a wealth of knowledge from their prior schooling. Although in some cases, the goal of a course is to reshape or challenge entering assumptions about the role of teaching, PTs can also have positive perspectives about teaching which complementary ideas can be built upon. The mathematics methods course could build upon PTs'attitudes, which are often more positive and fertile than expected. While the mathematics methods courses observed in this study did not appear to have an overt agenda or strategy to build upon PTs' past experiences, questions were raised about their view of the teaching and learning of mathematics. As the instructors taught methods for different mathematics topics such as multi-digit subtraction, PTs would use the standard algorithms in many cases and connect their prior knowledge about the procedure with the concrete materials. It would have been interesting for PTs' to explicitly compare different strategies and discuss the benefits of alternative algorithms.

While the two experiences we focused on, prior schooling and the mathematics methods course, can be of great importance in preparing elementary teachers to teach mathematics, our study found that the two only accounted for 20% of the variance of PTs' attitudes towards teaching mathematics. This suggests that the past experiences that we often try to work with may not account for as much as we thought it did. While important, past experiences might play a smaller part than we expect. We suggest that explicit efforts still be made in the mathematics methods courses to connect to PTs' prior knowledge. Many scholars who support a social justice approach to teaching have made a strong case for the importance of adopting an asset model by using students' prior experiences as resources (Cochran-Smith, 2004; and Ladson-Billings, 1995). In a similar way, we believe that teacher educators need to use preservice teachers' entering characteristics as resources and adopt an anti-deficit model. However, there are many additional factors that need to be explored over time, such as field experiences, student teaching, mentors, family members who are educators, and mathematics content courses, which could potentially influence changes in participants' attitudes and confidence. In addition, continued professional development opportunities can continue to build upon preservice teacher education experiences to increase teachers' confidence and knowledge. In the final section we make recommendations for teacher education and future research.

Recommendations

Although several scholars have argued that beginning teachers' socialization into teaching takes place when they are students, empirical work has not explored the extent to which past experiences influence preservice teachers (Scott, 2005). This study explored that issue as it pertains to mathematics teacher education and showed that past experiences only accounted for 12.5% of the explained variance in PTs' attitudes and confidence to teach mathematics. We believe that this could actually be a very encouraging finding. While past schooling experiences are a significant factor and need to be taking into consideration, there are many additional factors that account for and influence teachers' attitudes that need to be explored.

Teacher educators should engage PTs in worthwhile and authentic activities that help them to bridge their own personal factors with contextual factors to adopt and practice that can support student learning (Goos, 2005). It is particularly important to acknowledge that preservice teachers enter teacher education programs with a wealth of knowledge from their prior schooling. Harkness et al. (2006) suggested that mathematics methods courses should provide opportunities for PTs to engage in meaningful problem solving tasks to make sense of the mathematics and make connections to improve upon their future practices. Ebby (2000) argued that methods courses should shift from mastering practical skills to developing "habits of mind" such as "making sense of children's understanding and learning to take a reflective stance towards one's own teaching" (p. 93).

Future research should follow PTs longitudinally across teacher education programs and into their entry into the profession. In this study, the pre- and post-surveys were confined to one semester long mathematics methods course. Based on the factor analysis, the instrument also had room for improvement, as surveys do not fully capture the variables of interest due to self-reporting and restricted Likert scales. The sample was also restricted to the mathematics methods courses at one university during one semester. Multiple data sites over time and across institutions would allow for stronger comparisons. In addition to survey results, qualitative interviews that elaborate on these experiences would help us further investigate how PTs' attitudes are reshaped.

BUILDING COMMUNITIES: DEVELOPING A SHARED SENSE OF ELEMENTARY MATHEMATICS PEDAGOGY WITH GRADE LEVEL TEAMS

Sandra M. Linder
Clemson University
sandram@clemson.edu

Introduction

This study examines the effects of a professional development (PD) experience on second and third grade teachers at a Title I school in southeastern United States as they worked together to develop a shared understanding of teaching mathematics. This case study analysis (Yin, 2003) investigates participants as they collaborated with a university-based mathematics teacher education group within a semester long PD experience. This paper discusses the process of change for this group of teachers as they worked to break down barriers and question beliefs about instruction and student ability in mathematics.

Theoretical Framework

The literature relating to mathematics PD is extensive. Most empirical studies document the implementation and evaluation of PD models that are transformative in nature, meaning that they are dedicated to improving teacher quality in mathematics (Smith, 2001). These models differ from PD that is additive in nature, meaning that the purpose of the experience is to add new ideas or material to existing instructional practice (Smith, 2001). Recommended PD models described in the research literature contain what can be considered the four essential elements of mathematics PD:

1. PD should be ongoing and grounded in practice: Teachers require extensive experiences geared towards developing both mathematical content knowledge and pedagogical content knowledge (Hill, Rowan, & Ball, 2005). These experiences must connect to everyday teaching practices (Garcia, Sanchez, & Escudero, 2006).

2. PD should focus on mathematical content: Research indicates that teachers are inadequately prepared to deal with the discussions that can occur in a reform-minded mathematical classroom (Hill, Rowan, & Ball, 2005) and many elementary school teachers lack sufficient content knowledge to teach their students.

3. PD should have student learning as the ultimate goal: Guskey (2000) emphasized the need to determine the effectiveness of PD by the impact it has on student learning. Many studies conducted on models of PD measure effectiveness by teacher reaction or through district approval.

4. PD should create communities of teachers: Cobb, Stephan, McClain, and Gravemeijer (2001) describe the need for PD to enable teachers to collaborate with each other. Teaching is typically an isolated profession where teachers have little opportunity to collaborate to meet the needs of all students. Sustainable PD requires that teachers take ownership of their development through these communities of practice (Gellert, 2008).

The model developed for teachers in this study was grounded in the four essential components of mathematics PD outlined above. Prior to working with these teachers, the PD team spent two years observing classroom settings in four elementary schools as part of a state funded grant to gain a better understanding of their needs in terms of mathematics instruction. This information was used to create a PD model that was unique to the needs of these teachers. The PD team developed a model that had two main objectives: (1) To develop the pedagogical content knowledge necessary to implement an inquiry curriculum in the manner in which it was designed and (2) To develop a shared sense of purpose by analyzing a common instructional issue amongst participants. Although a focus on mathematical content was an absolute priority, it was also necessary to problematize participants' current instructional methods through the introduction of an action research agenda that would enable them to analyze student work as a team and, as a result, evaluate pedagogy to improve student achievement.

Methods

Research Question

The central research question guiding this study was: How does an ongoing mathematics PD model focused on developing an action research agenda impact the instructional practice of elementary school teachers? This question was examined through a case study design where multiple forms of data were collected during the experience and then analyzed and compared to determine overall results (Yin, 2003).

Sampling

Teachers were selected to participate in the PD model and concurrent research study through snowball and criterion sampling methods. When contacted by the PD team, all participants volunteered to participate in both the PD and the research study. The team of 11 participants (five second grade teachers and six third grade teachers) met two times monthly after school with one member of the PD team (who acted as both facilitator and researcher for this study) for a total of ten hours of formal, content-focused PD. In addition to these experiences, teachers read and critiqued articles relating to mathematics instruction, developed a research question and design, and collected and analyzed data from their individual settings.

Building a Community of Researchers

In order to scaffold participants as they conceptualized a research agenda, the facilitator/researcher first divided the group into grade-level teams so they were better able to consider issues relating to their students. The facilitator/researcher then asked participants to work together in each team to identify the specific needs of their students in mathematics. Once each team created a list of needs, the facilitator/researcher then asked each team member to write about their beliefs regarding how students learn mathematics and what it means to be an effective teacher of mathematics. The facilitator/researcher then extended this examination of beliefs by asking participants to compare their beliefs and their current teaching practices. Although this was an examination of teacher perceptions, the facilitator/researcher was able to scaffold participants towards the goal of investigating both student understanding in mathematics and instructional practice in mathematics. The culminating research question developed for both grade-level teams as a result of this examination was: What are the best ways to teach basic facts effectively?

Building Mathematical Understanding

The facilitator/researcher asked the 11 participants to complete a mathematics assessment prior to attending the first PD session to determine their needs in terms of building pedagogical content knowledge. This assessment was comprised of a selection of nine released items relating to number concepts from the National Assessment of Educational Progress (NAEP). The assessment was limited to items related to number concepts because second and third grade student achievement on a standardized assessment given quarterly showed weaknesses in this area. The PD team altered the nine items by including a reflection component where each participant was asked to explain the strategy used for solving each problem in writing. It was this reflection component that provided the most information for the facilitator/researcher to develop each PD session.

Data Collection and Analysis

Consistent with case study research, four forms of qualitative data were gathered throughout this study to determine changes in teacher beliefs and instructional practice related to mathematics pedagogy. Participants were asked to complete a reflection paper describing the results of their grade-level team research and their overall reactions to the PD experience. The facilitator/researcher provided a list of writing prompts to assist participants and to ensure information was provided relating to teacher beliefs about teaching mathematics. In addition, data was gathered through participant selected student work and classroom observations examined during PD sessions, anecdotal notes written by the researcher during PD sessions, and the reflection component of the NAEP assessments administered prior to and following the overall PD experience. Data analysis began with repetitive readings of each form of data to ascertain an overall impression and to identify overarching patterns or themes. From there, constant comparative methods (Strauss and Corbin, 1998) were used in a secondary analysis to examine themes across data.

Results

In the beginning of the PD process, participants expressed their concern that they would be forced to implement the inquiry-based curriculum the rest of the school had already been using. The facilitator/researcher worked to build a positive relationship and establish a sense of trust by seeking permission from administration to allow participants to teach mathematics in whatever method they felt was most effective. As a result, participants were more open to questioning their own practices. While they did not implement the curriculum fully, they did begin to ask open ended questions in their classrooms and provided students with tasks that were developed as a result of analyzing student work during PD sessions. Participants also began planning together and developing hypotheses regarding the most effective ways for students to understand basic facts. They quickly realized that summative assessments of student learning would be insufficient in determining student understanding.

Participants reported the value of listening to their students and increasing student discussions as part of mathematics lessons. They also recognized the need to “talk less” when teaching to allow students time for engaging in meaningful discussions. “I have learned that I need to let go of some of the control in my room and let my students come up with their own thoughts and conclusions about the problems. They might have a better way of looking at something or even be able to teach each other better than I could” (Participant 3). Their view of student abilities in mathematics was also challenged throughout the research process, “Many times I would give them a problem and we would work it out exactly the way I had in MY mind. I realized during these sessions that my students are capable of using different strategies to solve the exact same problem…I need to allow my students time to explore and try different mathematical strategies to figure out the answer” (Participant 6).

Even with these positive changes, participants still viewed themselves as transmitters of knowledge rather than facilitators during lessons. Often participants described how they needed to present information to students in order for them to build conceptual understanding through tasks. “I gained some insight into how my own team explains their mathematical processes to their students (Participant 1)”. They began to change their instructional practices to allow for open-ended questioning, conceptual tasks, increased communication, and student autonomy, however many continued to view the beginning of the lesson as the time when they “taught” students and the second part of the lesson as the time when these reformed practices would be implemented. Although perceptions of practice were beginning to change by the end of the PD sessions, as is evident in the examples reported above, participants in this sample did not completely transform their beliefs about the teacher’s role in mathematics instruction.

Discussion

Research has shown that while building teacher content knowledge in mathematics is a priority, without problematizing instructional practices and building a sense of community among colleagues, little change will occur in the classroom (Cobb & McClain, 2001). Professional learning and teaching communities have long been recommended for improving teacher quality in mathematics. The use of action research in the mathematics classroom holds potential as a means of solidifying and sustaining these communities. By developing a shared sense of purpose that holds practical implications for instruction, teachers will be more motivated to collaborate in PD opportunities. This study presents a model of PD that works to simultaneously build teacher pedagogical content knowledge and build a shared sense of community among colleagues engaging in action research. Teachers in this setting showed the ability to question their own mathematical understandings and their students' mathematical understandings. As a result, they were able to design a research agenda built around analyzing student work as a means to develop instructional practice.

EDUCATIONAL METAPHORS IN TEACHERS' CONSTRUCTION AND FRAMING OF PROBLEMS OF PRACTICE

Guadalupe I. Lozano
University of Arizona
guada@math.arizona.edu

Marcy B. Wood
University of Arizona
mbwood@email.arizona.edu

In this paper we study how teachers construct problems of the mathematics teaching practice. Identifying problem design as an important and understudied aspect of problem resolution, we consider conceptual metaphors as particular resources employed by teachers as they construct and frame problems of practice. We focus on a specific conceptual metaphor, the metaphor of education as a journey, and illustrate how teachers use variations of this metaphor in their constructions of a specific problem of practice. We examine how the framing of a constructed problem affects first the potential for resolving the problem and ultimately, the opportunities for succeeding at teaching and learning mathematics.

Researchers have worked to positively impact the teaching and learning of mathematics by studying problems of teaching. These studies have carefully catalogued the problems of teaching practice (as perceived by researchers and by teachers) and considered remedies for those problems (e.g. Ball & Bass, 2000; Junk, 2005; Lampert, 2001; and Little, 2003). While this is important and useful work, it fails to examine an important aspect of problem resolution: the construction of the problem. The design of a problem directly impacts the steps to (and even possibility of) a solution (Getzels, 1979, 1975). For example, the problem of a student's failure to learn could be framed by a teacher as either a student's innate cognitive deficit or as a lack of appropriate experiences. If the problem of learning is seen as a biological deficiency in the student, there is little a teacher can do to encourage learning. On the other hand, if the problem of learning is seen as a need for additional experiences, there is much for the teacher to try. Thus, the ways in which the teacher constructs the problem of teaching has immense consequences for his or her work and for the potential resolution (or at least mitigation) of the problem.

While we know some about what problems of practice teachers notice, we know very little about the tools and resources that teachers draw upon to frame problems and how those tools and resources might result in crafting problems that are more or less resolvable. In this paper, we will consider how teachers use conceptual metaphors to construct and frame problems of practice.

Our current work focuses on a specific conceptual metaphor, the metaphor of *education as a journey*, and illustrates how teachers use variations of this metaphor to construct and frame a particular problem of practice. We examine how the framing of a constructed problem affects first the potential for resolving the problem and ultimately, the opportunities for succeeding at teaching and learning mathematics.

Conceptual Metaphors as Resources for Constructing Problems of Practice

Problems, which we operationally define as perceived misalignments between what exists and what is desired, arise as people consider what is wrong, what counts as part of the problem, and what might be done to fix the situation. Thus problems are not immutable, universal Truths, but rather human creations which depend largely on the lens we use to frame a given reality.

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

Conceptual metaphors are one type of resource we often draw upon as we interpret realities and hence frame particular situations.

Conceptual metaphors are more than figures of speech. Instead, they are the use of one idea to frame or make sense of another (Johnson, 1987; Lakoff & Johnson, 1980/2003). Conceptual metaphors allow us to describe abstract domains, processes, and experiences by relating them to physical or tangible domains, processes and experiences. For example, we may describe life by relating it to a physical journey or frame teaching as conducting an orchestra or planting a garden. According to Lakoff and Johnson (1980/2003, 1999), Yero (2002) and others, the metaphors we use create, guide, and reflect our perceived realities and experiences. In a similar sense, the metaphors teachers use in connection to the teaching and learning of mathematics at once affect and reflect their classroom experiences and perceived realities. In particular, teachers sometimes use conceptual metaphors as resources for constructing or framing the problems of their practice. In this paper, we focus on one particular conceptual metaphor of education, the *Educational Journey* (EJ) metaphor, and illustrate how teachers use this conceptual metaphor as they frame and construct a specific problem of practice.

Researchers have documented the use of *Educational Journey* in teachers' talk (Munby, 1986) and have explored implications of this metaphor in a variety of teaching contexts (e.g. Milne & Taylor, 1995; Sumsion, 2002; and Thornbury, 1991). The *Educational Journey* metaphor conceptualizes education as a journey in which teachers are guides and learners are travelers (Clark & Cunningham, 2006). Such a journey may be further characterized in a various different ways: The learner-travelers, for example, may autonomously venture forth in a journey of discovery, making paths as they explore the mathematical landscape. Alternatively, the learner-travelers may all follow a pre-determined path in a journey planned and led by the teacher-guide, attempting to travel at a specific common pace, towards the same specific places. Such possible characterizations of the EJ metaphor give rise to different versions or strands of this metaphor.

Clark and Cunningham (2006) described one such version of the EJ metaphor, which they identified as the predominant metaphor in the No Child Left Behind (NCLB) Act of 2001:

> All students are following the same path towards the same destinations defined by shared standards. […] Standards can serve as ideal prototypes relative to which all individuals can be compared. (p. 278)

We will refer to this particular strand of the EJ metaphor as the EJ-NCLB metaphor. We note that an implicit entailment of Clark and Cunningham's characterization of EJ-NCLB is that the journey along the common path must happen at a certain pace, and hence progress is measured by timely student achievement on standardized tests (Clark & Cunningham, 2006, p. 279).

Another possible strand of the EJ metaphor is one we have termed the *Educational Journey Landscape* metaphor (EJ-L). This strand of EJ conceptualizes learning as exploration and discovery of a mathematical landscape: Students are autonomous traveler-explorers who journey along a variety of paths towards a variety of destinations. Students self-monitor their progress and re-direct their journey by learning from mistakes and looking for landmarks. Teachers are expert travelers who journey along with their students helping them notice primarily the features and landmarks of the paths they choose to travel, not just the destination.

For example, when teachers use the EJ-L metaphor, they say statements like the following:

- "Students' mistakes are learning opportunities that *redirect* their thinking"
- "We are looking at the powers of 10 but if we never *explore* the powers of ten children don't know how big those numbers are"

- "That approach is going to be more efficient, but first kids have to mess with the messiness of numbers to understand why the efficient formula works. When I can see that in fifth graders, there's no *stopping them* if they are given the appropriate experiences."

The first statement conceptualizes students' mistakes as opportunities for learning, and implicitly positions students as individuals who may themselves re-direct their journey by noticing their mistakes. The second sentence suggests that progress in one's education journey is tied to exploration, while the third sentence highlights students as self-propelled, persistent traveler-explorers.

Other authors have also used landscape metaphors to suggest learning happens as we traverse the landscape of ideas. For example, Yero (2002) conceptualized knowledge as a landscape, while Davis and Hersh (1982) conceptualized mathematics as a landscape.

These two strands of the EJ metaphor (EJ-NCLB and EJ-L) frame our analysis of how teachers use this metaphor when constructing problems of their practice. We explore which of the two versions of this metaphor is foregrounded in the way teachers construct problems. We also propose how the specific strand of the EJ metaphor foregrounded in the framing of a problem may contribute toward resolving, mitigating, or re-constructing the problem in productive ways.

Data Sources and Analysis Methodology

The data set used for this work consists of over 80 hours of video data documenting regular meetings of a teacher study group. The study group was supported by the Center for the Mathematics Education of Latino/as (CEMELA), a National Science Foundation Center for Learning and Teaching. The purpose of the group was to support elementary and middle school teachers in schools with large Latino/a student populations in thinking about how to teach mathematics in ways that could best support the learning of their Latino/a students. Ten teachers participated in the teacher study group: two middle school teachers (from the same school) and 8 elementary school teachers (from two different schools). All schools were located on the outskirts of a mid-size city in the southwest. The three schools serviced student populations that were predominantly Latino/a and had many students who received free or reduced lunch and/or were classified as English language learners. The study group met 25 times over two years for a total of 66 hours. Each meeting was videotaped (both whole group and small group activities), resulting in the 80 hours of video data.

In this paper, we limit our analysis to data from one meeting of the group. While we have extensive transcriptions and analysis of data from other days, we are choosing to focus on this particular data not only because it is rich in teacher talk about students and teaching, but also because it contains all instances documenting the voice of Patricia, a nationally known mathematics educator who visited the CEMELA teacher study group on the day we are analyzing.

We began our analysis by transcribing the video data from this meeting. This transcript documented Patricia's talk about the work of teaching and student learning which served as the basis for our characterization of the EJ-L. In our initial pass through the data, we noted that Patricia's talk embodied a distinct conceptualization of teaching and learning. In order to capture this conceptualization, we systematically explored Patricia's talk for evidence of conceptual metaphors. We first coded all instances of the EJ metaphor used in her talk. This coding proceeded by noting all instances of path schema identifiers: words and phrases indicative of physical movement such as that which may happen in a physical journey. Path schema identifiers include phrases such as go forth, come back, go over, beyond, along, to, and from (e.g. Clark & Cunningham, 2006, p. 272). This first layer of coding enabled us to capture all instances of Patricia's talk where the EJ metaphor could arise, since path schema identifiers flag this metaphor. We further coded the passages containing path schema identifiers to eliminate all instances in which the use of such identifiers was either literal (e.g., a teacher talks about a student moving a physical shape: "brought it over here") or otherwise not tied to a conceptual metaphor about teaching and learning (e.g., a teacher references a personal experience unrelated to teaching). The educational metaphors contained in all remaining passages marked all occurrences of the EJ metaphor. These where then collected, sorted by themes, and summarized (Miles and Huberman, 1994). The final summary constitutes our characterization of a new, specific EJ strand which we have termed EJ-L given its overall conceptualization of education as exploration of a landscape.

This same method (first coding for path schema identifiers, then refining the coding to arrive to all instances of the EJ metaphor) was used to identify all instances of EJ metaphor in teacher talk within this data source transcript. When possible, we then sorted the occurrences of EJ metaphor into one of the two strands: EJ-NCLB or EJ-L.

Finally, we identified, within all coded instances of EJ, those in which the metaphor appeared in conjunction with the construction of a problem of practice. In other words, we identified instances in which teachers perceived what existed as different from what was desired. This resulted in several illustrations of how teachers use the EJ metaphor as they construct specific problems of practice.

Teachers Construction of Problems of Practice and the EJ Metaphor

In this paper, we focus on a particular problem of practice: Students don't remember/retain mathematical knowledge/information. This problem was constructed and framed independently by three different teachers in the teacher study group, at three different points in time during the transcribed meeting.

The first teacher, Matilde, framed this problem by proposing that students don't retain information because the teacher needs to move quickly through the topics in the curriculum and this prevents students from having enough practice with the concepts. The teachers were discussing students who seemed to understand the concept of area, but were unable to accurately determine the area of a polygon.

> *Matilde:* Probably what happened... Because [the students] got that concept [area] and, for example, (incomprehensible), they got the concept and then *we need to pass, the teacher needs to pass to another thing*, so they just got the concept, but they don't have enough mechanical practice, so next year, they already touched the same thing and they kinda remember the same concept but they still don't have enough practice and this goes year by year.

In this instance, the problem is that students are unable to accurately determine area even though they appear (to the teachers) to understand the concept of area. In her problem construction statement, Matilde's use of the metaphor (we need to pass, the teacher needs to pass to another thing) conceptualizes the need for teachers to move relatively quickly from one topic in the curriculum to the next. Matilde also indicates that this kind of teacher journey is recurrent: it goes on year after year.

Matilde is predominantly framing the problem of students' knowledge retention through the EJ-NCLB strand of the educational journey metaphor. Her words foreground the need for all students to travel at the same, relatively quick pace, moving from one topic to the next in a teacher-led mathematical journey. Above all, Matilde's framing of this problem seems to identify the need for the teacher to move, and to move fast, through the curriculum as the reason for the perceived misalignment between what is and what is desired of the students.

A second teacher, Olivia, constructed this problem by stating that students don't commit certain facts to memory because they don't get lots of practice: teachers do enough and then *move on,* a pattern that repeats at each grade level:

> *Olivia:* But now, I mean, we've had classes where we, where it's OK for them to not to know by memory because there's different methods and different tools for them to learn it or to figure it out, but you're right: certain things are just kinda dedicated to memory... and that happens with lots and lots of practice, and without the content we don't do that. We do enough and then we *move on and the next* grade level, they have to start all over again and then we *move on* and then it's just kinda... 'Cause that's a complaint in every grade level with every teacher.

In Olivia's problem construction statement the EJ metaphor appears twice, as we have indicated through italics. Olivia's use of the metaphor also highlights the movement of the teacher away from one topic or objective towards the next, in an implicitly timed, teacher-led journey. This emphasis in teacher movement suggests again that Olivia's use of the EJ metaphor is aligned with the EJ-NCLB strand of the metaphor. Hence Olivia is also framing the problem of student retention of knowledge through the EJ-NCLB metaphor, and the teacher's movement is again related to the perceived misalignment between what is desired of the students and what actually happens. It is interesting to note, however, that in her construction of this problem Olivia remarks that a teacher moves when she has done *"*enough*"* rather than when the "need" to pass arises, as remarked by Matilde.

Liliana, a third teacher, constructed this problem by proposing that students don't retain information because students don't spend enough time explaining how *they go there*, how they go about solving problems:

> *Liliana:* […] Because just by coincidence we did the same, similar type of activity, and she says, hers is in sixth grade and mine is in fourth grade and it's two years and they're having the same difficulties. What's going on with these kids…that they're not retaining that information? And I think in my class, one of the things that contributes to that, is the fact that they don't spend enough time really explaining how *they go there*. So I've been trying to really give them that extra time.

In her problem construction statement, Liliana use the EJ metaphor only once, as indicated through the italicized path schema identifier. Liliana's use of the EJ metaphor foregrounds student movement, omitting any reference to teacher movement. Liliana's words "how they go there" seem to recognize that there is more than one way to "go there" and that students could retain information better by being able to each describe their own journey towards a particular mathematical destination. This suggests Liliana's use of the EJ metaphor is best aligned with the EJ-L strand of the Educational Journey metaphor. In particular, Liliana seems to be framing the problem of student retention of knowledge through the EJ-L strand of EJ. She foregrounds a lack of opportunity for students to explain how they go about solving problems, as the primary reason for the misalignment between what is and what is desired.

Working Towards Solutions: Alternate Framings of Problems of Practice

As argued and illustrated in our introduction, the design of a problem directly impacts the steps towards, and even possibility, of a solution (Getzels 1979, 1975). In this section we discuss how the previous illustrations of problem construction and their respective proposed framings through EJ-NCLB and EJ-L impact the possibility of resolving this problem and suggest mechanisms for more productive problem construction.

Framing through Educational Journey-NCLB

In our previous illustrations of how teachers constructed the problem of students' lack of retention of knowledge, the most notable characteristic of the framings through EJ-NCLB (Matilde's and Olivia's) was the foregrounding of the teacher movement, without explicit references to student movement. This prominent focus on the relatively fast-paced teacher movement has been identified as a feature of the Educational Journey Metaphor of NCLB as used teacher talk. More specifically, teachers using this version of the Educational Journey metaphor often emphasize their movement as teachers or their responsibility to continue moving students through content (Wood and Lozano, 2010).

Also, the framings through EJ-NCLB, in particular the identification of fast teacher movement as a reason for the perceived misalignment between what is and what is desired, led to problematizations of the actual problem, rather than to the consideration of possible solution. Matilde's problematization, for example, explicates the original problem of students' lack of knowledge retention by linking it to the new problem of the teacher's fast-paced movement. In this problematization Matilde seems to exchange the original problem for a less solvable one, one whose perceived solution hinges upon altering national educational policies over which she has little control. In this way, Matilde's problematization seems to position her further away from, rather than closer to, the possibility of considering attainable problem solutions.

Olivia's reference to a teacher who moves once she has done "enough" could suggest that Olivia perceives lack of student ability as an additional barrier to considering attainable problem solutions. From this perspective, Olivia's problematization seems to constrain the possibility of solving the problem perhaps more than Matilde's: Olivia may perceive she has little control over educational policies, and even less control over students' natural abilities or dispositions.

Both of these illustrations depict how the construction of a problem and its framing through EJ-NCLB, may be unproductive if it leads to a problematization of the original problem that further removes a teacher from the possibility of considering attainable problem solutions. Such framings can constrain (rather than enable) possibilities for solving the problem and, ultimately, a teacher's opportunities to be successful at teaching and learning.

Framing through Educational Journey-Landscape

In Liliana's construction of the problem of students' lack of retention of knowledge, the most notable characteristic of her framing through EJ-L was the immediate foregrounding of the students' lack of movement and their need to move, without explicit references to teacher movement. This central focus on students and their autonomous, individualized movement along various possible paths in the mathematical landscape, lies at the core of our characterization of EJ-L and was the basis of Patricia's distinct conceptualization of mathematics teaching and learning.

Liliana's framing through EJ-L, in particular her focus on the students and her identification of the need for *individual* students to explain their *own* way of "going there" seemed to present a tangible option for addressing and possibly resolving the problem. Liliana's construction of the problem through the framing EJ-L seem productive, as it renders the problem accessible and enables (rather than constrains) opportunities to be successful a the work of teaching and learning.

We caution, however, that purposefully framing the construction of problems of practice through EJ-L, may not always lead to clearly productive or readily solvable problems. Other factors, besides the use of various conceptual metaphors, may also contribute to rendering a constructed problem productive or unproductive, useful or not useful. For example, a teacher who constructs the problem of students' lack of retention of information through EJ-L, like Liliana, but concludes that his students' deficient natural abilities will prevent them from explaining "how the go there," has in fact constructed an unproductive problem. More research is needed on these types of problem constructions.

Conclusion

In this work, we have illustrated different ways of constructing a particular problem of practice, shown how conceptual metaphors may serve as key resources for undertaking the construction of such problems. Different variants of the conceptual metaphor of Education as a Journey served as tools to parse out different framings of constructed problems and, at the same time, suggested specific (more or less productive) perspectives to frame a given problem. Through Liliana's talk, for example, we saw how the EJ-L metaphor strand proved useful in allowing her to focus on changing student experiences, rather than immutable students abilities, or educational policies.

Our analysis also showed that new problematizations of a given problem can constrain opportunities for teaching and learning, especially if they exchange the original problem for a less solvable one, further removed from a teacher's sphere of influence or control. We saw, for example, how Matilde's problematization of student knowledge retention shifted her focus away from considering a change in students' classroom practices, and led her to focus on the less tractable realm of national educational policies, characterized by the same problematic metaphor foregrounded in her framing.

We believe, however, that certain problematizations of perceived problems can be productive for problem resolution and may render certain problems of practice more, rather than less, accessible.

These findings begin to suggest (to teachers, teacher educators, professional developers, and policymakers) how different resources might lead to more (or less) productive problems and eventually to better learning outcomes. Furthermore, this work suggests that policymakers play a central role in teacher problem construction: The metaphors they use as foundations for policy become resources for teachers as they consider how to frame the work of teaching. As a consequence, policy makers might consider how to craft policy with care so that it provides teachers with framings and resources that lead toward useful and productive problem construction.

PROSPECTIVE SECONDARY MATHEMATICS TEACHERS' REALIZATION OF THE LOGICO MATHEMATICAL ACTIVITY TRHOUGH ANALYSIS OF A CASE STUDY

Gulseren K. Akar
Bogazici University
gulseren.akar@boun.edu.tr

In this study I studied the nature of prospective secondary mathematics teachers' thought processes coming to understand how a high demand task differs from other tasks with respect to the mathematical activity it focuses on. In a teaching mathematics method course twenty- eight prospective secondary mathematics teachers were asked to reason on a case study for two three-hours- long class period. Data have shown that not only these students' recognition of the differences between the empirical activity and logico mathematical activity have developed but also their understanding of what a mathematical concept is and how it is learned have progressed comparatively through their focused analysis.

Background

Current reform in mathematics education has emphasized the importance of prospective mathematics teachers' awareness of teaching mathematics effectively (NCTM, 2000). Some researchers have provided useful frameworks for teacher educators for supporting prospective mathematics teachers with ways to learn to teach mathematics for understanding (Hiebert, Morris, & Glass, 2003; Simon, 1994,1995,2006; Simon & Tzur, 2004). These researchers agreed that teacher educators might take prospective teachers' attention to the tools by which they are to learn to teach rather than providing them with the end products of teaching mathematics. This paper is a preliminary report of how the integration of these frameworks (Hiebert et.al., 2003; Simon, 1994, 1995, 2006) can be useful for pre-service secondary mathematics teacher education. Particularly, this paper relates to the part of effective teaching on selecting and/or creating tasks effectively to teach mathematics for understanding (NCTM, 2000) at the secondary grade level. In this paper, I provide data showing how prospective secondary mathematics teachers' thought processes regarding what a mathematical concept is has developed through their recognition of the differences between logico mathematical activity and empirical activity. Their focused analysis of a case study allowed these teacher candidates to reflect on the mathematical activity on part of the students. In the following paragraphs, I discuss the following: Theoretical framework (Simon, 1994,1995,2006) this study is mainly based on, what logico mathematical and empirical activity is and how the results of this study might have potentially important findings regarding mathematics teacher education.

Simon (1995) proposed Hypothetical Learning Trajectory (HLT) as a framework for teachers and teacher educators to use in their classrooms. He stated that HLT has three main components: "the learning goal that defines the direction, the learning activities, and the hypothetical learning process-a prediction of how the students' thinking and understanding will evolve in the context of the learning activities (p. 136). Simon asserted that the teacher's hypotheses of students' thinking and conceptual development is dependent on the generation of learning activities and the nature of the learning activities depend on the teachers' hypotheses of the students' learning process (Simon, 1995). HLT presupposes that the teacher has some knowledge about her students from earlier experience such as teaching other students in similar situations, through pre-assessment, through knowledge of the curriculum students have gone through before taking the course etc. HLT assumes that the teacher/researcher will revise and re-plan her teaching accordingly based on the ongoing assessment of students' understanding. That is, the teacher/researcher creates hypotheses about where her students' current knowledge is depending on the assessment, verbal or written. This helps her to create more questions/tasks on which students can think further. This then allows her to have more data on what students know from which the next lesson period is constructed. In general, then, the teacher/researcher has a learning goal for her students to have. However, for each teaching session, she creates (sub)learning goals for her students depending on what they know. Thus, HLT is a recursive process from which each lesson is constructed on its own but toward the general goal of conceptualizing mathematics. In that sense, each lesson is an experiment.

As important as it is for teachers and teacher educators to have a learning goal for their students, in another study, Simon also stated that having a particular learning goal is not sufficient; teachers also need to be able to create or select tasks/ activities to bring about the desired thought processes on the students' part (Simon &Tzur, 2004). Similarly, research has emphasized that teachers' knowledge of curriculum (Shulman, 1986; Ball, Thames, & Phelps, 2008) is pivotal because their awareness of cognitively demanding tasks and their use of those tasks effectively in their classes has the greatest impact on both students' learning and their perceptions of mathematics (e.g. Ball, 2000; Lappan, 1993; Lappan & Briars, 1995).

Simon &Tzur (2004) as an elaboration on HLT emphasized that teachers' learning goal(s) for their students should not be confused with the students' goals. That is, as important as it if for teachers to have a learning goal for their students, the students' goal-directed activity is the main issue from which the conceptual learning develops. Teachers might have a learning goal for their students to understand a concept, however it is the students' goal-directed activity that brings about the desired change in their conceptions. Simon (2006) further emphasized that teachers' awareness of the students' goal-directed activities might provide them with useful ways to create or select among tasks. Simon (2006) introduced empirical activity and logico mathematical activity. He defined empirical activity as the process by which students collect a set of results and identify a pattern in those results without any insight into why that pattern is produced (the logical necessity). In contrast, the logico mathematical activity refers to the learned anticipation of the logical necessity of a particular pattern or relationship. Simon stated that the distinction he made is fundamental to what is meant by a mathematical concept and the process by which concepts in mathematics are learned (through logico mathematical activity). He further argued that the distinction he is making has important pedagogical implications in the sense that effective mathematics teaching might be established by selecting or creating tasks triggering the logico mathematical activity on the students part.

Simon (2006)'s emphasis on logico mathematical activity and Thompson (2008)'s emphasis on conceptual analysis has correspondence. Thompson (2008) proposed a way to identify and articulate the key mathematical ideas inherent to the high school mathematics. He hypothesized that once one answers the question of " what mental operations must be carried out to see the presented situation in the particular way one is seeing it?"(Glasersfeld, 1995,p.78 cited in Thompson, 2008), s/he might describe the mathematical idea that is foundational to the subsequent ones. He called this conceptual analysis and stated " …when conceptual analysis is employed by a teacher who is skilled at it, we obtain important examples of how mathematically substantive, conceptually-grounded conversations can be held with students" (Bowers & Nickerson, (in press) cited in Thompson, 2008,p. 46). In that sense, once prospective teachers have identified the logico-mathematical activity on the students' part, they might be able to create/choose lesson designs that can bring about students' learning.

The goal of this study is to investigate how prospective secondary mathematics teachers' analysis of a case study might help develop their awareness of logico mathematical activity and its distinction from empirical activity. This might contribute to their interpretation of tasks focusing on important mathematics. As Thompson (2008) mentioned, even curricula claiming that their focus is on conceptual understanding are full of tasks/problems with little reference to significant mathematical ideas. This means that, it is imperative for teacher education programs to help their student teachers construct useful ways to identify tasks focusing on significant—core—mathematical ideas that constitute basis for other important ideas. Findings might have the potential to strengthen existing mathematic teacher education programs (Thompson, 2008).

Since I was the teacher/researcher, when I am referring to the teacher, I will be using the phrase "she", in the following sections.

Methodology

In this study, I embrace the idea that knowledge is constructed via one's own experiences. We have no access to the objective reality independent of our own knowledge (Von Glasersfeld, 1988). Though, we have the capacity to adopt to the changes around us as long as those changes are made persuasive or preferable. Although knowledge construction is an individual act, teachers can design situations in which students can engage in informed explorations and reflective inquiry (Cobb, 1999). This way, the social interaction will stimulate questioning, conjecturing and justifying.

While planning each session throughout the whole semester, involving eight- three hours long class periods, I used the hypothetical learning trajectory (HLT) (Simon, 1995). First, I assessed the students' understanding of the specific mathematics idea that I would use in the case discussions. Secondly, I collected data on their thoughts on learning and teaching mathematics through written responses at the beginning of the method course. In all the classes I taught, I revised and re-planned my teaching based on each lesson in which an ongoing assessment was held and pre-assessing and post assessing for each lesson was conducted through written responses. Students were asked to write reflections based on the questions I provided them after each class. In particular, depending on the small group and whole group discussions, I had hypotheses about where my students' current knowledge is. This helped me create questions on which they can think further. This provided me with more data on what they know from which I planned my next lesson period. For the general course, I had the overarching learning goal for my students to conceptualize the mechanism of teaching, components of which were discussed previously (Confrey, 1992; Hiebert, et.al, 2003; NCTM, 2000; Simon, 1994,1995, 2004,2006). However, for each teaching session, I revised the (sub)learning goals for my students depending on what they know. This allowed me to create each lesson on its own but toward the general goal of conceptualizing the teaching mathematics for understanding. In that sense, I treated each my lessons as experiments such that I designed the kinds of tasks, hypothesized and described why certain activities might trigger the change in my students' thinking and hypothesized how they will be thinking given the certain instructional tasks. (Hiebert, et.al., 2003).

The case study that I used for this paper was on multiplication of fractions (Stein et.al, 1998). I used this case study on purpose because 1) it was one of the basic concepts I knew from pre-assessment that they did not know the reasoning behind the procedure " multiply the numerators and denominators in each fraction", 2) it would be a relatively basic concept about which they would be able to talk about the key developmental understandings as opposed to other concepts such as functions (Simon, 2006), 3) it would provide the most opportunity for my students to be able to think about the parts of effective teaching mentioned above and 4) the most importantly, it would provide a rich context based on which the empirical activity and the logico mathematical activity could be discussed for the following reasons. By analyzing such a case study might have create an opportunity to enable my students to compare and contrast the reasoning of students on the specific concept from which they could think about the distinctions between the evidence of empirical activity and logico mathematical activity.

I analyzed my each of my students' thinking one-by-one and in juxtaposition to each other before and after this lesson using the artifacts from their written responses to the questions I posed them. I also analyzed their reasoning during the lesson using the transcript from the videotapes of the teaching episodes. In addition, I analyzed the relationship between the specific steps of the lesson and students' responses to them such that the cause-effect relationship between the proposed lesson and the hypotheses I held would be evidenced. To make sure that hypotheses and conclusions drawn from the data were plausible, other researchers were consulted to challenge the conjectures and /or to affirm their reasonableness.

The following sections present excerpts from transcripts of the videotaped lessons and the students' reflections on the kind of questions I posed them before and after the lessons on discussing the case.

Results

At the beginning of the course, I assessed my students' thinking on what learning and teaching means. In general their thoughts were clustered around the idea that learning means " taking the information in from an authority" and teaching is "transferring the knowledge from the teacher to the student". This is not surprising news given the fact that these students were taught mainly with a focus on procedures rather than with a focus on conceptions before coming to the course.

After the first session, I wanted my students to write on: "what does conceptual understanding mean to you?" and "what does connections in mathematics mean to you?" Their written work clustered around the two interpretations of the meaning of connections at the beginning of the course. First one was that connections meant only to think about the general relationship among objects (such as function, derivative etc.). Second one was that real life phenomena can be explained using mathematics. However, what were not clear from the data was how the students were thinking about the nature of the connections (if they were thinking about the connections deeper within a topic among different core mathematical ideas or not) and how the connections are established. Thompson (2008) also mentioned the issue of "the connections among topics" in his plenary speech at PME, 28. He regretfully stated that the emphasis on the connections among topics has the potential danger of taking the attention from the importance of foundationally core mathematical ideas of high school mathematics. Then, during the next session, I asked my students to talk about what they think about the meaning of connections in mathematics without "re-stating the word connection". The following discussion has occurred:

> S_2: When we make sense of the new knowledge using our previous knowledge then this means we make connections.
>
> R: How are you making sense of the new knowledge using your previous knowledge?
>
> S_2: You learn the first topic and then you learn the second topic. Then, you connect them by realizing that they are related to each other.

S_3: Yes, for instance, when we learn about how to solve pool- filling problems, the teacher explains how we are using the formula for finding the solutions then it make sense to us.

S_4: But I think making sense of real life issues such as problems in physics etc. using mathematics is important too. When we learn for instance about quadratic functions, if we can apply that knowledge to the physics topics then it means we have made the connection.

And other students agreed with all what is said. Then, I decided that for students to realize the nature of connections as making relationships among key mathematical understandings (key mathematical ideas) centering around quantities from which new quantities arise (Thompson, 1994), I needed to provide them with a concept basic enough from which they can deduce the meaning of connections in mathematics at the finest level. My hypothesis was that realizing how the connections are made and between what mathematical constructs those connections are made would allow them to realize the logico mathematical activity so that they would be able to set their learning goals for their students at the finest level.

At the beginning of the lesson focusing on the case study, I asked my students to work on an re-designed form of the task on multiplications of fractions individually and then I asked them to categorize the level of the task. All of them said " a high level task". Then, I re-grouped them, three in each group, and provided each group with one of the text in which two middle school teachers', namely Kevin and Fran, preparation period, implementation and their reflections were discussed. Then I asked them to think about the teachers and students' actions in terms of their goals. They mentioned that teachers are trying to teach multiplication of fractions conceptually and the students are learning fraction multiplication with understanding. Then, I asked my students to focus on the "reason behind the teachers' goals in asking the particular what and why questions and students' focus in answering those questions. They first found the questions started with "what and why" terms and then we started talking about them one by one.

R: Why do you think Kevin is asking the question why and Fran is asking the question why? Is there a difference between them asking the question? what are their goals?

S_3: He [referring to Kevin] is kind of taking their [referring to the students] attention to the connections in their solutions. Like, what connections did you make while finding your solution.

S_4: He [referring to Kevin] is making the students realize their solutions. Like, I think, he is making them realize their way of solution rather than the result itself. Like, how they were reasoning while there are solving the problems.

S_5: For instance, in Kevin's class, when one of the students did not take one hexagon as the whole, then Kevin wanted his student to realize his mistake. But he did not tell him that. He asked the "what" question on page 169, to take his student's attention to the two hexagons as a whole rather than one hexagon. However, in Fran's case it is different. She asks "what " question to just get an answer.

R: Do you agree with what $S_5$is asking guys? [no hands yet]

Who agrees with her? [some hands up]

Who does not aree with her? [no hands up]

Who is not sure about it? [no hand up]

R: all right what about those not raising their hands? [laughs in the class]

S_1: I think in Kevin's case students are feeling as if they have to answer the teacher. Students are feeling as if they have to get over with the result as soon as possible. I mean Kevin is not allowing for his students' understanding.
R: okay. You seem to be disagreeing with S_5? You are saying Kevin is not after students' understanding of the concept? [looking at S_1].
S_1: Nods his head.
S_4: But anyway, Kevin is asking the question "what" to get at how his student is thinking. Like, he did not get whether his student was solving the problem procedurally or conceptually so he asked the question to understand whether his student is thinking procedurally or conceptually. I mean, he asked the question to get how his student was reasoning while solving the problem, how he thought about it.
S_6: I think in both cases [referring to Kevin and Fran's classes] those students know that ½ of 1/3 is 1/6. But the issue is that Fran is giving away the whole in her class but Kevin is not doing that. Both of them had the goal that their students would understand the "concept of whole " but Fran is directly giving away the answer to her students.

The excerpt above is important because of the following: when S_3 mentions the "connections while finding the solution" S_4takes it from there and elaborates on in such a way that the focus of students were on their reasoning rather than the result itself. However, this is not even well articulated that S_5 elaborates on the "reasoning and the connections" in a deeper way and brings the discussion on the key understanding " the concept of whole". Though she does not explicitly say that, she only mentions that the "what" question in Kevin's class was on the meaning of the whole. Then, S_6 kind of finalizes the issue as "whole as the interest of concept such that when students find the ½ of 1/3 they can go back to the whole and think about the result in terms of the whole" in that discussion between the teachers and the students. This shows that, these prospective teachers' attention was on the logico mathematical activity that the students have been engaging in. The empirical activity, although these prospective teachers do nor mention explicitly is that in Fran's class, although the task is the same as the one used in Kevin's class and the questions are kind of centered around "why" and "what" questions in both classes, the ways these teachers are engaging their students differs in terms of their attention to their students' focus on the logico mathematical activity versus empirical activity. That is, the deduction made in Fran's class is independent of the quantities of interest, though in Kevin's class students' deduction of ½ of 1/3 is through the quantities of interest. The claim that I am making in this discussion was even more evident in the following discussion happened during the next class.

S_4: Fran is not doing, is not asking questions to take students' attention to their reasoning, remember like we said before, we mentioned something like called specific math idea, she is not asking further questions that would allow her students to focus on specific math idea, she is not doing that. But in Kevin's case, when he is not satisfied with the student's answer he is asking more questions to take their attention to the conceptual thinking…
R: hihim
S_7 : I would like to mention the same kinds of things, in Fran's question, students do not need to think about what they did during the task, like she is directly focusing their attention to the question itself , like instead of thinking " what did I do during the task" , they are for instance in the question "what is 1/6 of 2 hexagons" the student the thing in that task was to make them think about the two hexagons as a whole, but the student does not need to think about it, like he is focusing on the question itself and he is finding 1/6 of two hexagons only. But in Kevin's

question, he is focusing on whether his student understood the two hexagon as a whole or not, he is examining that and he is making his students go back to their reasoning while engaging in the task. But in Fran's case, Fran is focusing only on the question and the student do not need to think about how they engaged in the task.
R: okay, what are the students' goal when the teacher asks the questions?
S_7: In Kevin's case students are focusing on their way of thinking. Like what I did here, what was my thinking here they are focusing on that with Kevin's questions. But in Fran's case it will be the same thing I said before but they are focusing only to the question, they are not focusing on what they thought.
The excerpts above show that these student teachers are not only able to think about the key mathematical ideas but also they are able to think about students' focus of attention, namely the quantities.

A few weeks later, I asked my students the question, "When you think about the Kevin and Fran's teaching and the task they have used in their classes, how would you compare and contrast their teaching in terms of empirical and logico mathematical activity?". The following excerpt is especially important because it shows how S_1 thinks about the question. As depicted elsewhere, at the beginning S_1 had thought that Kevin was not after understanding. However, the following data shows that his thinking on it has changed after the discussions during the classes.

> S_1: We have discussed Kevin's and Fran's tasks in terms of questioning and students understanding. We agree on that Kevin was trying to emphasize conceptual understanding better than Fran since he was asking high level questions that are not about numeric values but the connections and relations between concepts…In the Fran's case the teacher's focus is on one student and other students are expected to model that, students to go on procedures... Fran's "what" questions focus on numbers or results in each step and he helps his students to come up with the right numbers but Kevin's "what", "of what" questions requires students to focus on the relationships between the steps and he wants from them to internalize the concept. So Kevin's task is more prone to be considered as a logico mathematical task. The students in Kevin's class think of logical necessity among the steps but Fran's students try to model a student and focus on the results in each step.

Conclusion and Discussion

Data show that at the beginning of the course the line of reasoning these student teachers hold corresponds with what Thompson(2008) mentioned in his speech: that connections in mathematics involve the connections between topics. Also, they agree on the idea that the connections are made with the teacher's statement after the two topics are learned. This shows that they are not aware of the meaning of logico mathematical activity through which conceptions are learned. However, with the analysis of the case study, data show that these student teachers' understanding of logico mathematical activity has evolved. Particularly, with the teacher-researcher's attempts at taking these student teachers' attention to the focus of teachers questioning and students' answering in the case study, these student teachers' understanding of the meaning of key mathematical ideas and how those ideas are developed has progressed. In particular, taking these student teachers' attention to focus of the teachers' questions "what and why" asked during the classes in the case study, and taking their attention to the students' focus while answering those questions helped these prospective secondary mathematics teachers to become conscious about the nature of the logico mathematical activity.

Results have important implications for teacher education. As Simon (2006) proposed and the results of this study showed, prospective secondary mathematics teachers' awareness of what we mean by mathematical concepts and as Thompson (2008) emphasized, their awareness of the idea that connections should be made among core mathematical ideas has evolved.

FROM METHODS COURSES TO STUDENT TEACHING: EXAMINING THE EFFECT OF AN INNOVATIVE FIELD EXPERIENCE

Julie M. Amador
Indiana University
jamador@indiana.edu

Enrique Galindo
Indiana University
egalindo@indiana.edu

The main goal of the Iterative Model Building (IMB) approach is to improve professional development programs for future elementary mathematics teachers, and thus improve student learning in mathematics. The innovations of the IMB approach occur during mathematics field experience for pre-service teachers (PSTs) and include a central focus on children's reasoning through teaching experiments (Steffe & Thompson, 2000) and purposeful reflection on practice through Lesson Study (Lewis, 2002). Indicators of teacher quality were examined through analysis of lesson plans and lesson enactment comparing student teachers who had participated in the IMB approach with student teachers who had participated in traditional forms of field experience. Initial findings suggest that teaching aspects fostered by the IMB approach during the field experience had a positive residual effect during student teaching. Findings from the study will advance knowledge of how to prepare more effective elementary teachers.

Background

The Iterative Model Building (IMB) approach focuses on children's thinking and reflective teacher practice through an intensive field experience approach to improve and measure the quality of teachers. In the experimental field experience placement, pre-service teachers (PSTs) begin each class session by interviewing children through Formative Assessment Interviews with a focus on children's thinking (Steffe & Thompson, 2000). The PSTs then take the information learned from the interviews and create models of student thinking that explain student reasoning. Following Model Building, the PSTs consider their knowledge about student thinking and plan a mathematics lesson for the following week. The PSTs present their lessons in a host teacher's classroom and then engage in Lesson Study groups formed by 6 PSTs, the host teacher, and one field experience instructor, to reflect on the previous lesson and plan for the next lesson (Lewis, 2000). Each week, all PSTs in the field experience are involved with the cyclical process of interviewing students, building and discussing models of students' thinking, teaching or observing lessons, and participating in lesson study. Together, these components complete Phase One of the IMB cycle.

One year later, students that completed the mathematics field experience begin student teaching in elementary classrooms. All experimental components of the IMB approach are complete at the onset of student teaching, so from this point, teacher quality can be measured to compare student teachers that were in the IMB approach for field experience with students that participated in traditional forms of field experience. During student teaching, teams of university observers visit the host classrooms of the student teachers to observe mathematics lessons and interview the student teachers about teaching mathematics. These measures of teacher quality form Phase Two of the IMB project.

Theoretical Perspectives

Effective teaching requires knowledge of how individual students in the classroom think about specific content (Akerson & Hanuscin, 2007; Carpenter & Fennema, 1992; Carpenter et al., 1988; Carpenter, Fennema, & Franke, 1996; Fennema et al, 1996). In addition to considering the mathematical reasoning of students, effective teachers are reflective about their practice and often work collectively with others to improve their practice (Cochran-Smith & Lytle, 1999; Lewis, 2000). Teachers that embody these characteristics are able to engage their students in learning mathematics through the implementation of investigative tasks with specified cognitive complexity that is appropriate for the students that are being taught (Stein, Smith, Henningsen, & Silver, 2009). These two innovations, noticing student thinking and reflecting on teaching, are key tenets for effective mathematics teaching. The following describes these innovations in greater detail.

Teaching Experiments: Model Building

Effective teachers develop pedagogical content knowledge by noticing and attending to students' thinking and reasoning (Hill, Ball, Schilling, 2008; Jacobs, Lamb, & Phillips, 2010). Teachers who reflect on student knowledge and consider students' understandings when teaching provide children with a better mathematics education (Carpenter & Fennema, 1992; Fennema et al., 1996; Jacobs et al., 2010). Components of pedagogical content knowledge, such as Knowledge of Content and Students (KCS) can be developed through engaging in teaching experiments with children that orient teachers to student reasoning (Hill et al., 2008; Steffe & Thompson, 2000; Steffe, 2002).

Teaching experiments require a specific methodological approach in which the teacher must continually attempt to make sense of student explanations and actions (Steffe & Thompson, 2000). As the teacher works to continually interpret student behavior, he or she begins to develop hypotheses about student cognition and becomes familiar with the student's ways of operating. As the teacher engages in this process, he or she begins to create viable models of student thinking by making predictions based on observed student actions. When teachers understand how children are thinking about a specific mathematical topic, they are better prepared for teaching because they are able to formulate predictive models about student thinking as they enact mathematics lessons. Teachers that are able to anticipate student responses are able to formulate lesson plans and deliver lessons that consider models of student thinking.

Reflective Practice: Lesson Study

In addition to focusing on student thinking and reasoning, effective teachers develop pedagogical content knowledge by learning in professional communities (Lewis, 2000, 2002; Wenger, 1998). Lesson study is one format that can be used for professional growth in a community of practice. In lesson study, teachers develop, teach, and analyze whole classroom lessons to build an understanding of students' knowledge. When teachers reflect on their teaching and engage in discourse with others about their practices, the teaching community fosters an ongoing venue for teacher learning (Akerson & Hanuscin, 2007; Grossman, Wineburg, & Woolworth, 2001).

Lesson Planning

Teachers that have increased their pedagogical content knowledge by considering student thinking and reasoning, and reflecting on teaching practices, are able to formulate lesson plans that include components of effective teaching (Jacobs et al., 2010; John, 2006; Lewis, 2000). During the lesson planning process, effective teachers decide what will happen when teaching mathematics content and they formulate instructional decisions for the plan based on student understanding (Bumen, 2007; Gilbert & Musu, 2008; John, 2006; Panasuk & Todd, 2005). These teachers often consider how they will launch the lesson, provide an investigative task, and summarize student learning in the lesson to develop student reasoning (Van de Walle, Karp, & Bay-Williams, 2010). Effective mathematics teachers structure lessons that consider students' prior knowledge and reasoning to promote students "doing mathematics" (Stein et al., 2009, p. 6). *Doing mathematics* ensures that the cognitive level of the planned tasks are sustained when teaching. This process of lesson planning is one component of the Lesson Study cycle (Lewis, 2000).

Lesson Enactment

Once the plan has been created, teachers must sustain the cognitive level of the task to ensure students are thinking complexly, exploring mathematical concepts, and analyzing tasks as planned (Stein et al., 2009). The quality of this sustainability for maintaining the cognitive task of the lesson is dependent on the pedagogical content knowledge the teacher has previously developed from noticing student thinking and reflecting on practice in a teaching community. As the lesson is enacted, the attention to student reasoning becomes a considered component in the decision making process. Likewise, the reflective learning that took place from the community of practice should also be considered to deliver lessons that are effective.

Application to Practice

For this project, PSTs in the experimental group engaged in the IMB field experience approach that directly focused on student thinking and reasoning with teaching experiments and included a lesson study component for reflective practice. The majority of the research on these innovations in the past has focused on in-service teachers, with little attention being focused on the role of these innovations with PSTs. It would be beneficial to know how the innovations used in the IMB field experience affected teacher quality one year after the innovative approach when the PSTs were student teaching. As a result, this study seeks to compare student teachers that participated in the IMB field experience with student teachers that did not participate in the IMB field experience. The research will answer the following research questions:

1. What effect does the IMB approach during field experience have on PSTs lesson planning and lesson enactment one year later during student teaching?
2. How do lesson plans and lesson enactment during student teaching differ between PSTs who participated in the IMB approach for field experience and PSTs who participated in a traditional field experience?
3. How do the teaching characteristics of student teachers who participated in the IMB approach for field experience compare with the teaching characteristics of student teachers who participated in traditional field experience?
4.

Method

Data were analyzed using both qualitative and quantitative methods. Data sources include written mathematics lesson plans, the Mathematics Lesson Observation and Analytic Protocol, and the Classroom Teacher and University Supervisor Observation Form. An equal number of participants from both the experimental and control groups were invited to participate in the study. The number of willing participants from the experimental IMB group was significantly higher than the number of willing participants from the traditional control group. Participants consisted of seven student teachers that had participated in the IMB approach during field experience and three student teachers that participated in control sections of the field experience.

Each of these student teachers was formally observed teaching mathematics two times by university personnel and at least once by either his or her University Supervisor or Host Classroom Teacher.

Written lesson plans were collected from each teacher for each of the two observations. The written lesson plans were blinded and scored independently by two researchers according to a Mathematics Lesson Plan Rubric (see Table 1), based on the Launch, Investigate, Summarize lesson structure for effective mathematics teaching (Van de Walle et al., 2010). The two raters reconciled score differences to arrive at a consensus. After a consensus had been reached for each category on the rubric for each lesson plan, the mean of the scores from the IMB approach were compared with the mean of the scores from the traditional approach.

The Mathematics Lesson Observation and Analytic Protocol was used during classroom observations by trained university personnel and completed after each lesson observation. The protocol format was adapted from Inside the Classroom: Observation and Analytic Protocol from Horizon Research, Inc. This instrument focuses on reformed mathematics teaching and documents the Design, Implementation, Mathematics Content and Classroom Culture of the lesson; the protocol concludes with an overall capsule rating of the lesson. For each of these categories, Key Indicators and a Synthesis Rating were recorded numerically and Supporting Evidence for Synthesis Rating was recorded in written format. Each observer initially scored the lessons independently using the protocol and then the two observers met to reconcile differences in scores. Means were calculated to compare the IMB group to the traditional control group. All written comments were typed and analyzed qualitatively.

The second instrument, the Classroom Teacher and University Supervisor Observation Form, was completed by University Supervisors and Host Classroom Teachers. This instrument is comprised of six sections: Content Organization, Content Knowledge and Relevance, Implementation, Teaching Learning Interaction and Assessment, Active Learning, and Overall Assessment. A six-point scale was used to describe the extent to which effective teaching practices were evident during teaching. This protocol elicits numerical and written responses from the University Supervisors and Host Classroom Teachers. The numerical data from the protocols were analyzed to find the mean scores for the IMB group and control group for each indicating section. The written data were analyzed to discover evidence of effective mathematics teaching.

Data Analysis and Findings

The first source of data used to examine the effect of the IMB approach on lesson planning and enacting of the lesson was the written lesson plans. The rubric used to score the written lesson plans included four categories to rate different aspects of the lesson, namely: Objectives and Adaptations (2 points), Launch (3 points), Investigate (2 points), and Summarize (3 points). Scores obtained in each of these categories were totaled up for a possible rating of 10 points. Table 1 shows a portion of the rubric that includes the description of the highest level of performance for each category.

Category	Description of Highest Level of Performance
Objectives and Adaptations 2 points	Lesson includes specific prerequisites. Lesson includes specific measurable objectives. Lesson includes State Standards addressed. Plans for Gearing Up are appropriate. Plans for Gearing Down are appropriate.
Launch 3 points	Launch provides some context for the topic and to motivate students to work on the investigation. Includes ways to make sure that the problematic task is understood and that goals and expectations are clear.
Investigate 2 points	Investigation includes a problematic task at the cognitive level of "doing mathematics." Considers students' prior knowledge and leaves residue of mathematical value. Equity and accessibility are addressed. Includes possible hints the instructor will provide when needed, and things to pay attention to in order to observe students thinking and to assess students understanding.
Summarize 3 points	Summarize includes a description of how to organize the sharing to make sure the class is engaged in a productive discussion and reflection in which students learn ideas and strategies from each other. Includes possible questions to ask to encourage generalizations and to make sure students justify their answers.

Table 1. Section of the rubric used to rate written lesson plans.

After two researchers independently rated the blind lesson plans and reconciled scores, ratings for the two groups were analyzed. Given that the samples are small, statistical analysis cannot be used to determine if the differences found are significant. We decided to calculate the difference in ratings for each category as a percentage of the total possible points for each category. Given that the rubric can differentiate between 4 levels of performance in each category, we thought that differences greater than 20% of the possible points would be considered significant. Table 2 shows the scores for the written lesson plans. Written lesson plans for the IMB group consistently scored higher than those of the control group for most categories. On average, written lesson plans for the control group had a total rating of 1, whereas lesson plans for the IMB group had a total rating of 3 and thus the difference was 20% of the maximum possible score. We then examined the differences in rating by category. Three categories showed a difference in rating greater than 20 % for at least one of the lesson plans. These categories were objectives and adaptation, launch, and investigate. Thus written lesson plans of participants in the IMB group tended to do a better job of addressing the expectations for most aspects of the lesson plan. We are aware that average total scores for lesson plans for both groups were relatively small. We attribute this to the fact that the participants were not submitting these lesson plans for a grade in a class, but rather they included the level of detail they felt necessary for them to be able to teach their lessons. Which is not uncommon of inservice teachers too, they no longer write the elaborate lesson plans they were required to do when in methods classes.

	First Lesson Plan					Second Lesson Plan					
	O&A	L	I	S	Tot	O&A	L	I	S	Tot	2 L
IMB	1	.67	.92	.42	3	.88	.88	.75	.5	3	3
Control	.5	.33	.5	.5	1.83	.5	0	.5	0	.17	1
Difference	.5	.3	.4	-.1	1.2	.4	.9	.3	.5	2.8	2
% Diff	25	11.1	20.8	-2.8	11.7	18.8	29.2	12.5	16.7	28.3	20

Key: O&A–Objectives and Adaptations, L–Launch, I–Investigate, S–Summarize, Tot–Total, 2L–Average rating of two lesson plans, % Diff–Difference in ratings as a percentage of the possible points for that category.

Table 2. Average ratings in written lesson plans for IMB and Control groups.

One source of data to rate the quality of the lesson enactment was the Mathematics Lesson Observation and Analytic Protocol. Table 3 shows the average ratings for each category, out of 5 possible points, of the lessons observed that were taught by participants in the IMB and control groups. Note that for the overall capsule rating observers were asked to give their overall assessment of the quality and likely impact of the lesson, rather that just an average of all previous ratings. The five levels in the overall capsule rating were: 1) ineffective instruction; 2) elements of ineffective instruction; 3) beginning stages of effective instruction; 4) accomplished, effective instruction; and 5) exemplary instruction. The average overall capsule ratings for lessons taught by IMB participants were 2.71 for the first lesson and 2.52 for the second lesson. These ratings are close to a solid 3 or a low 3, which corresponds to beginning strategies of effective instruction. In contrast, the average overall capsule ratings for lessons taught by participants in the control group were 1.83 for the first lesson and 1.92 for the second lesson, which are close to a solid 2, which represents elements of ineffective instruction. Like with the written lesson plans, IMB participants were rated higher for most aspects of the lesson enactment.

	First Lesson Plan					Second Lesson Plan					
	LD	IM	MC	CC	OR	LD	IM	MC	CC	OR	2 L
IMB	2.93	3.21	3.57	2.86	2.71	2.5	3	3.5	2.67	2.33	2.52
Control	2.33	3	3.83	1.83	1.83	1.67	2.67	3.5	1.67	2.0	1.92
Difference	.6	.2	-.3	1	0.9	.8	.3	0	1	2.8	0.6
% Diff	11.9	4.3	-5.2	20.5	17.6	16.7	6.7	0	20	6.7	12.1

Key: LD–Lesson Design, IM–Implementation, MC–Mathematics Content, CC–Classroom Culture, OR–Overall Capsule Rating, 2L–Average rating of two lesson plans, % Diff–Difference in ratings as a percentage of the possible points for that category.

Table 3. Average ratings in Mathematics Lesson Observation and Analytic Protocol for IMB and Control groups.

When examining the differences in ratings in the enactment of the lesson by category, one category, classroom culture, showed a difference or 20% or more in favor of IMB participants. Another category, lesson design, showed a difference of 11% or more, also in favor of the IMB participants. Indicators that the observers attended to when rating lesson design included aspects such as whether the lesson incorporated tasks, roles, and interactions consistent with investigative mathematics; and whether adequate time and structure were provided for "sense-making." Indicators in the category of classroom culture included aspects such as whether active participation of all was encouraged and valued; and whether the climate of the lesson encouraged students to generate ideas, questions, conjectures, and/or propositions.

A third source of data we examined was ratings by University Supervisors and Host Classroom Teachers using the Classroom Teacher and University Supervisor Observation Form. A six-point scale was used to rate performance in each of the five categories, as well as for the overall rating. The mean overall rating reported for IMB participants was 4.91, compared to a mean overall rating of 5.33 for control group participants. The difference represents less that 7% of the possible points and we did not consider it to be significant. So, in the eyes of the host teachers and supervisors, the teaching of all participants was of about the same quality, for the teaching aspects they pay attention to. We are not surprised about this finding as the rubrics and observation forms developed by the project measure the teaching aspects we hope to foster, which may not necessarily be the same that others are looking for.

A final source of information on the lesson planning and enacting of the lessons was the written comments included by observers as evidence to justify their ratings in the lesson observation forms. While written comments included suggestions for all participants to improve their teaching, there was a pattern in the comments about the type of lessons taught by control group participants. The written comments characterized these lessons as traditional, with comments such as:

- Lesson was very scripted with a focus on following a procedure without making a connection to concepts.
- The lesson was again a traditional format. Students reviewed long division. The students did not collaborate with each other. The dialogue was mainly between student teacher and students.
- The instructor began discussing multiplication and reviewed subtraction though a competition at the end of the lesson. This extension was fact practice. Students never talked with other students; little, if any collaboration. No connection to life/applicable context.

Conclusion

The findings described above while modest, show promise of the IMB approach. They suggest that teaching aspects fostered by this approach in the field experience had a positive residual effect that was present during student teaching. Regarding the first research question, we found evidence that lesson planning and lesson enactment by IMB participants exhibited teaching aspects that were fostered during the field experience. In particular, aspects of the written lesson plan that showed strength among IMB participants were the objectives and adaptations sections, the launch part, and the investigate section. As far as the enactment of the lessons, IMB participants did show strength in the aspects of lesson design and classroom culture.

Regarding the second research question, we found evidence that IMB participants were rated higher than control participants in both written lesson plans and lesson observation forms. IMB participants were rated 20% higher in several aspects of their teaching indicating that they strived for student-centered teaching, making connections, and fostering collaboration among students. As far as the third research question, we found evidence to suggest that the teaching by control group participants tended to be more traditional, teacher-centered, with no connections to real life situations.

One limitation of this study is the small number of participants. While the findings reported here are valid for these participants, we will continue following up participants in upcoming cohorts to gather additional evidence about the benefits of the IMB approach. However, we should note that since the participants were volunteers, and they agreed to be observed by strangers, and to provide us with their lesson plans; one may assume that they probably were among the stronger students from each approach.

The Iterative Model Building (IMB) approach to elementary mathematics field experiences focuses on children's thinking and reflective teacher practice. We are encouraged by the initial results that participants are exhibiting during student teaching. For phase three of this study we will follow participants into their first year as teachers in our efforts to develop a research based approach to teacher preparation.

A TRANSFORMATION OF PRESERVICE TEACHERS' PERCEPTIONS OF THEIR BELIEFS OF MATHEMATICS AND SOCIAL ISSUES

Summer Bateiha
Western Kentucky University

Stacy Reeder
University of Oklahoma
reeder@ou.edu

Preservice teachers often come to college mathematics content courses with beliefs about mathematics that reflect a view of the subject as dichotomous, reserved for certain individuals, and disconnected from a world outside of the classroom. In this study, we examined what happened to a group of preservice teachers' perceptions of their beliefs about mathematics and social issues when they were taught in conjunction with one another. We found that connecting mathematics to social issues transformed these participants' ideas about the nature of learning both subjects.

Although integrating subjects in the classroom has been a concern for educators for over a century (e.g., Dewey, 1902), connecting mathematics to social issues has begun to rise as a major goal for many mathematics educators (i.e., Gutstein & Peterson, 2006). These educators often contend that the purpose of education should be social well-being and all instructors should explicitly address this objective in their classrooms regardless of discipline. However, in order to persuade mathematics teachers to do so, prospective teachers must transform many of their traditional beliefs about mathematics as dualistic, reserved for certain individuals, and disconnected from an outside world (Young, 2002). Therefore, in this study, we examined what happened to a group of preservice teachers' beliefs about mathematics and social issues when the two were integrated in a mathematics content course for elementary teachers.

Theoretical Lenses

Two theoretical lenses are used to explain the findings of the study. The first addresses beliefs that stem from associationist learning theory. This theory of teaching and learning emerges from the philosophy that reality is separated into categorical subjects and that learning about this reality is transmitting a set of facts from a more knowing authority to a less knowing being (Houser, 2006). However, often times this form of traditional pedagogy, which is still the predominate one in western schooling (Houser, 2006), positions the student as passive and inferior in the classroom, waiting to receive knowledge, rather than active, dynamic, and constantly interacting with and reacting to a reality around her. In theory, students who emerge from this kind of educational system can form beliefs about subjects that traditionally mean that knowledge is simplistic (e.g., there is one right way to do mathematics (Young, 2002)) and an authority holds this knowledge.

The second theoretical lens explores the idea of the formation of beliefs that are based on transactional learning theory. Unlike its counterpart, this theory insists that humans are engaged in a transactional give and take relationship with the world around them, and that reality is relational (Houser, 2006). From this perspective, teaching and learning takes on a different meaning. There is no longer an assumption that a prescribed set of facts exists as truth and can be transmitted as such. Subjects such as mathematics and social issues interact with and react to one another, continuously expanding and changing. When mathematics and social issues are taught from this perspective, it becomes the role of all participants in the classroom to negotiate meaning and decide whether or not ideas are valid, just as is done in society. When teaching and learning in this type of classroom, beliefs about the attainment of knowledge begin to transform. The role of the instructor becomes that of someone who develops opportunities for intellectual growth. These opportunities link students to a history and a world outside of the classroom (Dewey, 1938). In theory, mathematics and social issues become more complicated yet more accessible, and students can begin to author their own learning, transforming their beliefs about the nature of subjects.

Methodology

The study took place in a community college classroom in the Southwestern regions of the United States and spanned the duration of a full semester. Nineteen preservice teachers, all the students enrolled in the content course, participated in the study. Seven of the students were nonnative English speakers, and ages ranged from nineteen to forty two. Several students were nontraditional, having returned to school after several years of being away. The instructor of the course was also a participant in the study and a doctoral student at a nearby university.

The course had two major components, a mathematical one and a social one. At the beginning of the semester, the instructor of the course was given a set of topics to “cover.” These included but were not limited to developing an understanding of the real number system and operations within this system (e.g., addition, subtraction, multiplication, and division of integers, rational numbers and irrational numbers). The instructor’s underlying objective was to provide opportunities to develop an understanding of critical social issues such as healthcare reform, poverty, distribution of wealth, and consumerism. Tasks and activities for the course were deliberately selected and created with these objectives in mind; many of these were inspired by and adapted from readings in *Rethinking Mathematics: Teaching Social Justice by the Numbers* (Gutstein & Peterson, 2006) and utilized problem-solving approaches to teaching and learning mathematics (Wheatley & Abshire, 2002; Van de Wall, 2004).

The study was qualitative in nature and employed both case study (Stake, 1995) and practitioner-research (Anderson, Herr, & Nihlen, 1994) designs. Multiple forms of data were collected. They included a reflective journal kept by the instructor, student work, reflective student journal entries, and audio/video tapes of select class periods and informal interviews (referred to as mid-term conferences). Data were analyzed using a data analysis spiral (Cresswell, 2007), in which data were informally analyzed throughout the semester and later formally analyzed through several spirals through the data. Themes were identified during the formal phase of analysis, and examples were extracted through one final spiral through.

Findings

Initial Beliefs

Data revealed that students came to this course with many beliefs about mathematics and social issues that resulted from traditional schooling experiences. Most of the students initially saw the subjects as dichotomous--containing only right and wrong answers--and as only truly accessible to a more knowing other (Young, 2002).

Dichotomous Beliefs

Early in the semester, as students began reflecting on their previous experiences with mathematics, they began expressing the dichotomous view of mathematics that they held. In her reflective journal, one student wrote that mathematics in school is "teaching kids to always have the right answer or just teaching them to pass tests." Others wrote, "[t]here is a wrong way and a right way to do a math problem," and "math was the way the teacher taught it." Many students described mathematics as being a subject that has "one right answer" or is done "one way." In their descriptions of their previous mathematical experiences, almost every student, including those who enjoyed mathematics, referred to the idea that there is only one way to do mathematics. Doing mathematics one way sparked resentment towards the subject for many of the students. In a classroom discussion, the instructor noted one student describing being punished for not doing mathematics in a particular way. She said, "I used to have a teacher that would count off if we didn't do problems exactly like she wanted." Many students echoed this statement, saying they had similar experiences. Several students explained they were not encouraged to understand the reasoning behind the mathematics they studied. One student said her teachers always told her "that's the rule," so she began to refrain from asking.

Similarly, students in this course tended to view social issues as existing within two perspectives, a correct one and an incorrect one, often times based on their faith in others. Students used the words "right" and "wrong" when they discussed social issues. For example, when they began a discussion about healthcare reform, before studying the issue through mathematics, many students simply stated that healthcare reform is wrong, and after being placed in the political party that she opposed for a healthcare debate they had in class, one student said, "I could do this project if I was on the right side." In another instance, as students discussed the idea of socialism, several expressed that they believed socialism is "bad," without considering that we have socialism in the United States (i.e., public schools, fire departments, police officers, etc.). For many of the students, there seemed to be no room for common view points from the two sides or an alternative perspective to the two. There was just the right way and the wrong way.

More Knowing Other

Several students initially viewed mathematics as reserved for certain "other" people. In her reflective journal, on several occasions, the instructor noted one student saying, "I'm just not a math person." Another student wrote in her journal, "I think my brain does not automatically think mathematically it is something I have to work at," indicating that thinking mathematically is a special ability that she does not naturally possess.

Further, students viewed mathematics as a subject that is transmitted as whole and complete from an all knowing teacher to a less knowing student. One student wrote that in her mathematics classes "there was always someone showing the how to's, the right way per say of doing a problem." Although most of the students viewed themselves as not able to know without a teacher, the instructor of this course expected them to discuss and resolve issues on their own. She expected them to justify their thoughts and decide whether or not they agreed with one another. She was instigating the social construction of knowledge rather than using a more typical "show and tell" method (von Glasersfeld, 1995).

Students were initially frustrated with this process. During the first couple of weeks of class, as the instructor rotated from one group to another, various forms of one question kept emerging: "Is this right?" The teacher kept giving the same answers: "I don't know. What do you think? Why?" Students were not always pleased with these inquiries as answers. They seemed frustrated when she refused to answer their questions, as they seemed to exud little faith in themselves as capable of obtaining an answer without the instructor's validation. Various questions and comments such as, "Why can't you just tell us?" or "I don't know. It just seems right" radiated at each table. The instructor continuously asked students to convince other group members, and she probed their thinking by asking questions such as, "What made you think to go about the problem that way? Is there a difference between what you did and what she did? Where?" After the first week, one student wrote in her journal, "I am now nervous because this class seems like it is going to be a lot." Many students used the word "different" when describing the way the class was being conducted. For the first several weeks, the instructor wrote about the frustrations students depicted in the classroom as they were forced to determine solutions and validate ideas without her aid.

Similarly, students' beliefs about social issues seemed to be based on the verification of an "other." In her reflective journal, the instructor wrote about one student saying she had received her information from the news, while another student explained that her family had discussed these issues. Many students' perceived right and wrong perspectives seemed to come from their affiliations with certain political parties or their connections to significant others in their lives. Many students categorized themselves as Democrats or Republicans. One student explained that although she does not always understand issues well, "I do know that when it comes down to it I am a republican." On several occasions, the instructor noted students discussed their spouses, parents, churches, and coworkers' when they described their own ideologies.

The loyalty they felt towards their political parties and significant others was difficult for some students to overcome as they began to view issues from other perspectives. They seemed to feel it was a betrayal if they opposed one of the stances those others perceived as correct. One student explained how difficult it was to rethink some of the issues we studied because of her husband's viewpoint. In class, she explained trying to discuss issues with her husband but encountering resistance when she did so. She said, "He's a staunch Republican and he just doesn't wanna' hear it." Another student, after a discussion about distribution of wealth and a change in opinion said, "I feel like I'm betraying my party if I agree with you," as if she was doing something wrong by considering an alternate perspective.

For several weeks, students seemed uneasy about the notion of constructing ideas individually and verifying them socially. Ironically, in the world outside of the classroom, knowledge emerges from the questions that are asked, answered, and verified through individual curiosity and social interactions, not from an authoritative figure who just knows. In this class, however, students initially had this expectation for the attainment of knowledge.

Transformed Beliefs

As the semester progressed, students began to express their change in beliefs about mathematics and social issues. Although many initially viewed mathematics and social issues as dichotomous and only accessible to certain individuals, by the middle of the semester many students began viewing mathematics differently. Students began rethinking their beliefs about both the duality and accessibility of mathematics and social issues.

Pluralistic Beliefs

As students were exposed to multiple methods and solutions to problems, they began to reconsider their ideas about how mathematics should be done. Many students commented on the effect this course had on their recognition of the varieties of ways of understanding the subject. Students wrote:

- I have learned that math is a subject that causes you to think…I have realized that not everybody thinks the same way. There is always more than one right way…
- There are more than one way to get an answer and it's ok if it's not the way the teacher taught it…
- I really enjoyed this math class. It expanded my horizons and allowe[d] me to understand math a little bit better. I began to realize that there is not just one way to find an answer…

Moreover, after engaging in mathematics lessons that incorporate social issues and concepts, students began to change many of their beliefs about the nature of social issues. They began to reconsider their quick conclusions about which side is "right." One student explained in class that she initially believed she had to "choose a side" when she encountered arguments for or against certain solutions to social issues, but after the healthcare debate, she expressed that she was "torn" and did not know which side was right. Other students seemed similarly confused by their inability to quickly choose a side when considering social issues and concepts. They began to view issues as not so black and white, and they began to revert to mathematics as the connection to their beliefs rather than emotion or an external authority.

Although most of the students in the course continued to view social issues as stemming from two perspectives, they began to have difficulty categorizing each side as right or wrong. Students no longer seemed to be able to quickly label others' points of view as simply correct or incorrect. Many began viewing positives and negatives from both sides. Students wrote in their journals:

- After researching I found that on this topic both sides have great points and I am torn…
- I learned to keep my mind open. There are many good points on each side of the healthcare debate…

Working in groups and realizing that people view mathematics in different ways seemed to contribute greatly to students beginning to see mathematics differently. In their final reflections, almost every student commented on the effect of seeing more than one way to perceive or solve problems. They wrote:

- It was very insightful for our peers to help us with our problems. It allowed for different techniques to be shown…
- It was also a pleasant surprise to be able to see that there are many ways to achieve the right answer and that it was alright for everyone to have different opinions and approaches to logic…the overall acceptance and understanding of viewpoints was comforting…

Further, the transformation of students' beliefs about the nature of social issues seemed to stem in large part from considering other perspectives through mathematical research and working with students' whose perspectives were different than their own. Many students, during mid-term conferences, explained having never thought about diverse outlooks of issues. In their reflections, several students wrote about being affected by other viewpoints. Students wrote:

- The political debate was really interesting, especially since I was on a side that I had never investigated before. Each of the social issue lessons pushed me to think about issues I was choosing to not think about…
- I also found this project to be eye opening to others views…

One student explained that she was open to new ideas because of her interactions with group members. For her, the fact that we were all female and interested in education made a difference. In her journal, she wrote, "I also realized how grateful I was to be debating the subject with just women and teachers…We didn't have any irrational outburst because we were all understanding." In my reflective journal, I noted that the single gender of all the classroom participants might have been a factor in the development of an open, comfortable community in this class. I wrote about a student commenting that one of the reasons she was open to listening and discussing in this class was this factor. During that class period, several students agreed with her. However, I did not systematically assess this factor; therefore, further research is needed to conclude more definitively whether or not the results of the course were affected by the fact that the class was comprised entirely of women.

More Knowing Self

Along with reconsidering their ideas about mathematics and social issues as either right or wrong, students began to change their views of mathematical and social issue knowledge as reserved for certain individuals. During one class session, the instructor wrote about overhearing a student who had previously said that her "brain did not think mathematically," say, "I can do this kind of mathematics." One student who wrote about her bad experiences with mathematics early on in the semester, in a later classroom discussion said:

> Letting us do math this way is also good for students who come from different countries because in their countries, the teacher tells them to do problems one way and when they come here the teacher says do it another way. Like this, they can do it how it makes sense for them.

Other students wrote in their journals, "I'm learning that there are certain parts of math that do click with me," and "I think I would have done much better in math if my teachers let me do it like this." They began to express learning about themselves and their capabilities as mathematics learners and teachers after engaging in this course.

- I learned a lot about myself in this class. This class gave me a boost of confidence mathematically and as a future teacher. I felt so bad about math when I began this class and now I know that I can learn math and I can teach it too!...
- I learned how to teach math and that it's okay to go against the way I was taught as a child…
- So far, I've learned the importance of having a flexible mind when working with math. I need it to be reminded that there are many, many ways to solving math problems…

Students began to question their reliance on significant others in their lives for understanding social issues. They began to trust their own abilities to investigate and understand problems in society. Students wrote:

- I learned how important it is to investigate issues for yourself and not just believe what your friends tell you or what you hear on the news…

- We should not take our leaders information to heart, always question, always do your research…
- It was interesting to investigate both sides and then make my own choice…

Participating in this class opened up space for students to discover verification and construction of ideas from within themselves. Students began to author their own learning and understanding, validating and verifying their ideas without the reliance on others' authority. At the end of the semester, almost every student commented on the effect of realizing that mathematics can shape their beliefs about social issues.

- As a student of the math class, I realized that we are using "MATH" a lot in our real life, not only calculating for our receipt in a store but also reading what happens in our community. Statistic and many kinds of graph can convey a whole story…
- I loved the lessons that covered social issues. These lessons made me think outside of my personal box. Additionally, the lessons showed me just how important math is in our daily lives.
- I liked the lessons dealing with social issues. It brought another dimension to the class and it helped me see how math is used in other ways.

By the end of the semester, students seemed to no longer believe that they needed to rely on a more knowing other to understand mathematics or social issues. They began to view themselves as capable of thinking mathematically and they began to use mathematical information to explain why they accepted or questioned one social viewpoint over another. Connecting mathematics to social issues allowed students to become more autonomous learners and decision makers. They began to expand their beliefs about both mathematics and social issues and were able to extend their thinking about social issues beyond an emotional level, linking it to mathematics and using those connection to actively engage in democratic decision-making.

Implications

Data from this study indicate that most of the preservice teachers that engaged in this course were able to transform their beliefs about both mathematics and social issues. The study implies that combining the two subjects in the way they were in this course can affect beliefs about the nature of understanding mathematics and social issues; however, it is not without its limitations. A few students did not seem able to hurdle their initial beliefs. They were not discussed in this paper. Their resistance may be the result of many years of traditional classroom interactions, or the fact that the lessons in this class created too much dissonance for them, or any number of other factors. Further research is needed to determine what exactly maintained these beliefs and understandings in some students in this course. However, we mention this because it does imply that the interactions of a classroom cannot be completely encompassed within the confines of a paper such as this. Therefore, it is important to note that although meaningful change in beliefs can occur when mathematics and social issues are taught in conjunction with one another, it is not inevitable.

Although not without its limitations, this study seemed to be consistent with other scholars' ideas about the effects of certain learning theories. In accordance with ideas about associationist learning theories (Houser, 2006), most of the students in this course entered with traditional mathematics classroom experiences that yielded certain beliefs about the nature of learning mathematics. They came to the class with assumptions about what knowledge was and who had access to it. After exposure to pedagogical approaches that stemmed from a transactional theory of teaching and learning, those assumptions began to transform. As others have suggested (Houser; Dewey, 1938), teaching mathematics in a way that develops autonomy and connects to a history and a world outside of the classroom shifts ideologies about what it means to learn mathematics and social issues. Beliefs about what is right and who holds that knowledge shift from an outside reality and another individual to an interactive reality, in which subject interaction is complicated, and an autonomous self can know. Therefore, we would advocate creating space in the mathematics classroom where preservice teachers can transform their beliefs about mathematics and social issues when they are intertwined with one another in meaningful ways. Further, we believe that in doing so the importance of linking mathematics to social issues can become more explicit for preservice teachers. Although the preservice teachers in this course seemed compelled by teaching mathematics in this way, this is only one step towards teaching mathematics for social change. Additional research is needed to assess whether or not connecting mathematics and social issues in the way they were here can in fact translate to these teachers future classrooms.

PRE-SERVICE TEACHER CONNECTIONS: CONNECTING COLLEGE MATHEMATICS TO SCHOOL MATHEMATICS

Kevin M. Berkopes
Purdue University
kberkope@purdue.edu

This report summarizes findings from the study of 4 prospective secondary school teacher's connections between university geometry curriculum and secondary geometry. Connections are defined as knowledge and beliefs that link one's construct of university curriculum to his or her construct of secondary school geometry curriculum. Transcripts of individual interviews conducted with participants and participant generated maps of secondary geometry curriculum constituted the data for the study. Findings include connections categorized as positive or negative in reference to the promotion of future growth in knowledge and beliefs needed for familiarization of secondary curriculum and effective implementation of standards based mathematics teaching.

In 1985 Cooney called for a discussion of the relationship between teacher content knowledge and teacher beliefs about mathematics, recognizing that a teacher's conception of mathematics has a direct impact on the way in which mathematics is approached in the classroom. Five years later Ball (1990) expanded on the complexity of teacher knowledge stating that teachers needed to understand the nature of knowledge in the discipline, where that knowledge comes from, how it varies with time, how truth is established, and philosophically what it means to know and do mathematics in order to be effective teachers. Studies suggest (Borko et al., 1992; S. Brown, Cooney, & Jones, 1990) that teacher beliefs are influenced by teachers' experiences with mathematics and schooling long before their entry into the mathematics education workforce. These same studies state that without *significant* interventions, these beliefs are very difficult to change (Cooney, Shealy, & Arvold, 1998). Innovative methods courses can address some of the difficulties, but studies show that these methods courses are not enough (Borko, et al., 1992; Ensor, 2001) to overcome the issue that "teacher's conceptions are dependent upon their experiences as learners of mathematics"(Ernest, 1989, p. 13). Prospective teachers gain experience with mathematics in their own preK-12 experience, but also in university mathematics content courses. This site offers another opportunity where the knowledge and beliefs of these prospective teachers about mathematics can be influenced. Therefore the *development* of prospective teacher's knowledge and beliefs about teaching and learning mathematics in these courses should be a goal of their programs of study.

Knowledge, Beliefs, Connections

Knowledge and Beliefs

Both mathematical knowledge and beliefs have been identified as influencing the practices of mathematics teachers. Mathematical knowledge for teaching has been defined and Ball, 1990; Ball, Hill, & Bass, 2005; Ball, Thames, & Phelps, 2008; Hill, Rowan, & Ball, 2005) described as including more than common content knowledge and involves a complexity specifically of containing "knowledge of content and students, knowledge of content and teaching, and knowledge of content and curriculum"(Bray, 2011, p. 5). Knowledge is held onto much differently that what is described as beliefs, though it would be a mistake to state that knowledge is unchangeable and static. Beliefs are understandings about the world, situated within the individual, that are *understood* to be true. "What is knowledge for one person, may be beliefs for another, depending upon whether one holds the conception as beyond question" (Philipp, 2007, p. 259). Here we find that varying degrees of conviction result in the categorization of an understanding and existence within a context. Teachers' systems of beliefs, in particular, their conceptions of the nature and meaning of mathematics, may account for variations in practices (Thompson, 1992). However differentiating between knowledge and beliefs may be difficult. Philipp noted that (2007) "distinguishing between knowledge and belief is unimportant for research" (p. 259). Instead, importance is placed on the recognition that preservice teacher *knowledge* and *beliefs* will have effects on their future practice. These "complementary subsets of the sets of things we believe" must have origins specific to the individual (Leatham, 2006, p. 92). Adopting the view that knowledge and beliefs (K&B) are inseparable and university course work may contribute to the development of both, this research seeks to explore the development of connections between K&B about mathematics and K&B about teaching mathematics. In particular, I explore the relationship between K&B generated in a university content course, and how those are projected onto K&B of school curricula. To do so, I define the potential relationship between K&B about mathematics and K&B about teaching as connections.

Connections

Preservice teachers' own preK-12 experience and preservice teachers' exposure to mathematical learning during their undergraduate programs (C. A. Brown & Borko, 1992; S. Brown, et al., 1990; Lortie, 1975; Mewborn & Tyminski, 2006) have been identified as two possible origins of K&B. Relationships between K&B about mathematics and K&B about teaching are fostered when the development of K&B are in an environment that allow prospective teachers to articulate the relationships they see. These links are *connections* between one's construct of university curriculum (mathematics) to his or her construct of secondary school geometry curriculum (teaching). *Positive connections* are defined as connections that inform future growth in K&B needed to learn from the secondary curriculum and effectively implement the curriculum. *Negative connections* are defined as having the potential to impede future growth in K&B needed to learn from secondary curriculum and effectively implement the curriculum. Investigating connections between university curriculum and school curriculum is vital to understanding the success or failure of preservice teacher programs of study in influencing the development of K&B prerequisite for effective mathematics teaching. This study is designed to investigate types of connections linking university geometry course curriculum to the secondary school geometry curriculum as represented in the NCTM documents. Specifically:

> What types of connections are made between the experience in a university level geometry course and participants' understandings of school geometry?

Methods

Participants and Context

During fall 2010, undergraduate mathematics education majors, identified by their advisors, were sent a survey, designed to solicit participation in the study. Those students who had taken Euclidean Geometry, a university starting with high school topics and moving quickly to more developed material, were identified as potential participants. The course is taught by a professor with a professed interest in mathematics education. Anecdotally, the course is known to be helpful and pertinent to preservice secondary mathematics teachers. Potential participants were divided into two subgroups based on their answer to the following question:

> Do you see a connection between college mathematics courses and the curriculum you will be teaching in secondary schools?

Of the 15 potential participants, the two who responded affirmatively and two who responded in the negative were selected for and agreed to participate in the study.

Table 1

Participant Demographics

Pseudonym	Sex	Connection Categorization
Paul	Male	No Connection
Sophie	Female	Connections
Rachael	Female	No Connection
Janet	Female	Connections

Instruments

Two instruments were used to gather evidence of K&B as well as connections: an interview protocol and a mapping activity.

Interview protocol. Participants were interviewed for 30 minutes, after which the audio recordings were transcribed. An interview guide was developed that focused on eliciting evidence of the K&B about university geometry and K&B about school geometry. The exact sequence and wording of questions were decided during the course of the interview by the researcher.

To elicit evidence of connections, participants were asked questions such as:

> As you are taking a post-secondary mathematics course, are you constantly trying to make connections to your vision of your future geometry classroom and what you will be teaching? If so, how do you go about pursuing these connections?

All participants affirming connections were then prompted with a sequence of questions in order to stimulate further elaboration. Such as:

> Are these connections the result of instructor actions? Are connections to school geometry emphasized in a university geometry course?

Participants not affirming connections were exposed to a similar line of questioning in order to stimulate more information about the lack of connections made.

Mapping of geometry curriculum. During the interview participants were asked to develop an image of the secondary geometry curriculum. Specifically, the following prompt was used

> Any way you would like, please draw me your idea of what the curriculum for a typical secondary geometry course would entail.

Participants were asked to explain the facets of their drawings and share insights about lines drawn between words they identified.

Data Analysis

Drawings. The drawings were coded by the number and content of primary subsections and secondary branches. For example in figure 1, the drawing contains 2 primary subsections, specifically “proofs” and “constructions.” Secondary branches of these subsections were categorized and noted. In figure 1 from the primary subsection “constructions,” “perpendicular lines” and “angle bisectors.”

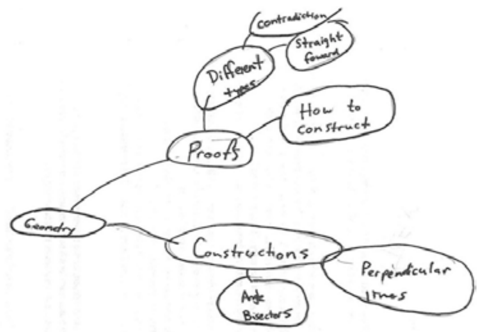

Figure 1. Paul’s drawing of school geometry curriculum

Additionally, the content of the maps were compared to the NCTM standards for school geometry. Similarities and differences in content were noted. For example Paul mentions proofs as primary subsection of school geometry curriculum and the NCTM standards incorporate proof, though much more intricately, as a primary subsection of the idealized school geometry.

Interview protocol. The interview data was coded using categories of positive and negative connections, regardless of claims regarding connections on original survey data used to identify participants. For example the following quote exemplifies a positive connection between the university geometry course and school geometry in explaining that the course curriculum informs and reviews what is entailed in the school curriculum:

> And um, I guess to kinda review geometry concepts in general and to go more in depth and learn more about, you know Euclid and axioms and stuff. (Sophie)

All participants were able to describe positive connections between university geometry and school geometry and shared additional ideas about connections between university mathematics courses and school curriculum. The introduction of comments in reference to other mathematics courses necessitated further coding to investigate connections more broadly. The following excerpt is an example of a connection between university mathematics and school mathematics that was coded as negative.

> None of that [mathematics content] is really ever going to come into play in high school math, as far as like helping me understand why something in algebra works. (Paul)

The interview data was compared with participant’s drawings data to build models of participants’ K&B of university geometry and its connection to their K&B of school geometry. For example, Sophie included a main subsection in the drawing exercise “axioms and common notions”. The participant specifically identified “axioms and common ideas” from the book of Euclid as some of the information drawn from the university geometry course. Thus an inference that there was a positive connection between K&B of university geometry and K&B of school geometry was made.

Results

The discussion will use examples from Paul and Sophie due to limited space, however results apply to all participants.

Across participants, drawings had noticeable difference in the number of primary subsections and secondary branches. Participants originally selected because they viewed university geometry and school geometry as connected had a more elaborate maps as measured by the number of primary subsections and secondary branches. Despite this difference, all four drawings contained very few subsections and branches. In comparison to the NCTM standards, which if drawn in a primary subsection and branching format would reveal four primary subsections corresponding to the overarching standards for grades preK-12: analysis of shapes and shape properties, location and spatial relationships using the Cartesian plane, apply and understand transformations, and use the above facets in problem solving situations. Many subsections branching from each of these primary standards are shared and elaborated in the standards documents (NCTM, 2000, 2009). The comparison between the drawings and NCTM standards revealed very little overlap, suggesting that K&B of school geometry were not informed by curricular content knowledge. For example in Figure 1 "proofs" was identified as a primary subsection, while the standards view of curriculum identifies "establish the validity of geometric conjectures using deduction, prove theorems, and critique arguments made by others" as a branch of "analyze characteristics and properties."(NCTM, 2000).

Participants had difficulty identifying the origins of K&B of school geometry shared in their drawings, but clearly identified their own experiences in high school geometry or mathematics and the university geometry course. Memories of high school geometry were vague as suggested by Paul's comments.

> I have vague remembrances of what I learned, but who's to say I learned the Pythagorean Theorem in geometry? I probably learned it sooner, so I don't know exactly what, if you asked me right now, cause those [pointing] proofs and constructions are different operations you do in geometry. But as far as content goes, specifically like midpoints, angle bisectors, stuff like that I wouldn't be able to tell you the complete list of what you are supposed to teach in geometry. (Paul)

When asked to elaborate, participants expressed concern about their knowledge of school geometry curriculum. For example:

> Um, I guess they [subsections] came from [the university class] or the things that we did in [the university class]… but I would have no idea, I would have no idea what the curriculum [school geometry] is. (Sophie)

Participants reported that thinking about connections while participating in the university geometry course was not a priority to them or in relation to the demands of the course.

> Um, when I was in [university] geometry I definitely wasn't thinking about that at all. It really wasn't even crossing my mind. (Sophie)

Here a contradiction arises in that connections were not fostered in the classroom nor at the forefront of thought, yet linking content in university mathematics courses to the school mathematics curriculum is reported by all participants in being important to their future careers. To investigate this a bit more participants were asked how they might know what to teach in a school geometry class. They identified the school textbook and their own experiences in school geometry as the primary resources for their K&B of the school geometry curriculum:

> I guess I would look at any materials that they [the school] have, like the book or whatever, and I would think back about what, you know, what I struggled the most with geometry. (Sophie)

Connections between K&B of Mathematics and K&B about School Mathematics.

Questioning about the geometry course encouraged participants to elaborate about other university mathematics courses and connections between these courses and their K&B about school mathematics.

> Yeah, I think it is important for them [university mathematics professors] to make a connection between what you are going to teach because, like for example, like abstract algebra I took last semester… I don't see how that connects at all to what I'm teaching. So like I don't understand why I spent my time on it. I don't feel like I'll need it, so I would have rather spent my time learning more about how to teach certain concepts, or maybe like taking a lower level algebra class where you really think about, you know you are not only a student, but a teacher and a student perspective in it. (Paul)

Paul expresses the view that abstract algebra has no value as a tool in his/her development as a teacher. All participants failed to see any connections between the mathematics content they were learning in their university courses and school mathematics. In addition, participants shared evidence of disassociating university mathematics and school mathematics as they identified emotional responses to university mathematics.

> Right now I'm in abstract algebra and… I'm wondering, why am I even in this class? When it doesn't even relate to anything. So, uh, I'm in this math and I did really bad on my first test and it's just making me really frustrated. (Paul)

Beyond the university geometry course, participants expressed no positive connections between university mathematics courses and school mathematics.

Conclusions

This research study set out to investigate connections between K&B about geometry and K&B about school geometry. Positive connections were inferred from drawings and interview data, however the connections were weak as evidenced by the lack of specific links between ideas identified as drawn from the university geometry course and tied to the school geometry curriculum. In elaborating on connections between university mathematics, evidence of negative connections was found. Participants identified emotional responses to university mathematics courses and specifically identified the lack of relevance of the courses as a challenge in preparing for the careers as teachers. Participants viewed their future role as teachers as including the delivery of curriculum and yet they expressed concern regarding their knowledge of that curriculum. In such a vacuum, sources of knowledge were identified as personal experience and the district adopted texts.

Connections to future practice were not emphasized in the participants' content courses, nor were there pedagogical strategies employed that helped inform their K&B of the secondary curriculum. Despite this environment, seemingly devoid of emphasizing connections to future practice, preservice teachers are still building knowledge and belief structures about the mathematics that they will eventually be teaching as evidenced by their responses to mathematics course work they were currently taking.

As posited by Ball (2005) curricular knowledge is a vital component of the overall knowledge necessary to be an effective mathematics teacher. Yet participants were unsure of how to build such knowledge in an environment that focused on common content knowledge. They expressed concern about their limited knowledge of curriculum and the lack of attention to this topic in their university mathematics courses. This lack of attention to the demands of their future profession, led the participants to identify textbooks as resources for what and how they should teach school geometry. This finding suggests that K&B about school geometry will continue to grow in alignment to existing school geometry curriculum as these preservice teachers begin to navigate their teaching career.

Finally, there was a trend of disassociation of the participants that directly affected their knowledge and belief structures in regards to mathematics. Negative connections stem from experiences in theoretical mathematics courses, such as abstract algebra, where students struggled to perform in ways professors valued. Lack of attention in such courses to projection of future practice led participants to focus on performance in the classes rather than building professional K&B for teaching.

CONTRIBUTING TO SELF-EFFICACY PERCEPTIONS OF ELEMENTARY PRESERVICE TEACHERS THROUGH MATH CONTENT COURSES

Fabiana Cardetti
University of Connecticut
Fabiana.cardetti@uconn.edu

Research continues to show that teacher efficacy is hard to change once it has been established and that it can be positively influenced even before teachers enter the classroom. This article presents the results of a study examining the potential impact of mathematics content courses on teaching self-efficacy perceptions using the Mathematics Teaching Efficacy Belief Instrument. Analysis of the data revealed a statistically significant increase in personal mathematics teaching efficacy of elementary preservice teachers that complete content courses specifically designed for them. Implications for teacher education and directions for future studies are also discussed.

The mathematics preparation of future elementary teachers has picked up momentum in the past two decades. In particular, efforts have been greatly influenced by studies such as Ma (1999); Hill, Shilling, and Ball (2004); and Ball, Thames, and Phelps (2008). These studies have built from the notion of pedagogical content knowledge introduced by Shulman (1986) and have illuminated the importance of developing mathematics knowledge for teaching (MKT). This knowledge for teaching encompasses both content knowledge and a specialized understanding of that content that allows teachers to effectively use their content knowledge to help students learn the subject (Ball, Thames & Phelps, 2008).

As mathematics teacher educators we seek to improve the preparation of our students by developing course experiences that would best prepare them for their teaching careers. We are now particularly interested in providing opportunities for elementary preservice teachers (PSTs) to develop MKT. Ball et al. said, "How well teachers know mathematics is central to their capacity to use instructional materials wisely, to assess students' progress, and to make sound judgments about presentation, emphasis, and sequencing" (Ball, Hill & Bass, 2005, p. 14). At our institution, the department of mathematics offers two mathematics content courses that have been specifically designed for elementary PSTs. These courses emphasize both content and pedagogy. The first of these courses will be referred to in this article as MATH1.

As teacher education researchers we seek to examine evidence of teacher learning and teacher education that help us find strategies to prepare future teachers more effectively. In particular, identity development has been described as a crucial feature within preservice programs: ‘‘the identities teachers develop shape their dispositions, where they place their effort, whether and how they seek out professional development opportunities, and what obligations they see as intrinsic to their role’’ (Hammerness et al., 2005, p. 384). In this study, we sought to examine influences of mathematics content courses in elementary PSTs teaching self-efficacy as these beliefs relate to the process of identity development.

Theoretical Framework

In recent decades we have seen increased emphasis on students' beliefs in teaching mathematics (Hart, 2002; Leder, Pehkonen & Tőerner, 2002; Spielman & Lloyd, 2004; Watson & De Geest, 2005). One important area of research on students' beliefs is that of teacher self-efficacy (Bandura 1977, 1986, 1997). Bandura (1986) defined self-efficacy as “people’s judgments of their capabilities to arrange and execute courses of action required to attain designated types of performances” (p. xii). It impacts the things we do, our efforts toward them, and how long we persist in working out solutions to problems. In fact, research about teacher efficacy in mathematics and science education has shown that levels of teacher efficacy are related to teacher content knowledge, teacher pedagogical content knowledge, and teacher beliefs and attitudes regarding the content (Gresham, 2008; Huinker & Madison, 1997; Swars, 2005). Thus, self-efficacy and MKT are strongly related. Students’ ability to learn content and pedagogy and their successful application in the classroom depends on their willingness and confidence to do so. Furthermore, research suggests that teacher efficacy is hard to change once it has been established (Hoy, 2000) and that it can be positively influenced even before teachers enter the classroom (Hoy, 2004; Smith, 1996) by providing experiences that promote teaching efficacy.

Researchers have examined the influences that methods courses and student teaching have in self-efficacy levels of preservice teachers (Hart, 2002; McDonnough & Matkins, 2010; Plourde, 2002; Swars, Smith, Smith, & Hart 2009). However, based on our literature review, fewer studies have been conducted to study the effects of content courses on teaching self-efficacy of undergraduate students. Typically, elementary PSTs fulfill their mathematics requirements early in their preparation. Thus, if we can identify and describe the mathematics content coursework that positively affect their sense of teaching self-efficacy, then these levels can be further strengthened in other learning experiences later in their studies.

In this context, Bandura’s (1986) construct of self-efficacy theory framed this study because it is based on the concept that people’s belief or perceived confidence for coordinating and carrying out a specific action influences how well they develop the basic cognitive, self-management, and interpersonal skills that contribute to career development and success. Levels of efficacy affect the amount of effort, persistence and resilience students are willing to undertake when faced with obstacles and failures (Bandura, 2001).

Enochs and Riggs (1990) developed the Science Teaching Efficacy Belief Instrument (STEBI-B) based on Bandura’s (1977) social cognitive theory to measure preservice teachers' sense of science teaching efficacy. Enochs, Smith, and Huinker (2000) have adapted the instrument to assess efficacy in teaching mathematics. The revised instrument is called the Mathematics Teaching Efficacy Belief Instrument (MTEBI) and consists of 21 Likert scale items ranging from “strongly agree” to “strongly disagree”. The MTEBI contains two dimensions: Personal Mathematics Teaching Efficacy (PMTE) and Mathematics Teaching Outcome Expectancy (MTOE). The PMTE contains 13 items and refers to the individual’s personal belief of his/her ability to be an effective mathematics teacher. On the other hand, MTOE contains 8 items and refers to the individual’s belief that effective teaching can enhance mathematics achievement of students regardless of external factors. An example of a PMTE item is, “I will continually find better ways to teach mathematics.” By comparison, an example of a MTOE item is, “Students’ achievement in mathematics is directly related to their teacher’s effectiveness in mathematics teaching.”

Several researchers have employed these instruments to explore issues of mathematics and science self-efficacy in PSTs. An early study by Huinker and Madison (1997) using both STEBI-B and MTEBI showed that content methods courses improved the elementary PSTs efficacy beliefs about teaching mathematics and science. More recently, Bleicher (2002) and Bleicher and Lindgren (2005) used the STEBI-B to help examine changes in science content knowledge and science teaching self-efficacy. They found that the PSTs increased significantly in both areas as they progressed in a methods course. Moseley and Utley (2006) obtained similar results when examining the effects of an integrated mathematics and science course on teaching self-efficacy. MTEBI was also used by Swars, et al. (2009) among other instruments in a longitudinal study examining the effects of a developmental teacher preparation program on multiple constructs. In particular, Swars et al. found that teaching self-efficacy beliefs varied over time as students progressed through two methods courses and student teaching.

In order to better understand how to prepare elementary PSTs for teaching mathematics well, it is important to build from existing research and to investigate not only methods courses, but also, the potential impact of *math content courses* on PMTE and MTOE. In this article we report the results of a study designed to examine changes in the perceptions of mathematics teaching self-efficacy of elementary teacher candidates after participating in the mathematics content course that has been specifically designed for elementary PSTs.

This mathematics content course, MATH1, offered by the department of mathematics, is a semester-long (14 weeks) course that meets twice a week for 75 minutes each time. The material covered in MATH1 is that typically found in textbooks such as Long, DeTemple, and Millman (2011); that is, numeration systems and their characteristics; in-depth look at algorithms for basic operations on whole, integer, and rational numbers, decimals and real numbers; and algebraic and proportional reasoning. Additionally, the department offers a second course subsequent to this one but with a focus on geometry. In contrast to the traditional blackboard-lecture mathematics classes, in these courses knowledge is built via explorations and students' discussions; the instructor's role is that of a facilitator providing guidance to lead students toward developing an advanced perspective on and profound understanding of the mathematical concepts. Students work, individually or in groups, on activities developed to understand the reasons behind familiar mathematical procedures, to explore and discover new concepts, and to analyze children nonstandard approaches. Additionally, students frequently present their ideas and solutions to the entire class. The focus of these tasks is on helping them construct their own knowledge and develop mathematical communication skills while building solid learning skills that will help them approach new mathematics topics in the future.

As part of a larger study investigating influences of math content courses geared toward elementary PSTs (Truxaw, Cardetti & Bushey, 2010), this study focuses on the experiences of the students enrolled in the focus math content course, MATH1. The research questions that guided this study are:

1. Are there significant changes in Personal Mathematics Teaching Efficacy in elementary teacher candidates before and after participation in the mathematics content course?
2. Are there significant changes in Mathematics Teaching Outcome Expectancy in elementary teacher candidates before and after participation in the mathematics content course?

Methods

Design and Participants

For this quantitative study we used a pretest-posttest design. The sample consisted of 24 elementary teacher candidates who were just beginning their teacher preparation coursework at a large public research university in the northeastern United States. These students were predominantly female (21), white (23), and typical ages ranged from 20 to 25 years old. All participants were enrolled in MATH1, the mathematics content course that involves a combination of both pedagogical and content instruction described on the previous section.

These students had completed at least two quantitative courses outside the School of Education to fulfill the school's quantitative requirements. In particular, the majority of the participants (15) had taken the course Mathematics for Business and Economics (calculus-one level). Participants had also taken either the Problem Solving course or the Elementary Discrete Mathematics course (real-world applications of non-routine mathematics).

Procedures

A survey (MTEBI) was administered at the beginning of the semester during the first week of classes to measure the entering level of mathematics teaching efficacy of the participants. The survey was administered again at the end of the semester during the last week of classes to determine whether there were changes in their beliefs before and after completion of the content course.

Instrument

The participants were asked to assess their mathematics teaching self-efficacy using the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI) developed by Enochs, Smith, and Huinker (2000). As mentioned earlier, the MTEBI includes two dimensions: Personal Mathematics Teaching Efficacy (PMTE) and Mathematics Teaching Outcome Expectancy (MTOE) with 13 and 8 items, respectively. The instrument uses a Likert scale with five response categories (5=strongly agree, 4=agree, 3=undecided, 2=disagree, and 1=strongly disagree). That is, high survey scores reflected higher levels of self-efficacy.

The PMTE addresses the preservice teacher's belief regarding his or her own ability to teach mathematics effectively. Scores on Personal Efficacy range from 13 to 65. The MTOE addresses the preservice teacher's belief in his or her ability to directly affect students learning outcomes. The scores on Expected Outcome range from 8 to 40. Enochs et al. (2000) found the PMTE and MTOE represented independent constructs based on confirmatory analysis and had Cronbach's alpha coefficients of 0.88 and 0.77, respectively, demonstrating the factors to be internally consistent (i.e., reliable).

Results

All the 24 participants in this study completed both pre- and post- MTEBI surveys; however, we were unable to match pre- and post-survey data for 6 of the participants because of missing identifiers. We analyzed the data in the two ways, described below, using statistical tests to determine whether there were statistically significant changes before (pre-survey) and after (post-survey) the mathematics content course. The statistical significance was established at the 0.05 level.

First, to account for the unmatched data points, the complete data set (N=24) was analyzed using independent-samples *t*-tests, on each dimension separately. The mean of the scores for the PMTE dimension increased from M=47.01 (SD=6.71) before taking the course to M=51 (SD=6.62) after taking the course and the results from the independent-samples *t*-test indicated that this increase was statistically significant; $t(46)=2.07$, $p=.04$. On the other hand, the mean of the scores for the MTOE dimension increased from M=27.67 (SD=2.96) before taking the course to M=28.70 (SD=4.30) after taking the course. This increase was not statistically significant according to the independent-samples *t*-test; $t(46)=0.98$, *ns.*

Additionally, the data from matched pairs (N=18) was analyzed using paired samples *t*-tests, on each dimension separately. Table 1 presents the descriptive statistics for the pre- and post-surveys along with the results of the *t*-tests on both PMTE and MTOE. As can be seen from the table, the means on both dimensions, PMTE and MTOE, increased from pre- to post-survey for the matched pairs as well.

Table 1. MTEBI Paired Samples *t*-tests Results Before and After the Content Course

MTEBI Dimension	Pre-survey		Post-survey		*t*	*df*	Sig. (2-tailed)
N=18	Mean	*SD*	*Mean*	*SD*			
Personal Efficacy (PMTE)	47.58	7.59	52.06	6.37	3.56	16	**0.003***
Expected Outcome (MTOE)	27.41	3.14	28.18	3.81	0.92	16	0.37

* Significant at the 0.05 level

The results from the paired samples *t*-test revealed that the difference in the mean scores on the PMTE dimension was statistically significant. The mean scores at the start of the semester was 47.58 (*SD*=7.59) with an increase to 52.06 (*SD*=6.37) by the end of the semester; $t(16)=-3.56$ (pre-post, thus a negative *t*-value indicates and increase), $p<0.05$. These results suggest that the content course, MATH1, had a positive effect on participants' Personal Self-efficacy levels.

While the mean scores on Outcome Expectancy also showed an increase going from 27.41 (*SD*=3.14) at the start of the semester to 28.18 (*SD*=3.81) at the end of the semester, the increase was not statistically significant; $t(16)=0.92$, *ns.* That is, there was not enough evidence to suggest that MATH1 influences the MTOE dimension.

Discussion

These findings contribute to the body of research on perceptions of mathematics teaching held by elementary teacher candidates. In particular, the findings provide insights into teaching self-efficacy beliefs of elementary PSTs that have implications for teacher education programs.

The findings show that the personal teaching self-efficacy of elementary PSTs, as measured by the MTEBI survey, increased significantly after the mathematics content course, MATH1. It is worth noting that these students had completed at least two traditional mathematics courses, some of which were at the calculus-one level, prior to taking MATH1; yet their sense of personal teaching self-efficacy increased significantly after MATH1. This may be explained by the in-depth treatment of school mathematics concepts in MATH1, and the multiple opportunities given to the students to discuss and explain their mathematical ideas *with* their classmates and *for* their classmates.

Despite the significant increase in PMTE, there was no significant increase in MTOE, even though the mean values increased (pre, *M*=27.41; post, *M*=28.18). This is not surprising since MTOE measures the belief in one's ability to affect learning outcomes regardless of other factors, and these students had not yet experienced teaching; thus, it may be more difficult for them to judge this dimension. These results are consistent with those of others (e.g., Bleicher 2007, Hoy & Woolfolk, 1990; Plourde, 2002) that have found that certain learning experiences can increase PSTs' sense of personal efficacy, but that outcome expectancy beliefs are harder to change at this level.

These results extend those of previous research studies focused on methods courses (Bleicher, 2002; Bleicher & Lindgren, 2005; Huinker & Madison, 1997; Moseley & Utley, 2006; Swars, et al., 2009) by identifying opportunities to positively impact personal teaching self-efficacy at an earlier stage. This positive sense can be further nurtured on future coursework that is more tightly related to their teaching paths (methods courses, field experiences: classroom observations, student teaching, etc.). The results presented here corroborate and complement earlier reported results of the larger study (Truxaw, Cardetti & Bushey, 2010). Those results suggested that students who participate in mathematics content courses, such as MATH1, seem better able to concentrate on the material in the required methods courses and their confidence in teaching mathematics is significantly higher at the end of the methods course than their counterparts. The current study helps us understand further contributions of these mathematics content courses on elementary PSTs preparation. Based on these results, we recommend that teacher preparation programs consider requiring courses, such as the one described here, for all their preservice elementary teachers. Courses such as these, which focus on mathematical content with an eye toward the PSTs' professional goals, may support the development of identities that could shape their current and future professional dispositions (Hammerness et al., 2005).

Further research is needed to support these recommendations. Our findings are subject to at least two limitations. First, these data apply only to one cohort of students in MATH1 that was taught by one particular instructor; and a second limitation is that these data may be particular to the teacher preparation program at our institution. Therefore, we encourage others to build from this research to address these limitations and to continue the important work of understanding the kinds of mathematics coursework that best support elementary preservice teachers.

Endnotes

1. The author gratefully acknowledges the support of the *Teachers for a New Era* Project at the university in this endeavor and the careful reading and valuable comments of Mary P. Truxaw on earlier drafts of this article.

In this theoretical research paper we describe a collaborative effort between researchers and university faculty to improve teacher preparation in middle school mathematics. Two powerful instructional frameworks, UDL and TPACK are dovetailed within in a web-based dynamic textbook, "Proportional Dynabook" that focuses on proportional reasoning. Theoretical tensions between special and general education teacher preparation programs influence the ongoing design of Proportional Dynabook. Teacher candidates used Proportional Dynabook in a graduate methods class to design instruction for a student struggling with ratio. Teachers developed deeper understanding of ratio and related pedagogical strategies that make ratio concepts accessible to diverse learners.

Classrooms are more diverse than ever due to recent legislation such as No Child Left Behind and the Individuals with Disabilities Education Improvement Act that require all students to have access to the general education curriculum and to be included in the same assessments (Van Garderen, Scheuermann, Jackson, & Hampton, 2009). To meet the increasingly diverse needs of students with learning differences who are being educated in the general education classroom, special education services are being brought to the general education classroom. The lines between general and special education are blurred and teachers are being asked to collaborate to meet the educational needs of an extremely diverse group of learners. These collaborative efforts are based on the idea that each teacher has specific knowledge and expertise that address the instructional needs of the class (Van Garderen et al., 2009). However, collaboration in theory does not address the friction that exists in practice. Philosophical differences in pedagogy and learning theory create tension in the design of instruction. While this tension can be an obstacle to the design of effective instruction, it can also be the vehicle that brings together special and general education researchers to conceive and design innovative instructional tools and practices to meet the needs of *all* students.

Students with high achievement, with learning disabilities and English Language learners are all receiving mathematics instruction from teachers who have been trained as math teachers or special education teachers but not usually both. Special education teachers tend to focus on pedagogy and interventions while general education teachers focus more on the content and structure of mathematics (Van Garderen et al., 2009). Now both teachers are given the formidable task of "raising the floor by expanding achievement for all, and lifting the ceiling of achievement to better prepare future leaders in mathematics…(Friesen, 2008, p. 51). The prevailing special education service delivery model has the special education teacher providing instructional supports within the general education classroom. Hence, the special education teacher remains focused on pedagogy and intervention and the general education teacher remains focused on the math content. Often the special education teacher is attending only to the needs of students with Individual Education Plans (IEPs) and who have formally qualified for special education services thereby underutilizing the additional teaching resource in the classroom. This model may prevail because the special education teacher shies away from the more challenging math content and there is little time in the day for both teachers to do collaborative planning. However, in light of diminishing resources and budget cuts, full utilization of teaching resources must become the norm if we are indeed to raise the floor and ceiling of mathematics academic achievement.

We can begin to make changes in the way we prepare both general and special education teachers to teach mathematics. In teacher preparation and professional development programs, researchers and teacher educators from the fields of general and special education must model collaborative practices and create dynamic learning communities. Silverman and Clay (2010) suggest that teacher candidates need social experiences where they can engage with mathematics in a way that that encourages the development of "deep, connected, unpacked mathematical understandings." Further, the authors suggest that the collaborative use of technology serves to establish the social environment necessary to promote higher levels of thinking and the development of deeper broader understandings of mathematics and pedagogy. Likewise, Shreyar, Zolkower, & Perez (2010) suggest that the 'text' created through dialogue, written response, and diagram, in a social environment such as the classroom, can transcend the actual text in use. In this way, the original text serves a vehicle for collectively making meaning of complex mathematical concepts, problems, and related pedagogy. The instructor in these models works to orchestrate the individual students in the class in such a way that, despite a beginning heterogeneous perception of mathematical concepts and pedagogy, the class ends up with a collective understanding of problems and approaches to solve them.

In this theoretical research paper we describe our innovative approach to engaging pre-service teacher candidates in mathematical and pedagogical thinking. First, we describe our collaborative development of *Proportionality Dynabook*, a web-based dynamic textbook aimed at supporting both special and general education pre-service teachers in their efforts to teach middle school mathematics. Second, we describe the frameworks of Universal Design for Learning (UDL) and Technological, Pedagogical and Content Knowledge (TPACK), which serve as the structural environment of our dynamic text. Third, we explain the curricular activity system designed to create a learning environment where pre-service teachers utilize this Dynabook in a way that encourages social and cognitive engagement in issues surrounding middle school mathematics instruction for diverse learners.

Dynabook

We draw inspiration from Alan Kay's 1972 concept for a tablet-shaped personal computer (see, e.g. Kay & Goldberg, 1977), which he called a Dynabook. Although futuristic visions for the impact of computing stretch back much farther than Kay and have been updated many times since, we see Kay's concept as a distinctive turning point – and the essence of Kay's Dynabook is at the heart of the possibilities now emerging for digital texts in mathematics. Kay's vision, however, requires more than mobile devices and the Web 2.0 capabilities that enable social networking, because Kay also wanted people to more easily and frequently engage with powerful ideas. Like Seymour Papert (1993), Kay saw the dynamic, interactive capabilities of computational media as opening up new ways to playfully engage with powerful ideas – through activities like programming, interacting with visualizations, exploring mathematical models, and playing with simulations.

The present project is a collaboration between SRI International, San Diego State University, San Francisco State University, CAST, Inc., and Inverness. SRI International is a research firm with expertise in math education and innovative uses of technology. San Diego State University and San Francisco State University prepare teachers to serve California students in general and special education, respectively. CAST, Inc. is a leader in educational technology and Universal Design for Learning (UDL). Inverness is a leading research and evaluation firm. Collectively, we have a unique combination of expertise in mathematics, math education, special education, teacher training, technology supported math instruction, UDL pedagogy, and evaluation, which has been productive in designing and building the first iteration of the Proportionality Dynabook.

As a team of researchers and educators, we are exploring and developing Kay's ideas through a mathematics dynabook intended for use by prospective middle school mathematics pre-service teachers and centered on a key middle school concept of proportionality. Just as the strategies of summarization and prediction (e.g., in comprehending reading literature), and questioning and modeling (e.g., in learning from a science text), are essential in comprehension, we believe that there are similar strategies essential in mathematics. These include exploring the same mathematics through multiple equivalent entry points and making connections among different representations. Through our collaborative research with mathematics teacher educators and special education experts, we determined that the goals for this book should be to (a) support and reward the candidates when engaging more deeply in mathematical thinking, (b) encourage candidates to draw connections among related concepts of proportionality, and (c) develop teacher candidates' awareness of potential student misconceptions and instructional options they could choose to support student development of more robust ideas about proportionality.

To support these ends, and cue these strategies, the fundamental structure of the "book" is not a linear narrative but rather a 3x3 matrix that can be navigated through different pathways. The columns of the matrix are concepts in three related strands of middle school mathematics that develop students' proportional thinking: ratio (in the number strand), similarity (in the geometry strand), and linear function (in the algebra strand). Although many middle school mathematics teachers do not recognize this, these three concepts are deeply connected. For example, "slope" is the ratio of two sides (the height and the width) of a slope triangle, and the application of triangles to the slope relies on the concept of similarity. By presenting these three concepts side by side, the Proportionality Dynabook aims to encourage teachers to explore these sorts of connections.

The rows of the Proportionality Dynabook are organized by three different "entry points" for engaging teachers in the mathematics. Teachers can become familiar with the mathematics first by exploring "challenging problems" – mathematics problems that are designed to be challenging to candidates and help them develop their own mathematical thinking. Candidates can further explore the mathematics by watching "video cases" of student thinking as students solve problems with ratio, similarity and linear functions. Finally, candidates can also explore lessons that are specially designed to take advantage of the dynamic medium of the Proportionality Dynabook by presenting mathematical ideas in a visual and interactive format. For example, in the linearity section, candidates develop the idea of linear function as they explore the relationship between timing of thunder and lightning reaching a campsite. This rich matrix of related concepts and related ways to encounter the concepts takes unique advantage of the ability to construct a "book" that does not need to have a strictly linear ordering of pages. In addition, a concept of an expert “tour” is planned, which can overlay a step-by-step trajectory on the book when it is desirable to guide candidates through the book in a linear order.

With our Proportionality Dynabook we seek to further develop the concept of the “book” as a social medium that enhances interaction between an instructor and his or her pre-service teacher candidates. For example, instructors can create “assignments” in the Proportionality Dynabook for their pre-service teachers, support activities of both reading and writing, and allow pre-service teachers to engage deeply with powerful ideas, and extend these benefits to a diversity of learners. By dovetailing the UDL and TPACK framework in the design of the Proportionality Dynabook, we seek to immerse pre-service teachers in use of this resource as an exemplary instance of technology-rich mathematics in three ways: to deepen their own content knowledge, to develop key pedagogical skills, and to support beneficial use of technology in teaching.

Universal Design for Learning (UDL)

Universal Design for Learning supports the needs of diverse learners by providing multiple means of representation, expression, and engagement (Rose & Meyer, 2006; Rose, Meyer, & Hitchcock, 2005). The core idea of UDL is to embed supports in the medium, which learners can optionally activate when they need support to continue their progress. The benefit of UDL as a framework is that it provides a research-based taxonomy of the kinds of supports that learners may need and that technology can provide. Learners need supports for (a) connecting multiple representation of important ideas, (b) interacting with ideas and expressing ideas in new ways, and (c) maintaining a high-level of engagement.

With regard to these three kinds of supports, UDL concisely summarizes a vast literature on the brain, learning, and the role of technology. For example, UDL suggests that providing for multiple representations of a concept not only enables deeper engagement with that concept but also enables access for a broader range of learners (McGuire, Scott, &Shaw, 2006). In the Proportionality Dynabook, UDL is introduced through videos, text, and diagrams as a framework to interpret the digital text. These features are embedded to give teachers ideas about how to support student access to and engagement with challenging mathematics. For example, a glossary is available which defines unfamiliar words and definitions by using a mixture of pictures and words. Multiple means of expression are available to users who can highlight words or sections in the Proportionality Dynabook and take notes in the margins. Further, when answering a question, they can write, draw a picture, explain verbally (into a microphone), or upload a file. To enhance engagement, “Stop and Think” prompts are strategically embedded in the text to encourage candidates to process the text more deeply. These features of UDL are combined with digital resources to increase TPACK in pre-service teachers.

Technological, Pedagogical, and Content Knowledge (TPACK)

Emerging technological advances combined with Schulman’s (1987) work on pedagogical content knowledge have lead to the technological pedagogical and content knowledge (TPACK) framework (Mishra & Koehler, 2006). To increase TPACK in teacher candidates, technology needs to be strategically introduced and utilized by the instructor. It is not sufficient for students to access the Proportionality Dynabook without guidance and thoughtful pedagogy. In addition to careful instruction, content must be rich and challenging for candidates to increase understanding of the complexities of TPACK. Dynabook contains many access points to the three components of the instructional environment: technology, pedagogy and content. It incorporates features of UDL through digital technology and multiple means of expression. Videos of student thinking are assigned to candidates so they have a framework for pedagogy.

The various videos will guide the candidate's developing pedagogy when designing instruction to address student misconceptions. The content aspect of TPACK is distributed through many parts of the Dynabook, especially through the challenging problems for candidates. These are guided problems that include prompts to help them access the underlying mathematics through "How Do I Say It?" and "Get Me Started" features when working through the problems. There are also several dynamic representations involved in showing the solution of the problems when students check their work. The next section focuses on how the Dynabook was presented to teacher candidates who are working towards a special education teacher credential.

Dynabook in a Teacher Education Classroom

The first year of this project was dedicated to planning the design and development of a dynamic web-based text that could improve how pre-service teachers learn middle school mathematics content and related pedagogy. The diverse research backgrounds of team members contributed to lively discussions and ongoing iterations of our evolving Proportional Dynabook. In its current form, we have a completed section on ratio. In an effort to examine how teacher candidates can learn mathematics content, specifically ratio, and related pedagogy with the use of Proportional Dynabook, we introduced our tool in an advanced level methods class for special education teachers at an urban university in Northern California. In California, special education teachers are awarded a credential to teach at the K-12 grade level after successfully completing a series of graduate level courses. Special education interns work as the teachers of record while they attend the university in the evening to complete credential coursework. Most courses center around assessment, pedagogy, legalities and literacy with only one course devoted to mathematics. Since teacher educators in classes such as advanced methods often teach specific strategies, they choose content areas that tend to be more accessible to new teachers, leaving mathematics methods to the mathematics professors in the general education department where special education teachers take their one math class. Mathematics is an area that is frequently overlooked because it is considered difficult and less interesting than other topic areas. It is our hope that the Proportional Dynabook will provide a fun and interesting way for teacher educators, who are not experts in proportionality, to engage their pre-service teachers more fully in the concepts and pedagogy related to teaching proportional reasoning to diverse learners.

Thirteen pre-service and intern special education teacher candidates participated in two classes dedicated to interacting with the ratio section of Proportional Dynabook. Participants had varying levels of mathematics proficiency and teaching experience. During the first session, we introduced Dynabook with a scavenger hunt activity through various sections of Ratio (i.e., Introduction, UDL, Challenging Problems, and Video Cases). In addition, our teacher candidates watched two instructional videos related to the shifts in proportional reasoning outlined by Lobato, Ellis, Charles and Zbiek (2010).

During the first observation of the Dynabook training and proportionality development session, all the researcher observers agreed that the teachers seemed a bit overwhelmed by all the new material and technology. In addition to learning a new technological tool, and a new mathematics framework (Lobato et al., 2010), they were also ask to think about middle school ratio problems that they found difficult to solve. Many might call these problems simple, but the students still had difficulty thinking through these problems and coming up with answers and novel ways to approach the problems. During a researcher debriefing after the first session, we realized that the teacher candidates were uncertain about their role in relation to the Dynabook. Questions like, "Who is this for?," and "Would I use this with my students?" made us realize that we did not provide enough background information about the development and purpose of Dynabook. In addition, we had not provided a rational for these teachers to truly engage with Dynabook in the way that we had hoped they would. It is our contention that if a special education teacher candidate does not have a reason to engage with challenging mathematics content, he or she will not and instead attend to the many other responsibilities required by a job or classwork. For the second session, we designed a specific curricular activity that would provide purpose and rationale for our teacher candidates to engage with Proportional Dynabook.

In the beginning of the second three-hour class session, the teacher candidates finished trying to solve the ratio problems from last session and post answers to the communal whiteboard in Dynabook. While one of the researchers used the large screen computer in the lab, each teacher candidate followed along in their own Dynabook on individual screens. The anonymous postings on the whiteboard initiated a lively discussion of ratio concepts and common misconceptions shared by several of the teacher candidates in the class. We described the rationale and purpose of this session by setting up a scenario where they were going to have to teach ratio to middle school students starting tomorrow. Specifically, they were going to prepare to address the learning needs of a student struggling with the concept of ratio as depicted in one of the videos in Dynabook. Each pair viewed the video of Kayla, and began to discuss her misunderstandings along with their own confusions and partial understanding of ratio. As we observed, pairs moved in and out of the different sections of Dynabook utilizing various features to improve their own understanding so that they could develop a script to address Kayla's level of understanding. Each pair remained engaged in discussion until the end of class.

In the video, Kayla, a middle school student, attempts to solve a ratio problem by incorrectly utilizing a procedural algorithm. Despite her answer not making sense, Kayla defends her use of the algorithm, representing a fairly typical procedural approach to proportionality in the absence of understanding. After carefully watching the video, the teacher candidates worked in pairs to create a lesson that addresses Kayla's conceptual misunderstandings. Each pair created a script for the lesson and used that script to create a movie of the lesson using *Xtranormal*, a free, web-based software for creating animated movies. We explained that by creating a script and movie, each pair must think about what words and language they will use to explain ratio. Then, by watching the movies, we have a way to share and discuss changes in the candidates' thinking about ratio and the pedagogy they used. As the groups were working on the movie, we told them they were free to take a break, but most groups did not stop. By the end of class, we observed that not only were the teacher candidates able to talk more precisely about ratio, they were also able to talk about how to assess student understanding of ratio. They discussed how to define what level of thinking the student is operating at according to the Lobato et al. framework and ways to get them to the next level. This is the type of engagement we had hoped to initiate with the introduction of Dynabook.

One of the researcher observers commented "that we have a way to really engage pre-service students in UDL and TPCK -- it was completely evident to me that the candidates were really in that space with their thinking throughout the evening. We need to remember to describe both the tool --- the Dynabook -- and the curricular activity system in which it exists. Both are necessary to achieve the reasoning we saw …. It is not our story that the Dynabook causes great pre-service classroom experiences' -- instead that the Dynabook is an enabler for a curricular activity system that increases candidate's social and cognitive engagement in these important issues. The Curricular Activity System language may be unfamiliar. We should capture both the tool's contribution and the activity design contribution -- that's the heart of it."

As we continue to develop and test the Proportional Dynabook, we hope to share our ideas and collect feedback from those interested in improving how we prepare teachers to think about and teach mathematics. Our next steps include formal testing and data collection to more thoroughly examine how the Proportional Dynabook can expand meaningful engagement and develop teachers' and students' sense of connections across the middle school mathematics curriculum.

FOSTERING BELIEFS AND VIEWS OF PRE-SERVICE MIDDLE SCHOOL MATHEMATICS TEACHERS ABOUT TECHNOLOGY

Thomas G. Edwards
Wayne State University
t.g.edwards@wayne.edu

S. Aslı Özgün-Koca
Wayne State University
aokoca@wayne.edu

The literature shows that beliefs and views of teachers have an important influence on their instructional decisions. Many pre-service teachers seem to hold negative views about the potential of graphing calculators as tools for concept development. In this research, we studied a section of mathematics teacher education students as they encountered activities we designed for use with TI-Nspire. This paper reports the extent to which portions of three 2 hour, 45minute class sessions were effective in pointing pre-service teachers toward more positive and cognitively richer views of calculators in mathematics instruction.

The use of graphing calculators in school mathematics classrooms is now in its third decade. Despite this fact, mathematics teacher educators continue to encounter numbers of pre- and in-service teachers who either eschew the use of calculators during instruction or voice support for their use, but "… only after students master things by hand." Among many pre-service teachers, there does not seem to be much awareness of the potential of graphing calculators as tools for concept development. Therefore, the goal of this study was to learn whether exposure to graphing calculator-based activities could foster pre-service teachers' awareness of and beliefs/views about the potential of graphing calculators as tools for concept development.

Conceptual Frameworks

We employed two conceptual frameworks to guide our study. The first is based on a broad model of the process of teacher change. The second deals with the roles that teachers ascribe to calculators.

A Model of Teacher Change

In order to better understand the process of teacher change, we used the model developed by Edwards (1996). This model was based on a constructivist perspective on learning. If one views the active construction of knowledge as a cycle involving interaction with something new, some sort of perturbation resulting from the interaction, reflection, and change (von Glasersfeld, 1983; Cobb, 1988, 1989, 1994; Confrey, 1991), it is a natural step to view the process of teacher change as an instance of such active, constructive learning. However, as shown in Figure 1,

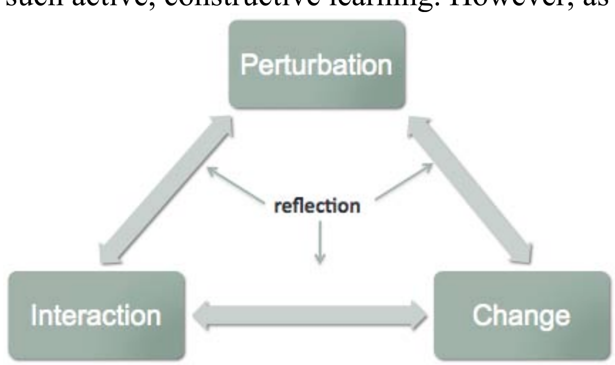

Figure 1: Edwards's Cyclic Model of Teacher Change

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

Edwards's cyclic model is a three-cycle, rather than a four-cycle, as others have proposed (see for example Underhill, 1991). As a three-cycle, interaction, perturbation, and change are the three points of the cycle, and reflection forms the connections between those points.

The Roles of Calculators

The second conceptual framework of this study centers on the classification of Doerr and Zangor (2000) for the roles of graphing calculators in the construction of mathematical meaning. Following 21 weeks of classroom-based observations, they were able to classify the patterns and modes of using graphing calculators in two pre-calculus classrooms. The modes of using graphing calculators were as a:

- computational tool to evaluate numerical and perhaps even algebraic expressions,
- transformational tool "whereby tedious computational tasks were transformed into interpretative tasks" (pp. 152-153),
- data collection and analysis tool when using Calculator Based Laboratory devices such as motion detectors or temperature probes,
- visualizing tool "to develop visual parameter matching strategies to find equations that fit data sets, to find appropriate views of the graph and determine the nature of the underlying structure of the function, to link the visual representation to the physical phenomena, and to solve equations" (pp. 154-155), and
- checking tool "to check conjectures made by students as they engaged with the problem investigations" (p. 156).

Since Doerr and Zangor explained that their checking mode emerged when students check their conjectures, we renamed this role as exploratory tool. Doerr and Zangor also concluded that the "nature of the mathematical tasks and the role, knowledge and beliefs of the teacher influenced the emergence of such rich usage of the graphing calculator" (p. 143). As Doerr and Zangor highlighted that teachers' beliefs are as important as their knowledge, the activity sequence in this study was aimed to bring presevice teachers face to face with their own beliefs through reflective activities.

Method

Twenty-four elementary education students who were seeking a mathematics endorsement for grades 7 and 8 took part in the study. All of the participants were students in an algebra course for middle school teachers. They were a mix of undergraduate and graduate students. Most were pre-service teachers, but a few were in-service teachers. The class met weekly for 2 hours, 45 minutes. The study took place over three consecutive weeks.

In the first two weeks, we engaged the participants in two TI-Nspire based lessons, one dealing with linear regression (Özgün-Koca & Edwards, 2010), and the other dealing with quadratic functions (Edwards & Özgün-Koca, 2009; Özgün-Koca & Edwards, 2008). In the third week, participants viewed video of 7th and 8th grade students completing the same TI-Nspire activities.

Our sources of data were four reflective writings that asked participants to respond to open-ended questions about the use of calculators to support mathematics teaching and learning. Reflection 1 was a pre-survey in which they discussed their views of the use of calculators in teaching and learning mathematics. The first reflective writing was completed one week prior to the first TI-Nspire lesson. Reflections 2 and 3 were completed immediately following each of the TI-Nspire lessons. They consisted of writing prompts aligned with the Technological Pedagogical and Content Knowledge (TPACK) model (Niess et al., 2009). Reflection 4 was a post-survey aimed at eliciting their beliefs about the use of calculators in mathematics teaching after their experiences in these three weeks. It was completed immediately after the participants viewed the classroom videos.

The raw data were transcribed as Word files and analyzed using Weft QDA software. This facilitated keyword searches and allowed us to analyze participants' reflective writings at the level of individual phrases or sentences. Data and investigator triangulation were used to ensure the trustworthiness of this study.

Results

Intentions to Use Calculators

In both the first and fourth reflective writings, we asked participants directly to discuss their intention to use calculators in their future teaching, or not. Fifteen of the 17 participants in the first reflective writing and all twenty of those who participated in the fourth reflective writing said yes to using calculators. Because there was not much difference in the proportion of participants who said yes to using calculators in these two reflective writings, we decided to look at the ways of using calculators that they mentioned in those writings.

We deemed using the calculator solely to check answers computed by hand or solely as a fast and accurate computational tool to be trivial uses of calculators. Two examples of participants' earlier writing about how they would use calculators in their future teaching that we considered trivial uses follow:

I would use calculators to engage students in learning to check their answers.

I would … show them things such as square roots and other operations that can't be computed by hand.

We then looked at the proportion of participants who mentioned any non-trivial use of the calculator in the first and fourth reflective writings. Only 7 of the 15 participants (47%) who said yes to using calculators in the first reflective writing mentioned a non-trivial use. However, in the fourth reflective writing, 17 of the 20 (85%) participants who said yes to using calculators mentioned a non-trivial use. Two examples of what we considered to be non-trivial uses of calculators mentioned in the fourth reflective writings can be seen in the following quotes:

Having a calculator to generate graphs that are easy to manipulate gives students the opportunity to recognize patterns both quickly (in terms of generating graphs) and independently.

I think the Ti-NSpire helps the kids visualize what they are doing, and this helps them understand better what is going on.

A Chi-square test revealed this difference to be statistically significant ($p<0.015$).

Roles of Calculators

Throughout the four reflective writings, participants mentioned various roles that they saw for calculators in the mathematics classroom. We decided to compare the roles mentioned in the first two reflective writings with those mentioned in the last two, because at the time of the first two reflective writings they had minimal exposure to TI-Nspire, while at the time of the last two they had experienced both TI-Nspire lessons. These comparisons were across two different reflective writings. Therefore, sometimes the number of times a role was mentioned is greater than 24, because one or more of the participants mentioned the role in both writings. We will focus on four of the calculator roles that emerged from their reflective writings, because these four exhibited a dramatic shift in focus.

In the first two reflective writings, participants mentioned calculators as a checking tool 10 times and as a computational tool 11 times. In the last two writings, there were only 2 mentions of the calculator as a checking tool and 3 as a computational tool. In contrast, during the first two reflective writings, the calculator as an exploratory tool was mentioned only twice, and the calculator as a visualization tool was mentioned 9 times. However by the time of the last two writings, the number of mentions of the calculator as an exploratory tool had risen to 18, and those of the calculator as a visualization tool had increased to 27. We believe this conceptual shift away from the more trivial roles of the calculator as a checking or computational tool toward more substantial roles as an exploratory or visualization tool is of practical significance, particularly in light of the relatively short duration of the participants' TI-Nspire experiences during the study.

How and When to Use Calculators

When we look at the things that participants wrote about how or when to use calculators, a sense of their Technological Pedagogical Knowledge development emerges. We again compared four types of responses, after mastering skills, not for basic facts or abuse, not for developing concepts, and to develop concepts, across the first two and last two reflective writings. In each case, there was very little difference in the number of responses when the first two writings were compared to the last two. In a number of instances, there was also not much difference in the things that they wrote. For example, on the first reflective writing, a participant wrote:

> *I think calculators are a great teaching tool as long as students understand the concept (know how to solve the problems first).*

Similarly, on the fourth reflective writing, a participant wrote that (s)he would:

> *not offer the students the opportunity to work with the calculators until I am confident that they understand the concept we are working with.*

We think these results show, not surprisingly, that dislodging beliefs about how and when to use calculators, or even if they ought to be used, will take more than the brief interaction that we provided our participants.

Issues Related to Student's Learning

Three issues related to student learning appeared across the four reflective writings. Some participants mentioned their belief that calculators are helpful for learning or understanding and are fun or motivating for students. However, some in their writing also revealed a fear of students becoming calculator dependent.

In the first two reflective writings, participants said that calculators are helpful for learning or understanding 11 times. By the last two writings, that number had grown to 22. Similarly, in the first two reflective writings, the fun or motivational aspects of using calculators were mentioned 3 times, but by the last two writings that number had increased to 9. While the numbers are small in both cases, there was also an increase in the number of times that a fear of calculator dependence was mentioned from 3 in the first two writings to 5 in the last two.

We interpret the first two increases as indicators of some developmental changes in participant's TPACK levels. As to the third increase, fear of calculator dependence may well be yet another pernicious belief that can only be altered via more time and experience with appropriate classroom uses of calculators.

Technological Knowledge and Confidence

Sixty-nine percent of the participants in this study stated that they were confident using technology in the mathematics classroom. The technology was not limited to TI-Nspire. Some participants stated that they would use TI-89, computers, or Smartboards.

I feel confident with technology in the classroom. I love computer & calculators. I found the TI-Nspire a little more difficult than calculators or computers.

Even though some mentioned that TI-Nspire was confusing, as this pre-service teacher did, this could be overcome by time and experience. Another participant mentioned that

I am not too confident at using technology in the classroom, but I intend to use it despite this. Once I gain experience and practice, especially with teacher specific technology, I'm sure my confidence will improve.

Here we see the importance of the combination of technological knowledge with disposition. When technological knowledge or confidence are non-existent, believing in the value of using technology or believing in or knowing the positive influence on the teaching and learning environment acts as the driving force to increase ones technological knowledge and confidence. In this case, technological pedagogical knowledge initiates the desire for an increased technological knowledge.

These pre-service teachers are still transitioning from being a student in a mathematics class to being a teacher. When they were talking about technological knowledge, some parts of their reflections focused on their technological knowledge as students. Perhaps that is why nine reflections mentioned the rationale for using technology was to serve a technology-driven student population.

With younger, technology driven students involving accurate use of calculators, and graphing calculators in older grades, will become more & more essential to solid understanding of mathematical concepts.

However, 16 reflections stated that their future students would need to know how to use technology for their own good and for their future mathematics classes.

I think it will be good for younger students to get some hands-on experience with the technology they will be using later in school as they get older.

Technological Capabilities of TI-Nspire

When we coded participants' reflective writings that followed their exposure to activities with the TI-Nspire, two codes emerged which referenced two capabilities of the TI-Nspire—linked representations and dynamic features. Twenty-three reflections in the third and fourth writings mentioned the importance of linked representations. They discussed that TI-Nspires became a better visualization and exploratory tool with the help of the linked representations.

Seeing is believing, being able to see the change in the graph as it correlates with points indicated.

We mainly used the calculator to plug in equations & move them around to create answers to equations about the technology and how it can be used to explore answers about graphing. It was a great visual to see how things happen on the axis when a parabola was moved.

The participants liked the dynamic feature of the TI-Nspire and commented on its effects on the teaching and learning environment.

Having a calculator to generate graphs and that are easy to manipulate gives students the opportunity to recognize patterns both quickly (in terms of generating graphs) and independently.

They can easily manipulate graphs and have a quicker time to understand how graphs can change with little work involved.

When empowered with linked representations, many participants opined that the dynamic feature created a teaching and learning environment for understanding.

I really like how the calculator can show how graphs shift. Also, how it changes the equation as you shift the graph. This lets kids see how it changes the equation. When the graph moves, I feel that this will help kids understand graphs and how they shift much better. It will no longer require kids to memorize all this info. With activities like this, they will learn it without even knowing it.

The fact that participants were not able to mention these features in the first two reflective writings is not surprising. They had little or no experience with linked representations or dynamic features on a graphing calculator at that point. However, statements such as the one above seize our attention, because they clearly highlight the importance of technological knowledge for mathematics education in the 21st Century.

Discussion

Reflections on the Teacher Change Model

We believe that the teacher change model presented earlier is a good fit for some of the phenomena we observed in this study. We designed the study so as to provide participants with a number of interactions. They interacted with TI-Nspire activities, they interacted with the reflective writing prompts, they interacted with the instructor, and they interacted with each other.

It was our hope that, through reflecting on these interactions, participants would encounter something to perturb their thinking, and such perturbation was evident in some of their reflective writings. Moreover, we provided participants with reflective writing prompts that we hoped would resonate with what was perturbing them. Then, we hoped to see evidence of a conceptual shift in their consideration of the potential of graphing calculators as tools for concept development. Again, we saw evidence of such change in participants' reflective writings. For example, one participant directly described just such a cycle when (s)he wrote:

I am <u>very</u> for using calculators when teaching math, because it will generate more constructivist based conceptual learning. Initially, I had thought calculators would be misused, because students would stop thinking when using calculators. After being able to use TI-Nspire myself with student activities, I realized how wrong I was. … Calculators are ultimately changing math learning for the better, following the trend of more conceptually, constructivist, activity-based teaching as opposed to lecture style, direct teaching.

We think this example suggests the power of the approach we used. If we were able to provoke such a shift in one participant's thinking based only upon such a short exposure to TI-Nspire and a few reflective writings, the potential of a broader-based longer-term exposure to the appropriate, effective use of graphing calculators, as well as other technological tools, seems clear.

Reflections on the Roles of Calculators Framework

Seeing the departure from the trivial uses of calculators towards the nontrivial uses of graphing calculators was encouraging. This could be related to the participants' experiences as students learning or doing mathematics with calculators. If their prior experiences were limited to what we called trivial uses, it would be expected that they only mention such uses when asked to think about the use of technology in the mathematics classroom. This result highlights the significance of the combination of technological knowledge with technological pedagogical knowledge. If a teacher knows the ins and outs of technology; that is, (s)he has well-rounded technological knowledge, this would not be enough to plan or implement an effective mathematics lesson using technology. The teacher needs to have the complete technological, pedagogical, and content knowledge in order to deliver a lesson that makes effective and appropriate use of technology. In teacher education programs, we can help our pre-service and also in-service teachers first face their beliefs, views, and knowledge, and then we can guide them to extend their knowledge toward a more complete TPACK.

When we reflect back to the roles of graphing calculators conceptual framework by Doerr and Zangor (2000), we see that the framework was very efficient in the analysis of our data. Other than the role as a data collection and analysis tool, we saw all the roles described by Doerr and Zangor emerge in the reflective writings of our participant teachers. This result again highlights the importance of the past experiences with graphing calculators (or lack of, in this case) of the participants. Moreover, when coding our data, we saw graphing calculators as a transformational tool also come up when participants described uses of the graphing calculator as a visualization or computational tool. Therefore, we decided to restrict our coding to clear-cut functional roles of the calculators in this study. Furthermore, some of the writings of the participants indicated that they were assigning different roles to the calculators that we could not categorize with our existing codes. For instance, one pre-service teacher wrote that

> *I am currently teaching and use calculators to show relationships between different problems and in multistep problems where I am trying to see if my student knows what steps need to be taken in order to solve a problem instead of focusing on their computational skills.*

Clearly, this could be coded as a transformational tool, but then we would lose the problem solving aspect. Another participant stated that "I think it is a good way to scaffold students to learn what used to be concepts that were out of their reach cognitively." Other keywords that they used that we could not code within our existing framework were graphing calculators to reinforce skills or concepts, as a supplement, as an aid, and as a resource.

At this point we believe that an extension of our conceptual framework is necessary. In addition to the clear-cut functional roles of graphing calculators as computational tools, checking tools, exploratory tools, and visualization tools, we can add another layer of pedagogical roles, as

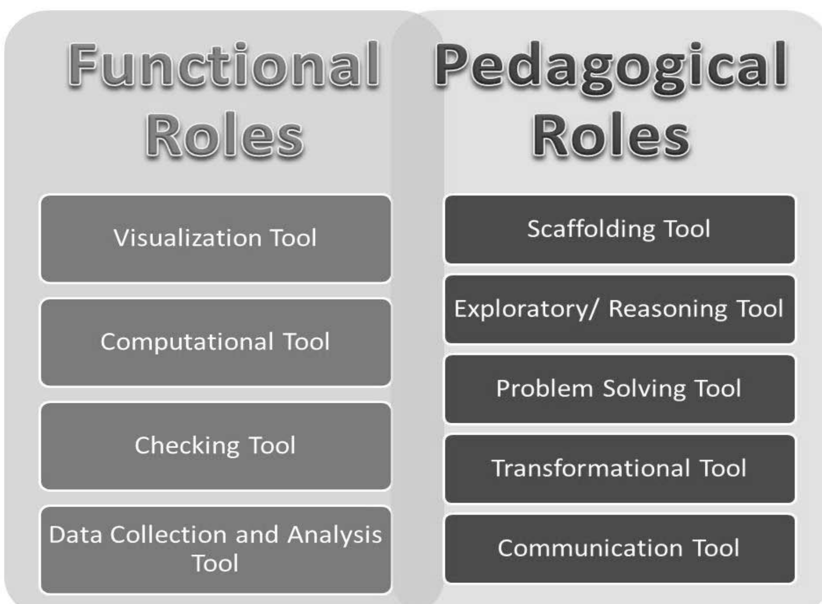

Figure 2. Revised Framework for the Roles of Calculators

in the NCTM (2000) process standards. One of the process standards suggests "reasoning tool" as a role, but we see some overlap between the exploratory tool role and a reasoning tool role. Therefore, we will add using graphing calculators as reasoning/exploratory tools, transformational tools, problem solving tools, scaffolding tools, and communication tools to the framework, as depicted in Figure 2. Still we expect that some of boundaries among these roles will be ambiguous at first.

In time, we, as teacher educators, and hopefully also the pre-service and in-service teachers we work with, will focus not only on what graphing calculators can do with their technological capabilities, thus highlighting the functional roles, but also how they can affect and enrich the teaching and learning environment, thus highlighting the pedagogical roles. Then all of our pre-service and in-service teachers might realize, as one of our participants did, that "engaging the students with technology will also be essential to effective teaching in the future."

A CASE STUDY OF PRE-SERVICE TEACHERS WRITING MATHEMATICS FOR TEACHING IN A SECOND LANGUAGE

Alberto Esquinca
University of Texas at El Paso
aesquinca@utep.edu

Olga Kosheleva
University of Texas at El Paso

This is a case study on the development of Mathematical Knowledge for Teaching (MKT) (Ball, Thames, & Phelps, 2008) among three pre-service teachers who are English language learners (ELLs). We investigate the potential of thinking and learning reflection logs (TLR) to promote the development of MKT. Participants were enrolled in a required course for teachers seeking middle grades certification. Data were gathered from informal interviews and participant-observation in addition to logs. Analysis focused on demonstrated use of MKT. Findings suggest that writing TLRs is beneficial for ELLs's development of MKT, among other reasons, because it necessitates the use of multisemiosis and it allows time to communicate understanding.

The assessment of mathematical knowledge among English Language Learners (ELLs) has become an important priority for mathematics educators concerned with equitable access for all students. The research literature has pointed out how language may impact equitable access. For instance, Abedi & Lord (1998) show that students' language background impacts performance on word problems in standardized tests. "English language learners scored significantly lower than proficient speakers of English" (p. 231).

However, alternative assessment, such as student logs in which students write out their thinking and propose solutions to mathematics problems, may pose challenges for ELLs as well. A study by Brown (2005) indicates that alternative assessments such as student logs demand high literacy skills, which might especially impact ELLs of beginning proficiency.

We argue that writing TLR logs potentially promotes pre-service ELL teachers development of MKT discourse. In this study, we focus on the challenges and opportunities that writing logs posed for pre-service ELL teachers at a university near the US/ Mexico border. Many pre-service ELL teachers at this particular institution have developed much linguistic and mathematical knowledge in Spanish (Lesser & Winsor, 2009) but are being trained in courses in English. We present the experiences of three pre-service teachers who are seeking to become certified to teach in the middle grades. Enrolled in a course on conceptual algebra, participants were required to write Thinking and Learning (TLR) logs.

Current approaches to teacher education outline Mathematical Knowledge for Teaching (MKT) that mathematics educators should have (Ball et al., 2008). Researchers are beginning to ask how this knowledge base can be built in teacher education programs (McLeman & Cavell, 2009). In this paper, we aim to understand how pre-service teachers' writing TLR logs contributes to their development of MKT.

Theoretical Framework

The discourse of mathematics is challenging—even for fluent English users. Mathematics discourse practices are characterized by argumentative modes including precision, brevity, and logical coherence as well as cognitive and linguistic abilities such as "abstracting, generalizing, searching for certainty, and being precise, explicit, brief, and logical" (Moschkovich, 2007, p.

10). According to linguist Kay O'Halloran (2005), mathematics discourse is characterized by the use of multiple semiotic resources for constructing mathematical meanings. Mathematical meanings are constructed three semiotic resources: symbolic representation, visual representation, and language.

In this work, we draw on the framework on Domains of Mathematical Knowledge for Teaching (Ball et al., 2008) to describe the mathematical knowledge that pre-service teachers must master. The following is compilation of definitions for categories discussed by Ball. Subject Matter Knowledge includes (1) Common Content Knowledge (CCK), which is non-specific knowledge of mathematics (and skills) that is common for many different areas where mathematics applications are successfully used; (2) Horizon Content Knowledge (HCK), which is knowledge of the "big picture" and awareness of interconnectedness of all mathematical topics; and, (3) Specialized Content Knowledge (SCK), which is mathematical knowledge unique to teaching. Pedagogical Content Knowledge (PCK) includes (1) Knowledge of Content and Students (KCS), which is mathematical knowledge connected to the knowledge of students' thinking (conceptions and misconceptions, motivation); (2) Knowledge of Content and Teaching (KCT), which is mathematical knowledge connected to teaching, including knowledge of design and instruction, creating sequence of relevant and adequate, challenging tasks, making decisions about selection of manipulatives and resources for the task; (3) Knowledge of Content and Curriculum.

In our approach, we used the MKT framework as an analytical tool to understand the development of mathematical knowledge for teaching. A mathematician compresses and "packs" the knowledge and data (e.g., one short formula may represent huge amount of data that is literally "packed" in this formula) (Ball et al., 2008; Ball & Bass, 2000). SCK knowledge indicates specific "unpacking" of mathematical content knowledge in such a way that it is specifically suitable for teaching mathematics. Writing in TLR logs is an opportunity to develop mathematical discourse for teaching. With proper guidance and appropriate prompts, pre-service teachers could "unpack" mathematical content knowledge specifically for teaching mathematics. We present the experiences of pre-service ELL teachers writing TLR logs, and their development of MKT as evidenced in the logs.

Methodology

For the present study, we drew on data gathered from a larger qualitative study on pre-service ELL teachers' development of mathematical discourse[1]. The larger qualitative study draws on qualitative research data collection strategies, including participant-observation, informal interviews and analysis of student writing. Participant-observation was carried out over the span of one semester in a section of a course on conceptual algebra; the first author attended 70% of class meetings. According to course materials, the course is an inquiry-based course covering mathematics concepts including fractions, ratio, proportion, functions, algebra and geometry with an emphasis on reasoning and mathematical thinking. Some of the habits which the course aims to develop in students are a) attention to the meaning of symbols and numbers, b) analysis of problem situations, and c) hypothesizing and justifying mathematics solutions. The course was organized so that students would become socialized to the discourse of mathematics. One of the main goals of the course is for students to develop mathematics concepts to such an extent that it is possible for them to converse about it. Problem-based activities that require mathematical solutions were the core of discussions. Students' mathematical reasoning and mathematical communication are promoted through problems requiring small group discussion, whole class discussion, and writing in TLR logs.

Participants

Three students were invited to participate in the research based on the observed use of Spanish in the classroom. All three received formal education in Mexico, and for all three writing TLR logs was a completely new endeavor. All three reported having taken ESL courses in high school or college. The pseudonyms used to identify them are Betty, (a Mathematics and Science major), Yolanda (a Special Education major) and Laura (a Bilingual Education major).

Data Collection

For the present study we used data from TLR logs to assess MKT. Students were assigned semiweekly TLR logs. The TLR logs were designed to allow pre-service teachers to extend their thinking beyond what was covered in class and for students to offer new insights about mathematical concepts. TLR assignment required students to use multiple meaning-making resources (symbolic representation, visual representation and language), which is an opportunity to write mathematical discourse.

The unit of analysis is the TLR logs, a weekly writing assignment in which students had the opportunity to use the discourse of mathematics for teaching. Each weekly log is analyzed for the demonstrated use of MKT (Ball et al, 2008).

Data Selection

Data were selected based on topic and comparability across student writers. Data were selected from the first six weeks of the course in which the topic of fractions, a key concept for these pre-service teachers, was covered. Moreover, data were selected from assignments that could be compared. Not all students completed every log assigned. We selected logs for week 2 (log 1), week 4 (logs 1 and 2), week 5 (log 2) and week 6 (log 1).

Data Analysis

Data analysis took place in two phases. In the first phase, four raters independently rated each selected log. Raters are all Spanish/ English bilingual doctoral students with an expertise in mathematics education. For each log, raters examined each of the following MKT domains CCK, SCK, and PCK. Each domain was rated based on the demonstrated knowledge of the three domains. Raters, who were instructed to not discuss their ratings among each other, used the rating scale in the figure below. Individual ratings were averaged and standard deviations were calculated.

Rate on a scale of 1 to 5
1= **little or no evidence** that student has/ is using this knowledge
2= **some evidence** that student has/ is using this knowledge
3= **evidence** that student has/ is using this knowledge, with room for improvement
4= **significant evidence** that the student has/ is using this knowledge
5= **abundant evidence** that student has/ is using this knowledge

A second phase was designed, after standard deviation was consulted. In this phase, which is ongoing, raters selected one log to discuss the features of the log that each rater was observing to determine writer's demonstrated knowledge of CCK, SCK and PCK. In this phase, raters reach a consensus on the aspects that demonstrate knowledge of each domain[2].

Findings

Regarding different Domains of Mathematical Knowledge for Teaching Fractions we specifically focus on how these pre-service teachers understood different representations of fractions, and how different models were used to represent a multifaceted concept of fraction.

Overall, Betty (the Mathematics and Science major) performs differently on log writing compared to Laura and Yolanda (the Bilingual Education and Special Education majors, respectively) do. Betty's efforts in writing TLR logs are usually low, while Laura and Yolanda are consistently high. Ratings for each student's performance in five focus logs; ratings are reported for each domain evaluated. The table in Appendix A compiles all the ratings, including average ratings. Next, we use average ratings to report each participants' demonstrated knowledge in each domain.

We assumed that Betty (Math and Science major) would receive the highest average in CCK and Laura (who reported a lack of confidence in both mathematics and English) to get the lowest CCK average. However, the results surprised us. Betty appeared with the lowest average in every log but one, while Yolanda showed the highest average in every log but one, as we can see in Chart 1.

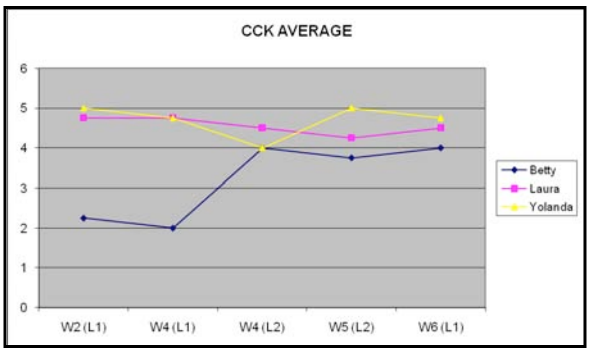

Chart 1. CCK average

Betty was very low in the first two logs but improved substantially in the following three. Moreover, Laura was the one who performed consistently, having almost the same rating in each activity log. Week 4 activity log number two "W4 (L2)" and week 6 activity log number 1 "W6 (L1)" showed the highest average overall by the three participants. Qualitatively, Betty copied brief definitions from the textbook that week, placing an emphasis on correctness. However, she did not use diagrams to further explain her meanings. This performance was generally characteristic of Betty's work in TLR logs. In an informal interview, she noted that she did not see the point of writing TLR logs. She fell behind in submitting her weekly TLR logs, but did manage to turn in a semester-end portfolio. She struggled to write logs in which she "unpacked" the mathematical knowledge. It seems that she found it hard to explain it in such a way that it would help children to understand.

Next, an analysis of SCK averages shows that Betty demonstrated the lowest evidence level on each week. Betty performed very poorly in the SCK domain. Meanwhile, Yolanda had an increasing performance every single week. Laura has almost the same grades in each week but week 4 activity log 1 "W4 (L1)". Yolanda had the highest average overall. However, the grades obtained by every participant were lower than the grades obtained by them in the CCK domain and hence, the SCK average was lower than the CCK average.

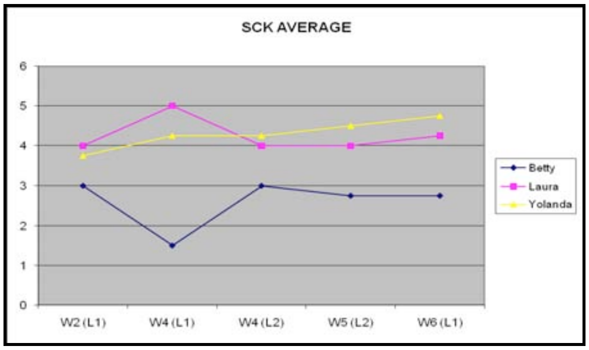

Chart 2. SCK average

Thirdly, the PCK domain gave the lowest grades overall as we can see in chart 3. Laura was the only one who decreased her performance every week but the second. On the other hand, Yolanda was the only one who increased her performance every week except the second one. Furthermore, Betty was the one with the lowest grades overall. Betty had the lowest averages in the first two activity logs and then she improved substantially.

Yolanda had the highest PCK average overall. To illustrate the point, taking an example from one of Yolanda's logs, she used her own words to explain two different meanings of fractions. When talking about division, she seemed to be confused about dividend and divisor, e.g., "3/6 in part-whole indicates three one-sixths and only need one whole. When we refer to division meaning, we are talking about how many 3s are in 6. That means that three wholes will be divided into six equal parts." She also provided pictorial representations using the area model. The representations seemed to help her understand the correct meaning of fraction as a division. She also discussed difference between continuous and discrete models. After that, she discussed whole numbers and fractions as part of a whole. Qualitatively, Yolanda's attitude about writing TLR logs was the most positive of the group. She regarded as a learning experience for both mathematics and English. She was conscious of the positive impact that writing logs had on her learning. She wrote about the logs that they help "to clear my understanding and while I was trying to explain at the same time I discover new concepts and ways to explain that will help as a future teacher." Furthermore, Yolanda demonstrated progress in the development of CCK when she says that she learned a significant amount of mathematical content by attempting to explain concepts instead of "rushing into a procedure." Revealingly, when she was asked if she would ask her future students write logs, she was enthusiastic about the benefits of writing them.

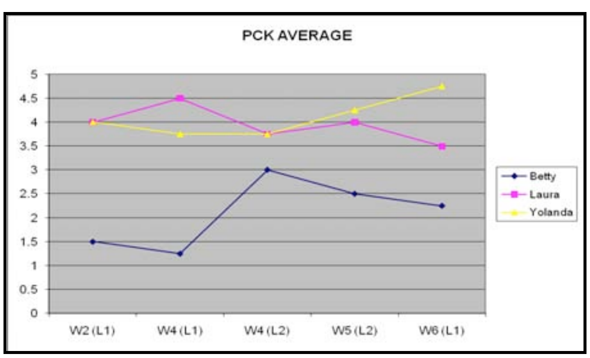

Chart 3. PCK average

In comparison to Yolanda, Laura said in an interview that her general mathematics knowledge was inadequate. She also noted that her English proficiency was still developing, and that she struggled to write the TLR logs. Laura was notably quiet in class; she never volunteered to present her solutions in front of the rest of the class—the only participant to not do so. Although Laura struggled, she was a very persistent student. In her semester-ending reflection, she wrote that, compared to other courses, in which she "was just memorizing formulas and procedures in order to pass the class" the class allowed her to learn the "meaningful part of math." Laura also stressed that she learned to understand many mathematical topics during the course. Laura is an example of a student for whom writing TLR logs may have been very fruitful. Writing them actually helped her to understand mathematics better.

Finally, in order to measure the reliability of the ratings, we calculated standard deviation. The four raters had the activity logs separately without discussing it among each other. Chart 4 shows the standard deviations resulting from the rating of each domain (CCK, SCK and PCK) in every weekly log by the four evaluators. The lowest standard deviation (0.66) obtained by the researchers corresponded to the week 2 activity log number 1 "W2 (L1)" in the SCK domain. Unfortunately, only three standard deviations showed in the chart were below 1.00. Additionally, CCK appears as the domain with the lowest standard deviation in every single activity log but the first one. PCK had the highest standard deviation average overall. Moreover, the average of the standard deviations of the three domains in all activity logs was 1.2.

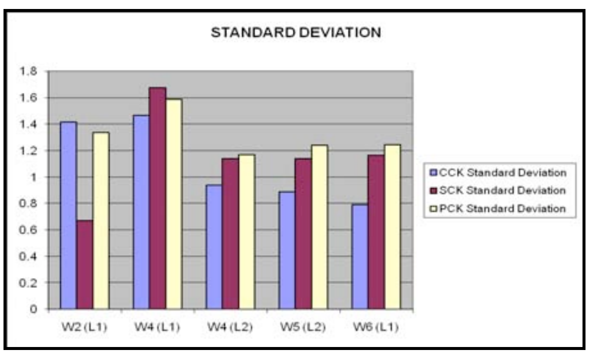

Chart 4. Standard deviations

Discussion

From the standard deviation data, we can conclude that it was necessary for raters to discuss and arrive at a consensus about what constitutes CCK, SCK and PCK. The process will make it possible to rate the rest of the log data. We have begun a second phase of research in which raters discuss their individual ratings with other raters. Raters pay attention to clarity and precision in symbolic representation, the use of examples, the use of visuals and a step by step presentation of a solution.

Still, we are able to comment on what our analysis so far can mean for training pre-service ELL teachers. Often this group may place an emphasis on teaching rules (procedural understanding) vs. teaching concepts. This aspect became relevant in the writing log where pre-service teachers discussed algorithms for operations on fractions. Still, we found that participants do develop MKT, but their learning trajectory is different.

On the one hand, writing TLR logs throughout the semester may allow students like Yolanda the experience and courage to develop mathematics discourse for teaching, particularly SCK and

PCK, which is very important for future teachers (Ball et al., 2008). Laura and Yolanda demonstrated consistently submissions medium to high levels of SCK and PCK. Their effort and level of detail were notable. However, sometimes their levels of CCK lead to some mistakes (e.g., omitted parentheses) that in turn lead to incorrect explanations. Writing TLR logs was especially beneficial for Yolanda. By the end of the semester, she was confident enough to go to the front of the class to propose a solution to a mathematics problem in English. While Laura's confidence never reached that point, in her reflection she notes that she learned from writing TLR logs.

On the other hand, the case of Betty is an interesting example because as a Mathematics and Science major she was expected to have high levels of CCK. Also, she was proficient enough in the second language to make verbal explanations in English in front of the class. However, her attitude about writing TLR logs was mostly negative. She regarded it as an unnecessary task in mathematics class. In her logs, she shows a preference for very concise, short descriptions. She prefers definitions from the book because they correctly represent the answers to the questions and, in her understanding are clearly explaining the meaning of the concepts. As she indicated in oral discussion, she doesn't understand the need for additional explanations or drawings. Thus, she submitted short logs, textbook definitions or paraphrased writing. She usually uses only traditional algorithms. She seemed to believe that no detailed explanations are necessary for these elementary concepts, and that everything is self-explanatory. When faced with some inconsistent example, she merely demonstrated that the result obtained was incorrect. Betty, as compared to Laura and Yolanda, may seem to receive no significant benefits from writing TRL logs. Moreover, it is evident that her SCK and PCK development is delayed because it is consistently evaluated at a low level. For students like Betty, it is important to make explicit the importance of unpacking mathematics for the purpose of teaching for her to develop SCK and PCK.

All mathematics students must become socialized in these mathematical discourse practices (Moschkovich, 2002; Gee, 1996; New London Group, 1996). We suggest that, to promote ELLs' equitable access to the discourse of mathematics for teaching, mathematics educators implement assessment strategies such as TLR logs. Writing logs has the potential to allow ELLs, such as the participants in this study, to develop MKT through writing. Writing mathematics discourse in TLR logs allows them time to plan and suit the message to the purpose of "unpacking" mathematics for teaching. Short & Fitzsimmons (2007) note that additional time for learning has been shown to benefit ELL students. Writing logs can be an opportunity to learn mathematics discourse, and, with proper guidance, mathematics student can learn to learn mathematics discourse. ELLs may require additional guidance that focuses on language choices (Schleppegrell, 2007). For instance, teachers can offer guidance focusing on 1) presenting a mathematical problem to be solved, 2) arranging mathematical symbols in patterned ways so that they encode a limited range of meanings, 3) accompanying the symbols with language to clarify the symbols using language to explain the problem-solving sequence, and 4) discussing the implications of the proposed solution. Finally, ELL writers can learn how to include visual images such as statistical graphs, geometric diagrams and other kinds of drawn or computer-generated visual displays, which illustrate the relationship in a space-time format (O'Halloran, 2005). Bringing attention to the discourse practices of mathematics can help support ELLs' development of mathematics.

Endnotes

1. Because pre-service ELL teachers were students in a college teacher preparation course, we use the term pre-service ELL teachers and 'students' to refer to the same group.
2. In this article we report on the first phase.

CROSS-SECTOR LEARNING: TRANSFORMING AN ELEMENTARY METHODS COURSE THROUGH COLLABORATION AND STANDARDS-BASED GRADING

Janet Hart Frost
Washington State University Spokane
frost@wsu.edu

Charles Brown
Ferris High School, Spokane WA
CharlesBr@SpokaneSchools.org

In this manuscript, we describe an unusual outcome of school-university collaboration use of standards-based grading (SBG) to transform the curriculum and assessment in an elementary mathematics methods course. This discussion includes a high school teacher's view of the value of SBG, a university professor's course changes, and students' response to the changes.

School-university collaboration has been a frequent area of study in teacher education research (e.g., Burton & Greher, 2007; Jeffrey & Polleck, 2010; McLaughlin & Black-Hawkins, 2007). However, few studies discuss the effect that this type of collaboration can have on the work of university faculty. In this paper, we discuss a collaboration of high school and college faculty focused on mathematics education that resulted in fundamental changes in an elementary preservice teacher (PST) mathematics methods course. The nature of the changes stemmed from the use of an assessment approach referred to as *standards-based grading* (SBG). In addition to bringing about change in assessment, the use of SBG had a transformative effect on course objectives and curriculum. The purpose of this paper is to demonstrate how the collaboration impacted the instructor's thinking about the course as well as to suggest the value of SBG in college-level courses.

Throughout the time that Janet taught her methods course, she was also a planner and facilitator of a professional development project that combined high school and college mathematics faculty (Frost, Coomes, & Lindeblad, 2009). During the project, a local large urban high school had decided to institute SBG as part of its district's consideration of future SBG adoption. Some of the teachers in the project and their colleagues were early initiators of this approach. Janet's conversations with a project participant and his colleague, Charlie, both early users, exposed her to the concept and rationale behind it. We begin this paper with Charlie's perspective on SBG as a theoretical framework before going on to Janet's discussion of the research method and transformation of her elementary mathematics methods course.

Theoretical Framework

After teaching high school for more than 25 years, I concluded that traditional grading had so little correlation with student understanding that I had to change. The old system of points, tests, quizzes, homework, and penalties created a game that some students learned to play even though their knowledge of math was limited. I'm fairly certain that my students who earned perfect scores knew some math, and those who earned zeros knew little math, but everyone in between remained a mystery. Searching for a more meaningful grading system led me to SBG.

Finding a consistent definition for SBG is a difficult task. The U.S. Department of Education, many individual states, and several prominent authors each have definitions of their own (e.g., Marzano, 2000; O'Connor, 2002; Popham, 2008; Tomlinson & McTighe, 2006; U.S. Department of Education, n.d.). In this section, I outline the parts of definitions consistent with my belief about what grades should mean, citing the sources that helped me to develop these beliefs.

Two main principles appear in the literature concerning effective grading practices (Marzano, 2000; O'Connor, 2002; Popham, 2008; Tomlinson & McTighe, 2006). The first principle is that achievement must be the only determining factor in assigning grades. The second is that grading practices should facilitate learning. From these two principles many characteristics emerge which help identify what I mean by SBG.

In order for grades to reflect achievement, most parts of traditional grading must be eliminated. Assignments, penalties for late work, extra credit, and punishment for inappropriate behavior have no place in effective grading practices (O'Connor, 2002). Summative assessments must be clear indicators of achievement towards pre-established standards (Marzano, 2000; O'Connor, 2002; Tomlinson & McTighe, 2006). Because grades must be an indicator of academic achievement, clear standards need to be established to determine how achievement will be measured. Changing to a SBG system requires teachers to develop the standards and the means to assess those standards.

This leads directly to the second principle. Having standards and the means to measure progress towards them allows teachers to assess throughout the unit. These formative assessments inform both the teacher and the learner on how to proceed. In other words, a teacher looking at the results of the formative assessments can gauge both the class and individuals' progress towards the standard. This powerful source of information helps guide differentiated instruction (Black, Harrison, Lee, Marshall, & Wiliam, 2003; Tomlinson & McTighe, 2006). Students can learn to use these formative assessments to plan for their own success as well.

With traditional grading, early quizzes often discourage students because these points always remain a part of their grades. Early failure leads to disillusionment and belief that the student is incapable of learning. When grades are used as a guide to instruction, no penalties arise from early misunderstandings. Instead, only the most recent assessments are used to determine a student's final grade.

Context and Methods

Context

The context for this qualitative study was formed by three components: the nature of the cross-sector collaboration, discussed above, that occurred while Janet was reconsidering her methods course design, the nature of the program in which the methods course occurred, and some specific aspects of the previous course design and grading approach that prompted a desire for change. Janet explains the latter two components below.

PST program. My methods course was part of a Masters in Teaching [MIT] program designed for PSTs who had earned a non-education baccalaureate degree and wanted to complete a short and intense program that would result in a teaching credential and a master's degree. In this program, PSTs did not take a mathematics content course. During the time they took the mathematics methods course, they were also taking methods courses in science, social studies, and literacy. The group of courses was taught in an 8-week session, with students attending each course two times per week.

Dissatisfaction with course design and grading approaches. I had several concerns about the PST course design. Many of the PSTs came to the course with low content understanding and mathematical confidence. This fact seemed to hinder them from understanding the methods being taught – they focused on the content, but complained that they were not learning enough about methods. As I tried to bolster PSTs' mathematics content understanding alongside the methods study I felt that I was trying to cover too much material in a short time, thereby only offering shallow coverage of the ideas.

In the course, I used traditional grading policies that allotted certain percentages to each topic and to student participation. However, I was concerned that students were ill prepared to master all of the ideas covered, due to the short course length and their heavy course load. For this reason, my grading was often lenient, resulting in PSTs receiving inflated grades that indicated higher levels of understanding than they had actually demonstrated. Yet, as Charlie discussed, the reverse could also be true. If a PST was late in submitting several assignment of high quality, the policy of taking points off for late submissions could result in grades that were lower than the level of mastery shown.

Method and Mode of Inquiry

This study was conducted as a combination of case study and action research. I regarded the PSTs and myself as participants. Data collected included documentations of the changes initiated over time, as indicated in course materials such as syllabi, assignments, and rubrics, and PSTs' response to these changes, as shown through course work and evaluations conducted twice during each course. My reflections were used as an additional data source on the process of making the changes.

Results

In this section, I explain several aspects of the changes made in my methods course, relating these changes to the cross-sector collaboration and the use of SBG. Course content changes and student comments in 2008 and 2009 are described in the first section, followed by the changes in grading practices during the same time period. These sections are accompanied by descriptions of the cross-sector collaboration that influenced my perspective. The last section addresses the course content and grading changes made in 2010.

2008-2009 Course Content and Schedule Changes

Course content. In order to address about PSTs' lack of mathematics content understanding, I increased time for content study and assessment. I attempted to cover the following mathematical content both years:

- Whole numbers, including number sense, place value, operations, facts, computation, and estimation
- Fractions/decimals/percents/proportional reasoning, including number sense, operations and computation, estimation, and conversions
- Geometry
- Algebra and algebraic thinking
- Data analysis/statistics, probability
- Integers, exponents, real numbers and other number types

It was not unusual for at least one of the topics to be dropped due to additional time needed for topics that students found difficult, such as fractions and geometry.

Methods topics focused on the NCTM (2000) and state process standards, including problem solving, reasoning and proof, communication, connections, and multiple representations, with brief attention given to technology and assessment. Students were asked to complete two lesson plans, teach "minilessons" in class, analyze a textbook unit in comparison to the process standards, and take tests on mathematics content.

Schedule changes. In 2008 and 2009, I increased the length of the course in order to cover the mathematics content and methods. On course evaluations, both positive comments and recommendations for improvement seemed to indicate that PSTs believed the mathematics content (assessed with tests), rather than the methods (assessed with lesson plans and curriculum analysis), was the most important aspect of the class. Some comments seem to indicate that the PSTs believed the tests were the only important assessment.

Sample positive comments:

- This course is great for deepening my understanding of basic mathematical concepts. I feel challenged in areas where I thought I was confident and the way I think about math has completely expanded.
- Open note tests were useful – took the pressure off and made me study more than I would have otherwise.

Sample recommendations for improvement

- More time for tests, focus only on what we are being assessed on because we don't have time to spend on other things… we have spent time on other things that were not related to what we will be tested on.
- I would suggest maybe allowing for more time on fractions and number concepts if possible.

Some of the recommendations also indicated that the PSTs felt the coverage of material was too fast.

- I feel like we rushed through a lot of the material to fit it all in and disregard whether we actually have a good understanding of it before we see it on the test. I think we need to take more time on some things and get rid of some things (like videos) that don't necessarily help us become better teachers.
- We go so fast, I do not feel I can fully master what we are learning.

I studied these comments, recognizing that the increased time was still insufficient to do a complete study of the mathematics content that PSTs would need to know. In conversations with my colleagues, I also learned that the additional course time could not continue, since the program could not include extended time for all the subject areas. Furthermore, more than half of the students earned lower scores on lesson plans and other opportunities to demonstrate understanding of the methods than they earned on math content assessments. This outcome showed the need for more focus on methods.

2009 Standards-Based Grading (SBG) Initiation

As described above, I had been concerned about grade inflation in my course but was unable to find ways to maintain a supportive atmosphere that also included high expectations and assessments that would indicate students' mastery levels. In 2008, student difficulties brought the issue of fair assessment and grading to the fore. As described above, a student's failure to submit work on time, due to family and work responsibilities, would have resulted in a grade far lower than his actual level of understanding. I regarded the situation as a dilemma – how could assessment be devised that would reflect the student's true level of mastery while still holding him accountable for prompt submission of assignments?

Conversations with high school teachers had led me to awareness of SBG. When the dilemma presented itself, I initiated conversations about the issues in my course and the use of SBG with one of the high school teachers in the professional development project and Charlie, a colleague of that teacher. I made the decision to implement SBG, focused solely on achievement of the learning targets for the course. Student disposition issues would be addressed through individual meetings with students to discuss issues that arose and strategies for addressing these issues.

The first use of SBG in the methods course occurred in 2009. The syllabus description of grading practices is shown below.

2009 Grading

Description	Score
Student demonstrates full and independent mastery of the objective.	4
Student demonstrates full mastery but has minor errors or requires some support or assistance to do so.	3
Student has significant gaps in mastery of the standard but shows mastery of most main ideas.	2
Student has significant gaps in mastery of the standard, including mastery of the main ideas.	1
Student did not submit work.	0
Your final grade will correspond with your final average across all of the competency areas: 4 = A, 3 = B, 2 = C, 1 = D. Please note assignment descriptions regarding fluidity of scores – in most cases, you will have more than one opportunity to demonstrate mastery. Your final score in each area is the score that will be used to determine your grade.	

Table 2. 2009 grading description

As described above, students were given multiple opportunities to demonstrate mastery of each learning target. If their assessed level of understanding increased, the older score was dropped in favor of the new score. If the new score was lower than a prior score on that learning target, it was averaged with the higher score. These scores were converted to grades only at the end of the course, so students could work to improve their scores without penalty until that time.

The use of SBG also required changes in rubrics used to score students. Samples of 2008 and 2009 rubrics are shown to illustrate the changes made in the first year of SBG.

2008 Lesson Plan Rubric

Lesson Plan #1 Points: Components and organization (6 points); detail and clarity of explanation (6 points); lesson plan represents activity accurately or summarizes created activity (6 points); presentation (2 points)

Lesson Plan #2 Points: Appropriate lesson *type*: consistent with NCTM principles and standards, current learning theory, appropriate mathematics methods as discussed in text and presentations, appropriate for identified grade level and good fit with unit plan (9 points); all lesson plan components included and organized appropriately (9 points); explanation of components is detailed and clear, all aspects of each component addressed (9 points); presentation (3 points)

2009 Lesson Plan Rubric

Lesson Plan Rubric	Surpasses Expectations	Meets Expectations	Below Expectations
Learning Targets (5 points)	All learning targets addressed in detail and with clear alignment. Learning targets are closely connected to previous learning experiences.	Instructional plan purpose, state learning targets, and content objectives are aligned (4 pts); previous experience explained (1 pt).	Aspects of learning targets not identified, unclear, or not aligned with each other
Assessment Strategies (5 points)	Multiple formative and/or summative assessment strategies and procedures for gathering evidence explained in detail and aligned with learning targets and experiences. Multiple learning modalities addressed in assessment plans. Ways of reducing bias explained.	Formative and/or summative assessment strategies are aligned with learning targets and experiences (2.5 pts). Procedure for gathering evidence for each student or for representative sample included (2.5 pts).	Assessment strategies incomplete or unclear OR lack of alignment between assessment strategy and learning targets OR inappropriate or no procedure for gathering evidence
Learning Experiences and Student Grouping (30 points)	Learning experiences match and complement the learning targets, include detailed plans for differentiation, remediation, and extension OR complex instruction with group-worthy tasks. Learning activities include detailed before, during, and after components that incorporate all 5 process standards. Includes culturally responsive, multicultural, interdisciplinary, and/or technology aspects.	Learning experiences aligned with learning targets (5 pts). Learning experiences include appropriate before, during, after components (10 points). Learning experiences utilize 3-4 process standards (problem solving, connections, communication, representation, and reasoning/proof) (15 points).	Lack of alignment between learning experiences and targets OR only 1-2 of before, during, and after components OR learning experiences utilize 2 or fewer process standards.
Student Voice (5 points)	Lesson plan provides multiple opportunities for student voice and student self-evaluation as well as opportunities to incorporate student voice into existing lesson plan.	Lesson plan includes at least one of student voice component.	Lesson plan includes no use of student voice techniques or Assessment For Learning strategies.
Organization and Conventions of Writing (5 points)	Proper structure and organization utilized. Writing conventions are appropriately addressed and all descriptions are clear. Fewer than 3 errors in writing mechanics.	Follows instructional plan format or very similar format (1 pt). Explanations clear (2 pts). Fewer than 8 errors in writing mechanics (2 pts).	Errors in following instructional plan format or missing important details from checklist. More than 8 errors in writing mechanics.

Table 3. 2009 lesson plan rubric

As I used the 2009 rubric, it was clear that additional changes needed to be made so that students could be assessed on each learning target individually, rather than on groups of targets.

In response to the use of SBG, some students offered positive comments in their evaluations, such as “Emphasized growth, not grades.” Others felt that the flexible scores and lack of concrete grades left them wondering where they stood. “I’m not a fan of the scoring of the course, because it makes me feel confused about where I stand.” This latter type of comment seemed to indicate that students were having difficulty making a cultural shift from a focus on getting an A to the new focus on demonstrating mastery of the learning targets.

2010 Changes

In this section, I describe the effect of introducing SBG and my subsequent reflection on the course content. This effect is demonstrated in the course content change and the 2010 lesson plan rubric. Student comments follow the description of the changes.

Course content and assessment changes. The changes enacted in the 2009 course and the ongoing detailed discussions with Charlie about his use of SBG prompted further improvements in 2010. As I recognized the need to delineate the individual learning targets and considered students’ scores and the impossibility of covering all of the mathematics content in the time available, it became clear that the focus of the course needed to shift. The curriculum needed to be much more narrow and focused with clearly defined learning targets solely related to learning methods, and the rubrics used to score the assignments needed to be more detailed and delineated.

The course content was changed to focus on the NCTM (2000) and state process standards, with additional discussion of levels of questioning and cognitive demand (Stein, Smith, Henningsen, & Silver, 2000), analysis of lessons that did or did not address the standards, revision of the lessons that did not, development and teaching of minilessons, and analysis of textbook units. PSTs were asked to identify the presence or absence of the process standards in commercial videos, their peers' minilessons, and the lesson plans they analyzed. Mathematics content was reduced to whole and rational number sense and operations, with a brief consideration of algebraic reasoning and geometry. This mathematics content was used as a context for considering the use of the process standards, rather than as an end in itself.

In the 2010 course, the 2009 grading description of the 0-4 scores was used. However, the lesson plan rubric was changed to separate out each component discussed in class.

2010 Lesson Plan Rubric
1. Process Standards Applications In lesson plan, student demonstrates at least three of the five process standards: a. Mathematical problem solving b. Reasoning and proof c. Mathematical communication d. Mathematical connections e. Mathematical representation
2. Standards and Learning Targets a. Learning targets, state standards, and learning activities are grade-appropriate. b. State standards, learning targets, objectives, and learning activities are all aligned. c. Class is informed about objectives/learning targets, including state standards.
3. Meaningful Learning a. Lesson is likely to be engaging for students. b. Learning activities are accessible to multiple skill levels c. Learning activities build meaningful in-depth conceptual mathematical knowledge and critical thinking ability, with appropriate cognitive demand. d. Learning activities address needs of all students, including those who struggle with the lesson or who are ready for more challenge. e. Lesson includes appropriate before, during, and after activities.

Table 4. 2010 lesson plan rubric

The change in the course content and rubrics had two types of positive effects. First, students could be assessed on delineated learning targets. By having specific information about their areas of strength and weakness, they could focus on making changes or asking for help in order to strengthen their demonstration of learning on the elusive targets. Second, I could immediately identify the areas of difficulty and adjust my plans to meet those needs.

2010 Student Comments

Student comments on the 2010 course indicated that the changes had many of the desired effects as well as pointing the way for further changes. Positive comments were more focused on the process standard of teaching through problem solving, which was a new idea for most students. They also recognized that the daily plans were often adjusted to meet the needs demonstrated in the assessments.

Sample positive comments:

- I liked the process grading. I think it gave us great opportunity to LEARN from our mistakes…. Janet was extremely helpful and understanding with our student needs.
- Going into depth about concepts really was useful. Observing and experiencing math lessons everyday gave concrete experiences and understanding of how to present lessons.

Recommendations for improvement also indicated PSTs' focus on methods and the desire to have more resources for and practice of lessons that utilized the methods taught.

- I would like more concrete examples of effective teaching. Janet was great at modeling practices but I would appreciate more reference materials.
- More in-class lessons without assessment so we can practice.

As a result of the student suggestions and my ongoing reflection, I plan to develop more opportunities for students to work collaboratively and individually designing and teaching lessons that reflect the process standards and high cognitive demand, as well as more in-depth study of teacher videos that model different ways of incorporating these ideas. Two additional areas of focus emerged from the assessment of PSTs' understanding. The first addition will be increased discussion of ways to engage students, since the PSTs did not express the same level of understanding of that idea as they did of the process standards and cognitive demand. The second addition will be analysis of student work, since PSTs have had little experience studying students' thinking and designing instruction to fit it.

Discussion

In an address to mathematics teacher educators, Jim Hiebert (2010, January) claimed that U. S. teacher education programs were failing to have significant effects on classroom teaching and learning. He suggested that varied and short teacher education programs cannot provide the critical mass of learning required to overcome PSTs' culturally developed beliefs about teaching. Therefore, teacher education programs should focus on helping PSTs become learners within the teaching context, rather than assuming the program can fully develop their teaching skills before they enter the classroom.

In this paper, we provide an example of how cross-sector collaboration and SBG led to new ideas about addressing issues in an elementary mathematics methods course, and ultimately the transformation of that course in a way that may address Hiebert's suggestion. The collaboration provided new perspectives: although often used in K-12, SBG was not used or discussed at the university level prior to Janet's work with two high school teachers and subsequent introduction of SBG in her course. This new perspective provided a possible solution to issues she had identified: use of SBG helped her to narrow and deepen her course content and it allowed more support for the process of learning, which PSTs noticed and appreciated. Thus, the changes made in this course indicate one aspect of course design – the use of SBG – that benefited Janet and her students. Janet gained insight and innovative ideas and the students gained a more effective curriculum and assessment system. When traditional grading practices are used, students – in this case PSTs – may not be treated as learners but as "knowers" by receiving summative grades that are factored into their final grade, rather than flexible scores that change as they demonstrate increasing mastery. SBG offered this kind of formative kind of assessment as well as providing input of how course content could be changed in response to PSTs work. At the same time, the principles and data from SBG informed Janet's instruction throughout the course, so she remained a learner as well. In this way, SBG had and will continue to transform the thinking and learning of Janet and her students, just as it did for Charlie in his high school teaching.

TEACHING TRIGONOMETRY: A DIRECTED LENGTH APPROACH

Joshua Hertel and Craig Cullen
Illinois State University
jtherte@ilstu.edu

This empirical study investigated the effects of an instructional sequence on pre-service secondary teachers' understanding of trigonometric functions. Guided by the APOS framework, we designed activities to promote a directed length interpretation of the six trigonometric functions using a dynamic geometry environment. Results of a paired t-test (two-tailed) showed a statistically significant difference in performance. Qualitative analysis of student work revealed a shift from ratio based strategies to directed length based strategies. Findings reveal the potential this method holds for transforming the teaching and learning of trigonometry.

Trigonometry is a subject that is highly valued. It has a long history as a component of the mathematics curriculum with methods reaching far back before the 20^{th} century. Trigonometry has appeared in both the Curriculum and Evaluation Standards (NCTM, 1989) and Principles and Standards for School Mathematics (NCTM, 2000). At the same time, it is also a subject that has been regarded as an important in domains outside of mathematics particularly those in science, technology, and engineering. Careers in physics, astronomy, computer graphics, optics, and many branches of engineering require an understanding of trigonometric functions and their application. Moreover, principles of trigonometry have a practical application in the work of carpenters, surveyors, architects, and navigators (Hoachlander, 1997). Despite its relevance, trigonometry continues to be a subject with which many students struggle (Blackett & Tall, 1991; Kendal & Stacey, 1998; Weber, 2005).

The modern approach to the subject, which considers both triangles and circles, is taught over a period of years as students progress from middle school to high school. Historically triangle trigonometry and circle trigonometry emerged from separate traditions and were developed for different purposes (Bressoud, 2010; Van Brummelen, 2009). Triangle trigonometry, which focuses on ratios between side lengths in a right triangle, has its origins in the surveying and measurement techniques used by the Babylonians and Egyptians. Circle trigonometry, which focuses on chords and their associated arcs, was developed by the Greeks in their study of the heavens. Anyone familiar with modern secondary mathematics will immediately recognize that these two approaches are visible in the predominant teaching methods, the ratio method and the unit circle method. There has been disagreement and debate over the use of these two methods since the “New Math” movement (Kendal & Stacey, 1998). Rather than choosing a side, we posit that both methods play an important role, laying the groundwork essential for building an understanding of trigonometric functions.

Framing the Problem

The study of trigonometry typically begins with a focus on the ratios formed by the sides of right triangles. This ratio method is effective for the purpose of solving right triangles and thus should hold its place in the curriculum (Kendal & Stacey, 1998). However, this method relies heavily on memorization (e.g., the mnemonic SOH-CAH-TOA) and computation. Using this method requires students to create nontrivial connections that pose many obstacles as they attempt to connect diagrams to numerical relationships and manipulate different ratios to determine side lengths (Blackett & Tall, 1991). In our opinion, the ratio method fosters a static interpretation of the trigonometric functions in which the value of a function for a given angle is related to a single right triangle rather than a family of triangles. Further, this method is limited to angles measuring less than 90° with particular attention on "special" right triangles (30°-60°-90° and 45°-45°-90°). Although this focus on specific angles is helpful in establishing benchmarks for comparison, it does not easily connect to an understanding of function.

The unit circle method, which defines sine and cosine as the coordinates of a point on the unit circle or as directed lengths, resolves a number of the issues with the ratio method. The domain in the unit circle method expands to include all real numbers. In addition, the method provides students with a straightforward way to compare the values of different angles by focusing on changes in directed lengths. This type of reasoning can also be used to identify the sign of the sine and cosine functions in each of the four quadrants without relying purely on memory. Unfortunately, this directed length interpretation is typically not extended beyond sine or cosine. Instead, there is often a focus on special angles (i.e., multiples of 30° or 45°) and reference triangles in order to help students see the connection between the quadrants. For many students and teachers, the remaining four trigonometric functions are interpreted as algebraic manipulations of sine and cosine. Thus, working with these four functions requires either reasoning about how they are related to the sine and cosine or recalling facts from memory.

Our research aims to help students build a robust and connected understanding of trigonometric functions and explores the role that dynamic geometry environments (DGEs) can play in its development. DGEs are one of the most widely used technologies in mathematics education. Many mathematics teachers and mathematics education researchers have focused their attention on the use of DGEs within the classroom. Designers of DGEs have stressed the central role that the software can play in linking geometry to other topics (Hohenwarter & Lavicza, 2007) by offering users a way to manipulate algebraic objects dynamically. We believe that DGEs may be one way to introduce a directed length interpretation and emphasize its connection to trigonometric functions.

Purpose

The purpose of this study was to develop an instructional sequence of trigonometric activities using a dynamic geometry environment and to analyze its influence on pre-service secondary teachers' understanding of trigonometric functions. These activities were designed to promote a directed length interpretation of the six trigonometric functions as functions that map one measurable quantity, angle, to another measurable quantity, directed length.

Research Questions

1) How can a dynamic geometry environment be used to develop pre-service secondary teachers' understanding of trigonometric functions?
2) How does an instructional sequence focused on a directed length interpretation of trigonometric functions influence the strategies used by pre-service teachers' when solving trigonometry problems?

Theoretical Lens

We used the APOS (action, process, object, schema) framework as a theoretical lens (Asiala et al., 1996). This theoretical perspective was built upon Piagetian ideas and designed for studying mathematical learning at the undergraduate level. According to this perspective,

> An individual's mathematical knowledge is her or his tendency to respond to perceived mathematical problem situations by reflecting on problems and their solutions in a social context and by constructing or reconstructing mathematical actions, processes and objects and organizing these in schemas to use in dealing with the situations. (p. 5)

Below we briefly discuss the four components – action, process, object, schema – and describe how we envision student responses on a single trigonometry comparison task from our assessment (Figure 1).

In the figure (below) line BC is tangent to circle A. How does the value of sin θ compare to the value of sec θ? (i.e., >, <, =) Explain your answer.

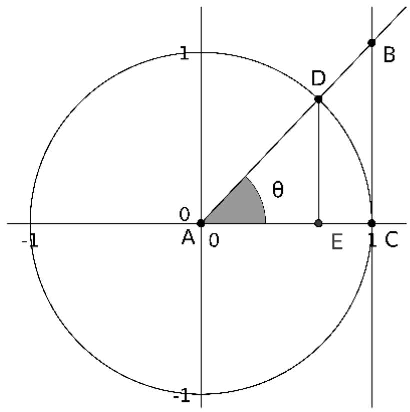

Figure 1. Comparison of sin θ and sec θ task

A student with an action conception of trigonometric functions would require external cues to solve this problem. These cues could include things such as using sine = opposite/hypotenuse and secant = 1/cosine. A student with this conception might also use an estimation strategy based on a benchmark (e.g., theta appears close to 60°) or a construction (e.g., drawing in the segments that correspond to sine and cosine). In any case, the student would need to write this information down and reason through the problem externally.

Following the APOS framework, the shift from action to process conception occurs when a student internalizes what were previously external cues. Thus, we anticipate that a student with a process conception of trigonometric functions would have a solution strategy similar to that of a student with an action conception. However, the student with a process conception would be able to work through the problem internally without needing external cues.

We believe that a student with an object conception of these two trigonometric functions would be able to approach this question from multiple perspectives. They would be able to reason about the secant without needing to compute a value or imagine the process of division. A student with an object conception might interpret the sine and the secant as directed lengths and conclude that secant is greater than the sine based on a mental image or use their knowledge of the range of the trigonometric functions to determine secant is larger (e.g., $\sec\theta > \sin\theta$ because $\sin\theta \leq 1$ and $\sec\theta \geq 1$). It is important to note that distinguishing between a process conception and an object conception is difficult without asking the student to explain his or her reasoning.

A schema is formed by the organization of actions, processes, objects, or a combination of these ideas. Based on this definition, schemas can be built by individuals holding any of the different conceptions. For example, a student might construct a schema using their action conception of sine and secant. They could then use this schema to estimate the values of sine and secant for the task in Figure 1. A student who had constructed a schema using an object conception would be able to respond quickly and efficiently to the sample task. They would have several methods for working through the problem and be able to identify the connections between them. For example, they might view the sine and secant as directed lengths while imagining the graphs of the functions. We see our current work as helping students move from action conceptions of trigonometric functions to process conceptions and aiding them in the development of rich and connected schema.

Methodology

The participants for this study (n=23) were enrolled at a medium sized Midwestern university in the United States. All participants were enrolled in a course that focused on the use of technology tools for the secondary school level. One student was a practicing teacher while the rest were pre-service secondary mathematics teachers. The course met once a week for three hours and was co-taught by the researchers. Three lessons dealt specifically with trigonometry; however, the course dealt with a variety of different mathematical topics. All students received the same experimental instruction.

Design of the Assessment Instrument

Following the APOS framework, we first analyzed what it meant to understand the concept of a trigonometric function. This was based primarily on our own understanding of trigonometric functions as well as relevant research. We then designed a paper-pencil instrument to assess students' knowledge of a directed length interpretation. The instrument included: a) one trigonometric identity question; b) three questions that compared the value of different trigonometric functions for a given angle (e.g., Figure 1); c) one question analyzing how increasing an angle changed the value of a trigonometric function; and, d) two questions that compared the magnitude of two trigonometric functions in the first quadrant. The overall aim of the assessment instrument was to determine if there were any changes in student reasoning about trigonometric functions as a result of engagement in the experimental instruction.

Design of Experimental Instruction

Our analysis of the concept of a trigonometric function also guided the design of our experimental instruction. We designed a sequence of instruction consisting of several different explorations within a DGE. The sessions were sequenced to first introduce the directed length interpretation and then connect this interpretation to the graphs of the trigonometric functions. Our goal was to engage students in activities that explored interpretations of the six trigonometric functions as functions that mapped angle measures to directed lengths in the coordinate plane. We briefly discuss the first session below.

The first session began with an activity exploring the “chord function.” This activity served two purposes. First, to connect to the historical origins of the word sine as the mistranslation of the word “chord” (Bressoud, 2010). Second, to demonstrate how the concept of function could be used to explore the relationship between angle measure and directed length. We first constructed a unit circle with central angle BAC (with point B fixed) and chord CD as shown in Figure 2. Students then considered how changing the size of angle BAC affected the directed length of segment CD. We then had the students reason about what it would look like if they were to map the angle measure to a point, D', on the x-axis and construct a copy of CD on D' with point D mapped to D'. Connecting the copies resulted in a rough sketch of the function y =

2 sin *x* (Figure 2). This lead to a discussion of the historic connections between the words "chord" and "sine." Focus then shifted to the standard unit circle representation of sine where half of the directed length of the chord CD is the value of the sine of angle BAC.

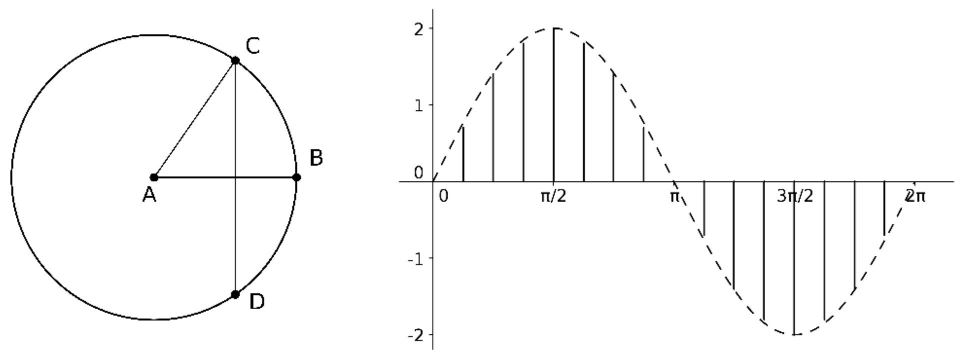

Figure 2. The chord function

Subsequent sessions explored similar constructions and mappings with the other trigonometric functions. Sessions began in the classroom and then transitioned to the computer lab where each student constructed his or her own sketch of the problem(s) using dynamic geometry software. Group work and collaboration were encouraged.

Procedure

Students completed the pre-test prior to the first session on trigonometry. The instructional sequence then took place over three consecutive class periods. Two weeks after the third session, the post-test was administered. Neither test was announced in advance. Students were given 25 minutes to complete each test and were not allowed a calculator. All questions were assigned a value of one point and the number of correct answers was totaled to obtain a score for each student. The highest possible score was seven. A two-tailed dependent t-test was used to test for significant change.

Written work was analyzed using a constant comparative method (Merriam, 1998) to identify and categorize solution strategies. One question was omitted from this analysis because it was multiple choice and did not include space for written work. Responses were analyzed and clustered into progressively more inclusive categories. If a response included parts of a strategy (either incorrect or correct) it was coded as having shown that strategy. Consequently, some responses received multiple codes because they exhibited more than one strategy (this occurred only on the post-test questions). This coding process resulted in the identification of three different solution strategies - ratio, directed length, graph - and a collection of answers that had no identifiable strategy.

Ratio based strategies (Figure 3) involved the use of ratios and mnemonic devices (SOH-CAH-TOA). These responses typically had specific ratios in their solution or cited facts (e.g., sine is positive in first quadrant). Also common were case based arguments in which a specific example was used to justify a more generalized statement.

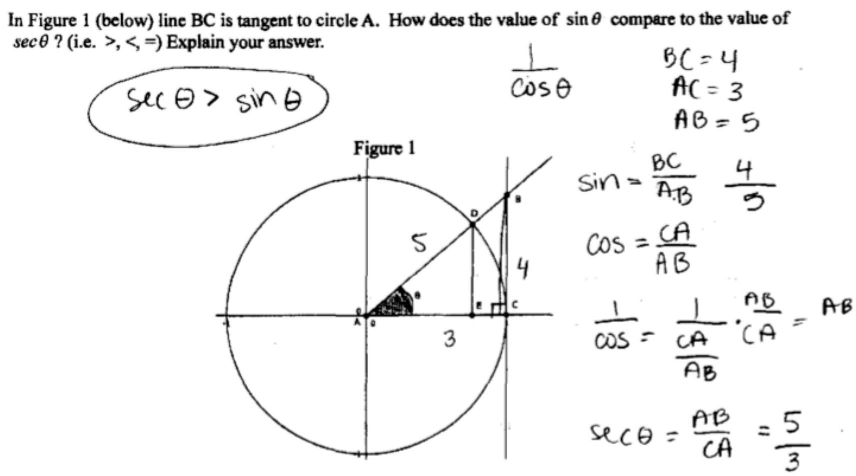

Figure 3. Sample ratio strategy

Figure 4 displays an example of a directed length strategy. These responses typically included the construction and labeling of segments corresponding to the value of a trigonometric function for a given angle. In some cases, discussion of the length of the segments followed.

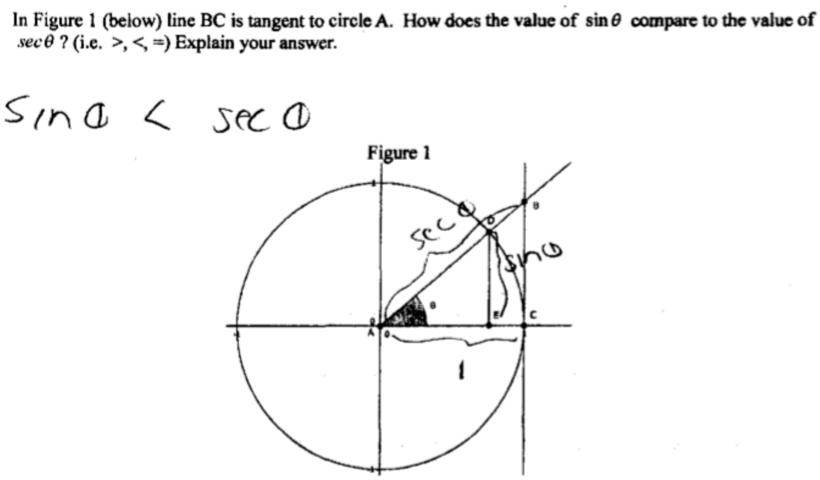

Figure 4. Sample directed length strategy

Graph based strategies included a graph of a trigonometric function in the response. Responses were coded as having no identifiable strategy when one could not be determined from the written work or no work was presented other than the solution.

Results

The mean of the pre-test scores was 2.26 with a standard deviation of 1.74. The mean of the post-test scores was 4.17 with a standard deviation of 1.92. Results of the two-tailed dependent t-test indicated that there was a statistically significant change in scores from pre-test to post-test $t(22) = 7.19$, $p < .0001$. The calculated effect size was $d = 1.04$. Results of the qualitative analysis of solution strategies are summarized in Table 1.

Strategy	Number of Instances (Number of Times Correct)						Total	% Correct
Pre-Test	Q1	Q2	Q3	Q4	Q5	Q6		
Ratio	11(7)	21(8)	21(10)	16(4)	15(4)	15(3)	99	36.36%
Directed Length	0	1(1)	1(0)	1(1)	0	0	3	66.67%
Graph	0	0	0	0	0	0	0	
No Strategy	12(5)	1(0)	1(0)	6(0)	8(0)	8(0)	36	13.89%
Post-Test								
Ratio	11(9)	6(3)	5(1)	6(4)	6(2)	6(2)	40	52.5%
Directed Length	9(9)	19(17)	18(11)	18(12)	6(5)	7(7)	77	79.22%
Graph	0	0	0	1(1)	2(1)	2(0)	5	40%
No Strategy	3(2)	0	2(0)	2(0)	8(2)	8(1)	23	21.74%

Table 1. Summary of pre-test and post-test strategies

Discussion

We attribute the statistically significant growth from pre-test to post-test to both the directed length interpretation as well as the use of a dynamic geometry environment. The DGE provides unique access to the directed length interpretation by allowing students to construct figures, identify specific attributes, quantify these attributes, and analyze the relationship between these quantities by graphing them in a coordinate plane. Thus, the connection between directed length and the graph of a trigonometric function can be easily made within a DGE. We believe this approach is useful in addressing many of the difficulties students have with trigonometry concepts (Blackett & Tall, 1991; Kendal & Stacey, 1998; Weber, 2005) by providing them with a flexible model for reasoning about trigonometric functions. Hence, this study demonstrates how DGEs can be used to foster student learning and shift the focus of trigonometric instruction.

Our qualitative analysis, presented in Table 1, resulted in two findings: 1) substantial changes in student strategy use and 2) increases in effectiveness across the three identified strategies. The ratio strategy represented 99 out of 138 (72%) of all coded responses on the pre-test and 40 out of 145 (28%) on the post-test. The direct length strategy, in comparison, represented 3 out of 138 (2%) of all coded solutions on the pre-test and 77 out of 145 (53%) on the post-test. These results show that many students who used ratio strategies on the pre-test transitioned to more flexible strategies using ratios and directed lengths on the post-test. In addition, the percentage of correct responses across all three strategies (ratio, directed length, graph) increased from pre-test to post-test. These numbers indicate that students improved in their ability to use strategies effectively. Together these results show that students not only understood the directed length concept, but also integrated it into their trigonometric schema.

Based on our analysis of the written work we are confident that the majority of the students have, at least, an action conception of trigonometric functions. Anything beyond this is speculation due to the nature of our assessment. What is clear, however, is that the instructional sequence aided students in developing ways to reason about these trigonometric functions on the post-test that were different from the ways they reasoned about them on the pre-test. This, in turn, lead to a significant improvement in performance.

Our goal is to assist pre-service teachers in developing rich and connected schema that contain multiple representations and interpretations of trigonometric functions. We believe that the action conception exhibited by the majority of pre-service teachers can develop into a process or object conception given further time and interaction with the directed length interpretation. In our opinion, this interpretation lends itself to a process (and later object) conception of trigonometric functions by providing students with tools to reason about the functions as *things* themselves instead of the *result* of memorized facts or algebraic manipulations. Future research should examine the benefits and drawbacks of this interpretation, determine its utility in the teaching and learning of trigonometry to different students at different levels, and explore the role that DGEs can play in this process. This will require the development of assessment tools to probe student thinking to establish if either a process or object conception is present. We believe the directed length interpretation has the potential to profoundly impact both the learning and teaching of trigonometry – embodying the idea of transformative mathematics.

IDENTITY DEVELOPMENT OF PRESERVICE ELEMENTARY MATHEMATICS TEACHERS IN STANDARDS-BASED REFORM PEDAGOGY AND ITS CONTRIBUTING FACTORS

Hyun Jung Kang
Arizona State University
Hyun.kang@asu.edu

The current study is part of an ongoing, longitudinal study of prospective teachers' identity development as a mathematics teacher. Drawing on case study of five teacher candidates, this paper investigated how their professional identity has developed over time and what the contributing factors of such changes. Findings indicated that most of student teachers entered the program with traditional perception of math teachers and it evolved endorsing more of a reform model. Prospective teachers' prior experiences didn't seem to be a great factor that contributed to change. The university instructor appeared to be the greatest influence and their mentor's teaching practices has a greater potential for modifying and re-constructing student teachers' professional identity and their teaching practices.

Preservice teachers enter teacher education programs with early experiences in mathematics and they have perceptions of themselves as mathematics learners and teachers (Drake, 2006). While participating in their university methods program, under the mathematics reform movement, prospective teachers tend to be exposed to reform-oriented teaching models. Prospective teachers need to understand what it is like to participate in the figured world of reform pedagogy, learn models of identities of reform pedagogy, and negotiate new constructions of mathematics (Horn, Nolen, Ward, & Campbell, 2008). They are constantly transitioning between their current model of what a teacher is, and practicing what their identity as a teacher may be through student teaching, as well as learning how teaching is done through modeling by a mentor. When they eventually transition into their own career, teachers are constantly constructing and reconstructing their identities as math teachers through the negotiating within the community of practice.

A recent study (Pressini et al, 2009) found student teachers' norms and expectations about mathematics teaching practices were fundamentally different depending up on whether they saw themselves as teachers or students. Other studies emphasize that having a clear self-image as a teacher is critical to translate what they've learned from their teacher education program into real classroom practice (Bullough, 1992; Kagan 1992; Mewborn,1999). These studies document that prospective teachers struggle with their teaching practices when they don't have a secure self-image of themselves as teachers. Whether they see themselves as a traditional mathematics teacher (image from early experiences) or if they endorse a modern model of teaching (provided by teacher education programs) their teaching practice will look fundamentally different.

Despite the importance of a teacher candidate's identity, we know little from the literatures about how teacher candidates construct their professional identity within complex contexts. Specifically, little emphasis was placed how mentoring potential teachers contributes to their construction of their teaching identity. In addition, there are few longitudinal studies that examine the effects of preparation of teachers over time. Although a teacher's transition is a continuous trajectory of learning and growing, the research is rather fragmented and isolated.

In summary, my study explores how novice teachers construct their professional identity of themselves as mathematics teachers as they move from their earlier perceptions of themselves as teachers to newer models of teachers within a longitudinal framework. Specifically, their struggle to develop their self-image as a mathematics teacher between two competing models is explored.

Theoretical perspective

I adopted a situative perspective because this perspective allows me to focus on a contextualized individual interacting in particular settings that have been shaped by social variables. Relying on Eynedy (2006) and Wenger (1998), I interpreted the identity as identity is an on-going process and a persons' identity is shaped and negotiated through everyday activities including their personal history. It means novice teacher's prior beliefs, knowledge, and experiences are important factors of identity construction. In specific, this study focused on two constructs that are particularly relevant to teachers' instructional practice: professional identity and the identity developing process. The construction of professional identity here means conception of how one defines oneself as a mathematics teacher in a negotiation with other participants in the same community. How relationships in this community develop is important because student teachers experience various relationships as they move along their path of learning how to teach.

In order to understand identity construction, novice teachers' personal history involving their prior experiences, relationship with cooperating teachers, and mentor's teaching practice were explored. All of these factors have been considered to contribute to a teacher's identity development. The following questions will be addressed,

1. What are the changes experienced by a prospective teacher during his or her identity development while transitioning from a university method program to their student teaching?
2. What are the critical experiences, knowledge and skills that contribute to the change?
3. How does the context of a teacher education program impact the identities and teaching practices?

Methods

The current study is part of an ongoing, longitudinal study of prospective teachers' identity development as a mathematics teacher. Drawing on the strengths of qualitative research (Merriam, 1998; Stake, 1995; Yin, 1984) case study method is utilized. The case study method will highlight the complex social context that attributes to development of teacher identity in a real-world setting.

Participants include five students enrolled in an undergraduate mathematics course that was offered by a state university. One of the participants was male and the remaining four were female. The investigator has followed beginning elementary school teachers from their last year of their mathematics method courses into their student teaching period, and will continue to follow them into their first year of full-time teaching. The method course designed to have students experience principles and ideas from NCTM standards. Within that framework, instructor specifically focused on students' thinking on learning and teaching mathematics.

Data collection for this case study consisted of interviews with student-teachers and their mentors, as well as their journals and direct classroom observations. During the method course, I observed all the classes for 16 weeks between August and December 2009, and wrote an observation field note each time to record how teacher candidates participated in the classroom. During the student teaching period between January and May 2010, I observed five participants' mathematics classrooms once a week. I interviewed all five participants regarding their prior math related experiences and experiences about their current teacher education program. All the interviews were audio-recorded and transcribed for analysis.

Analysis

Pattern coding from Miles and Huberman (1994) was utilized. Pattern matching of the collected evidence from field note observations and interview transcripts was conducted. Common themes were categorized, such as, prior school experiences, experiences of method courses, mentor relationships, impact of field experiences, their teaching philosophy and their current understanding of teaching practices (see table 1).

Table 1 : Analysis theme of interview and observation

Collected data	How does this relate to identity construction
<Interview> ►Prior experience -mathematical background -teacher education program	• Story telling is a part of identity (Drake, 2006), • personal history is important on identity construction (Wenger,1998) • How this program influence participant's prior belief of teaching mathematics
►Current social context - relationship with mentor and mentor's teaching practice	• How their identity is practiced by the master teacher (Wenger, 1985) • How they interpret/evaluate master's teaching practice? How is this model of teaching close to their image of mathematics teacher they want to be? (Brown et al, 1999) • degree of autonomy and participation is important (Wenger, 1985) • what they learn during this experiences
<Classroom Observation> ►Teaching Practice	• How does student teachers' teaching mathematics look compared to their mentor's teaching? • What is the basis of the major resources that student teachers use to teach mathematics? • How is their teaching practice close to their image of mathematics teacher they want to be?

The Survey of Professional Identity as Mathematics Teacher Survey

In order to grasp the overall view of five pre-service teachers' professional identity as mathematics teachers, participants were asked to do a quick survey of how they see themselves between two different teaching images: 1) traditional and 2) reform on a scale from 1to 10 where 1indicates endorsing more of a traditional model and 10 indicates endorsing more of a reform model. Before asking this self-reported survey interviewer discussed what the participants think about traditional and reform based image of teaching practice. This scale informed how these teacher candidates interpreted two different teaching images of modeled teachers (the same university instructor and different mentors) and how they viewed themselves between these models. The scale is reviewed in the following section.

Teachers from own experiences in general
Method course instructor
Yourself (at the end of field experience)
Current mentor teacher
Ideal goal (when full-time teaching)

1 2 3 4 5 6 7 8 9 10
Traditional Reform

Mentor Relationship

Under the mentor relationship, two areas were focused; student teacher's autonomy level and opportunity to teach mathematics. I considered autonomy level is important because even though they wanted to adopt newly learned method from teacher education program they are may not allowed using them and instead, they are supposed to follow mentor's teaching practice whether they like it or not. Student teachers' autonomy level was categorized as high, medium and low based on how much responsibility they had to prepare their lesson. The definition of each category is the following.

• High autonomy: As long as it covers standards mentor teacher let student teacher have full responsibility of preparing and teaching materials. Mentor's feedback is supplementary. Student teachers take over the math class from the beginning of student teaching and more than 90 % of observation time, student teachers teach the whole math class.

• Medium autonomy: Mentor and student teacher plan lesson together and teaching practices are integrated. Mentor teacher lead the math lesson and student teachers' participation is gradually increased.

• Low autonomy: Mentor teachers have full responsibility of planning and curriculum and students teachers adopt them. Student teachers take over the math class at the end of semester and their role in teaching math is supplementary. Less than 20 % of observation times, student teachers teach the whole math lesson.

Classroom Observation (Student Teacher's Teaching Practice)

During the classroom observation period, the major focus was placed on mentor's teaching practice and student teaching practice. Observation teaching practice is critical in this study because it provides what type of teaching practice mentor modeled to their student teachers and how student teachers adopt such model of teaching. In addition, it illustrates understanding of how their identity as a math teacher is practiced in a real classroom situation, student teacher's decision making, what resources they utilize for their teaching, their teaching pedagogy between two models (reform and traditional) compared to their beliefs about teaching mathematics.

Result

Table 2 shows the survey result of overall view of five pre-service teachers' professional identity as mathematics teachers.

Table 2 *Results From a Survey of Teacher Image*

Survey questions	*Participant ratings				
	Meg	Mike	Vicky	Kerry	Jackie
Prior math experiences 1) Successful in math? 2) Confident teaching math	1) Yes 1) Yes	1)Yes 2)Yes	1) No 2) No	1) Yes 2) Yes	1)No 2)No
How do you see math teachers from your own school experiences in general	5	3	2	6	3
How do you see the instructor of university method course?	10	8	9	6	10
How do you position your mentor as a mathematics teacher?	3	7	5	9	8
How do you position yourself as a mathematics teacher?	7	4	4	8	5
What is your ideal goal to reach when you move into your own career?	9	6	6	9	10

Note: All of the participant names are pseudonym and they are using the rating scale from above.

In essence, the results of this survey indicate that most of the participants challenged their initial beliefs about being mathematics teacher throughout their teacher education program, and their teacher identity evolved. However, one participant didn't endorse the reform pedagogy model as much as the other participants did.

Similar to a study conducted by Ball (1990), the majority of the participants in this study reported traditional experiences concerning their own school's mathematics teacher (M=3.8). All of participants agreed in the interview that the university instructor's teaching practice challenged their earlier image of mathematics teacher. When they moved to field experiences, 3 student teachers reported that their mentor's teaching was closer to reform pedagogy and the remaining two considered their mentor's teaching practices as more traditional. Compared to their mentor's teaching practices, all but Meg, considered themselves as being less reform pedagogy type teachers than their mentors. Meg said during the interview that she considered her mentor's teaching as more traditional than herself. When asked their ideal goal of what their self-image as a teacher might look like, most of the teacher candidates (80%) but Meg wanted to endorse more of a reform pedagogy style than what their mentors do in the classroom.

To better understand teacher candidates' identity as a mathematics teacher it is necessary to investigate relationship with mentor's teaching, how they teach mathematics and student teachers' autonomy level. The following table is the brief summary of participant's overall experiences of student teaching.

Table 3: Overall summary of student teacher's experiences during student teaching

	Meg	Mike	Vicky	Kerry	Jackie
Confidence in math	Yes	Yes	No	Yes	No
Success in math	Yes	Yes	No	Yes	No
Mentor type	traditional	traditional	reform	reform	reform
Self image of themselves	reform	traditional	traditional	reform	between
Grade level	2^{nd}	5^{th}	5^{th}	5^{th}	5^{th}
Autonomy level	High	High	Low	Medium	Low
Opportunity of Teaching mathematics	Take over math class from the beginning	Take over math class from the beginning	Take over at the end, relatively less chance compared to other participants	Gradually take over	Take over at the end, relatively less chance compared to other participants

In sum, here is a summary of each student's professional identity development.

<u>Meg</u>: she was confident in mathematics and she wanted to become a very reform based teacher (scale 9). Her mentor teacher was holding a traditional teaching pedagogy. But, as her autonomy level was high she was able to practice her identity as a mathematics teacher as she wanted to be. It is very often observed that the student teacher utilized materials from university program, which she evaluated as very reform, and focused on group work, discussions, games and sharing.

<u>Mike</u>: He, similar to Katie, was confident in mathematics and he evaluated that his mentor teacher hold a traditional view of teaching mathematics. However, from his own experiences, he adopted more traditional way of teaching than reform pedagogy. Thus, rather than taking reform pedagogy his goal of teaching practice was in the middle of traditional and reform. During the observation time, his teaching mathematics seems to closer to the traditional way such as working on worksheets all the time, time task, procedure oriented, and teacher directed.

<u>Vicky</u>: Unlike Meg or Mike, Vicky was not confident and successful in math during her own school experiences. During student teaching experiences, she was practiced by master whose teaching was evaluated as in between. Compared to other participants, she had little experience of teaching mathematics to her students. In the interview, Vicky said she loved what she learned from methods class and what her mentor is teaching in the class.

However, it seems that her lack of confidence made her uncomfortable of trying something not familiar with her.

Kerry: Her prior experience with mathematics was positive and her teaching pedagogy was not either traditional or reform. Her mentor was experienced and reform based teachers who took a considerable amount of Cognitive Guided Instruction (CGI) training from the district. Kerry and her mentor planned the lesson together and Kerry started teaching a part of math at the beginning and expanded her role to the whole lesson. Kerry told during the interview that she absolutely valued her mentor's teaching practice so she adopted most of her mentor's teaching practice.

Jackie: Similar to Vicky, she was not confident and successful in math during her own school experiences and she was practiced by master whose teaching was evaluated as reform.. Vicky said she loved what she learned from methods class and what her mentor is teaching in the class. She was the one who expressed the highest desire to become a reform based teacher. However, Jackie also had little experience of teaching mathematics as Vicky did. In the interview, Jackie said math would be the last subject to take over because she was not confident teaching it. Her lack of confidence of teaching mathematics appears to be an obstacle of practicing her identity as a reform teacher.

Contributing Factors

Prior Experiences

In this study, pre-service teachers' prior experiences didn't seem to be a great factor that contributed to construction of identity. Four participants reported their initial perceptions of mathematics teacher (more traditional) were changed into more reform, except one participant, Mike. For this participant, mathematics was his favorite subject and his best math teacher was the one who taught math in a traditional way. Drawing on his positive perspective to seeing a traditional teaching practice from his high school, he stated in his interview that he wanted to adopt a more traditional teaching practice. Specifically, he stated:

> My best math teacher was in high school, Russian man. He always tells us you shouldn't care why you do, just do it what I say and you would pass the test. That is what I did… This is how I see it and how I succeeded it and what I am trying to pass on.

Teacher Education Program

Among various variables that relate to identity construction, the university instructor appeared to be the greatest influence on their identity change. All of the participants replied in the interview that their university instructor brought different and innovative perspectives to the teaching experiences in mathematics. As shown in the table, students considered her as a very reform mathematics teacher, indicated by rating of the scale above (M=9). However, Mike, who adopted the least from teacher education program, stated during the interview that even though he liked the teaching methods provided by the instructor, he thought it was not grade appropriate for him. He considered using manipulatives are more suitable for primary grade such as K-3. When teaching 5th grade he thought that such methods wouldn't be appropriate for his students.

Relationships with Mentor

Drawing on apprenticeship metaphors from Lave and Wenger (1991), I particularly focused on student teacher's authority level, their negotiation process, and how mentor's modeled teaching influenced to novices' teaching practices. Regardless of level of autonomy, all of the student teachers stated that they had a certain level of autonomy, but they wanted to respect their mentor's teaching style. Also they wanted to rely on mentor's current teaching materials as well as adopted their teaching strategies. This result indicated that mentor's teaching practices has a greater potential for modifying and re-constructing student teachers 'professional identity and teaching practices.

Conclusion and Discussion

This analysis has shown that prospective teachers developed identities of what it means to be a what so called 'traditional' or 'reform' mathematics teacher through the teacher education program. Rather than prospective teacher's prior beliefs, the reform pedagogy of university instructor has influenced the most on their professional identity. When novices entered field experiences leaving from reform world, their masters' teaching model was various. The result indicated that no matter of masters' teaching model, all of my participant teachers stated that they considered mentors' teaching practices as major recourses. In addition, student teachers who had high autonomy level of teaching seem to have more opportunity to practice what they believed and what they wanted to try. It implies that how mentors support their student teachers is also a factor that influences novice teacher's initial teaching practices. It brings an attention that we need to pay more attention on mentoring program and also consider placement of mentors as a critical potentials in order for them to construct professional identity in ways consistent with the standards reform movement.

TRANSFORMATIVE TASKS IN ALGEBRA TEACHER PREPARATION

Barbara M. Kinach
Arizona State University
barbara.kinach@asu.edu

This paper reports on a study using algebra-tile tasks in the mathematics methods course to develop prospective secondary mathematics teachers' algebra knowledge for teaching.

Introduction

What is the nature and role of tasks in mathematics teacher education? The tenth-anniversary volume of the *Journal of Mathematics Teacher Education (JMTE,* December, 2007) targeted this under-represented area of research asking: What impact do the tasks of mathematics teacher education have on prospective teachers' mathematical and pedagogical understanding? Guest editors of the volume, Zaslavsky, Watson, and Mason, proposed a lexicon of tasks to frame this emerging area of research. Among the general task types highlighted were mathematical explorations, cognitive conflict, classification and analogical reasoning, examples and counter-examples, alternative and idiosyncratic algorithms, symbols and multiple representations, alternative problem-solving strategies, mathematical connections, use of technological tools, and inductive and deductive reasoning. Algebra researchers in this volume further examined the efficacy of concept-map (Schoenfeld et al, 2007) and big-ideas (Hsu et al, 2007) tasks to measure change in prospective teachers' understanding of algebra. Results of the research on big-ideas tasks unearthed the difficulties prospective teachers often experience when called upon to organize the ideas of a subject (in this case, algebra) into a network of interconnected notions so that, having taught one big idea (e.g., distributive law), other ideas (e.g., combining like terms) can be logically deduced from the initial "big idea." The concept-map studies show these tasks to be effective on two counts: first, as pre-and-post assessments of prospective teachers' mathematical understanding, and second, as cognitive tools for pre-service teachers to organize their thinking about a topic when planning a lesson. Interestingly, then, the research on concept-map tasks resolves, at least in part, the learning-to-teach dilemma that research on "big ideas" tasks unearths in a single volume of JMTE.

As these examples suggest, tasks research is an important source of insight into pre-service teacher understanding of the mathematics they are preparing to teach. The goal, therefore, in advancing this line of inquiry is to lay the framework for the creation of instructional materials and strategies that can help pre-service teachers improve their understanding and teaching of mathematics. In this paper, I focus specifically on task research in algebra teacher preparation by investigating the impact of one manipulative-modeling task, *The Imbalance Task,* on prospective secondary teachers' understanding of school algebra. Aiming to contribute both empirically and theoretically to algebra teacher preparation, this work is guided by the following two research questions: (1) What tasks promote algebra concept development in a secondary mathematics methods class? (2) How can we measure their development? In what follows, I explain the analytic framework that will be used to measure the quality of pre-service teachers' algebra knowledge; describe the study participants, data collection, and coding methods; illustrate *The Imbalance Task* which is the focus of the study; and analyze the enhanced algebraic insight that prospective teachers report from doing the imbalance task. The paper concludes with reflections on algebra teacher preparation tasks.

Theoretical Framework

Measures of Algebra Understanding

Guided by the framework of Perkins and Simmons (1988), I characterize deep knowledge (or understanding) of any algebra topic in this study as consisting of five interlocked types of knowledge (content, concept, problem solving, epistemic, and inquiry). The *content-level* of understanding refers to the vocabulary, skills, and isolated bits of information typically connected with a discipline or school subject. Characteristic performances that indicate this type of understanding are rote memorization and recall of previously learned material. The content-level is a superficial kind of understanding akin to Skemp's *instrumental understanding* (i.e., knowing the rules and procedures of mathematics without understanding the reasons for them).

The remaining three, non-content levels of understanding are akin to what Skemp called *relational understanding,* but differentiated by the focus of knowledge (concepts, problem solving, epistemic, or inquiry). In particular, the concept-level of understanding refers to a contextual understanding of what is typically called vocabulary. Concepts, according to Schwab (1967), are the key orienting ideas of a discipline (e.g., variable, function, equality, or rate of change in mathematics). The problem-solving level of understanding refers to (1) the heuristic ability to monitor and reflect on one's own thinking and (2) the procedural ability to execute on demand specific problem-solving strategies such as find-a-pattern, make-a-table, or induction. Epistemic-level understanding relates to the evidence and warrants for claims in a discipline. Algebra students exhibit understanding at the epistemic-level when they construct arguments and provide mathematical reasons to support their thinking. Inquiry-level understanding refers to independent exploration beyond the problem-solving level. At the inquiry level, students pose problems and implement strategies to resolve them with little assistance from a teacher or guide. What is resolved at the inquiry level is more complex than puzzles resolved at the problem-solving level.

Using this framework, I will analyze the changes in algebraic understanding that prospective teachers report as resulting from the imbalance task (Kinach, 2002).

Participants, Data, and Methodology

Data for this report were collected from a five-year longitudinal study of prospective teacher learning in the author's secondary mathematics methods course. Taught annually by the author, the course typically enrolled three to five students. Prospective teachers' written coursework, video of methods course discussions, and pre-service teachers' post-course responses to the following prompt constitute the database for the current study.

> Throughout the course, we explored ways to make mathematics meaningful for middle-grades and high-school students. *Teaching with manipulatives* (e.g., algebra tiles, attribute blocks, geoboards, etc.) was one of the teaching strategies we investigated. In the course of learning to teach with these materials, many of you commented that your own mathematical understanding was deepened. Describe (if possible) five instances in the course when your own mathematical insight grew as a result of your modeling work with manipulatives.

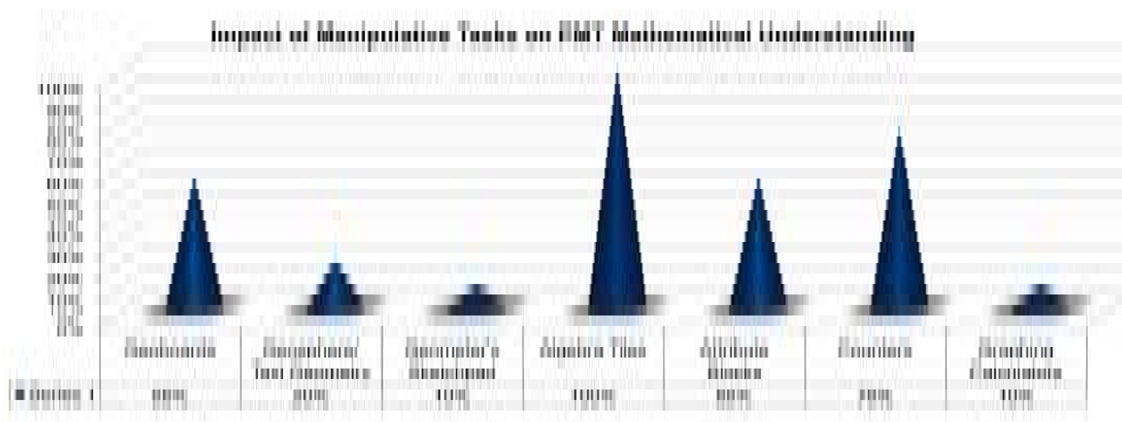
Using a qualitative design, data were first coded by manipulative type and task, and then sub-coded using the levels-of-understanding framework. Before describing and analyzing results for "The Imbalance Task" specifically, I summarize results from the larger study of manipulative modeling tasks and their impact on the mathematical understanding of methods students.

Results

Impact of Manipulative Modeling Tasks in the Larger Study

Twenty prospective mathematics teachers (PMT) responded to the above prompt resulting in 100 instances of self-reported growth in mathematical understanding from participating in ten manipulative-modeling method course tasks (Table 1). Collectively, the tasks employ seven manipulatives (algebra tiles, geoboard, clay/geosphere/taxi-geometry grid, counters, attribute blocks, graphing calculators, and dynamic geometry software called *The Geometer's Sketchpad)*.

Table 1



Algebra-tile modeling tasks scored the most instances of reported gains in mathematical understanding (Table 2). Of twenty prospective teachers, 100% report enhanced understanding at the concept level of the multiple meanings of the symbols "-" and "+". Next in rank was the imbalance task. 90% of the pre-service teachers reported knowledge gains at the concept level related to the equal sign, equation, variable, and at the epistemic level related to justification for the processes of equation solving, transposition, and algebraic factoring.

Table 2: End-of-Course Reported Gains in Algebra Understanding from Methods Course Manipulative-Modeling Activities

1) Algebra Tile Manipulative Modeling Tasks			
a. *The Imbalance Task*	**Form of Knowledge**	**Freq**	**Percent** (n=20)
Enhanced understanding of . . .			
equal sign	concept	18	90
equation	concept	18	90
variable	concept	18	90
equation solving	epistemic	18	90
justification for transposition	epistemic	18	90
b. *Two-Color Chip Task*			
Enhanced understanding of . . .			
Operation vs. signed number	concept	20	100
subtraction vs. addition	concept	20	100
addition vs. positive	concept	20	100
subtract, negative, opposite	concept	20	100
c. *Area Model of Factoring/Multiplication*			
Enhanced understanding of . . .			
Algebraic factoring	concept/problem solving	11	55
Area	concept	11	55
Area formulas	epistemic	11	55

The area model of multiplication tasks with algebra tiles produced new insights at the concept level into the connection between numerical and algebraic factoring (55%). Mathematical reasoning tasks with the ESS attribute blocks generated both concept and epistemic level gains in understanding about logic, Venn diagrams, and critical thinking in the mathematics classroom (55%). For the geoboard tasks, pre-service teachers reported concept-level insight into area and epistemic-level insight into the origin of area formulas and the Pythagorean Theorem (55%). Less frequently mentioned were epistemic-level insights into the relationship between the shape of space and definitions of different geometric objects (4%) from modeling tasks with the geosphere, clay, and taxi geometry grid.

Perhaps the most surprising result was the gain in concept- and epistemic-level understanding that these pre-service secondary mathematics teachers reported from using counters to represent whole-number division. Prospective teachers reported surprising new insights into the meaning of division (concept level) and justifications for division by zero (epistemic level). Fifteen prospective teachers (75%) commented that they had never encountered the mathematical rationale for division by zero during their mathematical education. The biggest revelation for prospective teachers was the epistemic insight that different mathematical reasons (or principles) justify why 5/0 and 0/0 are undefined.

Description of The Imbalance Task

Figure 1: The Imbalance Task

The Imbalance Task presents the classic "balance beam" analogy to solving equations in a new light as an inequality. The aim of the task is to stimulate prospective teacher thinking about solving equations in order to better understand the cognitive puzzles and challenges of young algebra students. The task relates a new idea of how the concept of solving equations algebraically can be solved geometrically in terms of an inequality and physically constructed visual of an unbalanced scale.

The Imbalance Task (Figure 1) asks prospective teachers to determine the number of small squares that the strip would have to equal for the scale to balance. Methods students construct the diagram in Figure 1 using the small squares (dimensions 1 by 1) and rectangular strips (dimensions 1 by *x*) from the student-set of algebra tiles (www.etacuisenaire.com). Note that the dimensions of the small square and strip are manufactured deliberately so that the strip does not equal an integral number of squares (i.e., $x \notin$ integers). The intention is for the strip to represent a variable capable of taking on different values despite the fact that the plastic model has a fixed length and width. Students using the tiles are, thus, to imagine the strip (*x*) as capable of varying in value. The value of the small square is 1.

By engaging familiar material in new ways, prospective teachers report deeper concept- and epistemic-level understanding of basic algebraic concepts and processes such as equation, equation solving, variable, and the equal sign. Next I analyze the changes in understanding that 90% of the prospective teachers reported from doing the imbalance task.

Analysis of Knowledge-Change Reports for the Imbalance Task

Insight 1: Meaning of the equal sign. About the equal sign, one methods student's comment is representative:

In working with the balances and algebra tiles, I had new insights into what the equal sign means – that both sides have the same weight or have equal quantities. I previously conceived it (the equal sign) as a do something symbol, even if it meant the "do-something" was to manipulate it to solve for a variable. Also this gave new ideas on what it was to solve an equation (choice of balance or imbalance).

Prospective teacher reflections like these suggest that despite advanced undergraduate mathematics study, foundational misconceptions persist at the concept level about the equal sign. Building upon Kieran's (1981) findings about how students misconstrue the equal sign in arithmetic, this result suggests further investigation of algebra students' concept-level understanding of the equality symbol and its meaning in equations. Is it common for advanced mathematics students at the college level to conceptualize the equal symbol in equations as a signal to solve for the variable? This bears further investigation as 90% of study participants held this view.

Insight 2: Equation and equation solving. The idiosyncratic representation of an equation as a scale out of balance generated many rich reflections about linear equations and the process of solving equations. Several representative reports illustrate the ways in which prospective teachers symbolic understanding of equations and equation solving were deepened through the idiosyncratic approach to thinking about these basic algebraic concepts and processes. One methods student wrote:

The balance model for equations introduced another concept that I had never thought twice about. I had always assumed that an equal sign meant equal, always equal. This model could treat equations in this way or it could present an equation as unbalanced or unequal, and it needed help to get balanced. I thought of an equation as a statement not a problem. This made me think of how many other ideas/concepts in math could have double meanings for my students. I realized that I needed to always try to understand and communicate better with them.

Another teacher candidate wrote:

A fourth insight occurred with the discussion of the meaning of an equation in terms of the balance model. I had always assumed that an equation was "balanced" to begin with, unless proved otherwise. It was a new insight for me to see how it could be interpreted as being unbalanced, with the process of solving equivalent to balancing the scale. This brought out the point that in mathematics, there is not necessarily one right way of looking at something. Sometimes insights are made just by approaching a problem from a different point of view. As a teacher, I want to encourage divergent thinking. I don't want my students to believe that there is only one way to reach an answer. This is not true to the actual "doing" of mathematics.

When prospective teachers operate on the scale by adding or subtracting equal quantities from both sides of the pan balance, they treat the equation as an entity or object in itself and exhibit a structural conception of equation (Sfard, 1991). The alternative procedural conception of equation would be present if students solved the equation by substitution. By inserting different numerical values of the variable into each side of the equation, numerical equality is eventually achieved (or not). This approach to solving linear equations treats each side of the equation as an algebraic expression whose numerical value can be determined by calculating the numerical value of the algebraic expression for different values of the variable. While all prospective teachers in this study exhibited concept-level understanding of equation solving of the structural kind, not all possessed epistemic-level understanding their equation-solving procedures. As the following example dramatically illustrates, justification of equation solving procedures was problematic:

When I learned equations, I learned that you want to get all similar things on one side. To do this, I was told that the equal sign is the moon and that to go from one side to the other side of the equal sign, you jump over the moon, changing the sign of the number or variable as you jump. I know now that what I learned was a trick. The balance idea for solving equations helped me see that the trick I learned was actually a substitute for showing me that what I should do is subtract, add, multiply, or divide equal amounts. I learned that if you treat the equal sign as a balance and solve the problem keeping the balance equal, then at the end you know what a strip will represent in terms of squares because they will be in balance.

Clearly, this student had learned to manipulate linear equations to find the solution without knowing the mathematical (epistemic-level) principles behind the symbolic manipulations. What she describes is the process historically called *al-jabbr,* or transposition. This is an equation-solving method that utilizes the notion of inverse operations to solve equations. Another methods student describes the epistemic-level understanding she gained to explain why transposition procedures work:

The balance model of an equation showed me a great way to understand why we "take" a number's opposite to the other side. Really, we are either adding or subtracting the same thing from both sides.

Insight 3: Different conceptions of the variable. By tilting the scale, this model of a linear equation emphasizes the point that the two functions under consideration are equal only for certain values of the variable. Prior to this activity, prospective teachers report that they missed the (obvious) concept-level idea that a variable *varies* in value. On this point, one teacher wrote:

What does the strip have to represent to balance the scale? This question showed me a deeper insight into the meaning of variables. Before I thought them to merely be representations of specific values. This exercise drove home the point that variables can take on many values, each having an effect on the balance.

Implications for Algebra Teacher Preparation

In this study, The Imbalance Task was transformative. It expanded prospective teachers' content-level understanding of basic school algebra concepts and processes (equal sign, equation, variable, equation solving) to include epistemic and concept level understanding of these ideas. Although the data set is small, the strong results warrant further research on this task and its effectiveness for enhancing pre-service teachers' algebra concept development in the methods course. The analytic framework used in this study emphasized the focus of knowledge (i.e., concepts, problem solving strategies, justificatory rationales) and not the form of knowledge (e.g., strategies or beliefs). This emphasis was useful for identifying the gaps in understanding that these advanced mathematics students brought to the process of learning to teach in the methods course. Aspects of this task design that deserve the attention of future researchers include the juxtaposition of symbolic (algebraic) and spatial (geometric) representations of mathematical concepts, processes, or rationales. Also worthy of more attention by designers of tasks for algebra teacher preparation are the task's employment of cognitive dissonance, analogical reasoning, and idiosyncratic approaches to familiar mathematical material.

Prior to the imbalance task, prospective teachers universally conceptualized an equation is a *statement* of equality (which it is). The unbalanced scale, however, suggested an alternative interpretation of an equation (e.g., $5x + 3 = 4x + 8$) as a *question* about two expressions ($5x + 3$ and $4x + 8$) or about two functions ($y= 5x + 3$ and $y = 4x+ 8$) and the conditions under which they will be equivalent. The idiosyncratic approach generated unexpected insights into basic algebraic notions. Future research on the affordances of such tasks especially in situations where years of proficient procedural practice hides from prospective teachers the underlying conceptual meaning and epistemic rationale for algebraic concepts and procedures learned long ago.

The "research-to-practice" relationship in mathematics education and in education more generally has been examined from a variety of perspectives. This research examined the research-to-practice relationship of mathematics teacher educators. Using the Mathematics Teacher Educator Instrument, developed for this project that addresses 11 dominant areas of research in the field, course syllabi were examined from Australia, Canada, England, Ireland, Italy, Malaysia, New Zealand, and the US. Our results suggest that major bodies of research are only moderately represented on course syllabi. Recognizably, the research areas identified on the instrument may nevertheless be enacted in mathematics teacher education classroom. Potential implications for mathematics teacher educators are discussed.

Introduction

Of great interest over the last decade have been the relationship, and often the gap, between research and practice in education (NCTM Research Committee, 2007). Numerous and robust research has emerged within the field of mathematics teacher education and mathematics education. Dominant research themes include: reflective practice, mathematical tasks, lesson study, assessment and evaluation, theory and practice connections, policy and politics of mathematics education, technology, beliefs and attitudes, content knowledge, pedagogical knowledge, and equity and diversity.

Our interest in this research is to examine the extent to which research is informing the practices of mathematics teacher educators, and thus the way in which pre-service teachers learn to teach mathematics. To examine research-to-practice in mathematics teacher education we analyzed pre-service mathematics teacher education course syllabi, provided to us from mathematics teacher educators from around the world. The question framing this research is: *How is research reflected in mathematics teacher educators' practices, as evidenced in course syllabi?* The aim of this paper is to take a purposive sample from the syllabi collected in order to evaluate the instrument developed for this research.

Theoretical Framework

According to the Merriam-Webster's dictionary, *syllabus* is defined as a summary, a course of study, or an outline. Matejka and Kurke (1994) proposed that there are four key functions of a syllabus: a legal agreement between the instructor and the student, the student and the university, and the instructor and the university; a communication device regarding the learning outcomes and goals of a program of study; a plan or description of the events to occur within the course; a cognitive map, outlining the way in which knowledge will be shaped by the content of the course.

Baker (2001) suggested that "the syllabus may have begun as a modern administrative overlay, but it has become a powerful teaching tool, … used to communicate important aspects of the course to students" (p. 391). We recognized that what is presented on the syllabi may be vastly different from what is enacted in the classroom. In many regions, the course syllabus, is as Matejka and Kurke (1994) suggested – a legal contract, a plan, a communication tool, and a cognitive map. As such, the details presented in a syllabus are at the very least a good starting point for examining the extent to which research is informing the practice of mathematics teacher educators – but may not present the full picture.

Very few studies exist that examine mathematics teacher education syllabi from a global or regional perspective. The studies that do exist largely focused on common elements (Taylor & Ronau, 2006), programmatic goals reflected in syllabi (Harrington & Enochs, 2009), and also tended to be regionally situated. We found no studies that explored the relationship between research and practice from the mathematics teacher educator's perspective. This research aims to fill this gap.

Relevant Literature

Reflection

Prospective teachers need opportunities to learn how and to engage in thinking about their teaching. Artzt and Armour-Thomas (2002) contended that for teachers to develop in their practice, they must engage in reflection before, during, and after implementing a lesson. In the same way, prospective teachers must participate in the various forms of reflection throughout their teacher preparation program (Chapman, 2008). Three different types of reflection have been proposed: a priori reflection, where a pre-service teacher thinks in advance about a topic; initeri, where a pre-service teacher engaging in reflection in the moment of a task or teaching; and a posteri, where reflection upon an action, lesson, or task occurs after the fact (Clark, Kotsopoulos, & Morselli, 2009).

Mathematical Tasks

As Watson and Sullivan (2008) noted, we may distinguish between "classroom tasks", that are "questions, situations and instructions teachers might use when teaching students", and "tasks for teachers", that are "the mathematical prompts, many of which are classroom tasks, that are used as part of teacher learning" (p. 109). The authors observed that tasks for teachers also serve different purposes. Consequently, the understanding promoted by mathematical tasks in teacher education is a blend of the pedagogical and mathematical, with an emphasis on one dimension or the other, depending on the way the teacher educator implements the tasks.

Lesson Study

Adopted from practices of Japanese teachers, lesson study in pre-service teacher education has been has been widely embraced internationally (Fernandez, 2005). Lesson study is a process aimed at improving teaching practices by involving groups of teachers collaborating and reflecting upon lesson plans developed jointly, and then taught by one or more teachers while the other teachers observe. Studies have shown that lesson study enhances the pedagogical practices of teachers, the development of pedagogical practices amongst pre-service teachers, and also improves student learning outcomes (Post & Varoz, 2008).

Assessment

Generally accepted in mathematics education is the need for pre-service teachers to engage in assessment practices through the act of analyzing pupil level mathematization. Studies in the area of assessment practices for pre-service teachers address various issues including the preconceived notions that affect pre-service teachers' evaluative skills (Morris, 2007) and the affects of pre-service teachers' traditional conceptions of mathematics assessment opposed to newer assessment reform ideas. The act of analyzing pupil level mathematization gives preservice teachers the opportunity to experience authentic assessment practices that encourage and support further learning.

Theory and Practice

Numerous scholars have identified the extreme challenges and great necessity in connecting theory and practice for pre-service teachers and practicing teachers (Jaworski, 2006). The need for connecting theory or research to practice stems from the concern that practices of teachers are not stimulated or perhaps supported by research, and are increasingly required to engage in evidenced-based discourses in their practice. Research in this area considers the ways in which pre-service teachers make connections between research and practice when learning to teach (McDonnough & Matkins, 2010), the consumption of research in the pedagogical approaches of practicing teachers (Mathern & Hansen, 2007), and theoretical perspectives (i.e., challenges with making connections; ways to occasion connections) (English, 2003; Heid et al., 2006).

Policy and Politics

Policy documents pervade mathematics education, particularly in the form of curriculum and teaching standards and guidelines for teacher preparation programs (NCTM, 2000; NCATE, 2003). Although these documents are US-specific, parallel documents drive what is taught and by whom throughout the world. In this light, mathematics education is considered a highly political act, to the point that the dominant population holds the power and "policy and most research about diversity, cultural pluralism and a Eurocentric curriculum evolve around this conception of power" (Popkewitz, 2004, p. 254).

Equity and Diversity

Widely documented in mathematics education is the underachievement and marginalization of ethnically, racially, linguistically, academically, or sexually diverse students (Lee, 2002; Richardson, 2009). There have been numerous factors identified as contributing to the underachievement and marginalization of certain populations of students that include: pedagogical factors (Esmonde, 2009), teacher biases and teacher preparation (Sleeter, 2001). Such research points to the fact that there may be serious deficiencies in the ways in which some students are permitted to learn. Consequently, the way in which teachers are prepared during pre-service teacher education is a central concern.

Affect

Beginning with studies on problem solving and meta-cognition, research on affect has developed further in mathematics education, as evidenced by the growing amount of literature (Leder, Pehkonen, & Törner, 2002; Maasz & Schlöglmann, 2009). Traditionally, three key components of affect are studied: emotions, beliefs, and attitudes (McLeod, 1992). Goldin (2002) also introduced the concept of meta-affect. For our aim, a specific sub-theme is worthy of consideration: teachers' affect, with a particular reference to teachers' beliefs about mathematics and its teaching and learning, seen as a driving force influencing teachers' instructional practice (Philipp, 2007).

Content Knowledge

In the current decade, many scholars have attempted to describe the aspects of a teacher's content knowledge that contributes to their teaching effectiveness. A US report called for mathematics teachers to possess deep understanding of mathematical content at least three years beyond the level they teach and delineates topics within specific content strands (e.g., number and operations; algebra and functions; geometry and measurement) that prospective teachers must know well (CBMS, 2001). Other scholars describe content knowledge for teaching mathematics in less content-driven ways. Ball, Thames, and Phelps (2008) categorized four domains of "mathematical knowledge for teaching" (p. 399), including common content knowledge, specialized content knowledge, knowledge of content and students, and knowledge of content and teaching.

Pedagogical Content Knowledge

Shulman (1986) described the different components of teachers' knowledge. Among them, there is pedagogical content knowledge, a special blend of mathematical and pedagogical and knowledge, described as "an understanding of what makes the learning of specific topics easy or difficult; the conceptions and preconceptions that students of different ages and background bring with them to the learning of those most frequently taught topics and lessons" (p. 9). As Ball (1990) observed, it is important to help prospective teachers to "learn to do something different from – and better than – what they experienced in mathematics classes" (p. 11). More recently, Even and Tirosh (2008) explored the issue of teacher knowledge and understanding of students' mathematical learning and thinking, as a significant part of pedagogical content knowledge.

Technology

Some of the issues and implications addressed through technology research include: professor demonstrated or modeled use of mathematics technology (Sturdivant, Dunham, & R., 2009), opportunities for pre-service teachers to engage in investigation of mathematics technology (da Ponte, Oliveira, & Varandas, 2002), and authentic implementation of mathematics technology by pre-service teachers (Lin, 2008). Studies have shown that when these three teaching strategies are enacted in pre-service classrooms, the result is a pre-service teacher with maximized and current knowledge and understanding of technology integration in a mathematics classroom (Blubaugh, 2009; Niess, 2001)

Methods

Using email, we solicited the submission of syllabi from colleagues around the world using primarily the listserv mailing lists from the Psychology of Mathematics Education. In total, 146 syllabi were collected which ranged from K-12 to graduate level. We were unable to obtain representation from every continent. This pilot research focuses on a sample of 10 syllabi (one or two each) in total from: Australia, Canada (2 analyzed), England, Ireland, Italy, Malaysia, New Zealand, and the US (two analyzed).

The Mathematics Teacher Education (MTEd) Instrument was developed and used to examine the syllabi (see Appendix A). The MTEd Instrument is a rubric that explores the level in which the research areas mentioned in the introduction are evidenced within a syllabus (see Appendix A for a brief version of the instrument). The level four criteria was an outgrowth of the existing research on optimal recommended learning opportunities for pre-service teachers learning how to teach mathematics (Arbaugh & Taylor, 2008). Low, moderate, and high tags were assigned to a syllabus based upon the cumulative level obtained from the syllabus, determined by adding up the assigned levels from each of the individual research areas identified. Descriptive statistics were computed to summarize overall levels across the 11 research areas analyzed.

Results and Discussion

Mathematical tasks, assessment, belief and attitudes, lesson study, and equity and diversity were the lowest represented on the syllabi (see Table 1). Additionally, assessment had the greatest amount of variability. All but one syllabus achieved an overall level of "moderate" in terms of representation of the research areas on the instrument (see Appendix A for a description of the overall level ranges). One syllabus achieved a "high" level in terms of representation of the research areas. None of the samples analyzed for the pilot achieved a low level in terms of research areas. The mean overall level assigned to the syllabi was 27.7 and the standard deviation was 3.53. The overall level assigned to the syllabi ranged from 22.0 to 34.0.

There is preliminary evidence to suggest that some areas may be particularly overlooked. We note again, that while our pilot analysis of course syllabi showed moderate evidence of research-to-practice connections for mathematics teacher educators, connections may nevertheless exist in classroom practices. However, the absence of evidence has led us to question the importance of course content transparency to students. Numerous scholars have argued that this sort of transparency is essential and indeed may be why some institutions have policy statements regarding course syllabi (Adler, 1999; Baker, 2001; Matejka & Kurke, 1994). It is also important to note that items may be stated on a syllabus and not enacted in the classroom.

Table 1. *Mean levels* (n = 8)

	Mean	Min	Max	STD Dev
Reflection	3.50	2.00	4.00	0.71
Mathematical tasks	1.90	1.00	4.00	0.99
Lesson study	2.20	1.00	4.00	1.32
Assessment	2.00	1.00	4.00	1.25
Theory and practice	2.50	1.00	4.00	1.08
Policy and politics	2.60	2.00	4.00	0.84
Equity and diversity	2.10	1.00	4.00	1.20
Beliefs and attitudes	2.00	1.00	4.00	1.05
Content knowledge	2.80	1.00	4.00	1.22
Pedagogical knowledge	3.00	1.00	4.00	0.94
Technology	2.80	1.00	4.00	1.14

Conclusions

In the pilot sample, research-to-practice was only moderately evident in the syllabi analyzed for our pilot study. The MTEd Instrument appears to be a useful tool for this analysis. Our goal is to now engage in the analysis of the full data set. There are several limitations to this study which include: language barriers existed for some colleagues who may have wanted to participate but could not translate their documents or understand which document we were interested in analyzing, the syllabi provided to us likely does not represent what is actually enacted in the classroom, this research only considered the research-to-practice take-up by mathematics teacher educators. It would be of great interest to explore the way in which the pre-service teachers incorporate (or not) research in their subsequent practice, distinguishing between pre-service teachers who participated in courses that exhibited low, medium, and high research-to-practice evidence within the syllabi. Finally, the MTEd Instrument may need elaboration or revision. We may have missed other major bodies of research that contribute to the field of mathematics teacher education and mathematics education. We also recognize that a wide range of culturally-relevant pedagogies exist and may be unique to a particular mathematics teacher education program. The MTEd Instrument is intentionally not designed to address culturally-relevant pedagogies but could benefit from such elaborations in certain settings.

Appendix A: MTEd Instrument (brief version)

Low evidence of research (less than 22)	**Moderate** evidence of research (total assigned levels from 22 -32)	**High** evidence of research (total assigned levels from 33 -44)

Categories	Level 1	Level 2	Level 3	Level 4
Reflection	**NO** or limited opportunities to engage in a priori, initeri, a posteri reflection.	Opportunities to engage in only **one** type of reflection.	Opportunities to engage in only **two** types of reflection.	Opportunities to engage in a priori, initeri, a posteri reflection.
Mathematical Tasks	No direct engagement with mathematical tasks.	Opportunity to engage only in **either** pupil or pre-service level tasks.	**Some** opportunity to engage in both types of tasks.	**Extensive** opportunity to engage in both types of tasks.
Lesson Study	No lesson planning.	Developing **individual or collaborative** lesson plans that are **not** enacted.	Developing lesson plans **individually or collaboratively** that is presented to the class.	Developing lesson plans **collaboratively**; presented to the class; **and reflected** upon collaboratively or individually.
Assessment	No opportunities to engage in assessment.	**Limited** opportunities to analyze pupil level mathematization.	**Some** opportunities to analyze pupil level mathematization.	**Extensive** opportunities to analyze pupil level mathematization.
Theory and Practice Connections	**No** opportunities to engage with research.	**Limited** opportunities to engage with research through course readings and discussions because of language barriers.	**Some** opportunities to engage with research through course readings and discussions (course is **somewha**t grounded in research and research is evident in the course content).	**Extensive and authentic** opportunities to engage in and with research (course **is** grounded in research and research is evident in the course content).
Policy and Politics of Mathematics Teaching	**No** evidence of any exploration of the political aspects of mathematics education.	**Limited** evidence of exploration of the political aspects of mathematics education.	**Some** evidence of exploration of the political aspects of mathematics education.	**Extensive** evidence of exploration of the political aspects of mathematics education.
Equity and Diversity	**No** evidence of any exploration of the equity and diversity considerations in mathematics education.	**Limited** evidence of such exploration.	**Some** evidence of such exploration.	**Extensive** evidence of exploration of the equity and diversity considerations in mathematics education.
Affect	**No evidence** of addressing the implications of affect on the teaching of mathematics.	Evidence of **addressing** affect in the teaching of mathematics.	Evidence of **addressing and challenging** affect.	Evidence of **addressing, challenging, and potentially changing** affect.
Content Knowledge	**No evidence** of exploration of content knowledge at any level.	Engaging in a **selective component** of content knowledge at the instructional level of the students.	Engaging in content knowledge **at the level of** instruction of the students.	Engaging in broader ranges of content knowledge **beyond the level** of instruction of the students.
Pedagogical Content Knowledge	Didactic methods of introducing pedagogical knowledge (little opportunity for critical analysis).	Interrogating pedagogical strategies (limited opportunity for critical analysis).	Interrogating and developing, pedagogical strategies (some opportunity for critical analysis).	Interrogating, developing, enacting, and analyzing pedagogical strategies (extensive opportunity for critical analysis).
Technology	No evidence of technology integration.	Didactic methods of exploring technology integration.	Evidence of pre-service teacher investigation and implementation.	Extensive evidence and demonstration of technology integration, modeling, and pre-service teacher implementation.

THEMES FOR VIDEO CASE INTEGRATION IN MATHEMATICS AND SCIENCE

Terri L. Kurz
Arizona State University, Polytechnic
terri.kurz@asu.edu

Video cases have frequently been developed for use in the education of preservice teachers in mathematics and science. While attending to the viewers' predilections, specific content preservice teachers desire in mathematics and science should influence how these cases are created and integrated. This article investigates the content elementary teachers prefer in a video case specific to mathematics and science. Using Personal Construct Theory, constructs were identified and then analyzed using hierarchical cluster analysis. Three primary clusters were discovered with a very small fourth cluster. These results can be used to guide the future creation and integration of mathematics and science video cases.

Introduction

According to Walen and Williams (2000, p. 4) case methodology "refers to a pedagogical method in which learners [such as teachers] examine situations that deal with the practice of that profession." Oftentimes, cases are used in teacher education (Cannings & Talley, 2002) Participants evaluate cases in a whole class university setting to try to anticipate and address issues that may occur and develop a repertoire to address these potential situations (Manouchehri & Enderson, 2003). Case study methodology has been shown to be a powerful component to improving teacher education in mathematics. Cases have helped teachers evaluate and address their classroom concerns, increase knowledge about practice, increase motivation about what encompasses effective teaching strategies and raise awareness of student learning (Manouchehri & Enderson, 2003; Walen & Williams, 2000; Wang & Hartley, 2008). Video cases are a common form of case, and they often designed to help prepare preservice for potential classroom situations while also providing a context for the university theory being addressed (Brophy, 2004).

Video cases have been shown to be advantageous in helping preservice teachers develop into more fruitful observers. In a study by Alsawaie and Alghazo (2010), video cases were shown to improve preservice teachers' ability to analyze mathematics teaching. In their study, an experimental group analyzed 10 video cases in mathematics throughout the semester; the control group did not. It was found that the preservice teachers who analyzed the videos were able to improve their ability to analyze mathematical lesson on two levels. The preservice teachers were able to focus on students' learning more than the control group. Additionally, they were able to identify and comment on noteworthy events within the video case. There was a large gap between the control group and the experimental group in these two areas. In addition, video cases have been shown to improve students' achievement on knowledge based tests (Kim, Sharp & Thompson, 1998; Sariscany & Pettigrew, 1997). And in a study by Stockero (2008), preservice teachers showed more depth to their learning when instructed using video cases. Those who had been instructed using video cases showed more complex thinking patterns in relation to reflective analysis. More specifically, the preservice teachers using video cases began to focus more intently on student thinking and evidence used to justify reasoning.

It is important to have a purpose when integrating video cases. "Although video can provide a concrete and vivid resource for professional study, unfocused viewing is like reading a text without a purpose." (Ball & Even, 2009, p. 256). In order to utilize video cases in the classroom, a purpose must be defined and used to guide its integration. The article addresses this concern by evaluating what preservice teachers want in a video case designed to support mathematics and science instruction at the elementary level. Mathematics and science are examined as these are two areas that preservice teachers have often have problems. Bischoff, Hatch, and Watford (1999) found that preservice teachers were unable to write lesson plans appropriately aligned to national guidelines in mathematics and science; only 1 out of 10 preservice teachers were able to do so. Stevens and Wenner (1996) found that most preservice teachers had very weak understandings of how to teach mathematics and science. The preservice teachers need more content and methodological guidance.

The predilections of elementary preservice teachers in the area of video case use and development in mathematics and science were evaluated. Specifically, if training preservice teachers using video cases while focusing on mathematics and science instruction, what content do they voice as pertinent and relevant to their training? What do they want to see and what supportive information do they want from these cases? Using Personal Construct Theory (Kelly, 1955) themes for the use of video cases were identified. These themes can be used to guide the future creation and integration of video cases in mathematics and science.

Theoretical Framework

Personal Construct Theory (Kelly, 1955) was used to guide the data collection and analysis. Within this theory, each person is viewed as a scientist and he/she makes active distinctions among objects. Elements and constructs are used for analysis. Elements are the items of analysis and constructs are a way of defining similarities and differences among the elements. Constructs are systems of thoughts and they are linked and interrelated to one another. Distinctions are shown mathematically as a multidimensional space where the distances demonstrate how closely related or unrelated constructs are to one another (Walker & Winter, 2007). In this study one element was used, video cases. Through questioning and comparing, preservice teachers identified the constructs. After the constructs were created, they were analyzed in terms of mathematics and science. Because this research is focusing on the use of video cases in mathematics and science, all of the constructs that were statistically significant at the 0.01 level were evaluated using hierarchal clusters to identify requisite themes.

Methodology

Participants

Ninety-three (93) preservice elementary school teachers were the participants of this study. They were from a culturally diverse university in the western United States. Sixty percent of the participants were students attaining a teaching credential in a fifth-year program after completing their Bachelor's degrees. The remaining forty percent were working on the fifth year program while also taking courses for their Bachelor's degree. Eighty-three percent were women and while this is a high percentage of women it parallels the demographics of preservice elementary teachers (Zumwalt & Craig, 2005).

Procedures and Materials

To gather the constructs for analysis, the stages as outlined by Beail (1985) were used to conduct and analyze the repertory grids in this study. In stage one, the elicitation of elements occurred; video cases were the only defined element. In stage two, the elicitation of constructs took place. The preservice teachers answered five different questions that focused on the use of video cases to: prepare for teaching, extend learning beyond what can be done traditionally, contrast traditional teaching, include topics you would like to see and to support preservice teachers' weak areas of preparation. Each of these questions provided feedback for the creation of the repertory grid constructs. Constructs can be supplied by the researcher(s) when using Personal Construct Theory. However for this study, participant-supplied constructs would be more appropriate as they would address the individual predilections of the novice teachers with less researcher bias. As well, elicited constructs provide better data for analysis (Fransella, Bell & Bannister, 2004).

Stage three involved the creation and administration of the repertory grid. This procedure requires the participants to classify and evaluate the given element on a numerical scale based on personal beliefs (Borell, Espwall, Pryce, & Brenner, 2003). Evaluating the preservice teachers' responses in stage two, the constructs were discovered and listed across one dimension of the repertory grid (Walker &Winter, 2007). Then the preservice teachers were asked to rank each construct on a five-point scale (cases demonstrating the given topic would not be helpful (1) to would be extremely helpful (5)). Any preservice teachers who left one or more of the constructs blank were not included in the analysis.

Stage four involved the analysis of the repertory grid, with a specific emphasis on mathematics and science instruction. All constructs were analyzed while emphasizing a statistically significant correlation to both mathematics and science education. Constructs correlating with mathematics or science that were other specific content areas (such as social science or language arts) were not included. The statistically significant construct "the integration of various subjects into a lesson (integrated curriculum)" represented these content areas. The significant constructs were analyzed using hierarchical cluster analysis. The fifth stage was the interpretation of clusters, to be discussed in the next section.

Results and Discussion

Design and Data Analysis

The first analysis looked for correlations between mathematics and science and the other 105 constructs identified. The relationships were determined using Phi correlation coefficients. Overall, there were 32 significant Phi correlations at the 0.01 level or below in reference to mathematics education and science education. These 32 constructs were then categorized into clusters to illustrate themes.

Ward's method was used to analyze the repertory grids with significant correlations of the preservice teachers using hierarchical cluster analysis (Ward, 1963). A Euclidean metric for determining cluster methods is one of the components of Ward's method. It differs from other methods that use a divisive algorithm to find clusters (Fraboni & Cooper, 1989; Fraley & Raftery, 1998). In utilizing Ward's method, "clusters are progressively formed on the principle of minimization of variance" (Morey, Blashfield & Skinner, 1983, p. 314). It is more appropriate for this study as it identifies similar ways of thinking and showing construct connections. Additionally, Ward's method is one of the better methods to use for clustering techniques as it shows dimension that is sensitive to profile elevation (Morey, Blashfield & Skinner, 1983). Inverse scree tests were used to find the number of significant clusters (Lathrop & Williams, 1989; 1990).

There were four distinct clusters discovered. Three of the clusters were complete clusters while the fourth cluster only contained one construct. Table 1 displays the constructs in their entirety along with the cluster membership. The mean average for each construct and an overall mean of each cluster is also presented. The means provide a guide to the degree in which video cases of this type are perceived to address preservice teachers' trepidations in mathematics and science. Constructs considered similar and in the same cluster were then described as a theme (Kelly, 1955).

Table 1
Video case descriptive statistics for each construct

Video cases demonstrating…	**Cluster Membership**	**Mean**	**SD**
Well-run classrooms	1	4.55	.77
Real teachers working with real students	1	4.48	.97
Classroom management	1	4.43	.85
Lessons to improve my weaknesses	1	4.42	.96
A variety of teaching techniques	1	4.42	.84
How to interact with struggling students	1	4.40	.84
What works in the classroom	1	4.30	.99
How the teacher adapts the lesson based on student understanding	1	4.28	.85
The integration of various subjects into a lesson (integrated curriculum)	1	4.10	.94
Cluster 1 mean		**4.38**	
Lessons with older students (grades 4-6)	2	3.98	1.18
Step-by-step procedures	2	3.90	1.24
The use of manipulatives	2	3.88	1.11
Student motivation issues	2	3.80	1.07
Lessons to guide my strengths	2	3.79	1.21
Attention getters	2	3.78	1.31
How to use visuals in the classroom	2	3.76	1.20
The use of educational tools with students	2	3.74	1.03
Classroom routines	2	3.70	1.25
Complex topics	2	3.65	1.21
Classroom organization	2	3.57	1.13
Projects with students	2	3.53	1.13
Group work	2	3.39	1.04
Cluster 2 mean		**3.73**	
Time management	3	3.76	1.24
Mainstreamed students	3	3.74	1.11
Trouble-spotting analysis	3	3.57	1.22
How to prep activities	3	3.48	1.24
Diverse student populations	3	3.47	1.20
Expert analysis of the presented lesson	3	3.47	1.32
Reciprocal teaching	3	3.42	1.28
Feedback given by the teacher	3	3.39	1.24
Time fillers	3	3.15	1.36
Cluster 3 mean		**3.49**	
How to collect and pass out materials	4	2.37	1.26

Cluster 1

Authentic, highly effective classrooms focusing on helping students understand was the first cluster. This cluster had the highest overall cluster mean at 4.38. Some of the constructs contained in this cluster included authentic well-run classrooms that show a variety of teaching techniques with multiple subject areas. In addition, teachers want to see lessons of what works in the classroom while factoring in preservice teachers' weaknesses. When developing mathematics and science video cases, preservice teachers want to learn how to run effectively managed classrooms with quality curriculum being modeled.

In terms of authenticity, it seems very important to preservice teachers that video cases show actual teaching without the lesson being edited down to perfection (Gainsburg, 2009; Sherin, Linsenmeier & van Es, 2009). The construct mirroring this idea was "real teachers working with real students." Lessons need to show actual, ordinary students with typical responses and actions to help preservice teachers bridge the video case to the actual classroom setting. Authenticity is a key element (Gainsburg, 2009); preservice teachers must view the case as genuine and unmodified to showcase what they will actually experience in the classroom as a new teacher.

Cluster 2

The second cluster was labeled *intermediate tool-based lessons with procedures showcasing cooperative learning*. The cluster mean was 3.73, the second highest mean of all the clusters. This cluster focused more on routines and procedures; it seemed to focus more on viewing mathematics and science lessons with an emphasis on how to use tools and visuals to help support cooperative learning in the classroom. Evaluating the constructs contained within the cluster, it signifies that preservice teachers need help with the procedures veteran teachers often take advantage of knowing. While procedures and routines may seem innate, the preservice teachers in this study point out that they need these skills to be modeled and showcased through the use of video cases.

When designing and/or implementing video cases, it is important to allow preservice teachers to see tools used in a cooperative setting. Inquiry-based instructional models generally encourage teachers to allow students to speak and analyze in a cooperative learning setting. This cluster shows that preservice teachers need to see this model in practice through the use of video cases. Video cases that demonstrate student thinking and talking in groups have the potential to help preservice teachers see and appreciate student thinking and understanding in a cooperative learning context (Ding, Li, Piccolo & Klum, 2007). Additionally, preservice teachers would like to see the use of tools at the intermediate elementary level to help them teach appropriately. According to Star and Strickland (2008) preservice teachers do have difficulty noticing what is mathematically significant when analyzing a video case. They need guidance to understand the mathematical content and how it supports student learning. Video cases developed and implemented with the use of tools, procedures and cooperative learning can be used to cultivate this concept.

Cluster 3

Preparing, timing and analyzing lessons with diverse students was the third cluster identified. This cluster's mean was 3.49. The primary theme for the cluster was the need to understand what the preservice teachers are viewing in a mathematics and science video case. They need feedback to better understand what they are seeing and how it relates to effective (or ineffective) teaching.

In addition, diverse student populations should be integrated into the video case with specific analysis of the students' varying academic and social needs.

Expert analysis of the video case is one of the components of this cluster. According to the constructs "Expert analysis of the presented lesson" and "Feedback given by the teacher," preservice teachers need experts to guide their viewing of the case. The experts can be available online or can be the university instructor. Using experts to guide video case observation is possible (Herrington & Kervin, 2007) and expert analysis can help the viewers understand what they are looking at and why it is (or is not) quality instruction (Beck, King & Marshall, 2002). Sherin and van Es (2005) describe video cases as helping preservice teachers notice and understand what they can and should be looking for in classroom situations, particularly what encompasses quality instruction in the classroom setting. It is important to also note that the video cases can also be analyzed with the university instructor serving as the expert while using support from the preservice teachers. With this kind of analysis, it bridges the authenticity of the video case to the preservice teachers allowing them to contribute to the analysis (Gainsburg, 2009).

Cluster 4

This fourth cluster has just one construct "How to collect and pass out materials" and was labeled *Materials distribution and collection*. The mean for this construct was 2.37. Because this cluster contains only one construct, it cannot be considered a coherent super-ordinate construct. Nonetheless, it shows that when teaching mathematics and science, preservice teachers need guidance and assistance from video cases outlining the distribution and collection of the necessary mathematics and science materials and supplies. Preservice teachers are novices and procedures such as the distribution/collection of materials may be perceived as confusing or overwhelming. Seasoned teachers have established a routine that seems natural and instinctive. So while collecting and passing out materials may seem straightforward and uncomplicated to experts, it can pose a daunting challenge to those just entering the field, particularly in mathematics and science where tools are often used.

Conclusion

The results of this study provide guidance regarding the integration of video cases in mathematics and science elementary preservice teacher education. Video cases have been shown to benefit preservice teachers' instruction; they can improve how preservice teachers' ability to analyze lessons greatly improves with their integration (Alsawaie & Alghazo, 2010; Star & Strickland, 2008). Stockero (2008) found that video cases can enhance how preservice teachers contemplate student thinking and reflective analysis. However, it is important to also consider not just video cases per se, but how video cases should be used in the classroom to support preservice teachers' learning and development. How effective video case integration is can be greatly influenced by how they are used in the classroom (Darling-Hammond & Hammerness, 2002).

Preservice teachers cannot be expected to know everything they need to be highly effective teachers, as they are novices. It is up to the experts (professors) to use the findings in this study to help guide the integration of video cases in university coursework. While preservice teachers may articulate that they need help with using tools to support instruction in mathematics and science, it is up to the professor to determine what tools can best meet his/her students' needs while integrating constructive video cases examples.

If one is going to implement cases, it is important to also understand preservice teachers' predilections in terms of video cases integration. Deciding how to develop or use video cases in the mathematics and science classroom is a multifaceted process (Wang & Hartley, 2003). The goals of the lesson, the finished instructional product, along with curricular ideas somewhere in the middle of the goals and finished product must all be considered. This research provides some guidance in relation to the requisite features as voiced by preservice teachers. These features can be used to support and enhance the teaching of mathematics and science by providing a framework for video case integration.

PRESERVICE TEACHERS USING LESSON STUDY: RESEARCHING THE NATURE OF LESSON STUDY DISCUSSIONS

Mi Yeon Lee
Indiana University
miyelee@indiana.edu

Enrique Galindo
Indiana University
egalindo@indiana.edu

In this study we researched elementary preservice teachers who are using lesson study in a mathematics field experience. More specifically, we document the nature of discussions in the post-lesson meetings by examining the topics discussed in these meetings and exploring if there is a change in the nature of the discussions. Findings suggest that lesson study, which is becoming a common way to foster communities of practice among inservice teachers, can be a useful tool in early field experiences to support preservice teachers to be reflective on their teaching and to learn authentic teaching knowledge.

Teacher education research suggests that teachers learn a lot from the professional community of practice they belong to, and that meaningful teacher learning occurs when teachers have opportunities to work in professional communities in order to solve problems that are relevant to their teaching practice (Ball & Cohen, 1999; Hiebert, Morris, & Glass, 2003). When teachers participate in communities of practice, they can learn mathematical content knowledge, pedagogical content knowledge, and how to respect other's knowledge (Nickerson & Moriarty, 2005), which helps teachers reflect productively on their profession.

A community of practice can be created when using lesson study. Lesson study is a model for school-based professional development that emphasizes reflection on practice. Lesson study is frequently used in preservice and inservice teacher education in Japan as a strategy for improving instruction (Fernandez & Yoshida, 2004; Stigler & Hiebert, 1999). In lesson study, a group of teachers work together to improve their lessons and produce knowledge for successful teaching by going through cycles of planning, teaching, observing and reflecting, and revising lessons.

However, in the U.S., the lesson study method has not been widely used in preservice teacher education, even though it has increasingly been applied to professional development for inservice teachers. Lesson study could be useful for preservice teacher education in that it can help produce good quality teachers, who have appropriate mathematical content knowledge, the desire to understand student thinking, and the ability to use resources effectively in order to promote students' meaningful learning (Hart, Alston, & Murata, 2011; Lewis, Perry, & Hurd, 2009; Parks 2008). Also, lesson study can encourage preservice teachers to have a commitment to lifelong professional development because teachers who have experienced the advantages of lesson study may have a positive attitude towards communities of practice, and this can be a driving force to continue collaborating with peers after becoming a teacher.

In this study we researched elementary preservice teachers who are using lesson study in a mathematics field experience. More specifically, we document the nature of discussions in the post-lesson meetings by examining the topics discussed in these meetings and exploring if there is a change in the nature of the discussions.

To achieve this purpose, the following research questions were investigated:

1. What topics are covered in a lesson study meeting?
2. What is the nature of preservice teachers discussions during lesson study meetings?
3. Are there aspects of the nature of discussions that can be quantified?

Literature Review

Theoretical Perspective on Lesson Study

Lesson study is based on two major theoretical perspectives: cognitive theories of teacher learning and situated learning theories (Lewis, Perry, & Hurd, 2009). Cognitive theories explain learning as changes in an individual's mental schema. From this perspective teachers construct their knowledge for teaching from their prior perceptions; that is, the knowledge development is accounted for as a transformation and a reorganization of teachers' prior knowledge (von Glasersfeld, 1995; Hashweh, 2003). In lesson study, participants confront conflicts between their own ideas and the ideas they receive from their colleagues, research, students, and curriculum and try to solve the cognitive imbalance through the practical research lesson and discussion. Situated learning theories explain learning as the result of participation in a community of practice. Participation and communication forms the identity of members, which affects their future actions and commitments (Lave & Wenger, 1991). Effective teacher learning occurs when knowledge for teaching, beliefs, and practice are shared in a community (Borko, Davinroy, Bliem, & Cumbo, 2000). In lesson study, preservice teachers can develop a professional community and establish those practices which are desirable for instructional improvement.

A Model of Lesson Study

Lesson study is a professional learning approach using a collaborative community for living instruction. Teachers using lesson study go through the following steps: (1) Setting goals; (2) Planning the lesson; (3) Teaching, observing, and debriefing the lesson; (4) Revising and re-teaching; and (5) Reflecting and sharing results (Fernandez & Yoshida, 2004; Stigler & Hiebert, 1999; Stepanek, Appel, Leong, Mangan, & Mitchell, 2007). Setting goals means identifying a research theme by considering students' current knowledge, the key concepts, and the existing curriculum. Planning the lesson involves developing a classroom lesson and writing a lesson plan. For the teaching, observing, and debriefing the lesson step a teacher from the lesson study group conducts a lesson while other group members observe the lesson to collect data about the effectiveness of the lesson. After the lesson, the teachers have debriefing time to discuss the data from the lesson. The revising and re-teaching step involves revising the original lesson plan based on feedback from colleagues and then teaching the same topic again to a new group of students with the revised lesson plan. Finally, in the reflecting and sharing results step, the lesson study group reports on what they learned from the research lesson and group discussion.

However, in this study, we will use the term lesson study in a more narrow sense. That is, we use it to refer to an approach which uses the steps mentioned above except for part of the fourth step. This is because participants in this study were not asked to re-teach a revised lesson plan due to constraints of the field experience. Therefore, this modified version of lesson study includes planning, teaching, observing, debriefing about the research lesson, and writing a revised lesson plan. Debriefing about the research lesson (lesson study discussions) consists of three stages: 1) the instructor's self-reflections; 2) a discussion of the lesson based on observations from peers; and 3) plan of the next lesson. In the first stage, a pair of PSTs who taught the lesson shares their observations about how the lesson went. In the second stage, the other participants share their observations about how the lesson can be improved. In the final stage, participants brainstorm ideas about how the next lesson should be taught.

Advantages of Lesson Study

Recently, the National Research Council (2005) noted that elementary children have to be taught mathematics by knowledgeable teachers, and that practice-based learning is important in order to produce knowledgeable teachers in mathematics education. The NRC emphasized the potential of lesson study because it could increase teachers' content knowledge, their understanding of students' thinking, and could help teachers pursue reform-oriented teaching. Marble (2007) researched a lesson study approach in an early field experience. He found that there was striking progress in lesson design, classroom management, the quality of students' engagements through meaningful activity, and the quality of student assessments. Furthermore, Lewis, Perry, and Hurd (2009) reported that lesson study improves instruction in several ways, namely, lesson study changes teachers' knowledge, beliefs, professional communities, and teaching-learning resources; and these changes are related to instructional improvement. Additionally, Lewis (2009) studied the nature of knowledge development in lesson study based on a lesson study case from a Japanese elementary school. She reports three kinds of benefits from lesson study: development of knowledge, interpersonal relationships, and personal qualities and dispositions. Research studies such as the ones mentioned above have shown that lesson study has been an effective tool in teacher learning. In this study we explored if elementary preservice teachers would also benefit from an adapted version of lesson study by researching the nature of post-lesson discussions in an early field experience.

Methodology

The Participants and the IMB Project

A lesson study group consisting of six preservice teachers, a field experience instructor, and an inservice teacher (host teacher), were the focus of this study. The six elementary preservice teachers (PSTs) enrolled in mathematics and science methods courses concurrently with the field experience course. Preservice teachers attended a 75-minute mathematics methods course twice a week and went to an elementary school once a week to teach children one lesson. The PSTs taught mathematics during the first half of the semester (6 weeks), and taught science during the second half (6 weeks). PSTs were juniors and most of them had considerable motivation to learn how to teach mathematics because they had to teach their students mathematics based on what they had learned in their mathematics methods course.

In the field experience, the six PSTs are placed in an elementary classroom to implement Iterative Model Building (IMB) cycles. IMB cycles consist of four stages: formative assessment interviews; model building sessions; teaching a lesson; and the lesson study meeting. Prior to the teaching of the lesson, pairs of PSTs conduct formative assessment interviews (FAIs) and then share information about children's thinking in a model building session. The goal of FAIs is to understand students' thinking about the topics of the lessons and use this information when planning future lessons. Then a pair of PSTs teaches a whole-class lesson that had been planned the previous week with the lesson study group, while the others in the lesson study group observe that lesson. After teaching the lesson, the lesson study group deliberates about the lesson, in order to give feedback, and discuss how to improve it for future teaching. Then another pair of PSTs presents a draft of the next lesson to the lesson study group and the lesson study members suggested ideas for improving the lesson. The PSTs take turns teaching the whole-class lesson each week, and each pair of PSTs teach two mathematics and two science lessons during the semester.

Data Collection

We watched videos of the lesson study discussions and analyzed their transcripts in order to investigate the interactions between the participants in a lesson study group. Only the second and the fifth lesson study meetings out of six mathematics lesson study meetings were used for this analysis. During the first lesson study meeting, PSTs were learning the lesson study method, while the sixth lesson study meeting included content for the preparation of a science lesson that would be taught the following week. Furthermore, the two PSTs who taught the lesson were the same in both the second and the fifth session, even though the roles of the main teacher and the assistant teacher were changed. Thus, we decided it was more meaningful to compare the second and the fifth lesson study sessions for the purpose of this study.

Data Analysis

To analyze data we used the content analysis method (Krippendorff, 2004) and the reconstructive coding method (Carspecken, 1996). Content analysis is used not only to find out the meanings of data but also to articulate some working categories of codes by counting the occurrences of those codes. Content analysis is conducted following three steps: (a) Locate the data that should be representative of some describable universe of content; (b) Do the coding; and (c) Do quantifiable analysis of the data. After collecting the data from the lesson study meetings, we started coding the data. For specific coding, we used the reconstructive coding method based on the principle of inference and the principle of pragmatics. We started with *emic* coding, which involves developing coding based on an internal understanding of the meaning of the data.

First, we began the data analysis by reading through the transcripts of the post-lesson discussions, focusing on the level of meaning that is evidenced in a *meaning field* or a *meaning reconstruction*. Then, we assigned a short-form label for meaning to sentences and then linked that back to data through levels of inference. We named the codes according to three levels of inference (high inference, medium inference low inference) – based on how close the codes were to the data. After labeling, this coding got layered in two ways: collecting the first level codes into families or super codes; and describing the relationships among the super codes as themes. Finally, these codes, families, and super codes were combined to produce thematic categories or statements by uniting and distinguishing between the various levels of codes. After completing the *emic* coding, we tried *etic* coding, which involves developing codes grounded in an external understanding of the meaning of the data. *Etic* coding was conducted by referring to the relevant literature in order to refine the *emic* coding as a pathway for quantifiable analysis of data (Lewis, 2009; Marble, 2007; Parks, 2008; Lewis, Perry, & Hurd, 2009). That is, we examined some of the categories used in those studies and looked for categories that overlapped with the ones we found in order to narrow down our codes into fewer categories by combining those categories. Through this process, we arrived at the refined categories of *lesson plan*, *student*, *collaboration*, *beliefs*, and *miscellaneous*. After the coding work, we counted the frequency of contributions of words related to each code in order to investigate if the nature of the preservice teachers' discussions could be described quantitatively.

Analysis and Findings

In this section, following the order of the research questions, we first describe the kind of topics covered in the lesson study meetings and then examine the nature of lesson study discussions and finally present our attempts to quantify the change in the quality of discussions.

Topics Covered in Post-Lesson Discussions at Lesson Study Meetings

Through the coding of the transcripts, we found that the topics covered in the lesson study meetings fell into five categories: *lesson plan*, *student*, *collaboration*, *beliefs*, and *miscellaneous*. The category of *lesson plan* includes lesson goals, gear up and gear down activity, launch, investigation, summarize, time, task, manipulatives, and group organization. The category of *student* includes students' thinking (strategies), difficulty, attitude, prior knowledge, students' needs, and response. The category of *collaboration* includes sharing experience, suggestion, reflection by lead teachers, feedback from observer teachers, and elaboration. The category of *beliefs* includes the beliefs about students, beliefs about teaching, and beliefs about mathematics. The category of *miscellaneous* includes things such as chatting and announcements.

Here are some examples of quotes in each category. A comment like "we met our objectives, which were finishing and sitting together, covering an area, counting sets of objects up to 60" was coded in the category of *lesson plan* because the comment mentioned the lesson goals. A comment like "They [students] all seemed more confident with the shapes than they are with like numbers" was coded in the category of *student* because it referred to the students' attitude. A comment like "I am thinking if you had done that you could have said what was the least number of shapes you could make it with or what was the largest number [of them]" was coded in the category of *collaboration* because it is related to a suggestion to improve teaching. A comment like "it's hard to get everything within that short time, [and] I think that's why I got frustrated because I wasn't trying to fit things in" was coded in the category of *beliefs* because the remark is related to teaching difficulty, namely beliefs about teaching.

The Nature of Preservice Teachers Discussions in Lesson Study

After investigating the topics discussed in lesson study meetings we researched the nature of those discussions. Three categories did show remarkable change in the frequency and quality of contributions from participants: *lesson plan*, *collaboration*, and *student*. We now describe the nature and quality of discussions for these three categories.

First, in the category of *lesson plan*, PSTs in the second lesson study were more focused on classroom management and group organization for implementing the activity. However, in the fifth lesson study, the preservice teachers focused on content knowledge as well as on pedagogical knowledge by emphasizing the connection between the previous task and the next task. Also, in the second lesson study, the facilitator, Susan, and the host teacher, Ms. Tyler, had the main roles leading the discussion about planning the next lesson; while in the fifth lesson study, the preservice teachers led the discussion about lesson planning.

Next, in the category of *student*, in the second lesson study PSTs focused mainly on the students' superficial attitudes rather than on their mathematical thinking. However, in the fifth lesson study, the preservice teachers reflected more on the students' thinking, with detailed sample evidence. Also, in the fifth lesson study, PSTs often quoted the result of probing the students' thinking, in the form of an interview, in order to back up their observations.

Finally, in the category of *collaboration*, in the second lesson study, the facilitator and host teacher chiefly led the discussion about suggestions and reflections on lesson. However, in the fifth lesson study, the role of the facilitator and the host teacher (who was absent on that day) changed, from a person who actively suggested opinions to a person who listened to preservice teachers' opinions and gave only simple feedback remarks such as "good," "I like that idea," and "Yeah." Also, in the fifth lesson study, preservice teachers reflected on the lesson in terms of launch, investigate, and summarize parts, referring to the structure of the lesson plan.

Quantifying Changes in Lesson Study Discussions

We attempted to quantify the change in the quality of lesson study discussions in two ways: the change in the number of contributions to each category of topics and the change in the frequency of participation in the lesson study discussions. Given that lesson study meetings are opportunities to reflect on practice and to deliberate on how to improve teaching, we thought that one indicator of the quality of such meetings would be that all participants contribute to the discussions. We also thought that the frequency of contributions of all participants would tend to increase throughout the weeks and get to a point when it would be about equal for all members. As a result of keeping track of the frequency of participants' contributions for each category, we found that the overall quality of lesson study meetings improved (see Table 1).

Category	Second lesson study	Fifth lesson study	Increase
Lesson plan	11	42	31
Student	40	56	16
Collaboration	85	106	21
Beliefs	8	9	1
Miscellaneous	12	18	6

Table 1. Change in the frequency of contributions made in post-lesson discussions

In the category of *lesson plan*, the number of contributions increased from 11 to 42. In the category of *student*, the number of contributions increased from 40 to 56; and in the category of *collaboration*, the number of contributions increased from 85 to 106. In the categories of *beliefs* and *miscellaneous*, the number of contributions increased from 8 to 9 and from 12 to 18 respectively. Based on this result, the change in the category of *lesson plan* was the most remarkable, with an increase of 31; *collaboration* was second, with an increase of 21; and the change for the category *student* was a noteworthy third, with an increase of 16. The increase in the category of *lesson plan* is attributable to the preservice teachers' active participation in planning the next lesson and suggesting appropriate activities. The increase in the category of *collaboration* is attributable to the active interaction between lesson study members, in things such as feedback and suggestions. The increase in the category of *student* is derived from the participation of various preservice teachers when reflecting on students' thinking and responses.

PST	Second lesson study	Fifth lesson study	Increase
Amy	8	10	2
Christina	26	19	-7
Erin	17	37	20
Hera	6	32	26
Jane	17	30	13
Mary	0	22	22
Susan	50	81	31
Ms. Tyler	34	Absent	

Table 2. Change in the number of participations in post-lesson discussions

In reference to the change in the number of participations in lesson study discussions, five out of six preservice teachers showed an increase in their contributions, while one preservice teacher showed a slight decrease in the number of her contributions (see Table 2). Also, the participation rate during the fifth lesson study shows more equal frequency of contributions than that of the second lesson study. Particularly, Mary who was the only African-American preservice teacher in the lesson study group and Hera who was shy about participating in the second lesson study discussion showed a remarkable change in the number of times they participated.

Discussion and Conclusion

In this study we investigated the topics covered in lesson study meetings and the nature of preservice teachers' discussions during their participation in lesson study meetings. We examined the nature of these discussions qualitatively and quantitatively. We found that in lesson study meetings, discussion topics fell into five categories: *lesson plan*, *student*, *collaboration*, *beliefs*, and *miscellaneous*. Based on the frequency of contributions in these five categories, we also found that the level of preservice teachers' discussions improved quantitatively and qualitatively through the use of lesson study meetings. In particular, the changes in the categories of lesson plan, collaboration, and student – in that order – were remarkable. When examining vignettes from the transcripts, we noticed that the improvement in the category of *lesson plan* came from preservice teachers' active participation in planning the next lesson. The incremental change in the category of *student* was derived from the preservice teachers' participation in reflecting on the students' thinking and responses. The rise in the category of *collaboration* was attributed to the active interaction between the lesson study members through feedback and suggestions.

From these findings, we can see that lesson study in their early field experience was helpful in supporting these preservice teachers to be reflective on their teaching and to learn authentic teaching knowledge. These results are consistent with those of other studies showing benefits of lesson study (Lewis, 2009; Marble, 2007). However, in this study, the change of beliefs was not as much as that found by Lewis (2009) in her study. This might be because, in this study, the preservice teachers' post-lesson discussions were guided by a facilitator in order for them to focus more on topic-centered discussions rather than in sharing their beliefs, and also because of the way in which we quantified this change, using the frequency of their contributions during the post-lesson discussion phase of lesson study.

This study has implications for preservice teachers and teacher educators. The first implication is that preservice teachers would benefit from participating in a professional community continuously into the future. Through this early field experience, based on the IMB project, preservice teachers exhibited the benefits of lesson study. However, to maintain the benefits gained from lesson study, preservice teachers will need to create or join in an inquiry community with their colleagues in the future, and discuss their teaching problems or questions and make reflection on practice a part of their professional practice. If this disposition takes firm root in their teaching practice, preservice teachers will be willing to apply this approach to their teaching after they become inservice teachers.

The second implication is that preservice teachers can benefit from using the lesson study approach in mathematics methods courses, as well as in field experiences. Lesson study is becoming more popular in professional development and many are embracing it as an effective way to improve teaching practice. In this study, we saw how these preservice teachers also benefited from lesson study. Our findings give some support to the importance and value of using this method with preservice teachers.

As an initial effort to challenge preservice teachers in teaching algebra for equity, we investigated constructing avatars in Second Life to simulate a diverse middle-grade class. Participants created avatars that had many of their own social-cultural characteristics along with algebraic knowledge. Specific research-based guidelines are necessary to assure authentic and viable avatars are developed for use in classroom simulations.

Introduction

As a multi-user interactive virtual environment, Second Life (SL) has great potential for providing interactive, effective and engaging teaching and learning for the field of education, including preservice teacher education (Bransford & Gawel, 2006; Cunningham & Harrison, 2010; Goodband, Bhakta, & Lawson, n.d.). Teaching and learning in the SL environment has been documented as extremely positive, enjoyable and facilitated (Gao, Noh, & Koehler, 2009; Ritzema & Harris, 2008).

As animated characters with human capabilities and communication tools, avatars can be utilized to facilitate teaching and learning with numerous potential benefits (Blake & Moseley, 2010). Despite the recent increasing research interests in avatar issues, constructing student avatars to facilitate teaching and learning in K-12 classrooms has yet to be fully studied (Annetta & Holmes, 2006; Hew & Cheung, 2008).

In this study, through constructing avatars resembling a diverse student population in a real-life middle-grade class, we intended to take the initial effort to provide virtual teaching experiences for preservice teachers, specifically in the area of mathematics education. We investigated, from the perspective of a project team, the process of conceiving and developing a group of avatars which will portray middle-grade students with various socio-cultural and mathematical backgrounds in the simulated virtual environment for teacher preparation. We expect to gain insights into how to design the avatars in the best way to help address equity in algebra teaching for preservice teachers.

This study describes a particular component of the work in the first phase of a 5-year NSF-funded project. The project aims to design, develop, and test technology-enriched teacher preparation strategies to address equity in algebra teaching and learning for all students. The project endeavors to discover methods to assist in closing the achievement gap between White students and students of color in mathematics. A hypothesis of the project is that technologies such as SL can support teacher preparation for a thorough understanding of diverse learners and apply deep and specific mathematical knowledge in teaching.

This study is aligned with the objective of the project to design technology-enriched teacher preparation strategies to address equity in algebra learning for all students. Virtual technologies will be employed to provide preservice teachers with initial teaching simulations and experience in diagnosing, presenting, and evaluating activities of middle-grade student avatars in the content area of algebra. We hope that through the interactions between the constructed middle-grade student avatars and preservice teachers in SL, the preservice teachers can be better prepared for teaching algebra for equity.

The following research questions guided our study:

1. What are the social-cultural and mathematical characteristics of middle-grade student avatars as constructed by participants in our study?
2. What are the perceptions about how avatar construction challenges preservice teaching in teaching algebra for equity?

Theoretical Framework

As illustrated by Sleeter (2001), most preservice teachers lack experience in confronting diversity issues in multicultural classes, failing to meet the expectations of working with diverse students. Other researchers also pointed out that ''very few teacher education programs have successfully tackled the challenging task of preparing teachers to meet the needs of diverse populations'' (Watson, Charner-Lind, Kirkpatrick, Szczesiul & Gordon, 2006, p. 396). Ladson-Billings (1994) argued, however, culturally relevant teaching will benefit students of color since they have a distinct history and culture they bring into the classroom as prerequisites that should be nurtured accordingly. According to Lewis (2009), prospective teachers should understand that many students of color have the following belief (Kunjufu, 2001):

I don't become what I think I can,
I don't become what you think I can,
I become what I think you think I can.

Providing knowledge and experience in the classroom for prospective teachers is a significant component of teacher education programs. Moreno and Ortegano-Layne (2007) asserted that we can learn through either directly or indirectly observing people in real or fictitious situations. SL offers exciting opportunities for simulated teaching and learning in teacher education programs among other major affordances provided by SL for education such as communication, experience (Hew & Cheung, 2008), scaffolds and professional development (Cunningham & Harrison, 2010), To be specific, SL "provide(s) access to authentic simulations of…situations that would be otherwise impossible to experience" (Cunningham & Harrison, p.98).

Regarding the content, mathematics educators and researchers have increasingly recognized the gatekeeper role of algebra in preK-12 schooling (Carraher & Schliemann, 2007). The concepts of change, variable, and operations have been identified as core algebra concepts in the middle grades mathematics curriculum (AAAS, 2000; Kulm & Capraro, 2008). In this study, we intended to restrict the range in mathematic ability of algebra, thus avatars were developed with these three mathematical concepts, and the related prior mathematical knowledge that leads to these concepts.

Methods

Seven graduate assistants participated in this study. All participants are pursuing doctoral degrees in Curriculum and Instruction at a large, Southwestern research intensive university. All but one participant has a background in mathematics education. The participants are actively involved in the NSF-funded project, fully aware of its aims and hypotheses. Before collecting the data for this study, researchers informed the participants that they were faced with preservice teachers who are poorly prepared for working with diverse students. Several meetings were held for the project involving graduate assistants. During the meetings, researchers clearly indicated that graduate assistants were expected to construct middle-grade student avatars in SL to represent a sample of diverse students and thus better prepare preservice teachers for issues relating to diversity. Researchers also informed graduate assistants that the goal of constructing avatars in SL was to start considering possible interventions for preservice teachers by simulating a diverse student population in a real-life middle-grade class.

Given the above prompts, the participants were asked to describe the process of constructing a middle-grade student avatar by filling in a survey. The survey consisted of several open-ended questions regarding the social-cultural and mathematical characteristics of the avatar they conceived. The participants were told that they were going to play the role of their constructed avatar in the virtual SL environment and interact with preservice teachers in later phases of the NSF-funded project (see Figure 1).

Through substantive analyses of the open-ended questions in the survey, researchers initialized a set of response categories. The first two researchers read the responses to the survey individually and exchanged their ideas about the responses. After identifying the key themes of the responses to the survey questions, the researchers modified the initial categories to accommodate the responses. Responses to the survey were coded on three dimensions: (1) social-cultural characteristics of the avatars and underlying reasons for those characteristics, (2) algebraic knowledge of the avatars, and (3) perceptions about how avatar construction can challenge preservice teachers in teaching algebra for equity.

Figure 1. Constructed middle-grade student avatars interacted with preservice teachers in the front of a SL classroom specially designed for the project.

Results

Social-cultural Characteristics of Avatars and Underlying Reasons

Participants were asked to describe their avatar's name, gender, ethnicity, grade, qualification for a free lunch at school, family life, first language, personality, and hobbies and interests. In terms of gender and ethnicity, most avatars were identical to the participants who constructed them (See Figure 2 and Table 1). Most participants explained that by choosing the same gender and ethnicity for their avatar as their own, they will be able to relate better to the avatar. Only two participants changed the ethnicity for their avatars from their own and one participant changed the gender for his avatar. The participant who constructed an avatar of a different ethnicity, African American in this case, stated, “The math performance of African American students is unsatisfactory. The achievement gap in math between African American students and White students has been well documented. Also, students of color are underrepresented in gifted classes”.

Figure 2. Examples of constructed student avatars.

Table 1
Summary of Avatar Demographic Characteristics

Avatar Name	Grade	Avatar Gender	Different From Participant?	Avatar Ethnicity	Different From Participant?	Free Lunch
Glenn Polandia	6	F	Yes	Hispanic	Yes	No
Browniana	NR	F	No	Hispanic	No	No
Yong Wang	8	M	No	Asian	No	No
NattyJo	8	F	No	African American	No	Yes
Chih-Yu	8	M	No	Asian	No	No
Tonya	8	F	No	African American	No	Yes
Angel	7	F	No	African American	Yes	Yes

The ethnicities of the constructed avatars included African American, Hispanic, and Asian. However, none of the participants developed a White student avatar. Results of the socio-economic status dimension of the avatars showed that only African American avatars receive a free lunch at school. Participants explained that according to their research and teaching experiences, many African American students are categorized in this socio-economic status.

Algebraic Knowledge of Avatars

In regard to avatars’ prior algebraic knowledge, the most frequently occurring theme was the concept of mathematical operation. All participants reported that their avatars have some prior knowledge of operation. Selected responses include, the avatar “was very good at multiplication tables when she was in elementary”, has knowledge of “fractions, ratios, decimals, operations with fraction numbers”, and generates “equivalent forms of integers, fractions, decimals, and percent". The least frequently occurred theme was the concept of change. Only three participants regarded knowledge of algebraic change as a part of their avatars' prior knowledge.

The results also showed that participants attached great importance to avatars' prior knowledge and lack of a solid foundation for algebra. For instance, when considering the connections between arithmetic and algebra, a participant wrote, "Student does not learn well in sixth grade and has hard time to connect to the math knowledge in the following grades", and "the knowledge base of my other peers is not very deep".

When describing their avatars' knowledge depth, most participants highlighted lacking the knowledge of underlying reasons and applications of formulas and theorems in problem solving as indicators of shallow knowledge depth. To be specific, "Though I [the avatar] may not always know why I am using the formulas and theorems, I know how to use them. My knowledge is probably more procedural. I have not yet gotten the full picture of the theoretical reasons for using some math knowledge"; "She [the avatar] understands only the superficial formulas in recognition. She cannot apply them", and "She [the avatar] can recall some algorithms and represent situations with symbolic representations. However, she has difficulties in posing and solving real-world mathematical problems using equations. She also has a difficulty in understanding the underlying reasons and applications of algebra concepts and algorithms."

The theme of variable emerged frequently, together with operations, in the category of misconceptions of algebra. Since the concept of variable is a higher-level concept than operation, most participants chose some misconceptions related with variable for their avatars. For example,

> *Because in his (my avatar's) previous arithmetic learning experience, he treats '=' as a procedural representation. For example, his habit of computation is:*
> *5+2=7+3=10-5=5*3=15*
> *In algebra, his misconception is*
> *5+X=2+7*
> *X=2+7+5*

The participants further illustrated that their choices for the prior knowledge, knowledge depth and misconceptions of their avatars were based on their personal experiences, classroom observations, and common misconceptions identified by the literature. For instance, participants reported that "Problem solving was a major weakness for me when I was in school"; "Some of the math problems encountered by my avatar are the same with which I was faced with when I was an adolescent"; "directly related to myself in middle school"; and "I will relate the avatar to my previous misconceptions in mathematics."

Perceptions about How Avatar Construction Challenges Preservice Teachers in Teaching Algebra for Equity

Some participants implied or directly stated how avatar construction can challenge preservice teachers in teaching algebra for equity. One participant provided a sharply focused description about why the avatar was constructed as a female student: "My experience has shown that young men often display more discipline issues than young women. I wanted my avatar to focus their troubles more on the subject (algebra)." It seems that the participant expected that the preservice teachers can primarily focus on how to teach algebra in the classroom rather than contend with discipline or behavior issues.

Other participants shared views of how their avatar construction can purposefully simulate a middle-grade student in a racially diverse class to challenge preservice teachers to teach algebra for all students. For example, some participants posed specific challenges or opportunities of teaching algebra for equity for preservice teachers through constructing avatars: "I want to see how teachers negotiate this balance of education, this balance of 'intelligences'"; "I want to see how teachers address and assess the weaknesses of their students"; "I feel that my teachers have to go slower because the knowledge base of my other peers is not very deep"; "My avatar would like to interact with her teacher in SL. She hopes that her teacher can know more about her culture, and teach her accordingly, integrating her culture and the content of algebra"; and "I hope that through playing a role of an African American student in SL, I can help prospective teachers get some experience about how to work with students of color. I hope that through interacting with African American middle grade avatars, prospective teachers can gain some instructional practices for meeting the challenge of teaching African American students, providing equitable learning opportunities for all students".

Discussion

Through this exploratory study, we have examined constructing middle-grade student avatars as an initial effort to address teaching algebra for equity. Our analysis suggests that without specific guidance in conceiving avatars, participants will tend to create avatars that have many of their own characteristics. In our case, participants only thought of minority students when considering a diverse classroom, as if White students should not be included in the model for a diverse student population. Disparate views of equity and diversity were prominent in our study and need to be addressed by further study. Our participants displayed a narrow view of African American students, especially in socio-economic aspects. We were left with the nagging question, "Why are only the African American students considered to have low socio-economic status (receiving a free lunch at school)?"

The findings of our study suggest that constructing a diverse group of avatars as an initial effort to help address teaching algebra for equity lead to positive outcomes. The avatar construction may facilitate preservice teachers' learning to teach algebra for equity in a virtual environment since the avatars bear diverse characteristics resembling middle-grade students. However, in the process of construction, participants need to follow specific research-based guidelines concerning characteristics of real middle-grade students. This finding is consistent with the previous study that good preparation and management is required in role-playing scenarios such as goal setting, context and role defining, and character researching and preparing (Teed, 2009).

Theoretically, this exploratory study offers a unique contribution by drawing on constructing middle-grade student avatars as a means to promote preservice teachers' learning to teach for equity. Although an important starting point, this study provides a foundation to further explore how virtual teaching experiences support preservice teachers' learning in the later phases of the NSF-funded project. This study implies that effective design principles and criteria should be fully considered for avatar construction (Blake & Moseley, 2010). This study also clearly indicates the need for additional research focusing on addressing preservice or in-service teachers' challenge with equity.

TEACHERS' MODES OF INTERACTING: EXAMINING CHILDREN'S WORK

Azita Manouchehri
The Ohio State University
Manouchehri.1@osu.edu

We examined the interactions of 10 prospective secondary mathematics teachers with video-based episodes of high school students' work on mathematical tasks. We analyzed and catalogued their comments on each case episode to determine their particular orientations along a continuum from naïve to mature in mathematical and content specific pedagogical domains.

Introduction

The use of illustrations of children' mathematical work in designing tasks for teachers has become increasingly popular in mathematics education (Smith & Friel, 2008; Seago, 2004; Goldsmith & Seago, 2008; Brophy 2004; Borko, Jacobs, Eiteljorg, & Pittman, 2008). Grounded in a situated cognition perspective on learning this approach assumes that by providing contexts in which teachers study concrete and tangible examples of children's mathematical practices meaningful opportunities for advancing their knowledge for teaching might become more immediately accessible (Brophy, 2004; Star & Strickland, 2008).). These assumptions have given rise to development of different genres of resources (videos, written cases, animations of practice) to be used in teacher education. Although the number of reported empirical studies that examine the utility of such resources on teacher learning is limited, a close inspection of what exists reveals several major gaps in discussions regarding the criteria used in both design and evaluation phases of the work. First, these reports fail to list the specific learning objectives (mathematical, pedagogical) that had guided the development of resources used in studies (Santagata, Gallimore, & Stigler, 2005; Goldsmith & Seago, 2008) or ways in which acquisition of those objectives were monitored. Second, little is shared about the quality of interactions of the teachers with such resources so to shed light on elements that might be considered when designing and/or implementing similar learning media. Third, even in the presence of claims to the effectiveness of such resources for teacher learning information regarding aspects of teacher knowledge that might have been enhanced from their use is not shared. These discussions are critical to the genre since they can greatly impact how these resources might need to be gauged against the particular strengths and orientations of the individuals using them (Homphrey & Boaler 2005).

In this exploratory research project our aim was to gain an understanding of factors that might need to be considered when designing and using video-based case tasks in teacher education in order to optimize their impact as learning tools. Using three video-based illustrations of children's mathematical work, we examined the quality of interactions of a group of 10 prospective secondary teachers with the video-episodes and their reactions to each. Two specific research questions guided our data collection and analysis:

1. What do teachers' extract from viewing video-based data of children's work on mathematical problems?
2. What factors seem to influence how teachers analyze and assess episodes they view?

Background and Context

The current study is a part of a much larger longitudinal research and development project in which we address three interrelated goals. The first goal of the project is to trace the development of mathematical thinking, problem solving skills and attitudes of a cohort of 70 children from 18 different urban communities as they progress from 7th through 10th grade in their respective schools. Children are interviewed twice a year, either individually or in small collaborative groups, experience technology-based explorations and work on a variety of problems from secondary school curriculum. The second goal of the project is to draw from what is learned about (and from children) to design educational resources to be used with secondary mathematics teachers so to enhance their mathematical knowledge for teaching. The third goal of the project is to study the impact of these materials on different teacher audiences, including prospective and practicing teachers at 6-12 grade levels. Of particular interest to use is determining ways in which different contexts might be designed and used to optimize among teachers.

A major design issue for us is determining what mathematical concepts to include in each case. We contemplate also the amount of information that needs to be utilized in the media. Additionally, we study the type of instructional materials that need to accompany the case based contexts to assure specific learning objectives are accomplished. Our primary objectives for using the vide-based case studies are to increase teachers' knowledge of mathematics and content specific pedagogy. The research reported here attempted to provide guide on these issues namely, what specific prompts might need to be included in the video based case tasks in order to facilitate development of mathematical knowledge of teachers. Our data collection and analysis focused on factors that enhanced or impeded meeting these objectives using three specific contexts.

Methodology

Participants

The participants consisted of 10 prospective secondary mathematics teachers enrolled in a graduate degree program at a large public institution. At the time of data collection all participants had completed three courses in methods of mathematics teaching. They had fulfilled all mathematics coursework required for a BS degree program in Mathematics. All participants had similar academic backgrounds (had taken the same number of mathematics courses, maintained GPAs above 3.4). Six of the participants were female.

Each participant was interviewed individually. During each interview the participants reviewed and analyzed 3 video-based cases. Each interview session lasted between 2 to 4 hours. All interviews were video and audio-taped. The video camera captured both the computer screen on which the videos were shown and the physical movements of the participants and their gestures as they interacted with the videos. This taping format allowed us to identify specific segments of the videos that seemingly gained the most attention by the participants.

Instrumentation

Data for the study was collected using three different video illustrations of children's work. A brief description of each video-episode is offered below.

1. (Similarity and congruence- 2 minutes and 40 seconds) illustrated a debate between two students as they tried to resolve meanings associated with (and consequences of) two different definitions found on the internet for similar figures. The teacher had asked students to first find the definition of similar figures on the internet and to then determine if specific shapes given on a worksheet were similar. The children had found two different versions of the definition (exclusive and inclusive). The children's argument concerned whether congruent shapes were also similar. The mathematical issue of the episode centered around the role of inclusive and exclusive definitions in mathematics.

2. (The rope problem-approximately 5 minutes) depicted a whole group discussion moderated by the teacher as four different students presented four different responses to the same task involving addition of fractions. Two of the methods offered close approximations techniques often used in real life. One method offered an incomplete process of finding common factors. One student had relied on the use of unit drawing. The mathematical issue of concern in this episode was the connections among these various methods, particularly the merit of approximation methods children had used in numerical analysis methods used in Calculus.

3. The third video-case (Horses and Humans problem-approximately 12 minutes) illustrated segments from clinical interviews with three children as they solved the same problem using different representational schemes. The problem concerned the use of system of linear equations. Each child had used a particular representational system for solving the problem (iconic, tabular and graphic) and without algebra. The mathematical concern of the episode related to importance of each representation for solving particular classes of problems in Algebra, Geometry and Calculus.

The participants were asked to respond to six questions at the end of each case:

1. What might be considered the major instructional issue in this segment?
2. What is your assessment of children's mathematical arguments? (Which of the responses is correct?)
3. What might have contributed to the children's thinking?
4. What mathematical concepts could relate to the topic of students' discussions?
5. Which of these concepts should the teacher pursue with children at this point in their discussion?
6. What other information might you need to offer a more accurate analysis of what you viewed or to suggest for how instruction might need to progress?

The first five questions were used specifically to capture the participants' knowledge in three specific domains: Knowledge of the discipline and its rules and principles; knowledge of connections among different mathematical concepts; pedagogical reasoning and decision making as it pertains to the knowledge of trajectory of concepts. The last question was used to document whether participants considered alternative approaches to teaching in light of different interpretations of mathematics that children shared. The participants were reassured that they could watch each of the videos multiple times, if they felt a need to do so.

Data Analysis

We documented the amount of time each of the participants spent on the analysis of each of the videos, the type of questions they asked the researcher during the interview, their interpretation of individual and group mathematical production and merit of what was proposed, ways in which they framed their analysis of each episode and their rationale for pedagogical solutions they offered. We recorded the number of times each of the participants reviewed each of the tapes and noted specific portions of the videos they choose to review multiple times.

Additionally, we coded the participants' interactions with each case along four broad-categories: Reflections on pedagogy and student work; reflections on mathematics of children and their connections to structure and form; explanation of mathematical topics that could be explored with children; and pedagogical actions which included suggestions for how a teacher could proceed with her lesson in the presence of children's ideas.

A network was generated for each of the three episodes first. These individual networks were combined later to build an interactional profile for each of the participants. At the conclusion of each individual analysis we compared the entire cohort's responses to each of the three cases in order to construct a model of interaction with video-data that took into account their mathematical and pedagogical orientations. These are described more fully below.

Results

Cataloging Interactions

Since a primary goal of our research was to identify the type of instructional materials we needed to develop in order to engage teachers in focused mathematical and pedagogical analysis, we coded their comments and analysis as they pertained to these two particular domains. As such, drawing from data the following indicators were generated and used to code their discourse:

Mathematical analysis

- Could identify critical points in each of the arguments that children had used or referenced in the episode
- Could explain why children's ideas were (or were not) mathematically sound
- Could identify the sources of children's difficulties from a mathematical standpoint
- Could identify trajectory of the content under study and how different mathematical topics could be addressed using children's particular suggestions and conceptions

Pedagogical (content specific) analysis

- Could explain why certain pedagogical moves were (or were not) adequate to pursue with children
- Could justify why certain topics should or should not be pursed with children
- Could identify the advantages and disadvantages of different instructional tools when trying to build on children's ideas to design follow up instruction
- Could identify specific and relevant approaches for pursuing discussions
- Could identify how the different pedagogical choices should be implemented individually, small group, large group discussions)

In analyzing the range of the teachers' modes of interactions with the videos and their discussions of the three cases, three specific categories of knowledge/orientation emerged: Mathematically Conceptually Mature, Pedagogically Mature (MC_mP_m); Mathematically Algorithmically Mature and Pedagogically Immature (MA_mP_i), Mathematically Immature and Pedagogically Mature (M_iP_m). Specific behaviors that characterized each group are summarized in table 2.

Category	Actions	Focus when reviewing topic
Mathematically Conceptually Mature, Pedagogically Mature (MC_mP_m) (n=2)	• Could articulate the basis for mathematical decisions children had made, offer other relevant mathematical concepts that could be pursued with them. • Suggested other instances of similar conceptual structure from the discipline, offer specific guides for how to extend children's intellectual work-space and a rationale for choice. • Referenced personal encounters with similar issues.	• Interpreted children's work • Identified strengths and relevance of children's ideas from the mathematical standpoint • Commented on connections among representations • Identified strengths and weaknesses of each approach drawing from a long term perspective on content development • Referenced the impact of curriculum and instruction on children's behaviors and mathematical performance.
Mathematically Algorithmically Mature, Pedagogically Immature (MA_mP_i) (n=2)	• Could explain the children's work and sources contributing to their development. • Could offer explanations of why certain mathematical actions were sophisticated. Could not identify trajectory of the concepts. • Managed to see the connections between different representations that children had offered. • Choice for practice was insensitive to context and particularities presented of the case.	• Identified children's errors or misuses of language • Commented on the amount of time it took children to complete tasks • Commented on how children might be guided in the right direction • Identified other instances where children may not be able to perform adequately
Mathematically Immature, Pedagogically Mature (M_iP_m) (n=3)	• Could not adequately unpack the mathematical work of children or their connections to other concepts. Could identify some related concepts that addressed the mathematics presented in the case. • Capitalized on the general practices (affective) suggested as effective for use (group work). • Could set some mathematical goals for children and instruction. • Could identify the impact of school curriculum and instruction on children's work and thinking. • Managed to draw from theoretical views on learning to offer perspectives on why certain pedagogical choices would be suitable.	• Attempted to interpret children's work • Commented on children's apparent talents and verbal ability • Asked questions about what would be appropriate to do • Asked questions about what children might mean • Asked questions about mathematical ideas • Asked questions about tasks that could follow each of the discussions
Mathematically Immature, Pedagogically Immature (M_iP_i) (n=3)	• Could not adequately unpack the mathematical work of the children or their relevance. • Endorsed decision making to students. • Did not formulate specific goals for the children's mathematical learning. • Not committed to learning.	• Avoided commenting on mathematics • Commented on the general attitudes that children had exhibited as they solved or discussed mathematical problems

Table 2: Behaviors and foci of attention of different groups

The different layers of knowledge and maturity of the participants directly impacted what they extracted from illustrations they viewed and how they interacted with them. Figure 1 illustrates a roadmap of anaytical pathways taken by different groups.

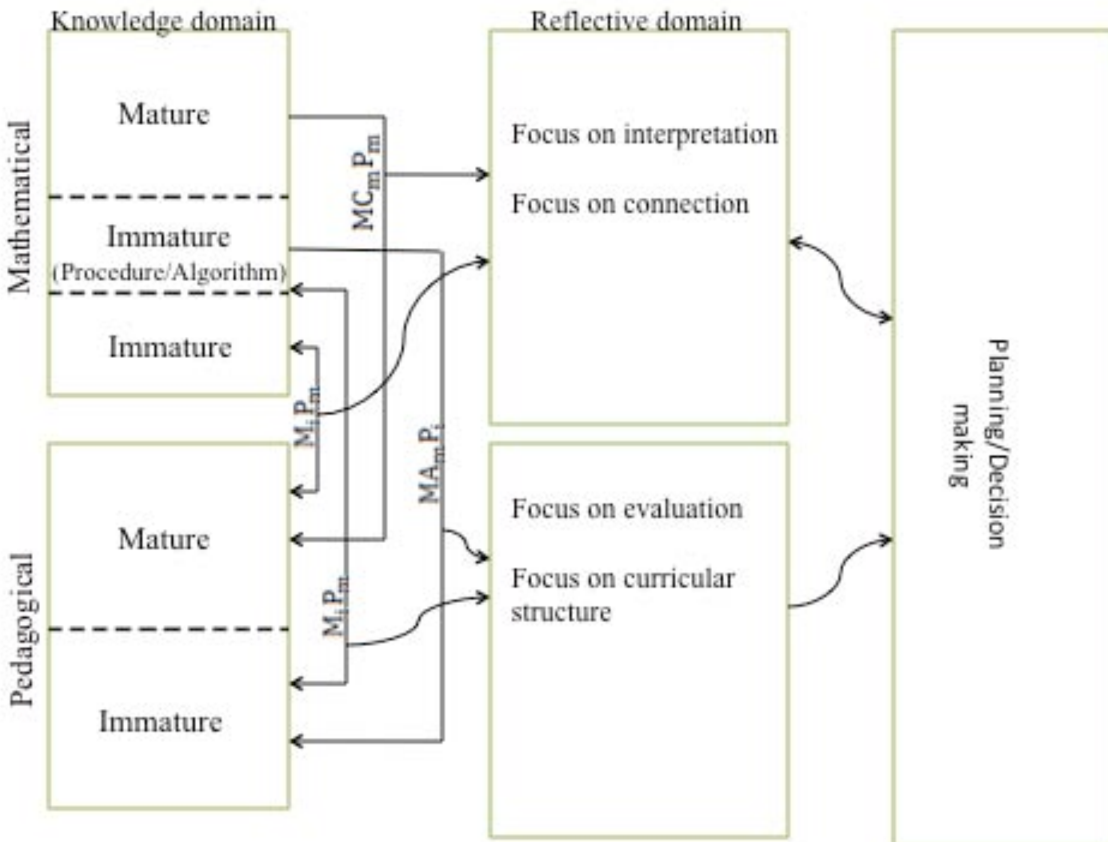

Figure 1: Interactional roadmap

The M_iP_i and MA_mP_i groups consistently spent the least amount of time on discussing the video data (Mean-4 minutes one each case). The MA_mP_i group quickly judged children's work as right or wrong and rarely addressed the connections among various ideas that children had shared. This group also identified what they perceived as gaps in children's understandings and resorted to conventional approaches for leading follow up discussions in class including (showing additional examples, describing procedures). Neither one of these groups expressed a need for additional information. Neither one of these groups showed a desire to consider alternative ways of interpreting children's ideas, unless they were asked to do so specifically..

The M_iP_i participants spent over a half of their analysis time discussing how the manipulative materials could be used to show children different concepts. These discussions did not address the particular ideas presented in the case. In analyzing children's work they focused primarily on affective dimensions associated with classroom learning (i.e. a teacher should acknowledge all answers as correct and praise children for their good work). The general tendency of the group was to avoid judging ideas and refrain from offering specific guides for how a teacher might proceed with instruction. In suggesting pedagogical actions they were willing to endorse mathematical authority to either the children or outside sources. These individuals did not ask questions during the interviews, felt secure in their knowledge about children and/or the pedagogical methods they offered. They were less committed to making sense of the children's ideas or testing their merit since they seldom referenced rationale for children's particular choices or practices.

In contrast, the M_iP_m group consistently spent the largest amount of time analyzing children's behaviors. They reviewed each of the episodes more frequently(n=3). They were concerned about whether they had fully understood the arguments that children presented or accurately assessed the competencies children had shown at each stage. These individuals successfully offered the largest number of mathematical concepts that could be explored in response to the children's ideas in each of the cases they examined. Lastly, these individuals routinely attempted to elicit feedback from the interviewer on accuracy of their analysis or ideas. Indeed, these individuals, when asked to generate a list of topics and areas about which they needed to growth, offered a more accurate assessment of their own educational needs.

Pedagogically and mathematically mature group members showed the tendency to fold back to reviewing the children's thinking at various points in their analysis. They used an "if-then" mode of reasoning when they offered perspectives on what a teacher could pursue in class.

Discussion

The findings of our exploratory study support four conjectures. First, the use of illustrations of children's work and thinking offer fruitful contexts for engaging teachers in generative mathematical and pedagogical inquiry. These discussions, if faciltiated robustly, can significantly enhance the quality of teachers' mathematical knowelge for teaching. Second, in order for resources of this type to have transformational power careful attention needs to be devoted to designing differentiated contexts for discussion and exploration by teachers in order to accomadate for particular strenghts or gaps that might exisit in their knowledge.

Our data indicated that teachers viewed and interpreted tasks differently. Naturally, in the diverse setting of a classroom or professional development program what teachers gain from activities depends largely on their particular learning trajectories. Therefore, in order to optimize the educational impact of case based tasks different structures might need to be put in place. This point drives our third conjecture which highlights the need for development of detailed instructional resources to augment case based tasks. Avilable case based resources, for the most part, rely on a set of guiding questions for individual investigations or group discussions. However, rarely do these materials offer mathematical guide for teachers. This gap is particularly paramount at the secondary teacher education level. A significant finding of this work concerns the sample of teacehrs who despite their immature understanding of mathematics tended to show great sensitivity and care when making decisions about how to proceed with anaylsis of children work or pedagogical decision making. This group seemed most receptive to learning and prepared to seek and justify the need for mathematical knowledge.

Lastly, our data indicate that video-based illustrations of children's work do provide an ideal outlet for motivating detailed analysis since they embody mutiple sources of data for teachers to consider when analyzing children's thinking. In commenting on children's work the teachers frequently referenced particular gestures children had exhibited as evidence of particular congitive actions in which they may have been engaged. Both verbal and non-verbal explanations of children created a space for discussions regarding affective factors influencing mathematics learning.

A particularly powerful outcome of the use of video-based illustrations was evidence of their efficacy for asessing mathematical knowledge for teaching secondary school mathematics. This was an un-expected outcome. Certainly, teachers' analysis allowed us to make and test conjectures regarding their current state of understanding of mathematics, and to formulate plans for the type of follow up activities that might productively advance their thinking. Such an outlet is particularly important for augmenting the content of courses designed for teachers and assessment tools used in teacher education.

Technological progress follows an exponential curve. In order to prepare teachers for middle school students who are accustomed to having digital technologies on hand, teacher educators must help teacher candidates (and in-service teachers) develop technological "habits of mind". This project focuses on the development, implementation, revision, and extension of an instructional sequence designed to support prospective teachers' development of increasingly flexible proportional reasoning skills. Results suggest that prospective teachers may learn how to integrate technology into teaching most successfully when the engage in these practices as part of their own learning rather than when taking technology-specific classes.

Prognosticators suggest that technological innovation will continue to grow at an exponential rate. Given that their social lives are enmeshed in social technologies, it is not surprising the subjects of our study, 38 undergraduates with an average age of 21 years old, are well aware of the ways in which accelerated technological change has altered their lives. What is surprising is that the majority of these prospective teachers feel that they are already "behind the curve" when it comes to figuring out ways to leverage innovations such as e-books and interactive technologies to teach mathematics. The goal of our work has been to explore the nature of this ambivalence by unpacking its constituent parts: prospective teachers' knowledge of --and confidence with—mathematics (proportional reasoning), instructional strategies, and technology in general. According to Mishra and Kohler (2006), teachers who integrate technology effectively in their practice have developed knowledge that lies at the intersection of Technological, Pedagogical and Content Knowledge (TPACK).

Theoretical Framework

In order to support prospective teachers' development of TPACK, we have created an online textbook called the "Dynabook" for use in University-based teacher preparation courses at either the undergraduate (prospective) or graduate (credential) levels. The Dynabook resource incorporates a "mash-up" of research findings and interactive tools from two here-to-fore bounded disciplines: mathematics education and special education. In particular, we have developed challenging proportional reasoning problems based on the work of Susan Lamon (1999) and content described in the Common Core State Standards (ref). The teaching frameworks include a) the Universal Design for Learning (ref), b) the proportional reasoning classification framework described by Khoury (2004), and c) the description of effective teaching shifts in proportionality by Lobato., Ellis, Charles, & Zbiek, R. (2010). Finally, the technological tools include applets for moving blocks on a balance, graphing points and lines, moving gears, creating tables, and links to scripting videos. Figure 1 shows how these pieces fit within Mishra and Kohler's TPACK diagram.

The idea of using TPACK as a framework for organizing modern prospective teacher education programs is not new. For example, Wilson, Lee, & Hollebrands (2011) describe how prospective teachers developed TPACK by examining each of these knowledge components via a video-case. First, the prospective teachers solved the *mathematical problems* using the software featured in the case. Second, they read the lesson plans in the case and discussed various *pedagogical practices* that the teacher in the case had demonstrated. Finally, they attended to the ways in which the students' activities were mediated by their "conversations" with each other and the *technology*.

Zbiek and Hollebrands (2008) discuss two ways that university instructors can support the emergence of technology-enhanced classroom norms in their methods classes. First, they can ask more cognitively demanding questions that can be explored using modeling software. For example, in the current project, we asked a series of questions regarding how weights can be distributed to make a see-saw balance. These questions were explored using a balance applet. Second, instructors can explicitly discuss their efforts to establish norms for argumentation within the classroom culture. For example, instructors may want their preservice teachers to become the ultimate arbiters of whether others' explanations are clear and accurate.

When instructors who use technology effectively can also describe the pedagogical practices they are enacting, the prospective teachers have opportunities for apprenticeship observation (Lortie,1975). In other words, the instructors are able to describe learning as a socially-situated process in which norms for discussion and participation are negotiated on an on-going basis and profoundly affected by practices in which they engage and the tools at hand (cf., Sfard & McClain, 2002; Cobb & Yackel, 1996; Sfard, 2008). Given the view that learning is profoundly affected by the tools we use and the discursive norms that emerge around these tools, how did one promote the aim of preparing teachers to teach mathematics in 21st century classrooms?

The Study

This study was conducted in one mathematics class for prospective middle school mathematics teachers. Activities from the Dynabook were enacted during 12 consecutive ninety minute class sessions. This particular report will focus on the three day sequence involved in using the balance metaphor to model a variety of proportional reasoning examples.

Subjects and Data Collected

The class contains 38 prospective elementary teachers who are taking extra mathematics classes to earn a "mathematics specialization". The particular course focuses on supporting the mathematics learned in middle school from a conceptual point of view. The data set includes, digital images of student work, videotaped classroom lessons, video-based interviews with students working on the tasks, results from a final "far transfer" balance question posed on the final exam, and pre-post results of proportional reasoning items on the *Learning Mathematics for Teaching* test (Hill, Schilling, & Ball, 2004).

Intervention: The Balance Sequence

In choosing contexts and tools that would be a part of the bricolage (Papert, 1993) we bring to bear to support our prospective teachers in proportional reasoning, we were mindful of both their experience as mathematics students and their preparation for teaching. We believed the balance model, or lever, could be a representation that would help us accomplish several things. First, we knew that balance, or more broadly lever, problems are prevalent in upper elementary and secondary texts. While one might argue that "textbook word problems" are not necessarily realistic, they *are* realistic in the realm of prospective teachers who will be helping students solve these types of problems.

Second, we wanted a representation or model on which they could build connections across problem contexts. Students often see proportional reasoning in algebra, geometry, physics, and other quantitative disciplines as distinctly different. Students can gain a conceptual understanding of levers, averages, mixture problems and the geometric mean by connecting them through a familiar model (Flores, 1995). The balance representation had the potential to help our prospective teachers recognize proportional reasoning in different settings and in so doing develop flexibility as proportional reasoners.

Third, we believe the balance or seesaw is an experientially-real context (Gravemeijer, 1999) from which students could potentially draw on their physical experience to immediately engage in personally-meaningful activity. In the absence of physical childhood experiences with seesaws, students could experiment with a physical or virtual model. Finally, our choice was further influenced by another of the design heuristics of Realistic Mathematics Education (RME), that is: students develop models of their informal activity, which become models for more formal mathematical reasoning (Gravemeijer, 1999; 2004; Stephan, Bowers, Cobb, & Gravemeijer, 2003). We believed the balance could serve as a powerful model, such as the empty number line, array model of multiplication, or ratio table. In reifying the notion of equal quantities in the symbolism, they could extend reasoning to contexts beyond those encountered directly with the model.

Results

Results from the paired t-test conducted on pre-post proportional reasoning items of the LMT indicated that the increase in average score was significant at the $p<.001$ level. This indicates that the class did learn how to identify and solve proportional reasoning situations, as well as some pedagogical knowledge associated with teaching such topics. The goal of the qualitative analysis was to explore *how* these pre-service teachers' discursive engagement changed over the course of the study. The outline for this "mini sequence" and the associated mathematical practices that emerged is shown in Figure 1.

	Day 1	Day 2	Day 3	Day 4
Activities	• View intro videos • Read transcript • Solve 3 see-saw problems	• Modeling solutions with applet 1 • Solving extension problems	• Using decimal distance measures	• Introduction of indirect variation
Associated Practices in which students engaged	Students used the drawing tools, video transcript, and experiential knowledge to solve problems. No way to check viability	Assigning any quantity to be represented by weights. Equivalence via multiple representations Notation emerges that reifies action with balance	Modified balance allows for more flexibility in weights, distances, and monomials	Approximately half the class was able to extend the metaphor of the balance to model indirect variation using notion of mathematical equality

Discussion

As mathematics educators interested in the development of prospective teachers' TPACK, we have attempted to create a challenging and cognitively demanding mathematical sequence and associated exploratory applets that engage them in activities that model the effective use of technology in classrooms. Our research has shown that the students did in fact engage in exploratory investigations wherein the balance applet became a strong visual mediator of communication. Moreover, as we had hoped, the use of the applet because reified through students' notation and hence their use of the applet –while initially integral as a model of their problem solving efforts—became reified through their notations as a model for more extensions to the balance metaphor both in terms of "short term" transfer items such as related problems as well as "long term" balance problems such as those involving indirect variation.

A SELF-STUDY EXPLORING THE PRACTICES AND TECHNOLOGIES OF A FACULTY ADVISOR IN SECONDARY MATHEMATICS TEACHER EDUCATION

Kathleen Nolan
University of Regina
kathy.nolan@uregina.ca

Pre-service teachers' negotiations of theory-practice transitions call for an exploration of innovative models for faculty mentoring and professional development. This paper describes a self-study research project to explore a blended real and virtual model for faculty advising (e-advisor) during secondary mathematics teacher education field experiences. One goal of the study is to disrupt traditional notions of teacher education programs as places to 'train' and 'prepare' teachers, with field experience being viewed as the supervised enactment of these preparation techniques. Drawing on concepts of Foucault, the research analyzes the traditionally performed roles of student teacher, teacher educator, and faculty advisor.

Description and Purpose of Research Study

In the field of teacher education, pre-service teachers often reminisce fondly on their experiences as students, holding tightly to their preconceived notions (formed through many years of the 'apprenticeship of observation') of what it means to teach mathematics and, in general, to be a teacher (Begg, Davis, & Bramald; 2003; Britzman, 2003; Lerman, 2001; Lortie, 1975; Nolan, 2010a). Disrupting and reconsidering these notions can prove challenging for both pre-service teachers and teacher educators alike. Pre-service teachers' time in a teacher education program represents a critical period of transition from student to student teacher to teacher. While there has been valuable research to date on the nature of the transitions required for becoming teachers (Garcia, Sanchez, Escudero, & Llinares, 2006; Jaworski & Gellert, 2003; Klein, 2004; Nolan, 2008; Ritchie & Wilson, 2000), the specific areas of teacher education field experiences and faculty supervision models are still relatively under-documented and under-explored in the research literature. This is especially true in the case of teacher educator self-study research that seeks to foster a continuum between the university and the field while, at the same time, disrupting the traditionally performed roles of student teacher, teacher educator, and faculty advisor.

This paper discusses one aspect of a larger project, referred to as the e-advisor project. The research is a three-year self-study of my own practice as a faculty advisor, working with pre-service teachers (interns) during their four-month field experience (internship). The purpose of the evolving e-advisor project is two-fold: (1) to create and sustain a professional development relationship between myself, as teacher educator and faculty advisor, and secondary mathematics interns through the use of multiple technologies (such as desktop video conferencing, video flip-cameras, online chat and discussion forums), and (2) to disrupt traditional notions of teacher education programs as places to 'train' and 'prepare' teachers, with field experience being viewed as the 'supervised' enactment of these preparation techniques. In other words, the overall intent of the self-study is to better understand and deconstruct the role of a faculty advisor in reconceptualizing secondary mathematics teacher education programs and field experiences. This paper focuses predominantly on the second purpose, using Foucault's concepts of discourse, dividing practices, and technologies of the self to analyze two particular storylines from the research data.

CONTEXT, METHODOLOGY, AND THEORETICAL PERSPECTIVES

As a mathematics teacher educator and faculty advisor in an undergraduate teacher education program, one of my greatest challenges is encouraging pre-service teachers to reflect and act on inquiry-based strategies for instruction and assessment in secondary school mathematics. Research indicates that, in spite of introducing new strategies during curriculum courses in teacher education programs, traditional textbook and teacher-directed approaches still prevail in many secondary mathematics classrooms (Lerman, 2001; Nolan, 2006). Pre-service teachers' negotiations of theory-practice transitions from university mathematics curriculum courses to field experience in secondary school classrooms call for an exploration of innovative models for mentoring and professional development. To respond to this call, I initiated a research project to explore the possibilities of a blended real and virtual model for faculty advising during field experience.

At my university (University of Regina), the culminating field experience in a four-year undergraduate teacher education program is a four-month internship experience in schools. Each intern is paired with a cooperating (mentor) teacher and assigned a university faculty advisor. As part of the faculty-intern mentorship relationship and professional development process, faculty advisors are expected to visit, observe and conference with their interns three-five times during this four-month internship. A mentorship based on only three-five visits over four months, however, is not adequate to bring about change in pedagogy nor to disrupt and challenge the view that teacher education programs merely train and prepare pre-services for the *real* experience of school classrooms. As a faculty advisor, my role in the internship feels superfluous, since the cooperating teacher is ultimately responsible for overseeing and evaluating the day-to-day activities of the intern. I have often reflected on my faculty advisor role in the context of feeling like a third wheel—one that does not have clearly defined boundaries or expectations associated with it, and one generally not valued on a journey mapped out for two (intern and cooperating teacher). Through these reflections, I became motivated to better understand my positioning (as a teacher educator and faculty advisor) and the positioning of the pre-service teachers with whom I work during this four month internship.

According to research (Towers, 2008; Van Zoest & Bohl, 2002), the school intern placements—the 'real' classrooms—are frequently not well-aligned with the inquiry-based philosophy and pedagogy being advocated in teacher education programs. In reconceptualizing mathematics teacher education, one must consider the importance of either selecting placement schools with an environment that is well-aligned with reform ideas or working toward "a redefinition and expansion of the role of teacher educator" (Van Zoest & Bohl, 2002, p. 285). In my case—in pondering the shortcomings of the traditional faculty advisor model at my university, including dissatisfaction with my superfluous role in the entire process— I was drawn to the opportunity for redefinition and expansion. I decided to develop a faculty advisor model that would supplement the three-five 'real' classroom visits with additional 'virtual' visits. Thus, the self-study project was initiated in order to understand my role as a faculty advisor and how I could make the role more meaningful to me and, hopefully as a result, also make it more valuable and meaningful to the interns and cooperating teachers.

As a methodology, self-study can be defined as the intentional and systematic inquiry into one's own practice. In teacher education, self-study is powerful because of the potential to influence pre-service teachers, as well as impact one's practice as a teacher educator. Furthermore, self-study can have a broader impact by informing other teacher educators' practice (Loughran, 2007) and thus other teacher education programs. According to LaBoskey (2004), self-study research practice should produce two kinds of knowledge: the personal embodied knowledge of the researcher that often leads to his/her own transformed and reformed practices, and a form of public knowledge that (could) contribute to the transformed and reformed practice of others (in this case, other teacher educators and pre-service mathematics teachers). Both these forms of knowledge are significant in the context of my own Faculty of Education, as well as beyond this context into other teacher education programs across the country and internationally.

Framing self-study in Foucauldian discourse analysis privileges teachers' stories (text and spoken discourse) while providing insights into the ideologies and power relations involved in the discursive practices of mathematics teacher education and field experience. This research draws on poststructural and socio-cultural theories to challenge and disrupt the traditional discourses of mathematics teacher education and field experience and to integrate more reflexive, critical approaches to learning to teach, and teaching to learn, mathematics (Skovsmose & Borba, 2004; Vithal, 2004). Foucault provides a framework for exploring the normalized practices and discourses of schooling as strong forces in shaping teacher identity and agency. Drawing on Foucault's concepts of discourse, power, dividing practices, and technologies of self (Foucault, 1977, 1988; Walshaw, 2007, 2010), this paper explores the practices and technologies of a faculty advisor in secondary mathematics teacher education.

Methods and Data Sources

To transform and reform my own practice as a teacher educator and faculty advisor, my research involves listening to the stories of pre-service teachers. Thus, data collection for this self-study includes interviews and focus groups with the three (3) pre-service teachers (interns) with whom I worked as a faculty advisor during two internship semesters (2009, 2010). The interviews and focus groups were conducted both in person and through video conferencing software. I also kept a self-study reflective artefact (in the form of a Weblog) to understand the role that the e-advisor model might play in the education of secondary mathematics teachers. Through the use of multiple technologies (such as desktop video conferencing, video flip-cameras, online chat and discussion forums, and collaborative authoring/editing through Wiki spaces), I sought to create and sustain a professional development relationship between myself as a faculty advisor and my pre-service teachers (the first purpose of this research study). The second purpose of the study—that of disrupting traditional notions of teacher education as 'training' and 'preparing' teachers—is the focus of data analysis for this paper.

With year two of the three-year self-study research project now complete, key findings have made an impact on our teacher education programs (see, for example, Badali & Nolan, 2010; Nolan, 2010b), in addition to being used to inform and shape the third year of my research study. During each of the first two years of this self-study, a Professional Learning Community (PLC) was sustained 'virtually' through the use of desktop video conferencing (*Skype* and *Adobe Acrobat Connect Pro*), as well as the recording and analysis of videos (*Flip cameras*), online chat and discussion forums, and collaborative authoring/editing through Wiki spaces. These multiple technologies enabled me to supplement the 'real' (traditional school) visits with 'virtual' visits, such that the faculty-student conferencing process evolved into a mentorship relationship that was ongoing, synchronous, and without geographical boundaries. In this brief paper, it is not possible to conduct a thorough analysis of the data, so instead I focus on two particular storylines in the data. The first relates to my attempts to disrupt traditional notions of faculty supervision and classroom observations through the use of flip video cameras; the second storyline conveys my efforts to understand the interns' perceptions of my role as a faculty advisor in their professional development during the internship semester.

Discussions and Interpretations of Data

In the first storyline of the data, I sought to deconstruct traditional models of faculty supervision based in surveillance and 'super'vision techniques. Typically, as a faculty advisor, I would position myself in the back of the classroom to 'observe' the interns, taking notes on anything and everything that the intern might want to know about her practice. While the intern may identify a few targets for me to focus on, it is generally expected that I comment on the lesson structure (set, development, closure, etc.) as well as student and classroom dynamics, from the start of the lesson until the end. My goal in this research, however, was to disrupt such techniques of observation and surveillance. One way I approached this was to ask each intern to use a flip video camera to record three (3) short segments of a lesson, which they uploaded to a website for me to access and view. It was challenging for the interns to understand how this process might provide me with enough visual and auditory 'evidence' of their teaching so as to provide them with appropriate feedback for their professional development. Once they were able to move beyond the notion of professional feedback coming in only one form and obtained by me being physically in the classroom from beginning to end of the lesson, I think that they actually learned a great deal from the process. Instead of the faculty advisor taking on the role of identifying what aspects of a lesson were worth focusing on and analyzing, I was requiring the interns to initiate this decision and reflection on their own, thus disrupting systems of power that "both produce and sustain meanings that people make of themselves" (Walshaw, 2010, p. 111).

After viewing the videos, I engaged in a *Skype* conference with each intern individually. I was able to begin this "post-lesson conference" in a manner quite different from the usual conferences that take place after I have been physically in the classroom for the entire lesson. This time I began the post-conference by asking each intern why she selected these particular aspects of the lesson to capture on video for me to see. As part of my research Weblog, I reflected on how these short video segments changed in focus as the semester progressed. At the start of the semester, each intern captured *herself* on video, generally positioned at the front of the room beside the whiteboard (or SmartBoard), displaying the traditional teacher-centred image of "teaching." As the semester progressed, however, the interns began to feature their *students*, including their conversations with each other and with the (pre-service) teacher, much more prominently in their "teaching videos." In negotiating their identities within the social and political networks of the discursive practices of schools, it seems that the interns began to engage in a reconstruction of traditional images of teaching and the disciplinary practice of the "panoptical gaze" (Foucault, 1977) that is offered by the university through its faculty supervision techniques.

The second storyline conveys my efforts to understand my interns' perceptions of my role as a faculty advisor in their professional development. During the final focus group session with the three interns (using *Adobe Connect*), I questioned the three of them on my role as faculty advisor and its overall value to them in terms of their professional development during the internship semester. The following excerpt is taken from the transcript of that focus group session:

> Intern1: If our coop is doing their job right they really *should* be doing that professional development process with us, so having you there is just kind of extra, I guess. I don't know if it's completely necessary. But if you *were* to do it, I would probably still prefer that you come out and see me.
>
> Faculty Advisor: What [Intern1] brings up is interesting… do you see my role from the university being different—or potentially should be different— than what the cooperating teacher has to offer you in your professional development?

> Intern2: Well, *I* have because [my cooperating teacher] was very new to this… I know that you two have had *some* contact, I don't know how much, but it was nice for her to be able to have you as a liaison kind of, to ask questions to and bounce ideas off of on what her role is because, really, she had no idea of what she was supposed to do.
> Intern1: And I know with [my cooperating teacher] it really *wasn't* different because he's done this before and he's had experience and… like, if I had had problems with him then I would want you there, I would *need* someone else, but since we got along then the roles kind of seem the same to me.
> Intern3: [My coop] and I have had that same conversation because [she] *has* had some interns in the past that didn't go over so well. I don't know, things seemed to go really well with us but if they *didn't*, like [Intern1] said, it would have been nice to have you out…

I didn't exactly leave the conversation here; in fact, I went on to 'dig a little deeper' into their responses to my question. Even though they eventually added that I may have provided them with a few things that their cooperating teachers did not (for example, a few ideas and methods, a once-per-month growth perspective that the coop could not give, etc.), the underlying message of their responses was essentially the same: I was "just kind of extra."

My efforts to disrupt the benign and distant role of the faculty advisor had been constituted by the interns as *extra* and *much the same as the cooperating teacher had to offer*. In their eyes, I had not expanded and redefined my role in the manner I set out to; instead, the interns constructed an identity for me as liaison, mediator, umpire, even peacemaker, but definitely *not* advisor or mentor. They specified that, as long as there are no "problems" with the cooperating teacher, I am not needed. However, the interns' constructed 'truth' of my value as a faculty advisor is not so simply stated if one draws on Foucault's concepts of dividing practices and technologies of the self as a means to unpacking it.

Once in the schools for their field experience, pre-service teachers are "confronted with the task of learning the discursive codes of practice" (Walshaw, 2007, p. 124) in the secondary mathematics classroom, and no longer in my own university classroom. It makes sense that interns would identify their cooperating teachers as being much better positioned to initiate them into these practices. Embedded within the discursive codes of classroom practices are dividing practices—those practices that function to categorize and distinguish people/contexts, and which can be seen to operate across various social situations. Systems of dividing practices have a strong impact on identity formation and "[d]ividing practices that are at odds with each other are most keenly felt by pre-service teachers as they move from one disciplinary institutional site to another" (Walshaw, 2007, p. 100). Since different practices across different contexts contribute to the constitution of one's identity, there can be a sense of internal conflict in attempting to reconcile competing practices. Foucault (1988) proposes that people come to understand (or know the 'truth' about) themselves through various techniques, or technologies. He describes four such technologies, which are interrelated and together form a specific body of reasoning techniques. For the purposes of this paper and brief analysis, Foucault's concept of "technology of the self" is most useful in understanding the truth games being played by the interns.

According to Foucault (1988), technologies of the self "permit individuals to effect by their own means or with the help of others a certain number of operations on their own bodies and souls, thoughts, conduct, and way of being, so as to transform themselves in order to attain a certain state of happiness, purity, wisdom, perfection, or immortality" (p. 18). Interpreting the interns' above response to my question on the value of my role as faculty advisor in the context of Foucault's concepts of dividing practices and technology of the self, I gain a better understanding of the interns' constructed truth stories. As Walshaw (2007) puts it, "the transfer from the university course into the school brought specific dividing practices sharply into focus" (p. 126). Since interns must strategically negotiate the social and political networks of power in the cooperating teacher's classroom, this probably means making a choice: between engaging the technologies and practices which are part of the cooperating teacher's mathematics classroom or engaging (valuing) the set of technologies and practices that I ask them to import, so to speak, from the university classroom. As long as everyone is "getting along" (which, in the context of the transcript excerpt, I interpret to mean that there are no obvious personality tensions or conflicts at work between intern and cooperating teacher) then my technologies and dividing practices are not needed; in fact, they are viewed as a third wheel on the journey, and not one that is easily reconciled by interns as they seek to "transform themselves in order to attain a certain state of happiness, purity, wisdom, perfection…" (Foucault, 1988, p. 18).

CONCLUDING THOUGHTS

Firstly, it should be noted (almost as an aside to the storylines of this paper) that introducing *virtual* visits with the interns has resulted in *real* examples of how the use of multiple technologies can create a faculty-intern relationship that establishes more of a continuum between university courses and internship field experience (Mulholland, Nolan, & Salm, 2010; Nolan & Exner, 2009). The significance of this relationship as interpreted by interns, cooperating teachers and faculty advisors is, however, an issue to unpack. I initiated this self-study research project in order to understand how I could make my role as a faculty advisor more meaningful and valuable to me as well as to the interns and cooperating teachers. Through the lens of Foucault, one sees how multiple 'truths' are constructed for what it means to be meaningful and valuable. I must not confuse *my* truth of what is meaningful and valuable with the *interns*' constructed truth for the same. At the very least, I should not expect my practices and technologies to have a visible (and immediate) impact on my interns' truths at this point in their teacher identity constructions and negotiations. As I delve more deeply into Foucault's concepts for the purposes of further analyzing this research, I appreciate that I am being asked "to always be mindful of the technologies and truth games that simultaneously mold and discipline ways of thinking and being" (Hassett, 2010, p. 462).

Nonetheless, by pursuing what I initially thought would be a meaningful way to fulfill my role as a faculty advisor I was surprised by several emergent aspects of the research. For example, I was able to engage pre-service teachers in dialogue on the role of field experience in shaping student-teacher transitions (even if I was not all that pleased with what I heard in the dialogue!); to disrupt notions of the roles of teacher education programs and field experience; and to challenge traditional images of faculty observation and supervision. Teacher education programs are currently steeped in a technical rational model, reflected in the normalized use of language such as teacher 'training' and 'preparation'. To challenge the dominant image of teacher education as the 'place' where theory makes the transition to practice through teaching tips and techniques, this research takes critical steps toward reconceptualizing secondary mathematics teacher education and associated field experiences.

INTEGRATING CONTENT AND PEDAGOGY IN SECONDARY TEACHER PREPARATION: COLLABORATING ACROSS DISCIPLINARY BOUNDARIES

Priya V. Prasad
University of Arizona
pvprasad@math.arizona.edu

Rebecca McGraw
University of Arizona

Chantel Blackburn
University of Arizona

Traditionally, there has been a sharp separation between mathematics content courses and methods courses for secondary school math education majors. Content courses, many times housed in mathematics departments, and methods courses, housed in colleges of education, provide two different but important perspectives on teaching mathematics. However, often these courses end up working at cross-purposes. This study examines the territory of cross-disciplinary collaboration between mathematicians and mathematics educators in order to understand the ways in which these courses can better integrate mathematical content and pedagogical issues. Observing these collaborations provides a window into the shared and conflicting philosophies of these disciplines.

Undergraduate mathematics teacher education in the U.S. typically consists of content preparation through mathematics courses taught by mathematics department faculty, general education courses taught by college of education faculty, and mathematics pedagogy courses taught by mathematics educators in either colleges of education or mathematics departments (depending on where the secondary teacher preparation program is housed). Recent modifications of this structure include (1) the addition of a “capstone” course focusing on connecting the mathematics students study in college with the topics they will teach, (2) the institution of separate sections of selected upper division mathematics courses for teachers, and (3) the integration of students’ classroom-based experiences with pedagogy courses and the expansion of pedagogy courses over multiple semesters. However, despite these changes, separation of the study of mathematics from the study of mathematics curriculum and pedagogy continues across much of students’ preparation for teaching. The separation persists, in large part, because effective methods for cross-disciplinary collaboration in service of teacher education are not well understood.

The separation of subject matter knowledge from teaching methods knowledge is unnatural and ineffective – teachers must use their mathematical knowledge *in practice* and continually build new knowledge *through practice*. Teacher preparation will be more effective when students are supported in building integrated knowledge; that is, knowledge of mathematics that is tied to issues and concerns of teaching, and knowledge of teaching that is embedded in mathematical understandings. How best to link content knowledge development to development of knowledge of pedagogy is a central question. It is a problem that demands the combined attention of mathematicians and mathematics educators. However, jurisdiction over teacher preparation is generally divided across separate and distinct academic units, and administrative and cultural barriers impede communication and joint work. Clearly, if teacher preparation programs are to be organized so as to support the development of integrated mathematical knowledge for teaching, then traditional disciplinary lines must be blurred and collaborations among mathematicians and mathematics teacher educators must become the rule rather than the exception. Without robust and generalizable knowledge about the processes and products of collaboration, productive collaborations will continue to occur in a hit-or-miss fashion, if they occur at all.

The research reported on here attempts to address this need through an investigation of five math/math-ed co-teaching collaborations. Each collaboration consisted of one university mathematician and one university mathematics teacher educator who co-taught both methods and mathematics courses for future middle and high school teachers. The following research questions guided the investigation.

- How do collaborations develop and evolve? What is beneficial and what is challenging about collaborating?
- What intellectual resources (knowledge, tools, practices) are brought to collaborations and developed through collaborations?
- How does the collaborative process influence the collaborators (e.g., how they think about content/methods, how they think about their practice)?

Theoretical framework

Underlying the investigation is a sociocultural perspective on learning, in which learning is understood to be a fundamentally social phenomenon inseparable from its historical, cultural, and institutional context (Vygotsky, 1981; Wertsch, 1985; 1998). Sociocultural theory assumes that access to the world is mediated by psychological and cultural tools (e.g., languages or other symbol systems). These tools perform supportive, constraining, and transformational functions. Sociocultural researchers examine interactions among human agents as mediated by psychological and cultural tools, and how these interactions are situated within local and broader contexts (e.g., classroom communities, disciplines, and institutions).

Within a sociocultural framework, an academic discipline is viewed as a set of theories, texts, and methods, but also as a community of individuals with particular social practices and styles of discourse (Lattuca, 2002). The methods and practices of disciplines frame the thinking of those who work within them; members of a discipline tend to "see" things in similar ways. At the same time, it is possible to find great variations among members of a single discipline with respect to methodologies, pedagogies, and epistemologies (Lattuca, 2001). Sociocultural researchers interested in cross-disciplinary collaborations must consider how individuals are situated within their respective disciplines, how the disciplines are situated within institutions, and how the disciplines are situated with respect to one another. They must also consider the historical contexts of these interrelationships. Studying any of these aspects of cross-disciplinary collaboration presupposes an understanding of each discipline in terms of (1) its historical, cultural, and institutional context, (2) its tools and methods, and (3) its social practices and discourses. Although a full, or even partial, description of the disciplines of mathematics and mathematics education is not possible in the space of this report, the following is a very brief summary of each discipline, focusing on historical context, methods, and practices.

Mathematics education developed as an area of study at universities during the early 1900s, with research in mathematics education growing out of the fields of mathematics and psychology (Kilpatrick, 1992). Nesher (1997) describes "investigations that could improve the practice of learning mathematics" and "defining (and redefining) the boundaries of mathematics as a subject matter to be learned in school" (p. 34) as two central activities within the discipline of mathematics education. To this list a third activity may be added: developing the pedagogical and pedagogical content knowledge (Shulman, 1986) of future and current teachers. Until quite recently, investigations within the discipline utilized mainly behaviorist theories and an objectivist research paradigm, with quantitative research methods borrowed from the "hard" sciences. In the 1980s, neo-Piagetian, constructivist epistemologies, and associated research methodologies, began to be adopted and utilized by mathematics educators and researchers. Such theories underlie much of the current research on mathematics learning, as well as the practices utilized by (and advocated by) mathematics educators in their instruction of pre-service and in-service teachers.

Mathematics education research took a "social turn" in the late 1980s, however, with the adoption of "theories that [view] meaning, thinking, and reasoning as products of social activity (Lerman, 2000, p. 23). Over the past decade and a half, the analytical lens has shifted from the individual to the group, and many researchers now focus on interactions around mathematics within small groups of students and across large groups of students and teachers (Tsatsaroni, Lerman, & Xu, 2003). Following this trend in mathematics education research, methods for facilitating the development of "mathematical learning communities" have become a focus of teacher education. Currently, both psychological and sociological perspectives influence the content and process of both research and teacher education. With respect to knowledge for teaching mathematics, current influences on the field include the idea of "principled knowledge" as described in *The Mathematical Education of Teachers* (Conference Board of the Mathematical Sciences (CBMS), 2001), the concept of pedagogical content knowledge (Shulman, 1986) and its key components as described by Grossman (1990), and descriptions of the mathematics teachers do in practice (Ball, 2003) and mathematical knowledge for teaching (Ball, Thames, & Phelps, 2005).

Mathematics is typically seen by its practitioners not as a cultural product, but rather as the study of external objects whose properties are not in doubt once discerned and established. "Every problem of mathematics gets solved sooner or later. Once solved, a mathematical problem is forever finished: no later event will disprove a correct solution" (Rota, 2006). This Platonic stance was challenged by discoveries in geometry and analysis in the 19th century, and by problems with the foundations of mathematics in the early 20th century. These events led to various solutions such as logicism, formalism, and intuitionism, all of which, however, retained as a central value the underlying certainty of mathematical ideas (Hersh, 1979). The logical structure of mathematics and the relative permanence of its ideas results in a culture that enjoys an extraordinary degree of consensus compared to other scientific disciplines. Mathematicians tend to view their subject as having a rigid structure, a cumulative nature, and an extraordinary compactness. Paradoxically, this allows for a combative intellectual culture—when there is little doubt that the truth or falsity of a proposition will ultimately be settled by appeal to external norms, there is no need for social practices of negotiation and compromise. Recently, however, some mathematicians have advocated grounding the philosophy of mathematics in human practice, viewing mathematics as a subject whose ideas and methods are still external to its practitioners but nonetheless embedded in human culture (Gowers, 2006; Lakatos, 1976).

Mathematicians can be characterized as working within a "realist" mode of inquiry, while mathematics educators are frequently "relativists." Becher (1987) suggests that an important division exists between these modes of inquiry. For example, scholars working in the humanities (relativists) tend to explore particulars or complexity and interpretation, while pure or natural scientists (realists) focus on universals and simplification (Frost & Jean, 2003). The research reported on here is grounded in an awareness of the ways in which disciplines may differ, but also a wariness of simplistic or naïve assumptions about the nature of disciplines. *Both* *differences in the disciplines themselves and beliefs about differences influence the cross-disciplinary interactions of individuals.*

Collaboration across the disciplines of mathematics and mathematics education is the focus of this research report. Although many definitions of collaboration exist, most include the following elements: (1) commitment to a common goal and the use of a coordinated effort to achieve it, (2) shared authority over the processes and products of collaboration, and (3) sustained engagement in interactions that promote collective and integrative cognition (Amey & Brown, 2004; Bruffee, 1993; John-Steiner, Weber, & Minnis, 1998). From a sociocultural perspective, a fourth element must be added – the development and utilization of a shared discourse through the appropriation and transformation of psychological and cultural tools. In our research, we seek to understand the how this shared discourse develops, how difference in disciplinary cultures are negotiated, and how mathematics teacher education can be enriched by the creation of interdisciplinary knowledge and practice.

A central goal of the collaborations reported on here was to interweave of content and pedagogy in courses in which these two elements have traditionally been separated. The method for achieving this goal was co-teaching, including joint planning, implementation, reflection, and evaluation. Of course, collaborators varied in the nature and development of their collaborations, including the ways in which they engaged together with students in the classroom. Analysis of the nature and processes of co-teaching encompass four broad areas – planning, content integration, teaching, and assessment (Davis, 1995). With respect to content integration, analysis is guided by the concept of "principled knowledge" as described by CBMS (2001), and categories and descriptions of "mathematics knowledge for teaching" suggested by Ball, Thames, and Phelps (2005), which include (1) common content knowledge, (2) specialized content knowledge, (3) knowledge of content and students, and (4) knowledge of content and teaching. The use of this framework allows for analysis of the extent to which collaborations between mathematicians and mathematics educators support the development of the specific types of mathematical knowledge that prospective teachers will need in practice. With respect to the analysis of the teaching component of the collaborations, we utilize the classification of the classroom roles suggested by Haynes (2002), which include model learner, observer, co-lecturer, discussion leader, case facilitator, and resource, and (2) the dimensions of collaboration described by McDaniel & Colarulli (1997), including the degree of integration of ideas and perspectives, the degree of interaction of faculty members with students, the degree of student engagement, and the degree of faculty interdependence.

Methods

Multiple data sources are being used to investigate the work of each collaborative team. All meetings of collaborative teams at their home institutions were audio-taped by the team members themselves, "records of practice" were created by each team for one unit of instruction per course taught, and team members were interviewed individually at regular intervals (approximately twice per month) by research team members during the semesters during which the collaborative teams co-taught. The interviews are being used to gain insight into underlying perspectives of the collaborators and the influence of their perspectives on the collaborations.

The unit of analysis in the study is the interactions between team members, as mediated by psychological and culturally specific tools, and as situated within sociocultural settings. For our purposes, an "interaction" is defined as a bi-directional instance of communication around a common topic. The beginning of an interaction is marked by entry into the topic by one collaborator, followed by an on-topic response by another collaborator. The end of an interaction is marked by disengagement from the topic by one collaborator. Analysis of movement between topics, i.e. “boundaries of interactions”, is crucial, as it is in these spaces where power relations are most transparent. Analysis of strings of interactions over time allow for the identification of patterns, with respect both to the development of the intellectual terrain and the nature and process of collaboration. Rather than depending on self-reports, data includes transcriptions of all meetings of collaborative pairs at their home institutions. The within-collaboration purpose of these meetings is to plan and reflect upon course activities, but from a research perspective the meetings are an irreplaceable source of unfiltered information about the nature of out-of-class collaborative work. Within the courses, videotape was collected for one unit of instruction (minimum of 3 hours of instruction).

Analysis includes the identification of tools and the ways they are utilized and transformed by team members as they interact with each other and with students, and patterns of interaction within teams (as mediated by tools), e.g., the development of a shared discourse, and how it evolves over the course of the collaboration. Discourse analysis techniques are being used to examine the evolution of speech patterns within teams, including the nature of speaking turns, and the use of contrastive pronouns (Edwards & Lampert, 1993; Gee, 2005). Consideration is paid to the way tools limit and constrain interactions as well as the ways they afford and transform it, with the goal of identifying both generative and limiting collaborative practices.

Analysis of the nature and processes of collaboration encompass four broad areas – planning, content integration, teaching, and assessment (Davis, 1995). We use qualitative data analysis software (Transana) to organize segments of interaction into conceptual categories, and analytical frames derived from the theoretical framework as starting points for analysis. However, we also develop meanings and relationships through the analysis process. With respect to teaching, analysis is guided by (1) the classification of the classroom roles of team teachers suggested by Haynes (2002), which include model learner, observer, co-lecturer, discussion leader, case facilitator, and resource, and (2) the dimensions of collaboration described by McDaniel and Colarulli (1997), including the degree of integration of ideas and perspectives, the degree of interaction of faculty members with students, the degree of student engagement, and the degree of faculty interdependence. Attention is also paid to issues identified in the literature on collaborative practice, including differences in roles, time demands, competing obligations, expectations, and differences in work methods (John-Steiner, Weber, & Minnis, 1998).

The trustworthiness and generalizability of findings are established by (1) the independent analysis of a representative samples of data by multiple individuals trained in the use of the particular theoretical and analytic frames adopted in this study, (2) the systematic search for alternative categorizations and meanings, and disconfirming evidence, throughout the data analysis process, (3) “member checks” in which findings are discussed with individual participants, and (4) the use of multiple sources of evidence (i.e., triangulation). With respect to triangulation, findings are based on the following data sources: (1) within-team meetings that occurred throughout the semesters of co-teaching, (2) bi-monthly interviews with each team member, (3) “records of practice,” including videotape, for of one unit of instruction per course taught, (4) interviews of colleagues at participating institutions, and (5) discussions of findings with team members.

Results

Preliminary results have yielded a promising window into the rewards and challenges of collaboration across fields. Collaborators participating in the study not only created meaningful strategies for the integration of content and pedagogy in their classrooms, but also uncovered their own basic assumptions about the effectiveness of particular teaching methods. Issues that arose across the teams included the lack of adequate preparation time, the challenges of decision-making with a partner (both within and without the classroom), and the demands of clear communication with students. However, every participating team felt they had a greater understanding of the norms and concerns of their partner's field of study as a result of the collaboration. Mathematics teacher educators spoke of gaining a greater sense of the importance of mathematical rigor and why mathematicians emphasized it so strongly in class. Mathematicians were exposed to alternate ways of teaching mathematics and, in some cases, carried these new methods into courses that were not co-taught(or even necessarily made up of preservice teachers. Results from two of the four sites, encompassing three collaborations, will be discussed in further detail here.

Southeast

This site was home to two collaborating teams who co-taught a total of five courses. Elizabeth Durand, the mathematician, and Cynthia Roberts, the mathematics educator, were initially wary of the other's knowledge in their own primary field of work. However, they found their teaching philosophies to be more aligned than they had previously assumed. Dr. Durand jumped eagerly into unfamiliar teaching actions, like facilitating class discussions, even as she struggled with being so far out of her comfort zone. Dr. Roberts, meanwhile, found more mathematical confidence from working with Dr. Durand. In contrast, the other team from this site, Angela Laurent and Dejan Merakovski, started their collaboration with extremely different teaching styles and underlying philosophies. This led to extensive conversations on the use of technology in the classroom and the development of appropriate tools for assessment. In fact, one discussion that spanned two semesters of their Geometry course concerned the creation and utilization of a rubric for grading homework. A career mathematician, Dr. Merakovski expected formal mathematical proofs from his students, and had previously relied on a primarily intuitive method of evaluating student work. He "knew" when a proof was sufficiently rigorous. However, since he and Dr. Laurent shared responsibility for grading homework, it quickly became necessary to create a system that ensured consistency in assessment. Dr. Laurent's solution to the problem was to create a formal rubric that clearly let students know what was necessary for a mathematically rigorous proof. For Dr. Merakovski, however, the rubric was too codified and seemed to take some of the elegance out of a well-constructed proof. This difference of opinion was central to understanding the different approaches to teaching and mathematics that these collaborators embraced. While Dr. Laurent proritized communication and clarity over other considerations, Dr. Merakovski felt that part of his job as a mathematics professor was to help students grasp some of the more ephemeral concerns of aesthetics in mathematics.

Developing good mathematical communication in students was a central objective in both collaborations. To this end, Drs. Durant and Roberts, frustrated by the quality of work they were receiving from their students, began to ask their students to critique responses that had been produced by their own classmates. Responses were culled from quizzes they gave and activities were built around assessing the responses for correctness, clarity and completeness. When working on these activities in groups, not only did students usually manage to appropriately assess their peers' work, they also gained the pedagogical experience of evaluating student work.

The pedagogical aspects of these activities were also assessed in the form of a test question that asked the preservice teachers to critique hypothetical student answers to mathematical problems.

Midwest

At this site, the collaborators had co-taught a course before they participated in the study, so they spent less time negotiating their way through the preliminaries of collaboration and more time explicitly thinking about strategies for integrating content and pedagogy. Moreover, due to the structure of the mathematics education program at this site, the mathematician, Ibrahim Haddad, had already garnered some experience with preservice teachers. Given the chance to be involved with the methods course, however, gave Dr. Haddad a chance to observe student teachers in action and experience life in secondary school classrooms. This exposure led him to reevaluate some of the assumptions he had made about the efficacy of certain elements of the curriculum for preservice teachers.

Since Dr. Haddad and his partner Chris Adams began the study as a functioning team, they began planning the courses with a shared vision: there would be a clear mathematical goal and a clear pedagogical goal for each class meeting of each course. They developed instructional cycles for both the content class and the methods class with the intent of constantly contextualizing content within classroom realities (content course) and continually modeling teaching methods by teaching content (methods course). Both instructional cycles included a "classroom connection," and both courses were designed with "mathematical habits of mind" as an articulated student learning goal. As both of these courses ran concurrently and there was a large intersection between the class rosters, Drs. Adams and Haddad found themselves occasionally losing track of which class was which. In fact, both classes were taught in the same classroom, on alternate days of the week. In planning meetings, the collaborators found themselves moving from discussions of one course into discussions of the other fluidly. Interestingly, the extreme amount of overlap seemed to make it easier for them to integrate content and pedagogy, since the confusion may have broken down preconceived notions of what subject matter belonged in each course.

Data analysis is ongoing, however initial analysis suggests that significant boundaries exist between the mathematics and education communities with respect to (1) appropriate use of in-class time, (2) methods and value of utilizing technology in the service of instruction, and (3) goals and processes of student assessment (discussed earlier). With regard to in-class time, we found the mathematics educators to be more likely than the mathematicians to think of class time as time for "doing mathematics" while the mathematicians saw greater value in demonstrating ideas to the whole class. Importantly, both types of individuals seem to believe that active engagement was essential for learning; the difference was in the role of in-class time in this process. All collaborators felt the fundamental tension of desiring both depth of understanding and coverage of content. With respect to utilization of technology, the mathematics educators developed Powerpoint slides for organizational purposes, to highlight key ideas, and to introduce problems. They also used technological drawing tools (e.g., GeoGebra). The purposes and value of such technology was questioned by the mathematicians, some of whom wondered whether the time and energy spent in learning and using the technology could not be better spent elsewhere.

Discussion

The purpose of the study described here was to investigate the processes and outcomes of mathematics/mathematics education co-teaching collaborations. Participants constituted five collaborative teams and have, to date, co-taught ten courses (mathematics and methods) for future middle and high school teachers. Although significant data analysis is currently in process, we are able to report some findings at this time. The collaborative experience was quite intensive - both intellectually and with respect to the sheer amount of time involved – but all collaborators agree that is has been a worthwhile endeavor. It is important to note here that co-teaching comes with a significant financial cost, since two professors receive credit for teaching one course. However, we would argue that resulting knowledge in the form of connections between mathematical and pedagogical learning for students, and knowledge of what is involved in working across the academic cultures of mathematics and mathematics education are valuable goals deserving of substantial investment.

MATHEMATICS EDUCATION AS AN EXTENSION OF DEWEYAN REFLECTIVE MIND DEVELOPMENT

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

I extend the theoretical work on reflective thinking by John Dewey—in particular, that education involves a certain type of mind development—into the supra-individual realm to argue that mathematics education can involve the development of mathematizing intellectual entities that stretch across student partners, small groups, whole classes, and even teacher professional development collectives. Beginning with the reflective development of their own minds in collaborative practice, teachers can learn the skills necessary to help individual students and collections of students become reflective mathematics problem-solvers.

Introduction

Although mathematics education has used a variety of psychological perspectives on the teaching and learning process to inform its work, these perspectives have, with rare exceptions, focused on how *individual students* make sense of mathematics. Intensive work with constructivist epistemologies, for example, involves only the individual pupil's cognitive constructions. Even social constructivist researchers, although acknowledging the social component of mathematics learning, still maintain the individual as the "locus of learning" (Davis & Simmt, 2003, p. 153) when they examine the social implications for learning; classes still are viewed as "groups-of-individuals" (Lave, 1996, p. 149).

When it comes to teaching mathematics, the story is much the same: Contemporary mathematics instruction is designed for augmenting the learning of individuals. Differentiated instruction is a clear example of carrying classroom mathematics learning to the individual-is-the-focus extreme, where some researchers suggest teachers should adapt their instruction to meet the diverse needs of unique individuals (Darling-Hammond, Ancess, & Ort, 2002). Other researchers have called for smaller class sizes (Bloom, 1984) to facilitate the teaching of the individual. Homogenizing the mathematics class through tracking or grade-level advancement is an attempt to "individualize the group," perhaps glossing over the richness inherent in classroom environments. The fact that students are assembled in a classroom to learn mathematics results from efforts to make schooling efficient and affordable, and not from a plan to create and harness community action for learning. In addition, the competitive nature of classes, the assignment of individual grades, and the assessment of the isolated individual's capacities through closed-book, written examinations confirms that although students are physically together in classrooms, mathematics learning has focus on the individual. This paper extends the theoretical work on reflective thinking by John Dewey—in particular that education involves the development of mind—into the supra-individual realm, to argue that mathematics teaching can involve the development of mathematizing intellectual entities that stretch across collectives such as student groups, classes, and even teacher professional development groups.

Theoretical Perspective and Method

Various researchers have suggested such dominant individualistic perspectives could be balanced with a perspective on the social (Boaler, 1999; Davis & Simmt, 2003; Davis & Sumara, 2001; Schoenfeld, 1994). Such a view would be beneficial, especially as many believe mathematics, as a domain, transcends any individualistic perspective (Ernest, 1990; Romberg, 1994). From this perspective, mathematics emerges through communicative correspondence, socially posed questions, and group deliberations; all mathematical discovery, all mathematical activity, all mathematical explanation can be seen to take place in a complex social context. As Boaler (1999) stated, “The behaviors and practices of students in mathematical situations are not solely mathematical, nor individual, but are emergent as part of the relationships formed between learners and the people and systems of their environments” (p. 260). Even Newton recognized this social dependence: “If I have seen farther than others,” he said, “it is because I stood on the shoulders of giants.”

The field of mathematics education has been developing novel approaches to the study of collective classroom learning (Cobb & Yackel, 1995; Davis & Simmt, 2003). This paper extends this work through a theoretical exploration of the ideas of John Dewey regarding education and reflective thought, as applied to supra-individual phenomena. In particular, I first synthesize his ideas about education, reflective thinking, and mind development, and then I apply these ideas beyond the individual; this theoretical coupling is an instrumental study that generates theory for broader application (Stake, 1994).

Results

According to John Dewey (1981/1933), the act of teaching mathematics is intimately involved with the development of mind, namely, of enhancing the mind’s capacity to think: “We state emphatically that, *upon its intellectual side education consists in the formation of wide-awake, careful, thorough habits of thinking”* (p. 177, emphasis in original). Dewey also stated: “LEARNING IS LEARNING TO THINK” (p. 176, emphasis in original); he believed that the teaching/learning process helped students develop their mental capacities. Dewey also proposed that minds can refine their mode of thinking through practice—this implies that wherever there is mind, there can also be “mind refinement.” He also maintained that minds could operate on different levels, i.e., not all types of thought were equal:

> Some of these ways [of thinking] are better than others; the reasons why they are better can be set forth. The person who understands what the better ways of thinking are and why they are better can, if he [or she] will, change his [or her] own personal ways until they become more effective… The better way of thinking … is called reflective thinking. (p. 133)

John Dewey considered reflective thinking as a special thought process. Out of the experience of life arise perplexities or problems, and “*demand for the solution of a perplexity is the steadying and guiding factor in the entire process of reflection”* (Dewey, 1981/1933, p. 122, emphasis in original). Reflective thinking involves careful scrutiny of available data, the formation of possible hypotheses, and their testing through action. There is “a question to be answered, an ambiguity to be resolved, [which] sets up an end and holds the current of ideas to a definite channel” (p. 121). It is a highly developed, refined, and disciplined mode of thinking, not exercised by all minds. Dewey (1981/1933) stated:

> One can think reflectively only when one is willing to endure suspense and to undergo the trouble of searching. To many persons both suspense of judgment and intellectual

> search are disagreeable; they want to get them ended as soon as possible. They cultivate an over-positive and dogmatic habit of mind, or feel perhaps that a condition of doubt will be regarded as evidence of mental inferiority. (p. 124)

A reflective thinker is able to overcome the urge to make a quick, unjustified, spontaneous decision about a perplexity and begin a process of inquiry that leads to knowledge generation and an understanding of the dilemma:

> It is at the point where examination and test enter into investigation that the difference between reflective thought and bad thinking comes in. To be genuinely thoughtful, we must be willing to sustain and protract that state of doubt which is the stimulus to thorough inquiry, so as not to accept an idea or make positive ascertation [sic] of a belief until justifying reasons have been found. (Dewey, 1981/1933, p. 124)

Through the process of reflective thinking, an individual is able to provide grounded evidence for beliefs held, and act in reasonable, justifiable ways. Refined thinking leads to refined actions, higher forms of thought leading to higher forms of action:

> [Reflective thinking] emancipates us from merely impulsive and merely routine activity…. it enables us to act in deliberate and intentional fashion to attain future objects or to come into command of what is now distant and lacking. By putting the consequences of different ways and lines of action before the mind, it enables us to *know what we are about* when we act. *It converts action that is merely appetitive, blind, and impulsive into intelligent action*. (Dewey, 1981/1933, p. 125, emphasis in original)

In addition, the reflective mind learns through all its actions: "A great advantage of possession of the habit of reflective activity is that failure is not mere failure. It is instructive. The person who really thinks learns quite as much from his [or her] failures as from his [or her] successes…. Nothing shows the trained thinker better than the use he [or she] makes of his [or her] errors and mistakes" (Dewey, 1981/1933, p. 206).

The formation of the mathematics teacher's *individual* mind is at the heart of the teaching process: "The only way to increase the learning of pupils is to augment the quantity and quality of real teaching (Dewey, 1981/1933, p. 140). If the teacher's mind can be adequately formed, reaching sufficient levels of reflective thought, then it is in a position to provide for the formation of other reflective minds such as the students (and as I will argue later, supra-individual minds like the class or professional development groups). Teachers who have developed and refined their minds carefully control their actions, basing their actions upon beliefs that are rigorously grounded on a foundation of evidence. Teachers should be consciously aware of why they act, and should be able to support their decisions and judgments with evidence. As Shulman (1987) stated:

> The goal of teacher education… is not to indoctrinate or train teachers to behave in prescribed ways, but to educate teachers to reason soundly on their teaching as well as to perform skillfully. Sound reasoning requires both a process of thinking about what they are doing and an adequate basis of facts, principles, and experiences from which to reason. Teachers must learn to use their knowledge base to provide the grounds for choices and actions. (p. 15)

Reflective teaching turns teachers into powerful agents that can influence strongly the students in their classrooms. These teachers carefully scrutinize their experience against their knowledge to reach justifiable conclusions and act accordingly. Other's opinions form ideas to be considered rather than mantras to be followed: "The material supplied from the experience of others is testimony: that is to say, evidence submitted by others that is to be employed by one's own judgment in reaching a conclusion" (Dewey, 1981/1933, p. 323). These teachers are powerful because of their powerful actions; powerful actions resulting from powerful modes of thought.

When teachers are reflective, they have a greater capability of helping their students to become reflective. Children naturally exhibit reflective behavior (Dewey, 1981/1933, p. 181); the key is only to capitalize on this natural instinct. In addition, "any subject… is intellectual… in its function—in its power to start and direct significant inquiry and reflection" (Dewey, 1981/1933, p. 149). It seems surprising then that many teachers are unable to combine naturally reflective children with subject matter that possesses reflective capabilities and generate reflective discussion. This is because many teachers are not yet reflected thinkers themselves. "Many a teacher is misled into supposing that he [or she] is engaged in disciplining the mind of pupils, when in reality he [or she] is creating an aversion to study and a belief that using the mind is a disagreeable, instead of a delightful, operation" (Dewey, 1981/1933, p. 183). As John Dewey mentioned:

> Only a teacher thoroughly trained in the higher levels of intellectual method and who thus has constantly in his [or her] own mind a sense of what adequate and genuine intellectual activity means, will be likely, in deed, not in mere word, to respect the mental integrity and force of children. (1904, p. 22)

Preservice, beginning, or experienced teachers should strive to become better reflective thinkers so as to better form the minds in their midst; collaboration is a principal means to achieve this.

Working in communities would help preservice, beginning, and experienced teachers develop their reflective capacities. The community provides an environment for the "steady infusion of new ideas" (Hiebert & Stigler, 2000, p. 15) and as a testing element for inquiry. Rodgers (2002) stated:

> No teacher outgrows the need for others' perspectives, experience and support— not if they are interested in being what Dewey calls life-long students of teaching. The community… serves as a testing ground for an individual's understanding as it moves from the realm of the personal to the public. A reflective community also provides a forum wherein the individual can put form to what it is he or she was thinking—or feeling—in the first place. (p. 857)

Schön (1983) explained the importance of community for reflection: "The teacher's isolation in [his or] her classroom works against reflection-in-action. [He or she] needs to communicate [his or] her private puzzles and insights, to test them against the views of [his or] her peers" (p. 333). Communities help teachers "to realize how difficult and yet how essential it is to be able to consider phenomena from various perspectives and to experience others' constructions of meaning in the development of one's own knowledge" (Feldt, 1993, p. 401). Rodgers (2002) also considers other benefits of community for reflective development:

> I have identified at least three factors that highlight the benefits of collaborative reflection: 1) affirmation of the value of one's experience: In isolation what matters can be too easily dismissed as unimportant; 2) seeing things "newly": Others offer alternative meanings, broadening the field of understanding; 3) support to engage in the process of inquiry: The self-discipline required for the kind of reflection that Dewey advocates, especially given the overwhelming demands of a teacher's day, is difficult to sustain alone. (p. 857)

The community provides both the support and training needed for reflective development. Teachers can be exposed to others' ways of thinking, and experiment and test ideas in a non-threatening environment (Stigler & Hiebert, 1999, p. 152).

By working in communities, teachers can develop and refine their minds' capacities for reflective thought. Feldt (1993) stated that Piaget himself "emphasized that … peer interaction, that is, discussion and intellectual exchange, facilitated the knowledge-acquisition process by serving as a catalyst for reflective thought" (p. 401). Shulman has said (as quoted by Frykholm, 1998, p. 318):

> This teaching [*Standards*-based] can only be achieved if we also buy a Deweyan model of teacher development where the end of teacher development is not some fixed and final set of teaching knowledge, understandings, skills, [or] competencies… If we recognize teacher learning is an ongoing process with a form of inquiry as its goal, then that type of inquiry must go on in institutions and settings beginning with teacher education and continuing throughout their careers. [These settings must be] characterized by teachers actively contemplating their own teaching and their students' learning, having the opportunity to reflect on these activities… and to do that with teachers who are engaged in similar activities, in a culture that makes space and time and rewards consistent with the notion that if teachers aren't learning, student learning will be a transient phenomenon. That is the Deweyan vision. (Shulman, 1995)

Working effectively with colleagues is an essential component in the reflective development of any teacher. In a way, a teacher's professional development group forms a cognitve entity that tutors the teacher.

Following Dewey's belief that minds can operate at different levels of effectiveness, I extend this idea to include that *mind*, wherever it may be found, either individual or collectively-formed, can function at different levels of cognitive thought—and reflective thinking forms a better mode of operation for *any* mind. Like the individual human mind, this implies supra-individual minds can operate at various cognitive levels as well, the highest and most developed being reflective and collective cognition. Sounds far-fetched? It shouldn't be: Researchers have been touting the brilliance of collectively-formed minds from lowly bacteria to the wisdom of human crowds for decades (see Shapiro, 1998 or Surowiecki, 2004 for concise reviews of this literature).

The mathematics classroom environment provides an ideal locale to bring together minds. In school, minds are brought together in one location, but their proximity in space does not necessitate their being brought *together cognitively*. Teachers have the opportunity of taking the individual minds present in their classroom and weaving them *together* to form a higher cognitive identity, galvanizing the collection of single student minds into a larger collective thinking unit—a class mind or a supra-student mind, if you will. Thus, mathematics teachers can be involved in mind formation at various levels: both the creation of larger minds and the refinement of existing minds toward reflective possibilities.

Discussion

A handful of researchers have begun to investigate mathematical learning in such collectives using the newly-developed theory of *complexity theory* (Davis & Simmt, 2003), which investigates the cognition of learning systems: Mathematics is a collective action by thinking entities that engage in communal mathematizing—as a whole—and provide substantial opportunities for individual contributions. Because "complex systems transcend their components" (Davis & Sumara, 2001, p. 88), creating novel phenomena unpredictable from the components' behavior, a new kind of research is needed to understand the behavior of these systems:

> At each level of complexity entirely new properties appear, and the understanding of the new behaviors requires research which I think is as fundamental in its nature as any other.… At each stage entirely new laws, concepts, and generalizations are necessary, requiring inspiration and creativity to just as great a degree as in the previous one. Psychology is not applied biology, nor is biology applied chemistry. (Anderson, 1972, p. 393)

Complexity theory allows mathematics classes functioning jointly as mathematizing superminds to be envisioned and studied from a scientific perspective. It opens up a vista heretofore unseen by previous individualistic perspectives.

These complex systems are composite entities formed from interacting, interrelated components: "For reasons that are not fully understood, under certain circumstances agents can spontaneously cohere into functional collectives—that is, they can come together into unities that have … potential realities that are not represented by the individual agents themselves" (Davis & Simmt, 2003, p. 141). These smaller entities interact synergistically to form a whole whose potentialities are larger than the sum of the parts. The whole becomes an object with power that did not exist previously in any of the components, and the whole often exhibits holistic learning capabilities at the system level (Delic & Dum, 2005). Examples of complex systems abound, from ant colonies to economies to nations. The human body is made up of trillions of individual organisms—cells—that are independent living creatures (they can even be separated from the larger host and kept alive, as in blood transfusions, organ transplants, skin grafts, etc.), but when brought together these tiny creatures interact in such a way as to form a larger whole that is much more than the sum of its parts. The cells exist together not only in one location, they also exist together functionally. And just as individual cells can form a larger person, so too can individuals in a classroom merge to form a larger learning entity—a mathematically functioning classroom "organism."

Complexity theory may help researchers understand classroom dynamics because students' actions are affecting the system they constitute while simultaneously being affected by that system (Davis & Simmt, 2003). The mathematical development occurring is an entire class phenomenon—the result of "joint productive activity" (Stein & Brown, 1997, p. 175). Knowledge becomes "stretched over" (Lave, 1988, p. 1) the entire class, not the domain or possession of any one individual; the mathematics is situated, social, and distributed (Putnam & Borko, 2000). Whereas individual and social constructivist paradigms focus on the individual as the "locus of learning," complexity theory sheds light on how the class as a whole develops mathematics. Individual knowledge in such a situation cannot be understood, complexity theorists claim, by slicing up the classroom and ignoring the larger collective entity of which the individual is an active part.

Conclusion

This paper has explored the writing of John Dewey on reflective thinking and mind development to extend these concepts into the realm supra-individual mind development. Just as a student can reflectively engage in mathematics problem-solving, so too can a group of students, or even the entire class. This perspective suggests that individual student mathematical learning can be augmented if teachers attend closely to cognizing classroom collectives (Davis & Sumara, 2001); these entities, as "mathematizing communit[ies]" (Sfard, 2003, p. 381), parallel the type of communities mathematicians learn and work in (Romberg, 1994). In particular, mathematics educators can apply the principles of good teaching espoused by John Dewey into a pedagogy that respects not only individual student or teacher learning, but various supra-individual learning such as partner, small group, whole-class, or teacher professional development groups. I have extended the theoretical work on reflective thinking by Dewey—in particular, that education involves a certain type of mind development—into the supra-individual realm to argue that mathematics education can involve the development of mathematizing intellectual entities that stretch across student partners, small groups, a whole class, and even teacher professional development collectives. Beginning with the reflective development of their own minds in collaborative practice, teachers can learn the skills necessary to help individual students and collections of students become reflective mathematics problem-solvers.

USING A LESSON EXPERIMENT TO INVESTIGATE THE PROMISE OF DIFFERENTIATED INSTRUCTION FOR PROSPECTIVE ELEMENTARY TEACHERS: AN AREA AND VOLUME LESSON

Megan Schnorenberg
University of Wyoming
mchambe5@uwyo.edu

Michelle T. Chamberlin
University of Wyoming
megdiane@uwyo.edu

A lesson experiment was used to investigate how differentiated instruction impacted prospective elementary teachers' conceptual understandings of area and volume. Results include how the differentiation supported learning as well as how to enhance future instruction. Information will be provided about differentiated instruction, prospective teachers' understandings and learning in measurement, and lesson experiment methodology.

The mathematical preparation of teachers has recently been a renewed topic of national attention. *Mathematics Teaching Today* (National Council of Teachers of Mathematics [NCTM], 2007) states teachers need to be "fluent in the language of mathematics and have broad and deep knowledge of mathematical content, processes, and contexts" (p. 119). Similarly, several sources are calling for teachers to possess "mathematical knowledge for teaching" (e.g., Delaney, Ball, Hill, Schilling, & Zopf, 2008; National Mathematics Advisory Panel, 2008). As such, there is little disagreement that teachers need a deep and robust knowledge of mathematics for teaching. The more challenging aspect however is "In what ways do the content-learning experiences in your teacher-preparation . . . program help develop the robust and connected mathematical understandings needed for teaching?" (NCTM, 2007, p. 197). This dilemma is magnified by the varying understandings, interests, backgrounds, and learning preferences that prospective teachers bring to their undergraduate mathematics courses.

Such student variance is evidenced in nearly all classrooms. To address such diversity in grades K-12, teachers have been using *differentiated instruction*, a process of proactively modifying instruction based on students' current understandings, interests, and learning preferences. Effective characteristics of differentiated instruction include clear learning goals, ongoing and diagnostic assessments that modify instruction, and challenging tasks for all students. The approach is supported by literature on learning and has resulted in the improvement of students' learning. Yet, very little research literature reports on the use of differentiated instruction at the undergraduate level, especially with prospective teachers in mathematics courses. Chamberlin and Powers (2010) demonstrated the potential of differentiated instruction at the undergraduate level by finding that prospective elementary teachers receiving differentiated instruction experienced greater gains in their mathematical understandings. Questions remain however about specifically *how* differentiated instruction impacts the learning of prospective teachers. The objective of this study is to investigate how differentiated instruction impacts the mathematical understandings of prospective elementary teachers enrolled in a mathematics content course.

Background and Theoretical Framework

Differentiated instruction is a process of proactively modifying curricula, teaching methods, learning activities, and assessments to meet the diverse needs of students and thereby to maximize access to, motivation for, and efficiency of learning (Tomlinson, 1999). These changes

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

are based on students' readiness (current understandings), personal interests, and learning profiles (learning styles, culture, and gender) (Tomlinson et al., 2003). Differentiated instruction is supported by theoretical literature on learning (Subban, 2006; Tomlinson et al., 2003; Tomlinson & McTighe, 2006) as well as empirical research. Empirical studies across several grade levels have found that differentiated instruction leads to achievement gains on standardized tests, including mathematics assessments (Hodge, 1997). While achievement gains have been found for all students and across all racial and socioeconomic groups (Brighton, Hertberg, Moon, Tomlinson, & Callahan, 2005; Tomlinson, 2005), some studies have found particular improvement for historically low-performing students, students with exceptional needs, and students with gifted abilities (Batts & Lewis, 2005; Brimijoin, 2002; McAdamis, 2001).

Several core principles guide differentiated instruction (Tomlinson, 1999; Tomlinson et al., 2003; Tomlinson & Eidson, 2003). First, assessment is ongoing, continuously informs instruction, and includes the assessment of students' understandings, their personal interests, and their learning profiles. Second, teachers attend to student differences, accepting students as they are but expecting them to become and understand all that they can. Third, all students participate in respectful work at a level attainable for them. Lessons for all students emphasize critical or creative thinking that promote individual growth. Fourth, the teacher and students collaborate in learning, maintaining a balance between teacher-assigned and student-selected tasks and working arrangements. Fifth, teachers are flexible in their use of groups, whole class discussion, time, materials, and classroom space. Finally, differentiated instruction is proactive rather than reactive. The teacher plans lessons that address learner variance from the outset rather than relying on adjusting instruction during real-time. Differentiated instruction is not synonymous with individualized instruction. Rather, it draws on flexible groupings, space, time, and materials to target instruction for *subsets* of the entire class, which fosters accommodation without the overwhelming effort of individualization. Furthermore, the teacher does not differentiate instruction during every class. Whole class instruction is still utilized but done so purposefully, informed by on-going assessment of students' needs. Teachers may choose to differentiate their instruction with regard to content, learning process, learning product, or learning environment.

Differentiated instruction is grounded in a sociocultural theory of learning, which also serves as the theory of learning for this study. Sociocultural theory emphasizes the role of social interaction and culture in the development of the learner (Vygotsky, 1987; Wertsch, 1991). Higher order functions develop out of social interaction and culturally organized activities. In addition, social and individual human action is mediated by tools and signs. These tools facilitate the co-construction of knowledge and aid in future independent problem solving activity. An instructional implication of sociocultural theory is that learning should be matched in some manner with the child's level of development. As such, Vygotsky proposed the zone of proximal development (ZPD), known as the difference in a child's performance when she attempts a problem on her own compared with when an adult or an older or more advanced peer provides assistance. Differentiated instruction, with its emphasis on continuous assessment and targeting instruction for students' ZPD, aligns with the basic tenets of socioculturalism.

Methods

For the present study, 19 prospective teachers enrolled in Math 2120 Geometry and Measurement for Elementary Teachers in spring 2011. The course utilized the book *Reconceptualizing Mathematics for Elementary School Teachers* (Sowder, Sowder, & Nickerson, 2009) and had three primary emphases: two- and three-dimensional shapes, symmetry and congruence, and processes of measurement. Megan was the instructor for the course, while both Megan and Michelle served as researchers for the study. The course included two in-class exams, a cumulative final exam, formative assessments, homework assignments, quizzes, a group project, and various writing prompts. All students in the course were elementary education majors with 63% sophomores, 26% juniors, and 11% post-baccalaureates or seniors. Students self-identified their mathematical backgrounds as ranging from high school algebra to calculus, and all students had taken the first two courses in the elementary education mathematics sequence. Students also varied in their self-identified like or dislike of mathematics, which they were asked to rate on a scale ranging from 1 (low) to 10 (high). Students' answers ranged from 1 to 10, with most students falling between 5-7 and the class average being 6.1.

Instruction was differentiated in multiple ways. Several pre- and formative assessments were used to gauge students' readiness, interests, and learning preferences. Varying activities and flexible use of small groups (sometimes heterogeneous, other times homogeneous) were implemented to meet students' different needs. Multiple modalities, in particular visual, audio, and kinesthetic mediums, were incorporated throughout the course. Students completed the same quizzes and exams, but homework assignments were differentiated. To differentiate the homework, students' progress was tracked using learning logs that outlined the learning goals for each unit. Students were given choices on writing prompts and the group project, as well as being able to select the medium through which material was presented for the project, e.g., website, skit, brochure.

To examine the impact of differentiated instruction on prospective teachers' mathematical understandings, a *lesson experiment* was utilized. The purpose of a lesson experiment is to engage in cycles of creating and testing hypotheses about cause-effect relationships between teaching and learning during classroom lessons (Hiebert, Morris, Berk, & Jansen, 2007; Hiebert, Morris, & Glass, 2003). It is a deliberate and systematic process that focuses on the key question, "What did students learn, and how and why did instruction influence such learning?" (p. 48). The process is composed of four steps that take on a character somewhat akin to teacher as researcher, reflective practice, and disciplined inquiry. The first step is explicating the learning goals for the students, which allows one to investigate whether and how the instruction helped the students achieve the desired goals. The second step is assessing whether and to what extent the learning goals are achieved during the lesson by gathering data on students' thinking from videos, transcripts, or students' written work. The third step consists of developing hypotheses for why the lesson did or did not achieve the learning goals. The fourth step entails using the hypotheses to revise the current lesson or to provide additional ideas about supporting learning that can be utilized and tested in future lessons. In conducting a lesson experiment, such steps are not necessarily performed in a distinct sequential fashion, although the order of the steps provides a general framework for progression. This approach provides a shift of focus from teaching in the moment to including preparation and reflection outside the classroom. In addition, the approach is a promising response to the gap between research and practice. While Hiebert and his colleagues foremost recommend lesson experiments as a way to help teachers learn from teaching, they also recommend the approach for teacher educators.

The lesson experiment took place the third week of the semester and involved a differentiation of activities based on students' conceptual understandings of area and volume. The purpose of the lesson experiment was to address how the differentiated area and volume activities impacted the students' learning. Table 1 provides the learning goals for the differentiated lesson (Wiggins & McTighe, 2005).

Enduring Understandings (EU)	Knowledge (K)	Skills (S)
1. A measurement system allows one to measure attributes with a unit appropriate for the particular context, including the ability to measure an attribute with different magnitudes. 2. In learning to measure, elementary students are best supported by a progression of a.) learning to perceive an attribute, b.) comparing objects with the same attribute, c.) measuring with a unit (nonstandard and then standard), and d.) working within a standard measurement system.	1. Area is the number of square units that cover a region. 2. Volume is the number of cubic units (solid or liquid) that fill a space. 3. Surface area and volume are independent. 4. Without a consistent unit, an attribute may have different measures.	1. Compare, order, and measure area and volume using nonstandard and standard units (including selecting an appropriate unit or tool). 2. Develop familiarity with standard units for area and volume (metric and English).

Table 1. Learning objectives for differentiated area and volume lesson

At the beginning of the course, students completed a measurement pre-assessment. The pre-assessment asked students to draw and offer an explanation of five attributes (length, area, volume, mass, and weight), to order groups of objects for each attribute, to match up various objects with an appropriate measure and unit, and to rate their comfort level with English and metric units. The pre-assessments revealed that some students had only developing understandings of area or volume (e.g., confusing the two, confusing volume with weight or surface area), that other students defined area or volume in terms of the measurement formula for a rectangle or a rectangular prism, and that most students were not familiar with the metric system. Thus, for the differentiated lesson and due to time constraints, students completed activities in either area or volume as per their performance on the pre-assessment. The activities led students through the learning progression for measurement (see EU2 above). Specifically, for the volume group, the first activity was to compare the volume of three cylinders, each formed from a standard sheet of paper but taped together in different ways. Second, they measured a cylinder with a non-standard unit and then compared their measurement with another group (who, unbeknownst to either group, was measuring the same sized cylinder, but with a different sized non-standard unit.) This activity highlighted the need for a consistent unit. The third activity was to measure the volume of a cylinder using base ten pieces to emphasize the advantages of a standard cubic unit. Finally, students filled a hollow base ten cube with water to realize that one liter is equivalent to the volume of a base ten cube and thereby to realize that one milliliter is equivalent to the volume of one cubic centimeter. The area group went through a similar progression, first directly comparing shapes of different area, then using a non-standard unit to measure area, then working within the metric system by measuring a variety of items using the faces of base ten blocks.

After the students completed their respective activities, each volume group presented their findings to an area group and vice-versa. For the presentation, students talked about how their attribute is measured, what metric units are used to measure their attribute, and related their activities to the measurement learning progression. Finally, in order to assess students' understandings on both attributes, a post-assessment was given in which students compared the area of two shapes and then justified their decision, considered the best type of unit for measuring volume (either a cylinder, cube, or rectangular prism), justified the measurement formula for the volume of a rectangular prism, and listed any remaining questions they had.

During the lesson experiment, various sources of data were collected from nine students, a subset of the students who agreed to participate in the research. The data sources included students' work on the measurement pre-assessment, students' work on the area and volume group activities, audio recordings of one area and one volume group, video recordings of Megan's instruction, and students' work on the post-assessment. Data analysis is in progress. Analysis to date has included examining the students' written work, coding their understandings and developing interpretations about area and volume in regard to the learning objectives. The associated audio recordings have also been listened to and students' thinking and discussion paraphrased to form initial ideas about how the social interaction and measurement objects are mediating students' learning. Future analyses planned include transcribing the audio and video recordings and using grounded theory and constant comparative approaches (Strauss & Corbin, 1998) to refine the interpretations of the students' understandings and how the differentiated activities impacted their social interactions and use of measurement tools.

Results

Preliminary results describing which learning goals were met refer to the objectives given in Table 1. With regard to K1 and K2, the lesson appeared to enhance students' understandings of area as covering a two-dimensional shape and volume as filling a three-dimensional shape, especially for students that demonstrated misconceptions on the pre-assessment. For example, on the post-assessment when asked about justifying that a shape had a larger area, all of the students either commented about placing the shapes on top of each other or counting the number of square units required to cover each shape. However, not many of the students described counting the number of square units. While the students appeared to develop an appreciation for area as coverage and volume as filling, they did not often describe quantifying these attributes by counting the number of square or cubic units. With regard to K3, students seemed to understand well that measuring an attribute with different-sized units leads to different measures, as students in both groups described this experience in their presentations. In addition, during interactions with Megan, it was apparent that the students were implicitly making sense of the inverse relationship between the size of the unit and the associated measure. For K4, the volume group was shocked by the realization that cylinders with equivalent surface areas may have different volumes. Also, due to their interaction with Megan, some students may have gained an appreciation for why the circumference and resulting radius formed by the sheet of paper has a greater impact on the volume than the height.

During the presentations and on the post-assessment, students demonstrated some strong understandings of S1, selecting appropriate units for measuring area or volume. Students clearly understood that circles or cylinders do not work well as units because when placed next to each other gaps remain. Nearly all students also deferred on selecting a unit for measuring area or volume that would include dimensions of different lengths, e.g., a rectangle or a rectangular prism. However, as evidenced on the post-assessment, it was not apparent whether students could articulate the complexities involved with using such units, e.g., the need to pay careful attention to which dimensions of the unit are used to measure which dimensions of the associated two- or three-dimensional object. With regard to S2, students appeared to gain an understanding that one milliliter is equivalent to one cubic centimeter. Due to a lack of commentary by the students, they did not seem to learn about any other common referents for standard units of area or volume. From listening to the area group audiotape, it appears that these students may have developed a general sense of the magnitude of the different metric units for area (EU1). For example, when completing an activity entitled ‘Guess the Unit’, they discussed the relative magnitude of a kilometer to a decameter to a meter. It is uncertain whether the volume group gained a similar sense of such magnitudes for volume as their activities seemed to deal less with this issue. Finally, with regard to EU2, all of the students seemed to understand the need to help elementary students understand an attribute, e.g., the idea of area as covering and volume as filling. However, it is not clear that the students understood all of the steps of the learning progression, as they did not talk about the later steps.

After analyzing the lesson, various hypotheses as to how the instruction helped students attain the learning objectives were determined. First, as recommended for K-12 students learning about measurement (NCTM, 2000), the activities provided the students with concrete and active experiences in finding, comparing, and exploring the attributes of area and volume. In fact, one of the students commented on the audiotape that he particularly appreciated the fact that these activities involved the activity of measuring rather than just listening to a teacher and performing computations on paper. This active process contributed to students’ understanding of area as coverage and volume as filling. Second, activities were purposely designed such that the students would proceed through the measurement learning progression (Inskeep, 1976; Van de Walle & Lovin, 2006) due to our belief that this progression is helpful for all learners regardless of age. In this particular lesson, the students also had misconceptions about the attributes of area or volume; therefore students were differentiated by being placed in the appropriate group and leading them through the learning progression. This differentiation also allowed the students’ interactions with the instructor to focus on their developing understandings. For example, while interacting with Megan, the volume group was able to further explore the formula for the volume of a cylinder. The lesson structure also allowed the students to learn from each other about the other attribute. From the presentations and students’ work on the post-assessment, it appears that as a result of the area presentation, the volume students learned about the option of placing shapes on top of each other to compare area and about a circle not working as a unit of area because of the resulting gaps. As a result of the volume presentation, the area students came to understand volume as filling, that cylinders do not work as a unit of volume, and that one milliliter is equivalent to the volume of one cubic centimeter.

Analyzing the data of students’ thinking also revealed some differences between the volume and area group. In general, the volume group was more active in verifying, justifying, and critiquing their own work. For example, on multiple occasions after determining the volume of a cylinder by using the formula $\pi r^2 h$, the students also verified their calculation by filling the cylinder and counting the number of units used. On another occasion, the students were very deliberate about wanting to know why the volumes were not equal for cylinders with equal surface areas. In contrast, the area group did not verify their measurement calculations, used estimation rather than actually measuring certain objects (such as the surface area of a door), and seemed satisfied with answers that appeared “fairly close” (when upon further investigation would have been shown to be somewhat inaccurate). With their reliance on estimation, the area students often thought of quantities in terms of English units and then made rough approximations to metric units. This approach was in contrast to the intent for students to become familiar with metric units. In hypothesizing about what instructional aspects led to the differences between the two groups, several possibilities were considered. First, the students in the volume group have been known through other class sessions to frequently pursue the reasoning behind their mathematical ideas and concepts. This raises the question of how to encourage such behavior on behalf of other students and how social dynamics and culture may play a role. Second, the difference could be attributed to the lack of measuring activity on the part of the area group. Because of this, in future offerings of this lesson and for other measurement activities in this course, the instructor may need to take an active role in making sure the students engage in the activity of measuring. Third, the volume and area activities themselves may have contributed to this difference. For the volume activities, the students were finding the volume of an object other than a rectangular prism. Thus, the students were using a volume formula with which they were less accustomed. Perhaps this led them to be more active in verifying their calculations. In contrast, for the area activities, the students were primarily finding the area of rectangles. Perhaps their familiarity with the area of such shapes decreased the need or desire to verify such calculations. Thus, upon utilizing these activities in the future, more irregular two-dimensional shapes in the area activities would be included.

In considering how the current lesson might be revised or formulating ideas about supporting future learning, two unexpected mathematical complexities arose. First, when selecting nonstandard units for the measurement activities, unforeseen complexities from using units with varying dimensions emerged. As a result, a successive lesson was taught in which students cut out nets of cubes and of rectangular prisms and discussed in small groups which of the two would serve as a better unit for measuring volume. Second, in covering shapes with sticky notes, the area group alluded that shapes with equal area may not necessarily be congruent. Thus, an additional lesson was taught using geo-boards to investigate the area of triangles and parallelograms which had the same base and altitude (and thus the same area) but looked very different. Finally, some learning objectives that did not appear to be met during this lesson were addressed in future lessons: the concept that a measurement is the result of counting the number of units that match the given attribute, the various magnitudes of metric units of volume, and developing familiarity with the metric units, including learning of common referents.

Discussion

Lesson experiments provide a means for connecting research and practice, as we found to be the case for us. In this lesson experiment, we were engaging in two roles: researchers in teacher education and teachers of mathematics content. We found this process to benefit both roles and to provide feedback between the two. Due to the collection of research data, we enhanced our interpretations of the students' thinking which thereby impacted our future instruction. Similarly, our instructional roles provided insight into the students' activities and experiences during class, enhancing our ability to hypothesize how the instruction was impacting the students' understandings. We also found continued promise in the use of differentiated instruction at the undergraduate level with pre-service elementary teachers. Differentiating by area and volume in this lesson enhanced the students' understandings, allowed us to maximize the use of class time, and possibly provided a model of differentiated instruction for the students. Indeed, we have been open with the students about the differentiation process and are undertaking other research projects to investigate the potential impact of this on the pre-service teachers' future pedagogical practices. Finally, the lesson experiment process has begun to reveal hypotheses about how differentiated instruction is impacting the students' learning and mathematical understandings – the primary purpose of this project.

We present the results of an exploratory study utilizing interactive video examples of reform teaching in an elementary mathematics methods course and their impact on pre-service teachers' pedagogical content knowledge (PCK) and ability to identify and interpret reform-based pedagogy. The study utilized a quasi-experimental research design in which all participants completed both a pre- post-pedagogical pedagogical content knowledge assessment and a pre- post-case analysis assessment. We present the results of this intervention; interpret the results and present implications for further research.

Introduction

In the United States, the current mathematics education reform movement works with teachers to develop pedagogy, which values a deep conceptual understanding of mathematics in students rather than a rote procedural understanding. The reform movement's emphasis on mathematical problem solving, reasoning, communication, representation and connections (NCTM, 2000) answer the call of the 21st century social and intellectual skills. Teachers must be prepared to teach in a manner that incorporates and integrate four knowledge domains, knowledge of: content for teaching, pedagogy, learning, and evaluation (Lappin, 2000). Despite the efforts of many talented researchers in partnership with inservice and preservice teachers, the impact on classroom pedagogy has remained minor. Thus, mathematics teacher educators and researchers continue to explore new and different ways to provide the momentum to enable reform-based pedagogy to thrive in working classrooms.

Shulman (1983) stated that, "…the teacher must remain the key. The literature on effective schools is meaningless; debates over educational policy are moot, if the primary agents of instruction are incapable of performing their functions well…" (p. 504). The traditional American teacher preparation program has three main components to develop preservice teachers abilities to perform their function: coursework that develops pre-service teachers' (PSTs) knowledge of both content and pedagogy and various field experience components. In order to prepare teachers to teach using a reform-based approach, mathematics teacher educators and researchers have taken an empirical look at various approaches within each of these three phases to help prospective teachers develop reform-based pedagogical approaches (e.g. Mewborn, 1999, 2000; Sowder, 2007; Ball & Wilson, 1996). This paper examines the results of an exploratory study utilizing interactive video examples of reform teaching in an elementary mathematics methods course and their impact on PSTs' pedagogical content knowledge and ability to identify and interpret reform-based pedagogy.

Perspective

Developing Reform-Based Teachers

The constructivist philosophy of learning originates from the research of Vygotsky and Piaget. Here, mathematical learning occurs from the active participation in one's own navigation of the curriculum. Knowledge cannot be objectified and then transferred, but must be discovered through the processes of perturbation, accommodation, and assimilation into existing constructs. Students use these tenets to learn mathematics by making sense of their own experiences and then also the collaborative sharing of these experiences amongst their peers. This type of mathematical teaching is demanding on the practitioner, and requires a specific skill set. Realizing its complexity, Ball (1990) suggested that teachers need to understand the nature of knowledge in the discipline, where that knowledge comes from, how it varies with time, how truth is established, and philosophically what it means to know and do mathematics in order to be effective teachers. The complexity and versatility of knowledge for teaching mathematics is important for the implementation of mathematics reform and also the future design of methods courses designed to train PSTs.

The release of the National Council of Teachers of Mathematics (NCTM) (2000) *Principle and Standards for School Mathematics* document describes an idealized future for mathematics classrooms in the US and echoes the international community in its call for access for all students to rigorous, high quality mathematics instruction. To make the transfer between ideal and reality is the task of the classroom teacher.

What students learn in their K-12 mathematics experiences is a reflection of the procedures in those classrooms. The construction of learning environments will invariably reflect the classroom practitioners' views on mathematics and mathematics instruction. An absolutist teaching of mathematics supports the behaviorist thought that mathematics is a rigorous, masculine discipline of which mathematics is out there, awaiting discovery, and can be learned by rigorous procedural applications. Research indicates "that classroom instruction, which tends to focus almost exclusively on the knowledge base, deprives students of problem-solving knowledge"(Schoenfeld, 2004, p. 263). As a product, this falls short of the goals set forth by mathematics education professionals.

The belief of mathematics and mathematics instruction being a process, or a series of ideas and refutations provides a different fundamental platform for learning. Discovery, improvisation, inquiry, student centered, these adjectives speak of the nature of this type of mathematical teaching and learning. This builds towards the high standards set forth by the international research community. This type of mathematical learning also reveals complexities of what is required of practitioners that are urged to teach this way (Hill, Sleep, Lewis, & Ball, 2007).

Studies suggest (Borko et al., 1992; Brown, Cooney, & Jones, 1990) that teacher beliefs are influenced a great deal by teachers' experiences with mathematics and schooling long before their entry into the mathematics education workforce, and without *significant* interventions, these beliefs are very difficult to change (Cooney, Shealy, & Arvold, 1998). Innovative methods courses can address these difficulties inclusive with exposing these practitioners to more clinical experiences. Field experiences can provide difficulties in that there is a lack of control for the beliefs of the inservice teacher. Therefore, the task may fall on technology to provide video cases imbedded in hypermedia in order to provide a quasi-field experience for preservice teacher training. This controls for contrasting beliefs, while simultaneously providing quality role models for preservice teachers to project methods onto their own vision of their future classroom and classroom practices.

Video Cases

Teacher education programs have long been criticized that its didactic instruction and limited field experience cannot equip pre-service teachers with the insight and experience dealing with the messy and complex teaching practice in the real world. In the last several decades, case-based method has increasingly been advocated as an effective method of preparing pre-service teachers for the real classroom context (Shulman, 1986; Merseth, 1996;

Harrington, 1991). Case teaching has a long and productive history in several fields of professional education such as law, business and medicine, but it did not gain attention in the field of teacher education until mid 1980s. The use of video cases in teacher preparation has grown substantially within the last few years.

Compared with traditional narrative cases, video cases offer further advantages. Primarily it satisfies the need for pre-service teachers to observe how teachers handle daily problems in real classrooms (Georgi, Redmond, Talley, & Cannings, 2002). Video cases also increase PSTs' opportunities to observe authentic teaching situations; each of which can be viewed multiple times. The opportunity to view and reflect on an episode multiple times allows for deeper understanding of the methods and environments that are being viewed. (Georgi et al., 2000; Sherin, & van Es, 2002).

In the preparation of preservice mathematics teachers, it has become apparent that importance must be placed on facilitating skills such as listening to, hearing, and watching students. Many programs such as CGI (Phillip, Armstrong, & Bezuk, 1993), IMAP (Phillip et al., 2007), and DMI (Schifter, Russell, & Bastable, 1999) have found success in the emphasis on studying children's thinking. Various studies have demonstrated the advantages of using video cases over written cases in promoting such skills. In a study that compares the reflective abilities of two groups of pre-service teachers in a mathematics methods course, the group that enrolled after the introduction of a video case curriculum tends to focus more on individual student's mathematical thinking (Stockero, 2008).The video cases applied in the curriculum are unedited recordings of classroom activities during middle school math classes. Compared with written cases, the unedited video series provide pre-service teachers with the opportunity to locate the important issues and concerns from the recorded classroom interactions. This finding is in accordance with Wang and Hartley's (2003) conclusion that, video cases are more efficient than written cases in facilitating the development of the knowledge and skills of observation. Sherin (2004) also pointed out that such development enhances the ability of identifying the issues that are critical to the profession, such as discovering and understanding students' mathematical thinking patterns.

In addition to helping teachers to realize the students' mathematical thinking levels, video-based pedagogy has also been demonstrated to facilitate teacher's reconstruction of their beliefs about how children learn mathematics and shape a student-centered rather than the teacher-centered perspective (Friel & Carboni, 2000). The use of video cases in teacher education is also found to be helpful in developing the pre-service teachers' ability to examine student ideas (Richardson, 1999; Sherin, 2004) and to clarify students' conceptual understanding (Sherin & Han, 2004).

Examining Pedagogical Content Knowledge

In his landmark article, Shulman (1986) raised the following questions, "Where do teacher explanations come from? How do teachers decide what to teach, how to represent it, how to question students about it and how to deal with problems of misunderstanding?" (p. 8). The type of knowledge teachers required to address these questions is what Shulman referred to as pedagogical content knowledge (PCK). Our position is that interactive video examples of reform-based pedagogy can be an accessible source of knowledge for PSTs to develop PCK. Thus we have employed Shulman's description of PCK to use as a lens through which to view what PSTs know and notice about reform-based teaching. Thus, as we analyzed our data for what PSTs knew and noticed about reform-based pedagogy, we examined it for evidence of PSTs' knowledge of students and student learning, appropriate and powerful mathematical representations, and PSTs' ability to interpret and make sense of students' mathematical work and thinking. In order to further frame our examination of PSTs knowledge and noticing of reform-based pedagogy, we employed the NCTM *Principles and*

Standards for School Mathematics (2000) document. Specifically germane to our assessments are he teaching and learning principles, the number and operations content standard, and the five process standards of: problem solving, reasoning and proof, communication, connections, and representations.

The purpose of current study was to examine the influence of video cases on pre-service teachers' pedagogical content knowledge. Specifically, this study addressed following research question, What is the influence of video cases on pre-service teachers' pedagogical content knowledge as it pertains to reform-based mathematics instruction?

Methods

Participants

Forty-two students enrolled in two sections of elementary mathematics methods at a large Midwestern university course participated in the study. The third author served as the instructor for the two sections. There were 38 Females and 4 Males. All participants were seniors enrolled in the methods course the semester prior to their student teaching experience. In conjunction with course, participants also spent 32 hours observing and teaching mathematics and science within an elementary classroom.

Measures

Pre-post pedagogical content knowledge assessment. Participants completed a pedagogical content knowledge assessment in a pre-post format. The open-ended questionnaire included four questions that assessed pre-service teachers' understanding of number and operations and how they might approach teaching this content. Specifically, the questions were: 1. What mathematics makes up number and operations?; 2. How would you teach topics in number and operation (i.e., what are some approaches, methods, etc.)?; 3. How do you know a student is struggling with ideas in number and operation?; 4. How do you know a student has a good understanding or mastery of ideas in number and operation?

Pre-post case analysis assessment. Participants also completed a video case analysis assessment, which was utilized to assess their ability to observe and notice reform-based mathematics teaching practices. Participants watched a video clip (6 minutes and 21 seconds) that showcased a sixth grade classroom engaged in learning fractions and percentages. After watching the video, participants completed a questionnaire with three questions that assessed their ability to notice teaching practices. Specifically, the questions were: 1. What do you notice about the teacher? 2. What do you notice about the students? 3. What do you notice about the mathematics?

Procedure

The study utilized a quasi-experimental research design where students enrolled in one section of math methods course acted as experimental and another section served as control. Both sections were taught by the same instructor, which removed any potential instructor effect. Participants in the experimental section had access to an online video case library that showcased reform-based mathematics instruction where as control section did not have access to the video case library. The video case library included 4 teachers teaching various lessons within the topic of numbers and operation with a total number of 37 video clips. The participants could search the video case library using a theme, keyword, or teacher. The themes included more broad categories, such as task launch, task exploration, student explanations, and task summarize, where as keywords were more specific instances of mathematics teaching practices. Participants from the experimental section were given seven bi-monthly assignments to watch a series of video clips and respond in an electronic reflection journal to three prompts: "What do you notice about the teacher?", "What do you notice about the students?", and "What do you notice about the mathematics?". The control participants, on the other hand, did not watch the video cases, and were instead required to respond in their electronic journals to a series of journal prompts selected from the end of chapter discussion questions in their course textbook. All participants completed both the pre-post-pedagogical content knowledge assessment and the pre- post-case analysis assessment described above.

Data Analysis

Researchers developed a coding rubric to analyze the pedagogical content knowledge and case analysis assessments. The rubric was developed using the assigned readings for the course (Van de Walle, 2009) and the NCTM *Principles and Standards for School Mathematics* document (2000). Specifically, the rubric consisted of acceptable responses for each of the questions and participants were assigned a 1-point for each correct response and could score multiple points for each question based of the total number of acceptable responses for the given question. The researchers coded each participant's assessments individually and then met to discuss their assigned scores and to reach consensus for the final score for each participant. One example of coding scheme for each assessment is in Table 1.

Pedagogical Content Knowledge Assessment
Question 1: What mathematics makes up number and operations?
Code: 0-2 (continuous); 0 points for "I don't know" or other incorrect answers; 99 for blank
Scale – provide 1 point for supplying each answer or similar worded idea (up to 2): • Identifies the four main operations (addition, subtraction, multiplication, division) • Identifies various number systems or classes of numbers (whole numbers, fractions, decimals, percents, ratio)
Case Analysis Assessment
Question 1 – "What do you notice about the teacher?"
Code: 0-9 (continuous); 0 points for "I don't know" or other incorrect answers; 99 for blank
Scale – provide 1 point for supplying each answer or similar worded idea (up to 9): • Teacher ask for/encourages different ways of explaining • Teacher asks students for students' attention • Teacher shows interest in student explanations/thinking • Teachers values student explanations/thinking • Teacher revoices/restates student thinking for class • Teacher encourages student-student questions communication • Teacher asks questions to encourage students to clarify/refine their thinking • Teacher moves around the room and talks to students during exploration time • Teacher provides opportunities to students to work on the problem on their own

Table 1: Assessment rubric samples

Results

Pre-post Pedagogical Content Knowledge Assessment

The results suggest that overall video cases increased students' pedagogical content knowledge of numbers and operation (See Table 2 for means and standard deviations). However, ANCOVA results suggest that condition was not a significant factor for participants understanding of what mathematics makes up number and operations (F(1, 41)=3.70, p=0.06); how to teach topics in number and operation (F(1, 41)=0.09, p=0.77); identifying student struggling with ideas in number and operation (F(1, 41)=0.48, p=0.49); identifying student mastery of ideas in number and operation (F(1, 41)=0.01, p=0.92).

Condition	Q1	Q2	Q3	Q4
Traditional	0.21 (0.42)	1.84 (0.83)	0.95 (0.62)	1.16 (0.69)
Video Cases	0.65 (0.77)	1.91 (0.90)	1.04 (0.64)	1.09 (0.67)

Table 2: Means and standard deviation of pedagogical content knowledge assessment

Pre-post Case Analysis Assessment

Results showed that pre-service teachers' ability to notice reform-based mathematics teaching practices increased when video cases were used (See Table 3 for means and standard deviations). ANCOVA results exhibited that video cases significantly influenced pre-service teachers' ability to notice students (from the video vignette) using variety of tools, student-student mathematical interactions and students giving procedural and conceptual explanations of equivalence, ($F(1, 40)=4.72$, $p=0.04$). However, ANCOVA results exhibited that condition was not a significant factor for pre-service teachers' ability to notice reform-based teaching practices ($F(1, 40)=0.28$, $p=0.60$); and identifying mathematical content ($F(1, 40)=2.58$, $p=0.12$).

Condition	Q1	Q2	Q3
Traditional	0.21 (0.42)	1.84 (0.83)	0.95 (0.62)
Video Cases	0.65 (0.77)	1.91 (0.90)	1.04 (0.64)

Table 3: Means and standard deviation of case analysis assessment

Discussion and Conclusions

Past research has indicated the use of video case examples can impact teachers' knowledge and abilities. Aside from the one significant result, the findings from this exploratory study do not seem to support these results. We provide a possible explanation for the lack of effect and present some directions for our further investigations.

A valuable aspect of using video cases is PSTs opportunity to have discussions with their peers and instructor of the episodes, what they noticed, and how they reflected on and made sense of their observations. Due to time constraints within the structure of the methods course, PSTs only gave written responses to the video cases and were not afforded this opportunity. We believe relying solely on written reflection limited the PSTs' opportunities for developing PCK. As a result of this study, we have realized that the time spent in class on reflection of the video cases is crucial to maximizing PSTs' opportunities to learn.

A second change we intend to make moving forward is to further refine our approach for examining PCK; specifically by using the construct of mathematical knowledge for teaching (MKT) (Hill, Sleep, et al., 2007; Ball, Thames, & Phelps, 2008). For example, the one significant result indicated use of video cases had a significant effect on PST's ability to recognize student indicators of reform-based teaching practices: students using a variety of tools, student-student mathematical interactions, and students use of procedural and conceptual explanations. We argue that these are aspects of, or are related to, PSTs' Knowledge of Content and Students (knowledge of the ways students think and learn) and Common Content Knowledge (the mathematical content teachers are responsible for teaching to students). We can also use MKT to frame our other results. For instance, we saw a change, although not significant, within aspects of Specialized Content Knowledge (mathematical knowledge used for teaching but not taught directly to students) as well as Knowledge of Content and Teaching (knowledge of task selection, appropriate representations, questioning strategies, etc.). In further iterations of this study, it is our intent not only to use MKT in our analysis, but to gear the discussions of the video cases within the methods course around MKT as well.

TEACHER CHANGE IN MATHEMATICS PROFESSIONAL DEVELOPMENT: UNDERSTANDING EXPERIMENTATION IN CLASSROOMS

Dan Battey
Rutgers, the State University of New Jersey
dan.battey@gse.rutgers.edu

Paula Guerra
Kennesaw State University

As a field, we know little about how teachers take up practices and sustain them (or not) due to professional development. This project provided professional development based on CGI and studied change in classroom practices over two years with K-3 teachers in an urban district with a high population of ELLs. Findings illustrate the complex nature of changing mathematics classrooms.

As a field, we know little about teacher experimentation in classrooms based on participation in practice-based professional education (PBPE) (Kazemi, 2008). Questions remain about which practices are taken up easily or which ones are more complex to bring across the boundary of professional development (PD), how practices are adapted or not taken up at all, which practices are sustained over time or which are left behind. At the same time, teachers do not have sole control of their classrooms.

In this paper, we present 2 years of analysis on a PD effort in an urban district in Arizona with a high population of English Language Learners (ELLs). The professional development in this study focused on embedding Cognitively Guided Instruction (CGI) within classrooms in this district. The purpose of the PD was to enable teachers to gain insight into how their students think, understand a variety of mathematical concepts, use that knowledge to inform their practices, and learn practices for supporting ELL students in mathematics.

The analysis entails two years of observations focused on the mathematics practices that teachers were experimenting with in their classrooms. We looked at when new practices emerged and if they were sustained. This study adds a detailed look at mathematics instructional change and the impact of PD on classroom practice. We begin by reviewing work that looks at the effects of change efforts on teachers' practice. The paper then shifts to consider what research says about how educators can best serve ELLs in mathematics.

Reform Efforts and Teacher Change

The research on effects of change efforts often focuses on the top down nature of PD efforts and teacher fidelity to the reform. This section looks at teachers' responses to change efforts as well as how teachers experiment within PD.

Teacher interpretation often gets framed negatively because reform efforts could be attending to rigid notions of fidelity, but not all adaptations are resistance or contrary to change efforts. Certainly, PD goes through a process of translation as it moves across levels of the school system (Eisenhart, Cuthbert, Shrum, & Harding, 2001). For instance, teachers can adapt policies according to their own students' needs (McLaughlin & Talbert, 1993, Tyack & Cuban, 1995). The adaption of PD to students is consistent with CGI, which is not meant to have rigid fidelity. In CGI professional development it is understood that teachers are best situated to adapt what they are learning to their classrooms. However, translation of change can also occur because teachers have little understanding of the implementation (Cuthbert, 1984). In that case, we would agree that teacher translation is problematic. When change efforts align with teacher beliefs and allow teachers to implement practices, PD can spur teachers to implement practices more aligned with children's home lives (Heath, 1983). Across this work, teachers adapt policy for student needs, connecting to families, but also for a lack of understanding.

Within this space of understanding teachers' responses to change, we understand very little about classroom experimentation during implementation and how this changes over time (Kazemi, 2008). We do not know which practices change first, which change last, how teachers implement and adapt new practices, and how or whether various practices are sustained over time. Bringing practices across the boundary between professional development and classrooms is extremely complex (Authors, 2008). It is not a simple issue of fidelity to a predetermined model since we expect teachers to design mathematics instruction in a way that is tailored to the needs of students. However, in bringing practices across this boundary, we know little about what makes practices easy or complex to translate into classroom practice and how sustainable particular instructional practices are over time. Understanding these micro-changes in practice could help professional developers design PD better by understanding how teachers respond to the demands that learning new practices places on them.

Supporting Latinos and ELLs in the Mathematics PD

With the increasing concern about Latino students and ELL students in particular, there is a growing body of work focused on instructional practices that engage Latinos in learning mathematics with understanding (DeAvila, 1988; Flores, 1997; Gutiérrez, 2002; Khisty, 1995; Moschkovich, 1999). While the current study engaged teachers of Latino students, this work is at the intersection of providing mathematics professional development in schools with a high population of Latinos who are designated as ELLs as well as those who are not. A major gap in the mathematics education literature is professional development that integrates learning about teaching mathematics for understanding and ways to support the learning of ELLs. In this project, we integrated some of the research literature about instruction that serves ELL students to support teachers in their mathematics teaching. We briefly review some of this work below.

In focusing on instruction for ELLs, we often see an overemphasis placed on mathematical terms without mathematical meaning (Khisty, 2006). While acquiring vocabulary is an important part of learning to use the register of mathematics, students' ability to "construct multiple meanings, negotiate meanings through interactions with peers and teachers, and participate in mathematical communication" is even more important (Moschkovich, 2007, p. 89). This is particularly important in mathematics, since many words hold different meanings in the mathematical register as compared to natural language (Khisty, 1995). Moreover, by placing an emphasis on vocabulary without properly contextualizing the mathematical terms, we run the risk of perpetuating deficiency models of students since focus is placed on what students cannot do rather than on what they can. As Moschkovich (2007, p. 90) argues,

> If all we see are students who don't speak English, mispronounce English words, or don't know vocabulary, instruction will focus on these deficiencies. If, instead, we learn to recognize the mathematical ideas these students express in spite of their accents, code switching, or missing vocabulary, then instruction can build on students' competencies and resources.

A related finding in this research is that using and valuing home language is critical. This practice is linked to higher achievement, especially in mathematics (Khisty, 2006). Beyond using students' home language, instruction must also draw on cultural understandings. Secada (1991) found that when the forms of language and culture in word problems do not match students' experiences, they have a difficult time developing solution strategies. In a study of think-alouds used in mathematics classrooms, Celedon-Pattichis (1999) determined that ELLs needed to translate the problem to Spanish, read it at least twice, attribute meaning, translate the meaning into mathematical symbols, and ignore irrelevant words. This research demonstrates the complexity of the cognitive activity that ELLs engage in when participating mathematically in classrooms.

Across this work on providing effective mathematics instruction to ELLs, we find that it needs to provide numerous opportunities to engage in mathematical discussion, speaking, listening, reading and writing the content as well as encourage meaning making within relatable contexts (Moschkovich, 1999). Additionally, to support this form of instruction, teachers need to be able to change curriculum to meet the needs of their students and reject deficit models framing students as intellectually inferior. This professional development attempted to integrate these ideas with more established research on CGI professional development.

Methods

This research study takes place in Monroe elementary school district, an urban school district in Arizona composed of four schools. One of the schools chose not to participate in the project and did not receive any treatment. The remaining three schools participated in mathematics professional development based on Cognitively Guided Instruction (CGI).

Participants and Background

These schools have been identified as having "not met" the adequate yearly progress for No Child Left Behind (NCLB). In the second year of the project two schools were in year two of not meeting, while one was in year one. A third year would make them candidates for being taken over by the state. In 2009, 52% of students in the district tested proficient in mathematics on the Arizona Instrument to Measure Standards (AIMS) as opposed to 62% the year before (2009 state average was 72%). On the Terra Nova, 35% of third graders tested proficient in mathematics compared to 40% in 2008 (the national average was 50%).

According to the Arizona District Report Card 2006-07, 45.7% of the teachers have been in the district three years or less. On the other hand, 33.1% of the district teachers had been working there for ten or more years. Also, 19% of the teachers held a provisional certification. The percentage of female teachers participating was 82%.

Teachers participated in the project during different periods: kindergarten and first grade teachers participated during the first two years. Second and third grade teachers participated during the second year. The project is ongoing, but only the years are included in this paper.

Twenty-one kindergarten and first grade teachers participated in the first year (cohort 1). Due to teacher turnover, we lost 7 teachers from cohort 1 in year 2. Two teachers also moved grade levels. In year 2, 23 new teachers began participating (cohort 2). Eight of those teachers replaced cohort 1 teachers in kindergarten and 1st grade. A total of 44 teachers participated in the study.

Professional Development Context

The professional development consisted of on-site monthly meetings and on-site weekly visits. The professional development focused on the principles of CGI, combining the earlier work on student strategies and problem types (Carpenter, Fennema, Franke, & Levi, 1999) with more recent work on algebraic thinking (Carpenter, Franke, & Levi, 2003) and counting (Schwerdtfeger & Chan, 2007). This broader take on the work allowed the professional development to be designed around the content in which teachers were currently working.

Workgroup meetings

The meetings lasted approximately 1.5 hours and were held at one of the three participating schools. The professional development focused on gaining knowledge of student thinking as a way to develop instruction towards teaching mathematics for understanding.

On-Site Visits

In addition to the workgroup meetings, the teachers and professional developers worked together at the school sites. We spent approximately one day each week on-site. During the weekly visits, the professional developers observed classes, worked with teachers and students, and were available for informal conversation about whatever the teachers wanted to talk about. Our goals were to support teachers, engage with them informally, and to explicitly draw on teachers' practices in designing future PD. Our time at the schools was important to remind teachers to experiment with new practices and to build relationships with students and teachers.

Measures and Analysis

Data for this paper were collected during a two-year period. We collected data using three measures: a teacher knowledge assessment, field notes, and interviews. This paper only details the classroom observations collected through field notes to examine teacher experimentation. We detail this measure below.

Classrooms' Observations

For the duration of the project, teachers were visited once a week during their math time by professional developers. The visits lasted from 30 to 50 minutes. During the observations, field notes were taken focusing on the new practices the teachers implemented when teaching mathematics, specifically those that were based on student thinking and tied to the content of the professional development. The professional developers dialogued about the practices and what they noticed with the teachers to clarify ideas and discuss future directions for the lessons. These notes included the kinds of participation facilitated in the class (for example, retrieving memorized answers vs. eliciting strategies), types of activities (word problems vs. drill worksheets, activities designed by the teacher or adapted from the textbook, or just the using the problems in the book), and types of interactions between teacher and students.

We looked across the field notes, noting themes and practices that appeared repeatedly across classrooms and teachers. Those practices became categories that were contrasted again with the notes, in order to confirm their validity. The authors then took notes on the frequency of appearance of those practices, as well as when they became a regular part of these teachers' classroom. The practices were coded according to semester they emerged and were only included in the analysis if the teachers maintained them in the classroom. These codes were analyzed and examined across years 1 and 2 for cohort 1 and for year 1 for cohort 2.

After a detailed reading of the field notes collected through two years 10 categories of interest emerged: (i) use of word problems, (ii) journals, (iii) student sharing, (iv) counting, (v) breaking apart numbers, (vi) use of tools (e.g. manipulatives), (vii) attending to the details of student thinking (e.g. organizing activities around student strategies), (viii) adapting the textbook, (ix) designing their own problems and (x) questioning student thinking. These categories arose from the content of the professional development sessions as well as the classroom practices observed. In addition, since the PD was informed by research, these categories represent mathematics teaching practices aimed at teaching for understanding. We cannot completely expand on these categories, but we briefly explain them below.

We drew on the original CGI work in focusing on use of word problems, student sharing, tool use, teachers designing problems tailored to student thinking, and attending to the details of student thinking (Carpenter, Fennema, Franke, 1996; Carpenter et al., 2003). In this same vein, using textbooks to meet the needs of particular students in the classrooms means monitoring "curriculum use and selection" (Franke & Grouws, 1997, pg. 334). In the words, there is no perfect curriculum and teachers must adapt curricula to meet the specific needs of their students. We also drew on more recent work on counting collections (Schwerdtfeger & Chan, 2007) and the algebraic thinking work that focused on breaking apart numbers while using the equal sign more flexibly (Carpenter et al., 2003). Another important code was teacher questioning as a follow-up to student thinking (Franke, Webb, Chan, Ing, Freund, & Battey, 2009). In the case of this paper, this merely means that teachers posed questions to students after a shared strategy. In this sense, it is a less detailed form of attending to the details of student thinking mentioned earlier. Lastly, we focused on journals as a way of recording student solution strategies and student thinking. This is a way of making student thinking explicit for teachers (Kazemi & Franke, 2004). These ten codes served as a way to look at the micro-changes that occur as teachers attempt to teach mathematics for understanding.

Results

New Mathematical Practices of Cohort One and Cohort Two in First-year Participation

In the coming paragraphs we review how the two cohorts of teachers behaved after being part of the professional development project for one year. The fact that cohort one consisted of teachers of kinder and 1st grade, and cohort had primarily 2nd and 3rd grade teachers should be considered when comparing these teacher groups.

In year 1, cohort one added a number of instructional practices into their mathematics classrooms. When appropriate we also present the percent of teachers that used the practices before the professional development. The practices cohort 1 engaged in the most were counting collections (44% of teachers, 6% already used this), tool use (38%, 13%), breaking apart numbers (25%), and using word problems (25%, 6%) (see table 1). To be clear, the teachers who used the practice are not included in the teachers who began the practice. For instance, 50% (44%+6%) of cohort one teachers counted collections by the end of year one (51% for tool use). Conversely, the least used practices were journaling (13%), editing the textbook (13%), designing their own problems (13%) and questioning student thinking (13%). While in some ways these might not seem like overly impressive percentages, 44% of cohort one began and maintained counting practices throughout the first year of the professional development in addition to the 6% who already used this practice. It is important to note again, that if teachers tried the practice once but did not continue it, it was not included in this analysis.

Teacher Group	Word Problem Use	Journals	Student Sharing	Counting Collections	Breaking Apart Numbers	Tool Use	Attention to Student Thinking	Editing the Textbook	Questioning Student Thinking	Designing Problems
	Practices									
Cohort 1 year 1 [a]	25%	13	19	44	25	38	19	13	13	13
Cohort 2 year 1 [b]	4	4	22	7	7	4	22	4	26	7

[a] n= 27, [b] n = 16

Table 1: Percentage of Teachers Engaging in New Instructional Practices

In year 1 for cohort 2, the instructional practices embedded in their classrooms more were student sharing (22%, 19% already used this practice), questioning student thinking (26%, 7%), and attending to the details of student thinking (22%, 4%). The practices that cohort two incorporated the least were word problems (4%, 4%), tool use (4%, 19%), journaling (4%, 15%), editing the textbook (4%, 4%), breaking apart numbers (7%), counting (7%, 4%), and designing word problems (7%, 4%). For seven of the ten practices, no more than 7% of the teachers engaged in them during instruction. However, it should be noted that the practices that cohort two engaged in more centered on student thinking and that 19% of teachers already practiced some form of student sharing.

The two cohorts were similar in taking on practices around attending to student thinking, student sharing, journaling, editing the textbook, and designing problems. The only difference that favored cohort two was questioning student thinking, but this difference was fairly minor. On four practices however, cohort 1 significantly incorporated them more into their classroom practice. Across word problems, counting, breaking apart numbers, and use of tools, between 18 and 37% more cohort 1 teachers incorporated these practices into their classrooms.

New Mathematical Practices across Years One and Two for Cohort One

The question guiding this section is how did their participation change in terms of the 10 practices in their second year of the PD? In looking across years one and two for cohort one, teachers increased their level of participation very little. While cohort one teachers did not decrease their use of any practices, they minimally increased their use in two categories. We discuss possible reasons for this in the discussion.

In table 2, you can see that the two practices that more teachers took on were counting (from 44% to 50%) and questioning student thinking (from 13% to 19%). None of the use of other practices changed. To say this is disappointing would be an understatement. The cohort that took more practices on in their first year of participation seemed to stop changing. Remember this was occurring at the same time as cohort two year one. So during the same year of professional development, while cohort one stopped taking on new practices, cohort two also did not take on many new classroom practices. The pattern seemed to point towards it being more difficult for teachers to take new practices on in the second year of the project across cohorts.

Teacher Group	Practices									
	Word Problem Use	Journals	Student Sharing	Counting Collections	Breaking Apart Numbers	Tool Use	Attention to Student Thinking	Editing the Textbook	Questioning Student Thinking	Designing Problems
Cohort 1, year 1 [b]	25	13	19	44	25	38	19	13	13	13
Cohort 1, Year 2 [b]	25	13	19	50	25	38	19	13	19	13

[a] n = 16, [b] n= 27

Table 2: Percentage of Teachers Using New Instructional Practices

Discussion

The classroom practices data shows that the first year teachers were trying and sustaining practices. For sustaining practices, we think these numbers are quite realistic. About 40% of the first year teachers maintained two practices (counting and tool use). Another 25% of teachers maintained two practices (breaking apart numbers, and using word problems) and 19% of teachers maintained two other practices (student sharing and attention to student thinking). There are a number of factors that could be limiting teacher change in year 2.

It is possible the project did not engage the teachers as well in year two. While this is a possibility, the same professional developer provided the training. Additionally, our relationships with teachers grew and we came to better know their classrooms. Another possibility is that we did not integrate the ELL practices well with CGI principles. Since it was the first time we attempted this, it is a possibility, but teachers changed I year 1 with this integration. The most likely explanation is that new educational policy in the state affected teacher practice of ELL students. This impacted all of out teachers in year 2 of the project and could have limited new practices they were willing to try in classrooms. We discuss this elsewhere (Authors, 2010).

Here however, we want to focus on the nature of experimenting in classrooms. One idea to be pulled out from this data is that practices that can be used as entire activities seemed to be taken up easier. Counting collections, breaking apart numbers, and word problem use are all practices that are supplemental activities to add on to lessons. This makes sense, especially if we see these activities as holding their own norms and ways of engaging students.

Practices that cut across lessons such as editing the textbook, designing problems, and questioning student thinking were slower to be taken up by teachers. These practices are ways of interacting in the math classroom across differing activities, from whole class to group work to individual practice. This may require more fundamental change from teachers since we asked them to change these practices to begin teaching for understanding.

If we take this notion of the types of practices that are easier for teachers to take up, we pose two questions for the field. Should we begin PD with practices that are add on activities for teachers to be successful with the principles of professional development early on? This is one way to interpret these findings and might be a way to begin to build trust with new instructional methods. Can we incorporate these more difficult practices in routinized ways so teachers can practice the norms of questioning students and designing problems? The notion of routinizing practices does not mean that we endorse simplifying them, but rather that we think teachers need to build standard ways around these practices before they can take on the complexity of more in depth student questioning. These ways of approaching PD may give us more insight into how to support teachers as they transition from learning with colleagues into learning with students in the classrooms.

UNPACKING START-UP DIFFICULTIES OF MATHEMATICS COACHING

Patti Brosnan
The Ohio State University
Brosnan.1@osu.edu

This study, representing a small part of a larger six-year mathematics-coaching project, focuses on the difficulties that can arise as schools take on a coaching program. The program studied provided guidance to district personnel regarding how to begin a coaching program. Sixteen schools were chosen at random and separated into two groups that were designated as having higher or lower student growth. Results indicate that schools that were more closely aligned with the program protocol had fewer difficulties and greater student growth.

Mathematics coaching used as a model for professional development has gained momentum (McGatha, 1999). Results are mixed as to how coaching influences teachers' practice and student mathematics achievement. Little is known about what factors determine whether coaching works. The roles and responsibilities of a mathematics coach are many and varied. For this paper, we define mathematics coaches as those who team with teachers in classrooms with students daily for six weeks before moving on to the next set of teachers (Brosnan & Erchick, 2010). The purpose of this report is to reveal some of the many issues that arise before coaching even begins.

The context for this study is a mathematics-coaching program that has been in existence for six years and has shown many compelling results. Having served close to 200 schools, many, but not all, schools have shown increases in both teacher and student mathematics knowledge (Brosnan & Erchick, 2010). Mathematics coaching can be both challenging and rewarding, but starting without careful planning can be futile.

Purpose of Study

The purpose of this study is to unpack what has proven to be a myriad of stumbling blocks in the establishment of mathematics coaching in schools. The mixed results that published papers have reported, may be related to how many of the to-be-noted difficulties schools, coaches, and teachers have at the beginning of the process. These difficulties that can and have arisen in establishing mathematics coaching in the program discussed here, will reveal how starting off in the wrong direction may lead to little or no measurable improvement in mathematics achievement.

The work discussed in this paper is part of a larger research study and professional development program aimed at preparing a cadre of mathematics coaches to work in classrooms with teachers to enact research-based instructional strategies. The goals of the larger project are 1) To increase coach and teacher mathematics content knowledge; 2) To increase coach and teacher mathematics pedagogical knowledge; and 3) To increase student mathematics achievement on standardized tests. Because the results of this larger project are mixed, and in an attempt to help schools that did not increase achievement, a study to determine factors that prevent coaching success from the outset was warranted. To prepare schools for entering into mathematics coaching, the project provides building principals and coaches with three important documents a *Coach Selection & Information Packet*, *Program Assurances* and a *Start-Up Packet*.

These three documents were designed to assist school administrators and coaches in getting the coaching program off to a good start. The *Coach Selection & Information Packet* includes information about the program, program results, coach qualifications, suggested coach selection procedures, and a coach interview protocol. Project members offer to assist in the selection of a coach and/or to administer and score a test in mathematics and pedagogy. Coach qualifications listed in the packet for administrators to consider include such things as degrees and/or coursework in mathematics and mathematics education, successful teaching of mathematics, successful teaching of students who struggle, experience working with adults, good personal relation and communication skills, and commitment towards student learning of mathematics.

Our *Program Assurances* document has proven to be a very important guide to program fidelity. This document is a signed contract between school administrators, the state department of education, and program directors. Program expectations ensure that each participant knows what is expected from them and for them while engaged in the work of the coach. For example, project personnel are expected to provide professional development for coaches, facilitators, site visitors, and administrators; administrators are expected to assist the coach in arranging teachers' schedules to align with the coach's schedule, not use coaches as substitute teachers, and build a school-wide positive disposition for mathematics; coaches are expected to team teach with four teachers daily for six weeks, have pre- and post-conferences with teachers, and administer program assessments; and teachers are expected to team with the coach, conference with the coach at least once per week, and be willing to try new approaches in practice.

The *Start-up Packet* provides facilitators and coaches the tasks that must be completed before coaching begins. These tasks are broken into immediate and on-going categories. The immediate tasks include things such as building relationships with teachers; aligning curriculum to the current standards; taking inventory of school supplies, equipment, and manipulatives; administering and scoring pretests for teachers and students; collecting, synthesizing, and analyzing student data records; and other important start-up tasks. The on-going tasks include working with data; collecting student work samples; building trust with teachers and principals; making reports to program facilitators and directors; and other important management tasks.

Theoretical Framework

The framework's approach depicts a learner-responsive pedagogy comprised of elements from three areas, 1) mathematics content; 2) pedagogy; and 3) socio-cultural contexts. The mathematical elements include a rigorous, integrated procedural/conceptual perspective on the content (Baroody, Feil, and Johnson, 2007), processes for understanding, and a content that is richly connected (NCTM, 2000). The MCP pedagogical elements include student-centered interactions, where assessment has an informative focus, and grounds instruction incorporating problem-based tasks. These elements are drawn from scholarship of those who focus on the critical features of instruction (Hiebert, J., Carpenter, T., Fennema, E., Fuson, K., Wearne, D., Murray, H., Oliver, A., & Human, P., 1997), teacher content knowledge and content knowledge needed for teaching (Ball, Hill & Bass, 2005; Leinhardt & Smith, 1985; Lampert, 1990; Ma, 1999), and teacher pedagogical content knowledge (Leinhardt & Smith, 1985; Ball, 2000; Shulman, 1986, 1987; Wilson, Shulman & Richert, 1987). These scholars recognized the complexity of teacher knowledge and the role of both content knowledge and pedagogical content knowledge (PCK) in effective instruction. PCK embodies an understanding of how to draw from one's own knowledge of the subject matter to make the content accessible to children, make sense of students' thinking and draw on their ideas to orchestrate classroom instruction so to advance mathematical learning through continuous formative assessment. Finally, the contextual elements for coaches and teachers include an understanding of the learner in terms of both cognition and culture, and a learning environment where authority is shared between the learner and the teacher. A commitment to action distinguishes the equity, diversity and social justice element, where knowledge of the learner and understanding content and pedagogy are not enough. Using that knowledge to further the growth of the learner is an intentional commitment.

The MCP instructional approach is grounded in the situated cognition (Lave & Wenger, 1991) perspective. As such, it incorporates Liping Ma's (1999) notion of positioning the content development of teachers' in the context of student learning and classroom practice. In mathematics education this perspective has been supported by a number of scholars of teacher education and preparation. For instance, Ball & Cohen, 1999- cited in Smith (2001), acknowledged professional development should be situated in the context of practice in order for learning to be meaningful and transferrable. Others have argued that such learning should provide teachers with enactment strategies that would allow them to enhance learning for all students (Manouchehri & Goodman, 2000).

What We Know About Coaching in the Literature

Coaching is grounded in the notion of building capacity for positive change in teaching practice and having highly trained practitioners *working with their colleagues* to promote learning and improve practice (Becker, 2001). Working with teams of teachers, these coaches share their expertise and provide feedback and assistance as teachers learn new teaching skills and solve classroom-related problems (Galbraith & Anstrom, 1995; Borko, Davinroy, Bliem, & Cumbo, 2000; Breyfogle, 2005; Franke, Carpenter, Fennema, Ansell, & Behrend, 1998). While researchers indicate that teacher coaching can be practiced using a variety of structural approaches, it has not yet been studied extensively (Biancarosa, Bryk, & Dexter, 2010; McGatha, 2009). Other studies have been designed to examine what coaches do but have not yet shown much connection to actual improved student achievement (Campbell & Malkus, 2009; Wei, Darling-Hammond, Andree, Richardson, & Orphanos, 2009). In studies in which university-based researchers have taken on the role of coaches and reported on their interactions with teachers in schools (Olson & Barrett, 2004), there has been only limited information about how and what type of professional skills have been developed at the coach level, and then effectively communicated with teachers in ways that knowledge is enacted in classroom practice.

Methods

Participants

In the larger study, the participants include approximately 185 schools, principals, coaches, and teachers. Most of the schools were in School Improvement Status and Title I served. Grade levels in buildings varied from K-8. Some buildings housed K-5 students, some K-3, 5-6, 6-8, and other groupings. In this smaller study, a random sample of 16 schools, principals, coaches, and teachers were selected. These 16 schools were then placed in rank order by student achievement growth. Half were placed in the higher growth school group and half in the lower growth school group.

Data Collection

For this report we use data from *Facilitator* and *Site Visitor Reports*. In addition, teachers and principals were interviewed once during the school year using a semi-structured interview protocol. These interviews focused on how teachers and principals understood the reform work and how they chose to follow program initiation protocols.

Facilitators are mathematics specialists who were chosen by the geographic area of the state in which they worked as university faculty or as state agency professional development providers. They are hired by the program to work four days per month. Two days per month, they attend the training as their coaches do to learn the program as presented, and the other two days per month they meet with small groups of coaches who work in the same geographic area. These small group sessions are designed to detail the work in enacting their duties as a coach. *Site visitors* are also mathematics specialists who work in state agencies around the state and are hired to work for our program to visit all of the schools participating in the mathematics-coaching program. Both the *Site Visitors* and *Facilitators* used the same measuring instrument, the *Site Visit Inventory*, to document what coaches actually do or report doing in the schools. This instrument serves as a tool to document evidence of the progress, challenges and issues that arise in coaching. The instrument was designed with the program framework, assurances, and the envisioned roles and responsibilities in mind to determine fidelity of implementation.

Data Analysis

The process of analysis was the same for each set of data, with the analytic procedures falling under constant comparison methods. First, data were entered into a qualitative research software program and reviewed by project researchers to discover emergent themes. Emergent themes in each data set determined the creation of additional codes added to pre-determined research-based codes. Data was then coded using NVivo qualitative analysis software, and sorted into the coded categories.

Findings

Mathematics coaching is a challenging endeavor. Careful planning at the outset makes a difference as to whether coaching may be successful in terms of improved student mathematics achievement. After analyzing the reports from the 16 randomly selected schools, the categories that emerged from the data include 1) Coach selection criteria, 2) Compliance with program *Assurances*, and 3) Completion of Start-Up Tasks.

Coach Selection

Although there were few data sets that actually revealed how coaches were selected, what we did learn from interviews was that in schools that began in a less-than-optimal way, the coaches hired by school districts had no greater mathematics knowledge than the teachers they were coaching; some either disliked or never taught mathematics; several union contracts required hiring by seniority only, resulting in several coaches who sought alternatives to classroom responsibilities; and others did not have the necessary leadership nor human relation skills optimal for the job of coach. In one situation we learned that the principal selected her “worst” teacher (principal’s term) in the building to be the coach. It would appear obvious that none of these situations would proffer much hope for a successful start to a coaching program.

In one of the principal interviews when asked about her coach’s leadership skills, she said, “He leads by example. At no time does he expect more from his teachers than he is willing to give.” Another principal said that he hired his coach from a small group of applicants, in a time crunch. He thought he made the right choice, given the applicants.

Compliance with Assurances

Engaging in large-scale school reform requires participants to be ever so vigilant in following guidelines gleaned from the literature and experience. Following our set of Assurances was our proactive approach to waylaying some of the usual pitfalls.

Assurance Constituent	Schools with Higher/Growth Mathematics Achievement	Schools with Lower/Growth Mathematics Achievement
Administrators are expected to		
• Assist the coach in arranging teachers' schedules to align with the coach's schedule	75%	50%
• Not use coaches as substitute teachers	87.5%	50%
• Build a school-wide positive disposition for mathematics in the building	62.5%	50%
Coaches are expected to		
• Team teach with four teachers daily for six weeks	62.5%	37.5%
• Have pre- and post-conferences with teachers	75%	25%
• Administer program assessments	100%	87.5%
Teachers are expected to		
• Team with the coach	75%	62.5%
• Conference with the coach at least once per week	75%	37.5%
• Be willing to try new approaches in practice	87.5%	50%

Table 1. Compliance with program assurances comparison

Data from Table 1 indicated that those schools that had greater levels of compliance with program assurances had a better likelihood of achieving greater growth. The reports also showed that those who started out in alignment with the assurances also demonstrated a greater sense of enthusiasm in the school at large resulting in building strong relationships from the start.

Site visitors reported that one coach works with four teachers but for only 30 minutes each. Another coach moves to a new building every two to three weeks and may work with 2-3 teachers at a time, depending on the situation. Another site visitor reported that some coaches are given far too many non-coaching responsibilities. For example one has breakfast, lunch and dismissal duties and is also part of the district Improvement Process team and is in charge of AIMS web for both mathematics and reading. She is the contact for two math/computer programs, Alex & Math Tracks. She also has the responsibility of reordering math materials and the like. Another coach is in charge of AIMS web testing, grade 2 and 5 oral reading fluency testing, and Orleans H Algebra Prognosis Tests.

Regarding one coach who did not like relinquishing control of the teaching to the classroom teachers, the site visitor wrote, "If she is the only one planning and teaching, she should not be so puzzled by the fact that when she does leave, they are discontinuing the use of the strategies." This same site visitor reported asking a coach why she was not coaching in more than one classroom, the coach replied, "… Their schedules had already been developed, with many of the teachers teaching math at the same time. And, they didn't want to change their schedules for the year." As a consequence, the principal told the site visitor, "You are not going to see what you want to see today, but next year we are going to fix it. There are 6 math teachers and next year she will interact with them like we need her to."

All of these statements indicate how important the assurances can be to whether a coach is able to their job well under certain conditions.

Start-Up Tasks

These tasks were designed to prepare coaches to coach. We felt that coaches need to know and align the curriculum with standards, know and understand student records and culture, and take time to complete test administration and build teacher relationships.

Task Description
Immediate • Building relationships with teachers; • Aligning curriculum to the current standards; • Taking inventory of school supplies, equipment, and manipulatives; • Administering and scoring pretests for teachers and students; • Collecting, synthesizing, and analyzing student data records; and • Other important start-up tasks.
Ongoing • Working with data; • Collecting student work samples; • Building trust with teachers and principals; • Making reports to program facilitators and directors; • Other important management tasks

Table 2. Sample Start-Up Tasks

Program Start-Up Tasks were important for our mathematics coaches to complete before they began coaching. First, these tasks are necessary for the coach to learn about curriculum, school data, and classroom culture. Secondly, teachers are so grateful to have someone do work for them that is very time consuming, and finally because of the many tasks done ahead of time contribute greatly to building rapport with teachers. The following excerpts from the facilitator reports confirm these observations.

Principal: “Teachers tend to be surprised when working through this analysis with [the coach]…it helps them understand the curricular needs of their students.”

“He has worked very hard to build a positive rapport with the teachers by doing tasks that are very helpful to their teaching but they just don’t have time for…such as the gap analysis sheets, vocabulary, matching lessons to the SST goals, etc. He works with grades 3-4-5 and he did a gap analysis study for them to go with the new series. He also found activities and lessons to fill-in the gaps not covered.”

“[She] gives students a pretest and goes over the results, making a spreadsheet identifying the strengths and weaknesses of the students.”

“I shared data from the [state] tests with the teachers. This was the first eye-opener for the teachers. The teachers don’t have time to analyze the test questions.”

Conclusions

The evidence in this study shows that following the prescribed program protocol is important to establishing a mathematics-coaching program. The selection process used in hiring a coach cannot be understated. Teachers having greater mathematics content knowledge, successful teaching records, good relationship building and leadership skills prove to be necessary characteristics in beginning coaches. In cases where there was little choice in how a coach was hired, i.e. union contract seniority regulations, there was more opportunity for a non-optimal selection.

One of the unique elements of the mathematics-coaching program studied was the design and adherence to program assurances. It is often the case that when university and school partnerships go awry, lack of implementation fidelity can certainly lead to a lack of program impact. The assurances in this study that seemed to make a difference in whether a school started off in better ways was whether the coach was able to coach as prescribed; whether the coach was stretched between buildings; or if the coach was given too many extra-program responsibilities. Also, in the assurances category, if teachers were reluctant to team with the coach, the possibility for the coach to build capacity was clearly diminished.

The program start-up tasks proved to be useful in getting coaches ready to do their job. For example, aligning the school curriculum to the current standards and synthesizing classroom student data reports were the two most highly touted ‘helps’ for teachers who say, they never have ‘time’ to do such things and the information is so important and useful.

School districts interested in establishing a mathematics-coaching program should consider using the program protocols described in this paper. Coaching is difficult in any capacity let alone falling prey to some of the pitfalls described herein.

PROPORTIONAL REASONING INSTRUCTION: A COGNITIVELY GUIDED APPROACH TO PROFESSIONAL DEVELOPMENT

Jessica A. de la Cruz
Assumption College
jdelacruz@assumption.edu

Content-specific cognitively guided instruction (CGI) professional development programs have been shown to lead to positive changes in instruction in the elementary grades. This paper presents the results of a study that investigates how teachers use new knowledge gained from a CGI professional development workshop, on proportional reasoning in the middle grades, to inform their instructional decisions. Four teachers' instruction and their rationales for their instructional decisions were examined before and after the workshop intervention. All four teachers' instruction changed to become more cognitively guided.

Introduction

The National Council of Teachers of Mathematics [NCTM] (2000) recommends that proportional reasoning become a major focus of the middle grades curriculum by interweaving it with percents, similarity, scaling, linear equations, graphs, probability, histograms, and problem solving. Furthermore, proportionality is involved in at least one of the focal points for each of the middle grades. Students who fail to develop an understanding of proportional reasoning in middle school are likely to struggle in algebra and other higher level mathematics (Langrall & Swafford, 2000).

Although proportional reasoning and facility with rational numbers are so important, research shows that many students struggle with them (Misailidou & Williams, 2003; Singh, 2000). In fact, preservice and inservice teachers often lack a deep understanding of proportionality (Bezuk, 1988; Conner, Harel, & Behr, 1988). Furthermore, teachers often have weak pedagogical content knowledge (Hines & McMahon, 2005) and knowledge of their students (Ruchti, 2005) related to proportional reasoning.

In order to understand the true breadth of the area of proportional reasoning, teachers must understand both the subtle (e.g. number structure) and obvious (e.g. context) nuances of proportion problems (Franke, Fennema, & Carpenter, 1997). Additionally, teachers need to be able to analyze a problem to determine the range of strategies that students are likely use when solving it. This ability better enables them to determine the difficulty level of a problem. According to Carpenter and Fennema (1991), "analyzing problems, strategies, and development allows for the ability to select critical problems both to differentiate between levels of performance but also to help children progress to the next level" (p. 9).

In 1989, Carpenter, Fennema, Peterson, Chiang, and Loef developed an approach to professional development, cognitively guided instruction (CGI), which focused on increasing teachers' pedagogical content knowledge and knowledge of their students in a specific content area. Since, participation in a content-specific CGI program has been shown to have a positive effect on teachers' pedagogical content knowledge and lead to changes in classroom practice towards instruction guided by students' thinking.

This study investigates how teachers use new knowledge gained from a CGI professional development program on proportional reasoning to inform their instructional decisions. Particularly, the ways that the teachers generated student thinking prior to and after gaining access to research-based models of students' thinking about proportional reasoning were examined. This study is intended to extend the CGI studies, which focused primarily on operations in the elementary grades, to proportional reasoning in the middle grades.

Theoretical Framework

A few assumptions about the goals of instruction and what instruction should look like underlie the CGI philosophy (Carpenter & Fennema, 1991). First, the goal of instruction is to increase students' understanding by connecting to their prior knowledge (Donovan & Bransford, 2005). To effectively structure instruction to build off students' prior knowledge and experiences, teachers must have strong pedagogical content knowledge, as well as a deep understanding of their students.

Second, effective instruction requires teachers to make informed instructional decisions, by continually reflecting on their instruction and students' learning. Thus, teachers must continually assess their students' understandings through using appropriate tasks and questions that enable students to showcase their thinking.

Third, for learning to occur students need to develop mathematical explanations and justifications and connect them to their existing body of knowledge. The teacher's role is to choose meaningful exploration activities and provide a learning environment where mathematical conjectures, multiple techniques, and mathematical dialog are valued.

Methodology

The professional development program which provides the context for this study is briefly described here. Data collection and analysis methods will also be discussed.

Professional Development Program

The context of this study was a two-day professional development workshop, followed by ongoing implementation support over the six subsequent months. The workshop design was inspired by the CGI studies. During the workshop, we discussed the research findings in the area of proportional reasoning that are related to (a) students' strategies; (b) problem types; (c) factors influencing students' success and strategy choices; (d) prerequisites to the development of proportional reasoning; and (e) developmental theories, specifically those of Piaget (Piaget & Inhelder, 1969), Noelting (1980a, 1980b), Milsailidou and Williams (2003), Lesh, Behr, and Post (1987) and Karplus et al. (1983a).

Written and video cases illustrating real classroom teaching episodes were also used to illustrate CGI. The teachers were asked to analyze the pedagogy, questioning, student thinking, and teacher's role within the cases.

Researchers have found that teachers are more likely to change their instruction as a result of professional development when supported (Steele, 2001). Here, when initiated by the teachers, the researcher served as a mentor to aid in planning and analyzing students' strategies.

Participants

The participants in this study, who volunteered, were four middle school teachers from the same school in a rural part of Virginia. The teachers had varying levels of experience from 1 to 22 years. There was one teacher from each grade, 6-8, and one who taught in eighth grade for the first half of this study and seventh grade for the second. The sixth grade teacher (Bob), seventh grade teacher (Abby), and the seventh/eighth grade teacher (Julie) were all in their first year teaching mathematics. However, Julie had four years of science teaching experience. The eighth grade, and veteran, teacher (Sue) had taught mathematics for 22 years. All of the mathematics teachers in the school participated in the workshop.

Data Sources

The data analyzed here were collected primarily through classroom observations, interviews, and document compilation. Each participant was observed and interviewed prior to the workshop to examine their instructional style and bases for making instructional decisions. In addition, documents were collected that illustrated how each teacher had taught or planned to teach proportion concepts.

After the workshop, each teacher was observed teaching ratio and proportion concepts on several occasions, ranging from 4 to 16 instances. The large variation in the number of observations per teacher was due to differences in the depth of curriculum coverage of proportions between sixth and eighth grade. Detailed field notes were compiled during each observation which focused on (a) what the teachers *did* and *said* during instruction, (b) how the students reacted to the instruction, and (c) how the teacher interacted with the students.

Following each observation, the teachers were interviewed by the researcher to determine their rationales for their instructional decisions. The interviews were recorded and later transcribed to capture the teachers' responses accurately. These interviews were semi-structured; they began with a predetermined list of questions, and appropriate follow up questions, and ended with questions related specifically to the observations.

Data Analysis

A case study and cross-case analysis was conducted to describe each teacher's instruction and rationale before and after the workshop. Systematic data analysis was used to derive causal descriptions and lawful relationships among the data. The three frameworks that guided the initial coding were derived from: (a) the content of the CGI workshop on proportional reasoning, (b) Franke, Carpenter, Levi, and Fennema's (2001) schema for analyzing teachers' actions on a CGI scale, and (c) Stein, Smith, Henningsen, and Silver's (2000) schema defining levels of cognitive demand. To ensure validity, the data was triangulated across methods, member checking was used, and colleagues of the author were asked to evaluate the author's interpretations of the data.

Findings

The purpose of this study was to answer the following research questions: (1) How did the four teachers generate student thinking through their instructional decisions *prior* to participating in the workshop? (2) What were the four teachers' instructional decisions based on prior to the workshop? (3) How did the four teachers change in order to generate student thinking through their instructional decisions after participating in the workshop?

How Was Student Thinking Generated through the Teachers' Instructional Decisions Prior to the Workshop?

All four teachers involved their students in their lessons to varying degrees before the workshop, but they all focused their tasks and questions on applying and remembering procedures rather than developing connections and understandings. Thus, the teachers rarely generated student thinking through their instructional decisions.

All four teachers used questioning to involve their students, but all their questions were categorized as placing low cognitive demands on students. For example, the teachers commonly asked students to: state the next step when applying a procedure, give an answer, or perform a computation. Two teachers were observed presenting a task with a high-level of cognitive demand, but their treatment of the task had the effects of lowering the cognitive demand. For example, one teacher had “tricky” problems, which were different than those the students had seen before, at the end of a worksheet. Those tasks were initially categorized as high-level tasks because the students need to form connections or “do mathematics” (Stein et al., 2000). However, the teacher immediately pointed out the tasks as “tricky” and prescribed another procedure for solving them, ultimately lowering the demands of the tasks to “procedures without connections”.

What Were the Four Teachers’ Instructional Decisions Based on Prior to the Workshop?

Sources. Prior to the workshop, the novice teachers relied on others for the majority of their lesson ideas: two teachers almost exclusively relied on their textbook while the other relied on worksheets and materials provided by colleagues. Unlike the novice teachers, the veteran teacher was not entirely dependent on other sources for lesson ideas.

The novice teachers lacked confidence in their ability to plan appropriate lessons to meet the Virginia Standard of Learning (SOL) objectives, which likely stemmed from their lack of experience teaching mathematics and their unfamiliarity with the content and pedagogical techniques for teaching. One teacher exclusively used the materials that came with the textbook. The role of the textbook was also significant for the veteran teacher. However, she created her own example problems to relate the new concepts to her students’ background knowledge and to be relevant to their lives.

Rationales. All four teachers followed the general sequencing determined by their pacing guides or the textbook, but the three novice teachers did so blindly. The three novice teachers did not have an overview of the general sequencing of their courses, indicating that no consideration was given to the order in which they introduced different mathematics topics. One admitted that she planned her lessons one day or one week at a time and followed the pacing guide. When I asked her how she typically planned her lessons, she replied, “Day-by-day. We have our planning guides, they are really helpful. It tells you day-by-day exactly what they need to know.”

All four teachers’ planning decisions regarding which types of tasks to include in their lessons, as well as how to sequence them, were influenced largely by what appeared in their lesson planning sources and by their goal to have students memorize and master procedures to prepare for state-mandated testing. However, the veteran teacher referenced what her students knew or where they were in their development of understandings when describing her reasons for her instructional decisions, while the other teachers did not.

How did the Four Teachers Change in order to Generate Student Thinking Through Their Instructional Decisions after Participating in the Workshop?

Student involvement and questioning. All four teachers changed, to varying degrees, to encourage more individual high-level thinking from their students. They did so by asking students to solve problems rather than exercises exclusively and by asking high-level questions in addition to low-level questions. They all asked more questions and used more tasks that I categorized as requiring high-levels of cognitive demand; unlike prior to the workshop, when all four teachers posed only low-level questions and tasks. All four teachers allowed their students to solve problems without any prior instruction on how to do so, but Abby and Bob always presented procedures after students were given the opportunity to solve the problems on their own. Prior to the workshop, none of the teachers allowed their students to solve problems without prior instruction.

Sources. The sources that Sue, the veteran teacher, and Bob used for lesson ideas only changed minimally, while the sources the other two teachers used changed more substantially. The novice teachers all still relied on the pacing guide to determine their overall instructional sequence of topics, while the veteran teacher was observed referring to the textbook for the general sequence of topics.

Immediately after the workshop, Julie became less reliant on the textbook materials. She began creating her own warm-up exercises to meet her instructional goals and to highlight her students' relevant background knowledge. Although she initially depended on the textbook to provide her with appropriately sequenced problems, she chose which problems to include in her lessons. In her second time teaching proportion concepts, after moving to the seventh grade, she relied even less on the textbook. Instead, she used what she learned in the workshop, together with problems from a SOL Test Bank, to plan her lessons.

In Abby's case, there was a substantial change in her planning sources. She crafted her own problems for worksheets on proportions, percents, and cross multiplication where before she only used worksheets others had created.

Similar to before the workshop, all the novice teachers said that the overall sequencing of their lessons was determined by the outlined sequence and timing given in their pacing guides. They did not seem to have an overview of the topics and sequence of their courses. They planned their lessons on a weekly basis, often without looking ahead in their pacing guides. There were occasions when they could not tell me what was coming up next or generally when they would be teaching a specific topic.

Rationales. After the workshop, three of the teachers expressed that they had sequenced tasks in order to further their students' development. Of these three teachers, the increase in Julie's attention to the sequencing of the tasks used was the most profound. The fourth teacher, Bob, generally articulated no particular reason for the sequences of tasks he was observed presenting, besides following the sequence in the textbook. However, all four gave some consideration to the numerical structure of the tasks.

Changes in the teachers' levels on the CGI scale. All the teachers increased at least one level according to Franke and colleague's (2001) CGI schema indicating that their instruction was more cognitively guided, after the workshop.

Julie had the most significant changes in her instruction and beliefs, from Level 1 to Level 3 or Level 4A. In Franke and colleague's (2001) schema, Level 1 corresponds to instruction that is not cognitively guided and Level 4B corresponds to instruction that is completely cognitively guided. Julie was at Level 1, prior to the workshop, for several reasons. First, she believed that her students were not capable of solving problems without the help of delineated procedures or their textbooks. During my observation, she did not allow her students to figure out how to solve problems on their own and from her description of her standard lesson plan, it was clear that Julie did not allow her students to invent their own strategies for solving problems. In fact, she never posed a "problem," instead she used tasks where procedures were given or exercises that were similar to previously solved tasks. Like the tasks Julie used prior to the workshop, the questions she asked her students required low-level cognitive demands of students; she did not ask them about their thinking.

After participating in the workshop, Julie satisfied all of the characteristics of a teacher at Level 3. First, while there was no change in Julie's expressed beliefs about how students learn mathematics best, her teaching style changed to corroborate these beliefs. In both instances she indicated that discovery was the best method for learning and that teachers should always allow their students to solve problems, but Julie commented that she learned how to teach in this way through the workshop. Post workshop, Julie *never* taught a procedure before allowing her students to discover their own ways first; in fact, in most cases she avoided teaching procedures all together.

Second, after the workshop, Julie encouraged her students to solve problems in different ways. She asked, "Did anyone do it differently?" so frequently that her students began to volunteer to share alternative approaches. Third, Julie used a variety of different types of problems after the workshop. She attempted to teach in a developmentally appropriate way by creating progressions of problems according to their difficulty levels or the strategies they were likely to elicit from her students. For instance, one of her lessons on proportions progressed from problems involving an integer factor of change to problems without integer factors of change and with large numbers, to encourage her students to first develop a factor of change strategy and then advance to cross multiplication (CM). She said, "I deliberately gave them a problem where factoring was going to blow their minds so that they would be forced into the other [developing CM]." She explained that she "wanted to lead them [her students] into discovering CM or needing the CM algorithm."

Fourth, Julie expected her students to share their thinking with the class, after the workshop. *Before* the workshop, the only questions Julie was observed asking had low-level demands, but *after* the workshop Julie also asked questions with high-level demands. In fact, as more time passed after the conclusion of the workshop, Julie asked more and more questions placing high-level demands on students. Immediately after the workshop, Julie asked her students to share their solution strategies with the class, but she focused more on the processes than on her students' reasons for their actions or why their strategies worked. Over time she asked more questions about her students' thinking, such as, "Why does this work?" or "Why did you put the numbers there [within a proportion]?" Julie's eighth-grade students really responded well to their new responsibilities involving solving problems and sharing their thinking. One of her students went to the board and announced, "All eyes on me. Ok…" and then she proceeded to explain her solution process. This was a drastic change; before the workshop, Julie's students were far more disruptive than participatory. Julie noticed this too and she attributed the change in her students to requiring them to *think*:

> Yeah ever since I switched it [switched her teaching to problem based rather than read in the book and fill in the blanks], he has been into it. Because he is using his mind. And you know, S [another student] did too [got into the lesson].

For these reasons, Julie was at least at Level 3 on the CGI scale after the workshop. But Julie also possessed some of the characteristics of a teacher at Level 4A. Julie may have been in transition to this level. She focused her lessons around problem solving. The majority of the tasks Julie posed were word problems after the workshop. She always asked her students to solve problems in their own ways and to share their approaches with her class. As I mentioned earlier, she based her instructional decisions on her students thinking, attempting to push them further along in their development of understandings. There was also at least one instance when she based an instructional decision during class on her students' thinking. This instance was when one of her students explained that he was writing percent proportions in the order in which the values appeared in the problem. In response, Julie posed a problem where this students' misconception would be highlighted. Later she explained to me, "They wrote it [a student said, 'It has to go 78 over 58 because it is 78% of 58'] and I thought I have to use the other [another] problem to show that it may not go in order."

Sue changed her instruction from Level 2 to Level 3. Prior to the workshop, Sue was at Level 2 for several reasons. Unlike the other teachers, Sue occasionally asked her students to solve problems on their own and repeatedly stressed the importance of relating new knowledge to students' background knowledge (e.g. "If they can tie it to something that they have learned previously, it tends to stick a lot better."). She also described being open to a variety of approaches to solving problems, which was characteristic of a teacher at Level 2. However, that behavior was not observed through her teaching. Because she showed her students how to solve problems with her anticipatory set, note-taking guides, and approach to dealing with students' difficulties, Sue was not at Level 3 prior to the workshop.

After the workshop, Sue's instruction changed in several ways to become more cognitively guided. The following changes led to a Level 3 characterization: (a) Unlike before, Sue allowed her students to solve problems in their own ways without first asking them to read about procedures for solving similar problems. (b) When her students had trouble figuring out a way to solve a novel problem, Sue posed questions to help them discover a solution strategy. She did not resort to dictating a strategy, like she did prior to the workshop. (c) She demonstrated the openness to a variety of strategies that she expressed previously. Her students also perceived her receptivity to different approaches; During one of my observations, Sue asked her students, "Do you have to do it that way?" and one student replied in a mimicking tone, "No, whichever way works for you." (d) Sue asked questions placing higher-level cognitive demands on her students, such as, "Why can we do that?" or "What is another way you could do this?" These types of questions encouraged her students to discuss their thinking, as well as develop connections and understandings.

Both Abby and Bob progressed from Level 1 to Level 2. Prior to the workshop, neither teacher allowed their students to solve problems on their own. Instead, they demonstrated how to solve problems and then asked their students to solve similar exercises. For this reason, it appears that they did not believe that their students were capable of figuring out their own ways to solve problems.

Both teachers were not observed posing questions or tasks that placed high-level demands on their students prior to the workshop. Actually, Abby and Bob used tasks and questions that could have been deemed high-level, but their treatment of them had the effect of lowering the tasks' cognitive demands. Neither Abby nor Bob asked their students about their thinking.

After the workshop, both teachers progressed to Level 2 on the CGI scale. They occasionally allowed their students to solve problems on their own, which they did not do previously. However, they both always taught procedures for solving problems after their students had been given a chance to solve them on their own. Bob recognized that there were a variety of proportion problem types and that those types can have an effect on students' thinking. He varied the types of problems he included on his proportion assessment and spoke about his decision being influenced by the fact that different numerical structures would encourage different strategies. Abby also considered different problem types and varied the numerical structures and contexts she chose to include in her lessons. However, she only allowed her students to use a factor of change or CM strategy. Additionally, both teachers elicited more thinking from their students after the workshop and asked some questions with high-levels of cognitive demand. Abby and Bob were not at Level 3 due to the fact that neither teacher freely allowed their students to solve problems in their own ways.

Conclusions

A content specific professional development program, regardless of content or grade-level, can lead to positive changes in teachers' instruction to become more cognitively guided. Although this workshop intervention was brief, all four teachers changed their instruction to become more cognitively guided afterwards. It is reasonable to assume that a longer professional development opportunity may have lead to greater positive changes in instruction.

GRADUATE EDUCATION PROGRAMS FOR IN-SERVICE TEACHERS HAVE BEGUN FOCUSING ON THE USE OF TECHNOLOGY IN MIDDLE AND SECONDARY MATHEMATICS SETTINGS TO OFFER OPPORTUNITIES FOR STUDENT LEARNING. DISCONNECTS BETWEEN IN-SERVICE TEACHERS AND TEACHER EDUCATORS REGARDING AVAILABLE TECHNOLOGY CAN HINDER EFFORTS TO SUPPORT STUDENT LEARNING THROUGH TECHNOLOGICAL MEANS. IN THIS STUDY, WE IDENTIFIED THE ACCESSIBLE TECHNOLOGY IN-SERVICE TEACHERS IN A MASTER'S PROGRAM HAVE IN THEIR CLASSROOMS, AND PROVIDED THE INFORMATION TO THE TEACHER EDUCATORS OF THE GRADUATE PROGRAM. AFTER GATHERING TEACHER EDUCATOR PERCEPTIONS OF THE TEACHER PARTICIPANT TECHNOLOGICAL DATA, WE SUMMARIZED HOW THIS PROCESS MIGHT REDUCE SUCH DISCONNECTS AND PROMOTE MEANINGFUL TECHNOLOGY INCORPORATION IN THE PROGRAM.

INTRODUCTION

The challenge of providing teacher education that encompasses appropriate use of technology for student mathematical learning spans traditional discipline borders in graduate programs (NCTM, 2000; Signer, 2008). Cuban (1986) and Lloyd and McRobbie (2005) make a case for professional development that provides opportunities to learn about pedagogically appropriate technology, focusing on activities similar to teachers' current classroom practice. However, graduate education and professional development programs are struggling to follow such advice, in part due to varying advice on how technology education can best influence classroom practice (Dede, Ketelhut, Whitehouse, Breit, & McCloskey, 2009; Wilson & Wright, 2010). This paper describes a study aimed to improve technology education within a graduate program designed for in-service mathematics teachers.

Graduate and professional development opportunities for teachers are central to national improvement efforts, and effective classroom implementation of new teacher learning is seen as a determining factor of success (Lemke & Fadel, 2006; O'Dwyer, Russell, & Bebell, 2004; Penuel, 2006). Putnam and Borko (2000) explained, "professional knowledge is developed in context, stored together with characteristic features of the classrooms and activities, organized around the tasks that teachers accomplish in classroom settings, and accessed for use in similar situations" (p.13). Also, professional development with technologies related to local curricula, standards, and current teaching practices are more likely to have a positive impact on implementation of that technology (Martin et al., 2010; Penuel, 2006).

Since Cuban (1986) first emphasized the importance of making explicit connections between technology and teachers' specific types of instruction, the subject has received substantial attention. In particular, professional development involving technology can impact teacher practice in significant ways, and has been shown both to increase and fundamentally change student learning (Pea, 1985; Penuel, 2006; Ravitz, 2009; Ringstaff & Kelley, 2002; Stevens, To, Harris, & Dwyer, 2008). The work of Stevens et al. (2008) and Martin et al. (2010) addressed the connection between a teacher's professional development about technology and student learning outcomes. Stevens et al. (2008) found teachers' self-efficacy and self-determination improved through participation in a professional development program focused on technology and was correlated with "positive educational outcomes for students" (p. 215). In Martin et al.'s (2010) study, after participating in a technologically-focused professional development program, teachers' use of mathematics technology had a strong and positive relationship to student achievement across elementary and middle school levels. While these results are positive, researchers emphasize the importance of keeping technology tied to classroom practices (Glazer & Hannafin, 2006; Mouza, 2009).

The purpose of this study was to examine perceptions of teacher educators regarding availability and use of technology for mathematics teachers enrolled in their graduate classes. Specifically, we sought to answer the following research questions: (1) What original assumptions and beliefs do teacher educators have about the availability and use of technology in the K-12 classroom? (2) How are teacher educators' plans for instruction with technology influenced by knowledge of the availability and use of technology in the K-12 classroom? and (3) What are the felt needs about technology expressed by teachers and teacher educators in a technology-rich professional development setting?

Methodology

Participants and Setting

This study focused on a two-year master's program in mathematics for secondary teachers[1].

Teacher Educator	*Subject Matter Expertise*	*Number of Courses Taught in the Program*
Dr. Heilmann	Mathematics Education	More than 3
Dr. Torres	Applied Mathematics	None
Dr. Selvidge	Mathematics	More than 3
Dr. Atteberry	Mathematics	1

Table 1: Teacher Educator alias and description.

Designed for middle and high school mathematics teachers, courses are offered year-round through online and blended educational settings. The program incorporates a variety of online technologies during the school year and combines face-to-face and distance instruction in the summer. At the time of the study, participating teachers were primarily from two states in the Rocky Mountain region, and will hence be called teacher participants.

While this study summarized data from the 35 teacher participants taking courses during the summer, our main focus was on the four teacher educators who taught the courses. The four courses offered were Mathematical Problem Solving, Modern Geometry, Teaching Geometry, and History of Mathematics, with each teacher educator instructing one course (see Table 1).

Data Collection and Analysis

We investigated the research questions using a combination of survey and interview methods with both teacher participants and teacher educators. First, we administered an open-ended survey to the teacher educators, the Technology Input Survey (TIS). This seven-item survey asked about beliefs regarding the technology available to teacher participants. Two questions gathered information on how teacher educators planned to incorporate technological instruction, and how the instruction would assist teacher participants in teaching with technology in their own classrooms. All four teacher educators completed the survey.

We then developed and administered a second survey, the Classroom Technology Survey (CTS). Completed anonymously, online, by all teacher participants in the month before summer classes began, this survey consisted of nine open-ended questions about what technology was available and used in teacher participants' classrooms and how participants characterized the use of technology in their classrooms. The response rate for the CTS was 22 out of 35 (63%).

In addition to the surveys, we conducted semi-structured interviews with each teacher educator of the summer courses. A summarized version of the CTS data was shared with the teacher educators shortly before the beginning of the summer term. Interview questions were asked to elicit responses on the implications of the CTS data, such as "What is your initial reaction to the information presented? Does the information we have shared with you influence your plan to teach the course this summer? If so, how? If not, why?" The individual interviews took place two weeks prior to the summer courses started and were audio recorded and transcribed.

The TIS results were first summarized for each teacher educator, and responses from the question, "What information about teachers' use of technology would be helpful to you as an instructor" were incorporated into the CTS. Other responses were summarized and grouped according to the research questions they addressed. Following collection of the CTS, descriptive statistics were calculated regarding the type and frequency of technology teachers reported was available and used by them. Completely opened-ended questions (such as how teachers characterized the use of technology in their classroom) were open-coded (Creswell, 2007) then arranged into categories before being summarized into the examples provided in the summary given to teacher educators (see Figure 1). In a similar process, instructor interview transcripts were open coded to distinguish themes among instructor perspectives about the CTS data. Researcher and data triangulation occurred through the TIS and interview analysis process.

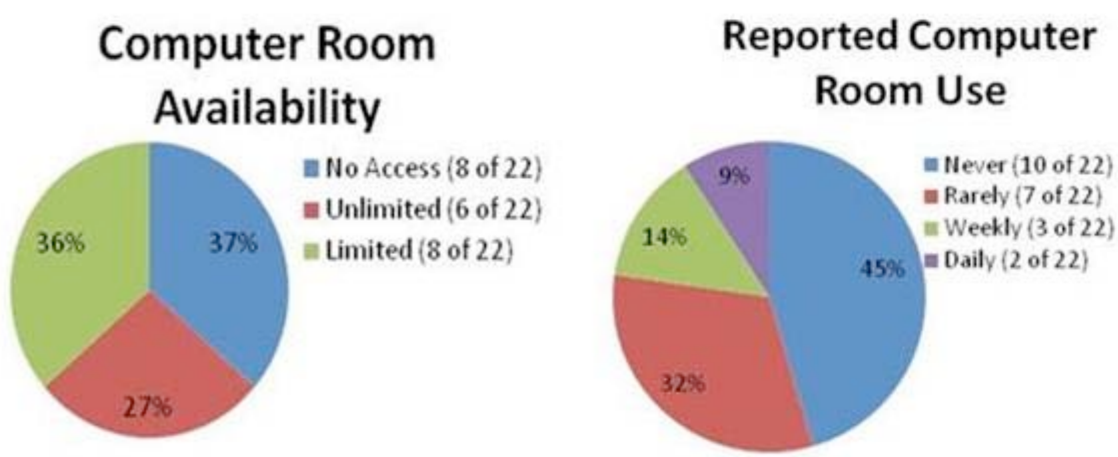

Figure 1: An example item from the CTS summary of teacher participants' reported availability and use of computer rooms.

Results

Teacher educators' beliefs and assumptions about the availability and use of technology in teacher participant classrooms were altered after presentation of the CTS data. Prior to seeing this data, each teacher educator believed all teachers would have access to graphing calculators and that most would have access to a computer lab with dynamic geometry software. Three of the teacher educators reported they believed SMART Boards would be available to some of the teacher participants. Drs. Atteberry, Selvidge, and Heilmann, all having prior experience with in-service teachers as learners, reported making the assumptions based on conversations with teachers and previous teaching experience. Dr. Torres based her assumptions on her experiences working with other in-service teachers, attending sessions at conferences dealing with classroom technology, and reading reports of classroom technology availability. After receiving the CTS data, all four teacher educators indicated being surprised by the high number of interactive whiteboards available to the teacher participants; specific reactions for each teacher educator are described below.

Dr. Atteberry believed his role as an instructor was minimal in connecting technology to the teacher participants' classrooms. Dr. Atteberry also expressed his belief that calculators and other technology were overused in classrooms. He stated, "I worry about people creating graphs so much with technology they can't do it anymore...we have a lot of evidence of that...when I taught calc I [to undergraduate students last year]." Dr. Atteberry said he planned to use technology in his course, "only minimally - I would concentrate on showing different kinds of problems that can be facilitated with the computer or graphing calculator."

After reading the results of the CTS, Dr. Atteberry expressed surprise at the prevalence of whiteboard and digital projectors in the teacher participants' classrooms. He asserted that the cost of the technology must be less of a hindrance for having the technology than he originally believed, but that the information seemed unlikely to change his instruction during the summer course. Dr. Atteberry said he still had numerous questions, and offered suggestions for the next steps in continuing to provide information to teacher educators: "The glaring thing that's missing on these kinds of things are, 'did you feel that using the technology was helpful for your students in high school?...Did they learn better, are they more motivated? What is your evidence? What was good about it?" Dr. Atteberry felt that asking the teacher participants to gather data from their classes about students' perception of technology would be quite valuable, since students may be 'engaged' with a type of technology such as a computer because they thought of it more as a video game than mathematics. Dr. Atteberry also recommended asking teacher participants the question, "what technology would you wish someone would invent?" because, he said, "they'll probably have an idea of something they need and it may be invented and just not available or nobody bought it."

Dr. Torres thought SMART Boards and programs such as Geometer's Sketchpad were used in geometry instruction, and would like technology to be used in teacher participants' classrooms in ways that support mathematical conversations with students and provide powerful demonstrations for students. She also believed in-service teachers do not integrate technology into teaching because they fear their students will be prohibited from using the technology on required exams or in college classes (e.g., where calculators are not allowed). Dr. Torres planned to incorporate video cameras for individual recordings during her class, with possible use of Geometers Sketchpad and Excel, but she claimed this technology use was far removed from the context of the teacher participants' classrooms. Dr. Torres planned to use assessments that incorporated electronic submissions, which could be connected to technology in teacher participants' classrooms.

When given the information from the CTS, Dr. Torres said the data were useful in helping her make decisions about what technology to use in instruction. For example, Dr. Torres mentioned she would like to know if teachers can get past the firewall at their respective schools – if they cannot, then showing YouTube videos might not be a tool she should use. When asked how, specifically, the information presented might affect her instruction, she said that, due to the nature of the course, it probably would not affect her plan for the way the course would be taught. However, Dr. Torres said that if it were a different course, more information about software would have been helpful. She deduced from the information we gathered that "new sites, new software" are things the teacher participants want to learn with the condition that they will have access to them in their classroom. Similar to Dr. Atteberry, Dr. Torres also wanted to know how computer programs such as Excel were being used in the classroom for the preparation of documents or for doing mathematical problems with equations.

Like Dr. Torres, Dr. Selvidge wanted teacher participants to use technology in their classrooms to support student exploration of mathematical ideas. Dr. Selvidge stated she had no specific plans for how to make the connection between technology in her course and the teacher participants' classrooms, but she planned to emphasize GeoGebra because she believed the teacher participants had access to computer rooms and the program was free for all users.

Upon receiving the CTS data, Dr. Selvidge indicated she was encouraged to think about technology use in more "innovative" ways, given the prevalence of technology such as interactive whiteboards. Like Dr. Torres, Dr. Selvidge wondered about the comfort level the teacher participants might have regarding technology and openness to learning about new technologies. Dr. Selvidge was also curious to know how various technologies can be used in mathematics classrooms to enhance learning. She mentioned specific interest in learning how technologies such as SMART Boards, writing tablets, iPads, document scanners, and programs such as GeoGebra, Dropbox, and Google Docs might be applied by teacher participants in their own classrooms to enhance learning.

Dr. Heilmann's assumptions about teacher participants' access to technology were similar to Dr. Selvidge's. He believed if teacher participants had access to SMART Boards then they would use them daily. Dr. Heilmann stated he would like technology to be "fully integrated into [teacher participants'] classrooms" and listed several technologies he would like teacher participants to use (e.g., networked graphing calculators, web 2.0 computer applications). Dr. Heilmann reported his plan to teach the summer course using GeoGebra because teacher participants could take this technology back into their classrooms. Dr. Heilmann also had plans to poll his students to determine how many had access to computers in order to best incorporate the GeoGebra lessons.

After examining the results of the CTS, Dr. Heilmann stated "there is more technology in the classrooms than I thought...it's very helpful to know what's there and the potential for use." Dr. Heilmann added his surprise about the prevalence of GeoGebra: "eight of the 22 [teachers] already use a technology that was planned to...introduce. So...when it comes to that lesson I may have to do some differentiated instruction. And so now I'm thinking to myself, do I really know enough to really push people that use GeoGebra in their instruction? So that's what I learned from this survey." He made clear that the data we provided him would be used to make decisions, and concluded, "It makes me pause and ask myself, 'do I know more technology than the teachers in the classroom that I'm going to be having?'" Dr. Heilmann commented on a specific change he would also be making in his course: he no longer needed to poll the teachers about the availability of computers in their classrooms. Dr. Heilmann's only other comment was to mention how the survey data could be inflated, and he suggested observations to verify the data.

Educational Implications

Providing graduate education to positively influence mathematics classroom practice is a major hurdle for program instructors and administrators. In this study, we followed Cuban's (1986) guidelines that technology education should be grounded in teachers' current practice in order to help link education to practice (Putnam & Borko, 2000). Teacher educators reported the data on K-12 technology use and availability was useful in (a) answering their original questions stated in the Technology Input Survey, (b) aligning their beliefs about teachers' availability to technology, and (c) self-reflecting on the appropriateness of graduate program technology instruction intended for transfer to teachers' classrooms.

Teacher educators all reported being surprised by at least one shared from the CTS. For instance, all four teacher educators were surprised at the large number[2] of teacher participants with unlimited access to an interactive whiteboard. Stemming from this revelation, all four noted that the information made them (re)consider the role of technology planned in the courses they would teach. For instance, Dr. Selvidge said that she had "not been thinking a lot about how to use it to enhance instruction...I sort of feel like after having reading this that I need to step it up a little bit." Even though Dr. Atteberry and Dr. Torres stated this information would not change how they planned to use technology in their summer courses, it did make them consider aspects of technology and ask additional questions about the topic. New questions brought up by teacher educators included the role the technology had in the K-12 classroom, how technology use supported student learning, and how technologically adept the teacher participants considered themselves. The teacher educators commented that these questions might only be answered through observations or interviews with teacher participants.

Data on teacher participants' reports on use and availability of classroom technology was offered to teacher educators to support their reflection on their own college instructional practice. The offer was timely in that it happened in the month before they taught a summer course that had a significant technology component – teacher participants were using technology as learners in the summer courses. The goal was to provide teacher educators an occasion to become more aligned with teacher classroom practice and to be more reflective about their instruction. We recommend future studies continue this effort, and expand on the reported survey and interview data by including classroom observations of both teacher educators and teacher participants. The efforts in this study were worthwhile in providing teacher educators information that can help structure graduate education in beneficial ways for in-service teachers. In making the connection from learning to practice clearer for educators, we hope to improve teacher education and subsequently student learning.

End Notes

1. This material is based upon work supported by the National Science Foundation under Grant No. DUE0832026. Any opinions, findings and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

2. Eighteen of 22 teacher participants reported having unlimited access to an interactive whiteboard, such as a SMART Board, in their classroom.

This paper reports results of an analysis of data from a mathematics coaching professional development program. The goal of the study was to investigate whether a relationship exists between program implementation fidelity and student achievement. Data were obtained from Mathematics Coaching Program (MCP) documents collected during the 2009-2010 school year. Documents included site visitor inventories, end-of-year inventories, and facilitator weekly logs. From these data emerged four categories for future analysis: 1) coach leadership; 2) alignment with MCP assurances; 3) coach's role; and 4) coach and teacher emphasis on student thinking. Initial results indicate program implementation fidelity impacts student achievement.

Mathematics education in the United States has been unfavorably compared to that of other countries for decades (Miller, Sen, & Malley, 2007; Nelson, 2003). Numerous reasons are suggested as to why a majority of the students in U.S. schools seem to lack both an understanding of and an appreciation for mathematical literacy. By the time many of them reach high school, mathematics is one of their least favorite subjects and they fail to see its relevance to any aspect of their lives. Therefore, it becomes critical to ensure that mathematical instruction at the elementary school level encourages and inspires students while providing them with the necessary knowledge to not only be successful, but also be prepared for the rigors of middle school and high school mathematics.

Even though elementary mathematics education sets the foundation for each student's future success, most students at this level are taught by teachers with limited mathematical preparation as few were probably required to take more than two or three mathematics content courses and possibly one mathematics content pedagogy course (Fennell, 2007). Literature confirms that teacher preparation programs and professional development need to emphasize both mathematical content knowledge and mathematical pedagogical content knowledge (Cavanagh, 2008; Hill et al., 2005; Li, 2008). In light of these suggestions, calls for designing professional development programs that target teachers' subject matter understanding while increasing their sensitivity to children's thinking have been wide spread (Becker & Pence, 2003; Bruce & Ross, 2008; Cavanagh, 2008; Hill et al., 2005; Li, 2008; Murray, Ma, & Mazur, 2009).

This report is part of a larger longitudinal research project that closely studies the link between a mathematics coaching professional development model and student learning (Brosnan & Erchick, 2010). While there are several studies examining how mathematics coaches impact teachers (Bruce & Ross, 2008; Gerretson, Bosnick, & Schofield, 2008; Lord, Cress, & B. Miller, 2008; McGatha, 2008; Murray et al., 2009), there remains a concern that is yet to be addressed as to whether or not mathematics coaches impact student achievement (Murray et al., 2009).

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

Results indicate that the (MCP) model, which has been in schools throughout Ohio in partnership with The Ohio State University (OSU), is having a positive impact on student achievement (Brosnan & Erchick, 2010). The purpose of this paper is to report results of a more focused yet preliminary analysis of program data to determine whether there was a relationship between program implementation fidelity and student achievement.

Theoretical Framework

The theoretical framework for this study was based on the roles and responsibilities of a mathematics coach as discussed in the literature and on the conceptual framework of the Mathematics Coaching Program model (Brosnan & Erchick, 2010). The roles and responsibilities of a mathematics coach take on many forms and change from day-to-day. Literature (Fennell, 2007; McGatha, 2008; Reddell, 2004) summarizes most of the roles and responsibilities of mathematics coaches into the following categories: 1) implementing standards and research; 2) planning and facilitating professional development; 3) working collaboratively with classroom teachers and administrators; 4) analyzing and interpreting data; and 5) organizing and coordinating mathematics resources. To ensure that students are receiving necessary mathematical instruction, mathematics coaches align their curriculum with local, state, and national standards and encourage classroom teachers to carry this into instructional practice. Coaches also need to be familiar with the most up-to-date research about teaching and learning so that they can influence teachers to use more effective methods of instruction. Since content knowledge and pedagogy are weaknesses for many elementary mathematics teachers, coaches are responsible for planning and facilitating professional development opportunities that will provide teachers with the necessary knowledge and instructional practices to be effective in the classroom. Collaboration with classroom teachers is critical and includes such activities as co-planning, co-teaching, reflecting on, and occasionally modeling a lesson. Mathematics coaches work with teachers and administrators to examine data and use it to guide future instructional and assessment practices. They also serve as the resource person responsible for gathering, organizing and coordinating the use of mathematical resources such as manipulatives, calculators, and rulers. These roles and responsibilities, while not exhaustive, provided a general framework from which implementation fidelity of the MCP model was investigated.

Additionally, the conceptual framework of the MCP model guided our study of the relation between implementation fidelity and student achievement. This framework focuses on learner responsive mathematics education with respect to both coach-teacher interaction and teacher-student interaction, consisting of elements from mathematical, pedagogical, and socio-cultural context (Brosnan & Erchick, 2010).

Background

The MCP coaching project that is the focus of this paper was developed over six years ago at OSU as a means by which to provide embedded professional development to mathematics teachers in the state of Ohio. The original recruitment for the program targeted low-performing schools around the state as determined by results of the Ohio Achievement Test and Ohio Proficiency Test. Three years of professional development and administrative support for the program are funded through grants from the National Science Foundation and the Ohio Department of Education. While school districts are responsible for funding the mathematics coaches, the monthly professional development is provided at no cost to schools. Coaches attend two consecutive days of training each month and two non-consecutive days of collaboration with other coaches clustered geographically and led by an MCP facilitator. Quantitative and qualitative data are collected within various aspects of the program.

The MCP model consists of the following four areas: 1) MCP conceptual framework; 2) coaches' professional development; 3) design and structure for implementation; and 4) accountability and quality control (Brosnan & Erchick, 2010). For the purpose of this paper, data analysis will focus on the two latter areas of design and structure for implementation and accountability and quality control.

Methodology

Participants in this study were ten coaches in schools participating in the Mathematics Coaching Program that showed the greatest and the least growth between the school years of 2008-2009 and 2009-2010. To determine the top five and bottom five schools in terms of student achievement growth, a spreadsheet analysis of Ohio Achievement Test (OAT) results was used to compare scores from the year prior to the first year of participation (2008-2009) in MCP with those at the end of the first year of participation (2009-2010) in the program. Difference scores (09/10 – 08/09) between each grade level in the building were calculated and the sum total of the differences was identified. The top five schools were those with the largest positive sums and the bottom five were those with the largest negative sums. Some schools for which OAT results were not available for both years were eliminated from consideration as well as those schools whose scores were extremely inconsistent across grade levels.

Data Sources

This paper presents results from an analysis of documents obtained through the MCP during the 2009-2010 school year. Data collected and considered for this research included: 1) site visitor inventories; 2) end-of-year inventories; and 3) facilitator weekly logs.

The site visitor inventory is an extensive document completed by MCP personnel during a full-day visit and observation at each school staffed with an MCP mathematics coach. As part of the site visitor inventory, classroom observations are documented, interactions between coaches and teachers are noted, and a series of pre-written interview questions regarding their work as coaches are administered. Site visitors received training on how to conduct site visits.

End-of-year inventories are completed by facilitators - MCP personnel in charge of overseeing small groups of coaches - towards the end of each school year. The contents of the end-of-year inventory are virtually identical to the site visit inventory, but do not include components that require the facilitator to actually visit schools. Facilitators work with coaches on a more personal level than do the site visitors, making the end-of-year inventory a contrasting perspective to the site visitor inventory.

Facilitator weekly logs are completed by facilitators, and are intended to document encounters with coaches at small group meetings as well as other discussions and conversations between facilitator and coach.

Analysis

Employing an interpretive case-study approach, analysis of the data took place through documenting emerging themes and recursive evaluation of findings (Merriam, 1988). Categories for qualitative analysis emerged from two sources: review of MCP data and existing literature on implementing coaching models. Issues of validity, trustworthiness, and credibility, as recommended by Lincoln and Guba (1985), were dealt with by utilizing multiple data sources, as well as independent coding by three researchers.

Results

The role of mathematics coaches in their first year of work with MCP creates many new challenges. Coaches are not only responsible for learning the program, but are also tasked with developing rapport with teachers and administrators, promoting their role as a coach within their building, balancing their time between planning, teaching, data analysis, collaboration with teachers, providing professional development and attending their own professional development sessions each month. Becoming a coach is a complex process, but one that can be mutually beneficial and can create a positive learning community among coaches, teachers, administrators, and, most importantly, students.

Prior research categories related to coaching and iterative analysis of the multiple data sources suggested several categories of differences between those schools showing the greatest and the least growth in student achievement. The four most prominent, recurring themes were 1) coach leadership, 2) alignment with MCP assurances, 3) role of the coach, and 4) coach and teacher emphasis on student thinking. Coach leadership refers to the demonstration of leadership by a coach within the school. Alignment with MCP assurances refers to how well a coach's school followed the MCP guiding principles for coaches and administrators. Role of the coach refers to the types of activities for which the coach felt responsible. Finally, coach and teacher emphasis on student thinking refers to the evidence describing the types of opportunities in which coaches and teachers allowed children to serve as problem solvers and use their own mathematical ideas.. Brief case studies of the five schools showing the least growth, as well as the five schools showing the greatest growth, will be used to demonstrate instances of these four themes.

Cases from Schools Showing the Least Growth

A commonality among the schools demonstrating the least growth was that the coaches in those schools often demonstrated a lack of leadership; not leading professional development at their schools, passively participating with fellow coaches, and an unwillingness or passiveness to engage with uncooperative principals. What follows are samples from the various data-source documents that give examples of coach leadership in the schools showing the least growth:

- Facilitator End-of-year Inventory on Coach X: Coach X is a pleaser. She does not tend to take the lead during Columbus PD. She has a quiet spirit, but gains approval from her peers by listening and understanding their needs. Coach X needs to stand up to her principal and qualify what she is doing and what she needs to take off her plate. She tends to follow her table-mates rather than make suggestions to solve problems.
- Site visitor form for Coach Z: I believe Coach Z has a lot that could be shared with the teachers, if only she took the opportunity.
- Facilitator End-of-year Inventory on Coach Y: Coach Y needs to model professional behavior by not being on her tech devices during meetings or conducting side-bar conversations when inappropriate, this gives the perception that she is not engaged with the other coaches and is not on task.

For the schools demonstrating the least growth, the most prevalent trend was the tendency to stray from the MCP assurances document. Principals are expected to support coaches in their work with teachers, and are asked to not interfere with the proposed coaching schedule by requiring coaches to do office work and non-coaching related tasks. Coaches are also asked to work with 3 or 4 teachers over a 6-week period of time. What follows are samples from the various data-source documents that give examples of the types of challenges coaches encountered with respect to following the MCP assurances:

- Site visitor form on Coach X: This coach is constantly being asked to do "chores outside her MCP assignment". She is asked to serve on building and district committees, collate OAA questions for teachers, deliver packets of "to-dos" to teachers that are inconsistent with MCP. However, when the coach is coaching, she is following the MCP model. Just that her time is limited. Quote from Coach X: I prefer to be with kids and not doing office work!
- Site visitor form for Coach Y: Things Coach Y does that are NOT COACHING:
    - AM duty 7:25-7:45 which is Hall duty; PM duty 2:00-2:15 Dismissal duty
    - Design Team committee which meets 2 times a month for 2 hours after school and once a month all day
    - Out of the building [beyond the 4 days required by MCP].
- Site visitor form for Coach Z: The principal tells her certain groups/targeted grades. She visits those classrooms first…So….she has 11 total teachers to work with and she is coaching in 5 different classrooms.
- Facilitator End-of-year Inventory on Coach X: The principal did not support all of the assurances of the MCP initiative. Coach X was caught in the middle between MCP directives and her assignments from the school principal. Coach X stayed true to MCP when allowed to do so. When the principal over-rode her assignment, it was difficult for Coach X to coach as needed.

Coaches in schools showing the least growth also demonstrated two additional themes; confusion about the role of the coach, as well as a struggle to emphasize student thinking in the classes in which they worked. This included modeling how to teach without coaching teachers on how to learn from their modeling, serving only as an intervention teacher, and feeling uncertainty about how to approach coaching. It also included a heavy emphasis on students working in groups, but failed to focus on developing more substantive mathematical tasks for students. What follows are samples from the various data-source documents that give examples of coach struggles in schools showing the least growth. These examples define the role of the coach and focus on student thinking:

- Site visitor form on Coach X: I got the idea that in the K-4 classrooms when students are in "groups" Coach X is taking a "group" and working with them, but not really changing much else.
- Site visitor form on Coach Z: The visit in the 3rd grade classroom did not show me an intellectually engaging lesson….it was all question/answer test prep.

She is not confident in her abilities and second guesses her coaching
I did not see evidence of her 1) Coaching the teacher in learning how students think, 2) Coaching the teacher in how to use the mathematical knowledge in the room, 3) Coaching the teacher in questioning techniques, and 4) Coaching the teacher in using the process standards regularly.

Cases from Schools Showing the Greatest Growth

The following cases describe the most common aspects seen within schools showing the highest margin of growth after one year of mathematics coaching. The coaches in these schools possessed similar traits, approached challenges in similar ways, provided leadership consistently, and followed the MCP model most closely.

Coaches within high growth schools showed leadership qualities both within their schools and during monthly professional development sessions. Within their schools, these coaches understood and promoted their roles as coaches. They ensured that teachers understood they were co-teachers and not evaluators. As well, these coaches took measures to build trust with teachers while also communicating to their administrators that they would discuss general information about student achievement, but would not betray the confidence of their colleagues.

- Facilitator End-of-Year Inventory on Coach A: Coach A has approached her job by establishing trust with her staff and taking things slowly. This method has worked for her in that more and more teachers are seeking to work with her.
- Facilitator End-of-Year Inventory on Coach B: What does the coach find most challenging in the coaching process? At first, getting everyone (administrators, staff) on the same page. The district's expectations of the math coach were different from MCP at first.

At monthly MCP professional development sessions, these coaches were highly engaged, modeled leadership qualities and set professional examples for their colleagues.

- Facilitator End-of-Year Inventory on Coach C: Coach C participates at every meeting. I commend her for not following others at her table and getting onto her computer…her professional approach to the MCP PD is to be commended

Schools with the highest growth consistently showed evidence of adherence to the MCP assurances document. Coaches worked with three to four teachers every six weeks co-teaching rather than modeling, principals offered strong program support, and coaches engaged in few additional duties beyond their coaching duties.

- Site Visitor Form on Coach C: Coach C is in four rooms each day. She also has time built in where she takes an enrichment group, she has one planning time and lunch. According to her schedule and discussions, she spends the majority of her day coaching.
- Site Visitor Form on Coach A: She plans, co-teaches, models and debriefs. She has built capacity with the teachers.
- Site Visitor Form on Coach C: Coach C suggests when coaching, that she and the teacher go back and forth in facilitating the lesson.
- Site Visitor Form on Coach D: Coach D said she is coaching 4-5 hours, or most of the day.

Another commonality among schools with the highest growth was the structure of the coaching process. The MCP coaching model is designed to include a pre-lesson and post-lesson conference in order to encourage collaboration and reflective practice between coaches and teachers. Coaches in high growth schools spent more time in pre-lesson and post-lesson conferencing. Further, these conferences were *planned* and intentionally included in the coaches' daily schedule.

- Facilitator End-Of-Year Inventory on Coach A: Coach A puts time in her weekly schedule for pre and post conferences with the teachers she is working with, and for planning activities. She spends time debriefing, especially with her one afternoon teacher.
- Facilitator End-of-Year Inventory on Coach C: She allows the teacher to realize where the lesson could be improved and guides the conversation to encourage self-discovery of transforming their classroom to a more student-centered culture.

Finally, coaches and teachers in high growth schools consistently emphasized the MCP principle of focusing on student thinking.

- Site Visit Form on Coach A: Coach A helps remind me the kids need to do the talking and thinking. I say so and so has a question….who can answer for them?...the kids help each other.
- Site Visit Form on Coach D: One teacher told Coach D….you taught me it is ok for students to be loud and communicate." "A lot of the teachers are letting kids loose."

General Observations

Utilizing the scoring rubric completed by facilitators and site visitors on their respective inventories, trends emerged demonstrating differences between the coaches in schools showing the most versus the least growth. Coaches in schools showing the most growth scored as well or better than coaches in schools showing the least growth with respect to: 1) co-planning with participating teachers; 2) co-teaching with participating teachers; 3) coaching related to student thinking; 4) coaching related to using mathematical knowledge in the classroom; 5) coaching on questioning strategies; 6) coaching on process standards; 7) coaching on identifying rich problems and activities; and 8) debriefing lessons with teachers. In addition to differences on the preceding coaching categories, the scoring rubrics also indicated that site visitors and facilitators did not view the two groups of coaches to be different in their content knowledge and knowledge of coaching. However, coaches in the higher growth schools received far more favorable scores with respect to pedagogical knowledge and comfort level with the program.

Discussion

Results from this study, although preliminary, show potentially useful areas that may be worthwhile to explore in order to better understand the relationship between the implementation of effective coaching and student achievement gains. All participating coaches were part of the same coaching program, yet each had unique experiences with the participating schools, teachers, and project goals that impacted their ability to effectively encourage instructional change and student achievement gains.

The MCP assurances document is designed as a mechanism to help ensure that coaches are able to effectively do the job of a mathematics coach. The situations showing the greatest alignment with the MCP assurances were also those showing the largest student achievement gains. Specific components of the MCP assurances document, such as the role of the coach, occurred frequently in the analysis. Coaches showing evidence of the viewpoint that it is the role and responsibility of the coach to plan, co-teach, and debrief lessons with participating teachers were far more likely to be coaching in a school showing the largest student achievement gains. Although the actual substance of the planning, co-teaching, and debriefing procedures enacted by coaches is not a component of this analysis, the discrepancy in viewpoints about the role of the coach found in this analysis indicates that a commitment to a coaching approach that honors all components of the teaching process (planning, teaching, and reflection) could be related to instructional change and subsequent student achievement gains.

Conclusion and Implications

As a result of this investigation, it is apparent that further research is necessary to form a more concrete understanding of the factors that most deeply impact student achievement in schools with mathematics coaches. Further, from this data emerged four a priori categories for future analysis within this data set: 1) coach leadership, 2) alignment with MCP assurances, 3) role of the coach, and 4) coach and teacher emphasis on student thinking. As well, it is proposed that at least one of the data sources be improved – the Site Visitor form – to create a more provocative instrument that can produce detailed accounts of the impacts of these proposed categories upon the coaches' ability to do their jobs. It is also proposed that a greater number of MCP participating schools be investigated. Additionally, an increased number of observations of coaches in those schools could begin to more clearly elaborate the components of the assurances that appear to have the greatest impact on student achievement.

SECONDARY MATHEMATICS TEACHERS INCORPORATING DIGITAL TECHNOLOGIES INTO THEIR CLASSROOM PRACTICE

Veronica Hoyos
National Pedagogical University, Mexico
vhoyosa@upn.mx

The work we present here contributes to research on teacher learning on the issue of incorporating mathematics technology into classroom practice, approaching relatively new in-service teacher training design and using Zbieck & Hollebrands (2008) revisited theoretical framework of analysis related to introducing innovation in school. The main data were obtained from videos of participant teachers taken during their classroom practice. These teaching videos revealed five different ways that participant teachers achieved to incorporate mathematics technology into their classrooms.

Introduction

According to Cobo (2009), there are many new digital artefacts that have the potential to be used in classrooms. From his point of view, the educational field has benefited from the irruption of digital technologies, especially with the emergence of the Web 2.0.

However, as the same author set out, the advent of new technologies generates the possibility for new student abilities and skills. Then, it makes teachers face real challenges: they have to be acquainted with new digital resources and should learn how to integrate these technological tools into their classrooms.

In this context it is plausible reconsider the following research questions.

i) In reality, what has been the influence of digital technologies in school, especially regarding mathematics learning?

ii) What do teachers think about using digital technologies in mathematics classrooms?

iii) How do mathematics teachers achieve using digital technologies into their classrooms?

The work we are presenting here contributes to answering the third question, building upon previous work accomplished mainly by Zbieck and Hollebrands (2008), Ruthven (2007; 2002) and Ruthven and Hennessy (2002).

Specifically, we have already set up an exploratory study on the practice achievements of in-service secondary teachers, as they try to incorporate mathematics technology into their classroom.

Finally, in relation with the two first questions, we will only revise here some relevant research results mainly noticed by Olive et al. (2010), Ruthven (2007; 2002) and Zbieck & Hollebrands (2008).

Background

Technological Tools in School

In according with Olive et al. (2010), at the end of 80's and during the 90's there were great expectation in relation with the potential of new technologies to transform the way mathematics could be taught and learned (Howson & Kahane, 1986, cited in Olive et al, 2010).

However, as Ruthven (2007) points out, in opinion of revolutionary software designers (as S. Papert, the LOGO creator), the uses of technology in education have often simply replaced paper with computer screens without changing tasks. More over, computers have been used to "simply transfer the traditional curriculum from print to computer screen" (Kaput 1992, p. 516), in ways that resemble traditional worksheets and structured learning environments, rather than working to transform learning (Tyack and Cuban 1995. Cited by Ruthven, 2007).

Even it happens that *"the most insightful… teachers working in conventional schools understand what they are doing today… [as] not being the ideal they wish for"* (Papert, 1997. Cited by Ruthven, 2007). Papert then suggests (Ruthven, 2007) *that "as ideas multiply and as the ubiquitous computer presence solidifies, the prospects of deep change become more real*" (Papert, 1997. Cited by Ruthven, 2007).

In his analysis of the relationship between teachers, technologies and structures of schooling, Ruthven (2007) mention that, indeed, contemporary theories of educational change, just like those of technological innovation, acknowledge how these processes, like change for integration of technology into classrooms are shaped by the sense-making of the agents involved (Spillane, Reiser & Reimer, 2002. Cited by Ruthven, 2007).

Teachers´ Conceptions about Using Digital Technologies in Mathematics Classrooms

Specifically, in this section we will only refer to the work published in 2002 by K. Ruthven & S. Hennessy on teachers' ideas about their own experience of successful classroom use of computer-based tools and resources.

These authors obtained teacher accounts that were elicited through focus group interviews involving mathematics departments in secondary schools. They then analyzed these interviews qualitatively and quantitatively so as to identify central themes and primary relationships.

Then, in relation with the use of technology they found that teachers thought that it can serve as a means of: (i) *Enhancing ambience through changing the general* form and feel of classroom activity; (ii) *Assisting tinkering by helping to correct errors* and experiment with possibilities; (iii) *Facilitating routine by enabling subordinate tasks* to be carried out easily, rapidly and reliably; and (iv) *Accentuating features by providing* vivid images and striking effects which highlight properties and relations.

Ruthven & Henessy also obtained teacher information in relation with those themes more directly related to major teaching goals: (v) *Intensifying engagement related to securing the participation of students in classroom* activity; (vi) *Effecting activity related to maintaining the pace and productivity of students* during lessons; (vii) *Establishing ideas related to supporting the development of student* understanding and capability.

Finally, these authors also obtained information related with key learning topics connected with teaching uses and goals: (vii) *Improving motivation through generating student enjoyment and interest, and (viii)* building student confidence; (ix) *Alleviating restraints through mitigating factors which* inhibit student participation such as the laboriousness of tasks, the requirement for -and the demands imposed by- pencil-and-paper presentation, and vulnerability to mistakes being exposed; and (x) *Raising attention through creating the conditions for* students to focus on overarching issues.

It is worth to mention that Ruthven (2007) points out to the fact that each of 10 mentioned constructs represented a desirable state of affairs which teachers seek to bring about in the classroom, to which they see the use of technology as capable of contributing. But, as Ruthven says, that is only a model based on teachers' de-contextualized accounts of what they saw as successful practice, not supported by examination of actual classroom events (Ibidem, p.56).

In the work we are presenting here, we report the teaching practices that 15 secondary math teachers achieved into their classrooms, after they participated in an online comprehensive course on the use of technology and to do mathematics with technology (based on a problem-solving approach).

Methodology

Design of an Online Training Course

From the work realized by Zbieck and Hollebrands (2008), which synthesize tenth years of research on the topic of incorporating mathematics technology into classroom teachers´ practice, we extracted a structure to set up an online training course (OTC) of six months on mathematics and information technology topics for secondary mathematics in-service teachers. Specifically useful in this aspect was Zbieck and Hollebrands' (2008) re-conceptualization of the PURIA model of Beaudin & Bowers (1997), which also allowed us to analyze the data obtained as those derived from the introduction of technological innovation.

The general context we set the OTC up in was within the official educational policies current in most of the world's countries. According with them, in-service teachers should learn how to incorporate mathematics technology into their classrooms (see for example, Assude et al. 2006). In Mexico too, official educational policies are supporting the integration of new technologies into teaching, with particular attention to the teaching of mathematics.

To train teachers so that they could meet the task of incorporating mathematics technology into their classrooms practice, we implemented an exploratory online training course (see: http://upn.sems.gob.mx) of six months with 15 in-service secondary teachers that would allow the participants to learn to use technology and learn to do mathematics with technology.

Both of those mentioned aspects (learn to use technology and learn to do mathematics with technology) constitute important modes in the PURIA model of development along a learning continuum (Zbiek & Hollebrands, 2008). In fact, that model implies that teachers experiment different modes or development states to advance toward successfully incorporating technology into classrooms: The Play, Use, Reccomend, Incorporate and Asses modes.

As Zbiek and Hollebrands said, the growth during the P and U modes includes the transition of the technology as the developer's tool into the teacher´s instrument for doing mathematics.

Moreover, in the Incorporate and the Assess modes, the teacher's attention turns, implicitly or consciously, toward the use of technology as a pedagogical tool, including the development of instructional orchestrations (Trouche, 2000. Cited by Zbieck & Hollebrands, 2008), or elaborated plans regarding use of technology in the social dimensions of classrooms. Finally, the Recommends mode seems marked by a transition between mathematical and pedagogical aspects of the technology (Zbieck & Hollebrands, Ibidem, p.295).

Data Collection

On the Different Technological Resources Displayed throughout the Online Training Course (OTC)

The OTC's topics we addressed for teachers learning to use technology were related with computer programming, particularly an introduction to HTML and JavaScript programming, design of algorithms and their representations, algorithm development, flow charts, and codification. These topics were taken up with the specific purpose that the teachers could experiment a change in the way they approached to study mathematical algorithms.

The training course also included reviewing sequences of activities on the use of interactive software (eg. Logo, Geogebra, Aplusix, Excel, RecCon, FunDer); and exploration of a wide range of digital possibilities put in the Internet, for example, the library of virtual materials (eg. http://nlvm.usu.edu/en/nav/vlibrary.html) of Utah University (USA).

On the Mathematical and Pedagogical Tasks along the OTC

Some of the maths topics studied (with the purpose of teachers did mathematics with technology) were introductions to the fundamental arithmetic theorem, Goldbach's conjecture, graph theory, and calculating roots of polynomials (with the bisection method and the *Regula Falsi* method, the secant and Newton's method) purposed to review some of the algorithms important to secondary math contexts, as well as the distinct possibilities of representing them in mathematics and computing.

Although we can observe that those topics are notably more advanced than the included in the standard secondary mathematics curriculum, they were planned so as to present the teachers with a challenge to their existing knowledge and to solve problems on topics they do not necessarily already master.

In relation to the pedagogical activities displayed throughout the OTC, it was included four weeks of activities (two at the end of the first 10, and two at the end of the next 10 weeks) where teachers had to:
(a) Choose one high school mathematical topic, along with the software, tools, or digital materials they thought it would be useful to use on teaching the chosen topic; (b) orchestrate a classroom work session with their students in a convenient way according to their chosen digital material; (c) video-record that work session; (d) upload a seven minute version of that recording to YouTube; and (e) finally, upload to the training platform a descriptive report of the video's content together with its URL.

In fact, it was from this last segment of activities that were extracted the main data that generate the results we are presenting here.

Results

By the online training course (OTC) that we could instrument, we obtained evidence that showed teachers displaying the PURIA modes of Play, Use, and Recommend, and we also could observe how they started to display the Incorporate mode to integrate mathematics technology into the classroom.

Description of Teacher's Different Ways of Incorporating Mathematics Technology in Classrooms

There were only 9 teachers (from the total of 15 that participated in the group of observation) that accomplished all of the tasks required during the online training course. We summarize the participant executions in the following table. They are classified focusing on the topic and the digital tool teachers chose and the way they realized how to incorporate mathematics technology into their classroom practice.

	General data (a) Teacher initials (b) City of residence	Topic and digital tool chosen & Video URL	Method of incorporation into classroom practice.
1	(a) HA (b) Veracruz	- Resolution of equations - PPT software http://www.youtube.com/watch?v=PlLYsIO-Vh0&feature=related	Classic pattern of teaching, in the sense that the teacher uses a LCD, a laptop, and some software to explain or introduce a math topic.
2	(a) AG (b) Baja California	- Relation between a function and its derivative - Geogebra http://www.youtube.com/watch?v=Lk2yVHDjexA	Classic pattern of teaching (see the specification above)
3	(a) AM (b) Guanajuato	- Simplification of rational algebraic expressions - Java and HTML http://www.youtube.com/watch?gl=MX&hl=es-MX&v=N1FwbEo5KGI	The teacher adds to a classic pattern of teaching, questioning students on related math topics.
4	(a) HM (b) Baja California	- Calculation of the area of geometrical figures (2D) - Geogebra http://www.clipshack.com/Clip.aspx?key=CDF72468862861A8	The teacher adds to a classic pattern of teaching choosing appropriated digital tools to justify or confirm complex calculations.
5	(a) FM (b) Veracruz	- Graphics and ecuations of functions - Geogebra http://www.youtube.com/watch?v=BXAE2b5U3M4	The teacher adds to a classic pattern of teaching choosing appropriated digital tools to justify or confirm complex calculations.
6	(a) AL (b) Sinaloa	- Design of geometrical figures and calculation of areas - Geogebra http://www.youtube.com/watch?gl=ES&hl=es&v=yhXs8BLMFlM	The teacher is able to orchestrate student computational work, driving student activity by means of a work template.
7	(a) SM (b) Colima	- Equation of a straight line - Geogebra http://www.youtube.com/watch?gl=MX&hl=es-MX&v=X4c8IHEzQsM	The teacher is able to orchestrate student computational work, driving student activity by means of a work template.
8	(a) OV (b) Baja California	- Resolution of inequations - Aplusix http://mx.youtube.com/watch?v=gwGcPtyXYbs	The teacher orchestrates the use of both digital tools and paper and pencil in order for students to compare affordances and results issued from both contexts
9	(a) FG (b) Hermosillo	- Mathematical proprieties of instruments in Physics - PPT software http://fcogurrola.blogspot.com/	The teacher is able to orchestrate student computational autonomous work, based

			on the organization of student projects and small group cooperation.

Summarizing, the analysis of the teaching videos revealed five different ways of teaching that showed how teachers started to use mathematics technology in classrooms:

(a) A pattern of incorporation of the technology probably derived from the classic approach to teaching (see cases 1 and 2 in the table). This is to say that the teacher uses a LCD, laptop, and software to explain or introduce a math topic. One could name that way of using technology as *a classic pattern* of introducing mathematics technology in the classroom.

(b) A modified version of the classic pattern that added teacher interaction with the students, basically by teacher questioning to the whole class (see case 3). Or the teacher adds to a *classic pattern*, choosing appropriate digital tools to justify or confirm complex calculations (cases 4 and 5).

(c) An instrumental approach of the activity (Verillon and Rabardel, 1995; Assude et al., 2006) mainly directed by the use of a script. In these cases (see #6 and #7 in the table) the teacher is able to orchestrate some student computational work.

(d) An orchestration (Trouche, 2004) of the activity using different instruments or artifacts, plus group negotiation of meaning. In this orchestration the teacher uses both digital tools and paper and pencil in order for the students to compare both executions and results (case 8).

(e) An organization of cooperative work centered on student appropriation of technology. Here, the teacher is able to orchestrate student computational autonomous work, based on student project work and small group cooperation.

In order to see some raw data of each type found, readers may access the URLs in the table. Next we will show some pictures of them, and also the conclusions.

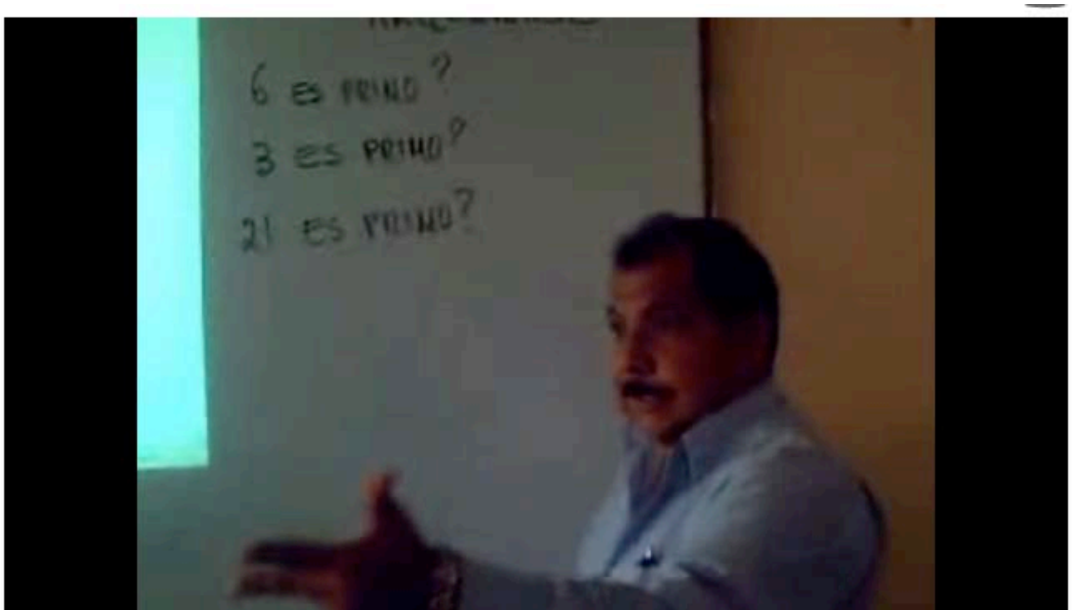

Figure 1. Classic pattern of teaching, adding teacher questioning to the whole class (see case 3 in the table).

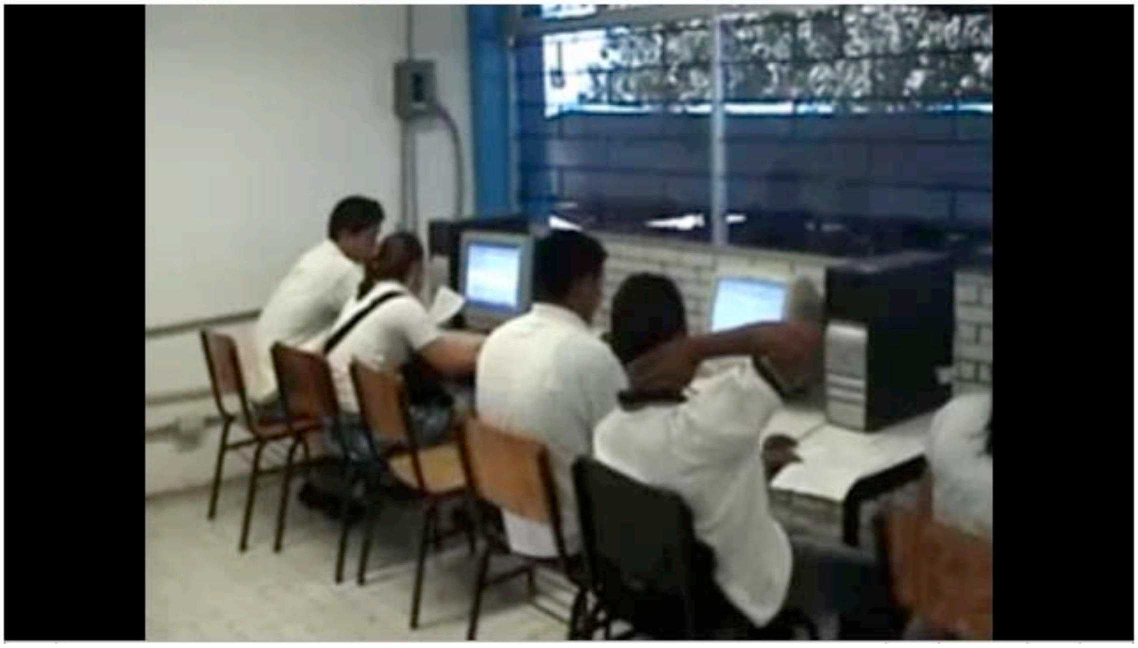

Figure 2. The teacher drives an instrumentalization of the activity led by the use of a work template (see cases 6 and 7).

Conclusion and Work Prospective

The different ways teachers displayed their integration of mathematics technology into classroom instruction allows us to make a qualitative appraisal of their craft knowledge (Ruthven, 2002) related with the use of technology in their teaching practices, which came after they participated in the online training course already mentioned before.

Thus it becomes feasible to predict teacher progress in the process of learning to use technology for teaching mathematics. According to the extended PURIA Model (Zbieck and Hollebrands, 2008), participant teachers would pass to the last mode of using technology (the Assess one) through involving themselves in assessing or noticing their students' mathematical thinking (see, for example Jacobs, Lamb and Philipp, 2010; or Herbst, 2010).

Finally, a base for attaining the next stage in teacher development, mainly in cases 1 to 5 in the table (which are less advanced than the others teaching types, basically because in these cases teachers do not turn to see what their students are learning by using technology) could be conformed by three principal components that would be used as methodological or pedagogical tools to develop professional teacher knowledge.

i) Teacher working on the construction and/or adaptation of digital resources to incorporate them into their mathematics classrooms (Gueudet &Trouche, 2010);

ii) Teacher planning and video-recording their own practice, plus uploading their videos to the digital platform already in use (Hoyos, 2010);

iii) Teacher involvement in noticing student mathematical thinking (Jacobs, Lamb and Philipp, 2010), and reflecting from a teaching representation approach (Herbst, 2010).

THE TEN DIMENSIONS AND PEER COACHING: A COLLABORATING COMBINATION FOR PROFESSIONAL DEVELOPMENT AMONG ELEMENTARY MATHEMATICS TEACHERS

Limin Jao
Ontario Institute for Studies in Education of the University of Toronto
limin.jao@utoronto.ca

The combination of peer coaching, and the resources and professional focus provided by the Ten Dimensions framework can prove to be effective model of professional development. Through teacher interviews and pre- and post-observation meetings, this study determined how teachers engaged in peer coaching, and what components of the framework support the process. The pairing of a Grade 1 and 3 teacher found that initial hesitancy in having a colleague observe them teaching was eased by supplementary resources. The teachers felt that peer coaching made them more aware of their teaching practices and they enjoyed working with a colleague.

Mathematics education reform documents (NCTM, 1989, 1991, 2000) emphasize the need for change in the mathematics classroom environment from one in which the teacher transmits knowledge to the students to one in which teachers and students interact as a community of learners in mathematical investigation and exploration. There are many challenges involved in creating such a learning community and also in determining the extent to which teachers progress towards this ideal of math reform. Teachers do adapt to change, but they require instruction on the nature of the required changes. Mathematics reforms are complex, however, and most reform efforts underestimate the complexities. Teachers can help each other change, and peer coaching has been used to help teachers improve their teaching practices (Loucks-Horsley, Love, Stiles, Mundry & Hewson, 2003).

This study aimed to discover how elementary school teachers engaged in a peer coaching model of professional development. The research questions were:

1. How can the Ten Dimensions of Mathematics Education act as a framework to focus efforts of professional development?
2. What components of the peer coaching process nurture professional growth?
3. What are the perceived benefits and challenges of the peer coaching process?

Conceptual Framework

For profession development to be effective, it needs to be intentional, ongoing and systemic (Guskey, 2000). A peer coaching model of professional development along with the support of a framework such as the Ten Dimensions of Mathematics Education (McDougall, 2004) has all three of these characteristics.

Peer coaching involves the pairing of two colleagues in a session with classroom observation, giving feedback and discussion to allow both members a chance to learn from one another (Loucks-Horsley et al., 2003). Both participants have a chance to reflect on what they observe along with their own teaching practices in order to grow. This reciprocal gain is one of the major benefits of peer coaching. Having an extra set of eyes in the classroom gives teachers another perspective that they may not have come up with on their own reflections (Guskey, 2000). The colleague can help identify both strengths and weaknesses for the teacher to focus on along with seeing practices that they may not have had exposure to beforehand.

At first, there may be hesitation to engage in the process as the teacher may be uneasy at the prospect of being observed and evaluated, but being paired up with a colleague that they trust will calm some fears (Arnau, Kahrs, & Kruskamp, 2004). An environment of "trust, collegiality, and continuous growth" (Loucks-Horsley et al., 2003, p. 208) will ensure that participants feel more comfortable. Each member of the pair must acknowledge the body of knowledge that they bring to the partnership as well as the expertise that their colleague can contribute to the dialogue (ross, Rolheiser, & Hogaboam-Gray, 1999). As long as both participants focus on the goal of professional development and maintain a level of respect or their peers, the advantages will certainly outweigh the disadvantages (Slater, & Simmons, 2001).

This study uses the Ten Dimensions of Mathematics Education (McDougall, 2004) as a conceptual framework to improve the quality of mathematics education in elementary classrooms. The Ten Dimensions of Mathematics Education framework was developed through a multi-year research project (McDougall et al., 2006; McDougall, 2004; McDougall & Fantilli, 2008; Ross et al., 2002). The framework was created to give teachers areas in which they can focus their attention in order to improve their teaching, knowing that many of the Dimensions are interlinked and focusing on one invariably leads to improvement in other areas.

The Ten Dimensions are: (i) Program Scope and Planning (focusing on the inclusion and integration of all strands of mathematics in the classroom); (ii) Meeting Individual Needs (teachers should use different teaching strategies and techniques to cater to the needs of the diverse student body); (iii) Learning Environment (consideration of classroom organization, cooperative groups, teacher feedback and student input/choice improves student achievement); (iv) Student Tasks (teachers should use rich tasks within the mathematics classroom); (v) Constructing Knowledge (a variety of instructional strategies and effective questioning techniques should be used); (vi) Communicating with Parents (parents should be involved with their child's mathematics learning); (vii) Manipulatives and Technology (students should be allowed to use and experiment with these tools); (viii) Students' Mathematical Communication (teachers should provide opportunities for students to use both oral and written forms of communication); (ix) Assessment (teachers should use diagnostic, formative and summative assessment to report on student achievement); and (x) Teacher's Attitude and Comfort with Mathematics (teachers should develop a comfort level with mathematics and promote a positive attitude towards the subject).

The School Leadership Handbook for Elementary Mathematics (McDougall, 2004) includes resources for educators who are using the Ten Dimensions. An interview protocol includes questions that can be asked before an after the lesson. There are general questions about the lesson format and content, and specific questions related to key areas of each of the ten dimensions. These questions help the observer to understand the thought processes of the teacher as well as to prompt the teacher to reflect on their own practices. Through this questioning, participants will gain a better understanding of the dimensions and the qualities that need to be focused on for improvement in these domains. An observation template lists 'look-fors' and guiding questions specific to each dimension. This template can be written on during the lesson and as a prompt for the observer's own field notes.

The Ten Dimensions framework encourages teachers to focus on key areas that will generate higher levels of student achievement, giving teachers an intentional approach to their growth. With set goals and areas for improvement that are selected by the teacher, the personal interest and investment towards professional change is undoubtedly present. Teachers focus on one or two dimensions at a time. In order for a substantial consideration to be made in each of the ten dimensions, ongoing commitment for professional development is required. Thus, the intentional and ongoing commitment to professional growth fostered by the Ten Dimensions coupled with a systemic change through peer coaching facilitates an effective vehicle for professional development.

Method

This study spanned two years and concluded in November of 2008. Four schools from a large urban city in Western Canada participated in the study. The teachers and administrators in the participating schools attended a professional development session about the Ten Dimensions of Mathematics Education. In this session, teachers learned about the Ten Dimensions framework, were introduced to this project about peer coaching and were invited to join.

The teachers and administrators then completed the Attitude and Beliefs Survey (Ross, Hogaboam-Gray, McDougall, & Le Sage, 2003) to determine how their current practices fared with respect to current mathematics education trends. Each of the 20 questions on the survey is related specifically to one of the Ten Dimensions and the higher the score on each dimension, the more the educator's attitude and teaching practices are aligned to reform trends. A low score may be impetus for the educator to focus on that particular dimension for personal growth. Individual teachers could decide which areas they wanted to concentrate on for personal improvement.

Participants

Within each school, colleagues were paired up. There were some teacher-teacher pairings as well as teacher-administrator pairings. There were a total of 10 pairings within the four schools.

In this paper, I discuss the findings from the pairing of Grade 1 teacher, Meredith and Grade 3 teacher, Christina. Meredith has been teaching for 25 years in the Primary division and also has experience teaching Kindergarten. Christina has taught her entire career at Grace School. In her 19 years of teaching, she has taught at both the Primary and Junior level.

Teacher Interviews

Participants were individually interviewed at the beginning of the study. These semi-structured interviews were approximately 45-minutes long and teachers were asked questions about their professional background, views and beliefs as a teacher, and goals as a mathematics educator. As well, interviews about the peer coaching process itself were conducted immediately after each peer coaching session.

Peer Coaching Sessions

The peer-coaching sessions consisted of three parts: a pre-observation conference, classroom observation, and a post-observation debrief.

In the pre-observation conference, the observer would ask the teacher a series of guiding questions from the Ten Dimensions of Mathematics Education resources (McDougall, 2004). These questions uncovered the lesson topic, structure, activities, and goals. Guiding questions specific to the teacher's chosen dimension were also asked and the teacher shared the area in which (s)he wanted the observer to focus.

During the classroom observation, the observer could use the observation template provided in the Ten Dimensions resources or could make informal notes of their choosing. The observer could interact with the students if they wished.

The post-observation debrief followed a similar format to the pre-observation conference. Again, a series of guiding questions from the Ten Dimensions resources were asked and teachers reflected on their lesson through the lens of the dimension of focus. Observers shared their observations of the lesson, specifically mentioning points that relate to areas that were highlighted for focus by the teacher. Judgments about the teacher were withheld unless the teacher asked for suggestions for improvement. A final question asking the teacher about their next steps concluded the post-observation debrief.

Data Collection and Analysis

There were four peer coaching sessions in total, such that each teacher observed her colleague twice and was observed twice. All interviews, pre-observation conferences, and post-observation debriefs, were audio-taped and transcribed by the researcher. Qualitative analysis was completed using nVivo8 software.

This study used a grounded theory approach to determine the effects of peer coaching on the participating teachers, thus, I allowed the data to dictate the outcome as the themes that emerged from the data analysis became the foundation for the major findings of the study (Glaser & Strauss, 1967). Coding was completed by first highlighting key ideas and these ideas were then grouped into themes.

Findings

In examining the pairing of Meredith and Christina, insight was gained from their experiences with the peer coaching model of professional development. They shared their feelings about the process itself, the benefits and challenges of the peer coaching model and how the Ten Dimensions framework and its resources anchored their efforts of professional development.

The Ten Dimensions Framework

Both Meredith and Christina selected dimensions that were of personal interest to them. Meredith wanted to select dimensions which she though had the most impact on students and of personal interest. She shares:

> To me, [Dimension 5] seemed very important. They are all important, but to me, [Dimension 5] gets back to how we present this, how we allow them to explore, how we allow them to tell use what they know already and go from what they know already to where they are going. I thought that was a really important one. We use manipulatives so much because it helps them in their concept development so I just thought it was really important. I just picked the ones that were really important to me. I think that [Dimension 5] is one of the key things and manipulatives fit into everything that I do in math. (Teacher interview, November 28, 2008)

By selecting two dimensions to concentrate on, Meredith was able to improve in a focused way in an area in which she was passionate.

Christina also selected Dimensions 5 and 7 for professional growth. As she wanted to improve her teaching practices, Christina explained that the Ten Dimensions of Mathematics Education framework gave her specific areas in which she can improve her teaching.

Christina shared that the resources, including the Attitudes and Beliefs Survey and the School Mathematics Improvement: Leadership Handbook were able to provide valuable information about the areas of her teaching in which she wanted to improve. She says: “[The Ten Dimensions] have made me more aware of how I can give [the students] an activity whether it be a problem of the day or a mega problem of the week or whatever it is and then give them the time to come up with their own strategies or connections” (Teacher interview, November 28, 2008). She adds, “It has actually made me more aware of how I am teaching” (Teacher interview, November 28, 2008).

With a clear focus for areas of professional growth, both teachers were ready to engage in the peer coaching sessions. Neither teacher had experience with the peer coaching process and both were apprehensive about how to organize and use the process to improve their teaching practice. The Ten Dimensions provided areas in which the teachers could focus for professional growth as well as resources that could guide them during peer coaching sessions.

The Peer Coaching Process

The teachers enjoyed the structure of the peer coaching process. The pre-conference allowed the teachers to focus on their goal of professional growth before heading into the classroom. Each member of the pairing could ease into the process through asking, answering and reflecting on the questions that were specific to the dimension chosen by the teacher.

The teachers used the guiding questions provided by the protocol instead of having to create their own questions. With their busy schedules, the teacher shared that they were grateful for the resources provided by the Leadership Handbook.

The interview protocol helped the participants to explore teaching behaviours and practice. These questions were specific to their chosen dimension and allowed observers to ask relevant questions even if they were unfamiliar with key components of the dimension. The guiding questions allowed both observer and teacher to instantly frame their thinking within the guidelines of the dimension. As Christina puts it, the guiding questions allowed her to “pinpoint” key areas pertinent to the chosen dimension (Teacher interview, November 28, 2008).

The observation template helped to anchor the observer’s thoughts. Meredith thought that she should focus her notes on the areas in which Christina wanted feedback. As such, she used the area of focus as the main heading for her notes and added secondary comments that related to the prompts on the observation template only if they were relevant to Christina’s improvement plan. She explained that the guiding questions and observations template helped her to focus on what to look for specific to the dimensions, however, she said it was “most helpful to know what the teacher wants me to look for” (Teacher interview, November 28, 2008).

Christina used the observation template as more than just a prompting device. She thought that the template was easy to use and simplified the process. Christina explained that “it was really well laid out and we could just quickly jot down what we were looking for” (Teacher interview, November 28, 2008).

Both teachers found the resources provided to be helpful in the peer coaching process. As they had never engaged in such a process before, Meredith and Christina valued having these tools to guide them and focus their thinking to parallel with their chosen dimensions.

Challenges of the process. A challenge that the teachers faced was the amount of time that the process required. Even before engaging in the peer-coaching process, Christina expressed that "just having the time to meet, to share, to go into each other's classes to observe, and talk about what was really great and what we need to do further" would be of benefit to her development (Teacher interview, October 5, 2007). After engaging in the process, she reiterated that it was a challenge to find time for the peer coaching process. In order to save time, the actual observation would often take place during the observer's prep time, however this was complicated to schedule. Christina shared one example of how they were able to schedule a session:

> This week, we did it during our prep time. While my students were at gym, I went into [Meredith's] room. We coordinated so that she would have her math class at that time, and, she did the same during her music time. I taught math in the afternoon, where I would not normally teach math because I like to [teach math] in the morning. (Peer coaching session, May 15, 2008)

The teachers' initial hesitation towards the peer coaching process quickly disappeared after going through the process for the first time. Although both teachers expressed concern for having a colleague and a researcher observe them teach, they quickly realized that they were so engaged in their teaching that observers would not affect nor effect their work. Meredith shared: "After awhile, I did not even know you guys were in the room. I am too busy and I am trying to get to as many kids as possible" (Peer coaching session, January 23, 2008).

The teachers are hesitant about being judged by observers, however, their overwhelming desire to improve reinforced to them that peer coaching can illuminate their practices and allow them to improve in the areas in which they were focusing on. The teachers' positive outlook towards this process allowed them to focus on the benefits rather than focus on the challenges.

Benefits of the process. Both teachers admit that the benefits of the peer coaching process clearly outweigh the challenges. Meredith and Christina shared that one of the biggest benefits was the chance to dialogue with a colleague. The teachers appreciated getting feedback after being observed. Meredith shared about this component on several occasions. First, she said she likes to have "something that someone else could look for" (Peer coaching session, January 23, 2008) and later she said, "It is good to get the feedback. [Christina] notices things that I may do naturally, but I do not notice, so that is good" (Teacher interview, November 28, 2008).

It was the act of collaboration that had profound effects on the teachers. The teachers saw that they were more than just sharing their observations with their colleague, but were able to work together to improve each other's practices. There was a reciprocal investment in their growth in that each teacher contributed ideas and suggestions for improvement.

Going into a colleague's classroom as an observer served as both a chance to provide feedback to the teacher, but also a chance for the observer to watch another professional in action. Meredith enthusiastically talked about this benefit: "Christina is such a good role model. I really enjoyed [observing her], because I see her way of going about it" (Teacher interview, November 28, 2008). In watching a colleague the teachers could further reflect on their own practices. Meredith said that watching Christina made her think about what she was doing in her own classroom.

In her final interview, Christina summarized the benefits of the peer coaching process:

> We enjoyed doing [peer coaching] together and it was nice to be a part of the learning process on both ends. Not only being in the spotlight, but also having somebody else come in and say, 'I really like the way you did that, and this is what I observed' and reinforcing what

you may have already known or maybe we have a tendency to be a little bit too harsh on our own self, being the perfectionist that we think that we are. (Teacher interview, November 28, 2008)

Conclusions

In this research project, the goal was to discover how a peer coaching model of professional development effects elementary school teachers and how the Ten Dimensions of Mathematics Education acted as a framework for professional growth. Through teacher interviews and in-class observations of peer coaching sessions, it was found that teachers benefited from engaging in a peer coaching model. Although the participants admit that there are challenges in engaging in professional development opportunities, their underlying goal of being better teachers to improve the quality of learning of their students and the support that they receive from their principal and each other is worth the hardship.

For professional development to be effective, it needs to be situated in school and classroom based contexts (Walker, 2007; Zwart, Webbels, Bergen, & Bolhuis, 2009). The peer coaching model allows for feedback to be shared between colleagues as a result of classroom observations and invites teachers into each others classrooms to observe teaching strategies in practice. The participants in this study described that the quality of their reflections was deepened based on the feedback that they received from their colleague and that they learned new strategies from observing their colleague in the classroom.

In the peer coaching process, the participants shared that it was stressful to be observed by a colleague, however, found it reassuring to work with a colleague whom they trusted and knew would be respectful of their shortcomings. These findings are consistent of the work of previous research emphasizing the need for teachers to take a respectful responsibility to collaborate with their peers (Arnau et al., 2005; Klingner, 2004). A guideline of the peer coaching model used in this study asked the observer to state observations rather than judgments of what they saw in the classroom. This guidance allowed the teachers to focus on improving the areas in which they wanted to improve rather than promote a feeling of evaluation (Slater & Simmons, 2001). Both participants shared that they welcomed additional feedback from their partner, thus giving evidence that there was mutual respect between the teachers.

In this project, peer coaching was examined as model for professional development. The use of a framework such as the Ten Dimensions of Mathematics Education (McDougall, 2004) allowed the model to be more effective by focusing the efforts of the participants. Resources from the Leadership Handbook facilitate the peer coaching process, alleviating some of the challenges that arise from never having gone through the process before and general pressures of the field. Teachers reported that peer coaching had many benefits. Among them include a chance to watch a colleague in action, a chance to see other students in other classrooms and/or grade levels, a chance to get feedback, and reflect on their teaching. These benefits, however, were outshone by the joy of being able to work with a colleague, to share, discuss and collaborate with a fellow educator in an often solitary profession.

TEACHER COLLABORATION FOR THE IMPROVEMENT OF GRADE 9 APPLIED MATHEMATICS PROGRAMS

Limin Jao
Ontario Institute for Studies in Education of the University of Toronto
limin.jao@utoronto.ca

Douglas E. McDougall
Ontario Institute for Studies in Education of the University of Toronto
doug.mcdougall@utoronto.ca

In secondary schools, multiple teachers often teach the same course. The Collaborative Teacher Inquiry Project invited teachers, department heads and heads of schools to work together to improve their Grade 9 Applied Mathematics programs. The focus of this study was to find out the benefits and challenges of working collaboratively. Teacher interviews resulted in findings that highlight that collaboration can happen in many ways. In order for the collaborative team to be successful, members need to have and work towards the same goals. A conceptual framework such as the Ten Dimensions of Mathematics Education can provide this focus.

Traditionally, teachers work alone in their classrooms, planning in solitude and delivering material as they see fit (Hargreaves, 1994; Lortie, 1975). Although pre-service teachers work collaboratively with peers and mentor teachers to create activities, lessons, and unit plans, once out in the workplace, they are often left to their own devices.

The Learning Consortium's Collaborative Teacher Inquiry Project had three purposes:

1. To improve the teaching the learning of Grade 9 Applied Mathematics;
2. To investigate the use of the Ten Dimensions of Mathematics Education framework to improve student achievement in secondary school mathematics; and
3. To investigate collaborative inquiry as a professional development strategy.

For the purposes of this paper, the authors wish to focus on the third purpose. The Learning Consortium is a partnership between the University of Toronto and four local school districts in the Greater Toronto Area. From these four school districts, 11 schools participated in the project, which spanned three semesters from January 2009 to May 2010. Participants included teachers, department heads/curriculum leaders, and administrators.

Conceptual Framework

The relatively formal structure of subject departments is a long-term and widespread phenomenon at the secondary school level. Such a structure serves administrative, communicative and pedagogical purposes. Not surprisingly, professional development at the secondary level, collaboratively-based or otherwise, has been traditionally department-based. It has been assumed that the natural cohesiveness of subject departments provides a logical starting place for collaboration among teachers.

A number of studies have confirmed that, in secondary schools, the most efficacious communities tend to reside at the level of subject-matter departments (Talbert & McLaughlin, 2002; Siskin & Little, 1995). There is evidence that these loosely knit teacher communities can influence approaches to classroom practice (Gutiérrez, 1996; Johnson, 1990), as well as shape responses, positive or otherwise, to reform (Ball & Bowe, 1992; Coburn, 2001; Little, 1995).

Within a department, teachers are socialized into a tradition with its own norms of teaching, learning, grouping, and assessment (Siskin, 1997), which in turn shape their work and their students' classroom experiences (Gutiérrez, 1996). Departments typically have an infrastructure in place to allow for collegial work on professional projects like course modifications, implementation of new curriculum or learning about technology. Subgroups of teachers often arise to meet short-term demands, such as modifying or even creating new courses of study.

Most research into teacher collaboration has focused on the logistical parameters of delivery and evaluation. Recent efforts have looked at the potential for improving "on-the-job" collaborative opportunities for teachers in a seamless, situated fashion.

Guskey (2000) defines professional development as a process that needs to be intentional. In order for professional development to be effective, participants need to have clearly stated goals and expectations. These explicit purposes and goals focus participants to ensure that they will work together with the same purpose as opposed to working against each other towards divergent goals. These goals must be meaningful and applicable to those involved in the professional development. As such, all parties will feel involved and the personal commitment towards their goals will ensure a deeper investment towards the process. If it is to be worthwhile, professional development must be developed with participants who are motivated, based on clearly defined goals that can be measured.

The Ten Dimensions of Mathematics Education (McDougall, 2004) is a framework consisting of ten research-based domains of mathematics education that help teacher to focus their professional development efforts. This framework encourages teachers to focus on key areas that will generate higher levels of student achievement, giving teachers an intentional approach to their growth. The ten dimensions are: (i) Program Scope and Planning (encouraging teachers to consider all strands, expectations/outcomes and key ideas of the mathematics curriculum); (ii) Meeting Individual Needs (teachers should vary lessons and instruction to cater to the needs of all students); (iii) Learning Environment (varied student groupings and student input should be used); (iv) Student Tasks (teachers should vary the types of tasks that are being used in lessons and all tasks should be meaningful); (v) Constructing Knowledge (multiple instructional strategies and thoughtful questioning techniques help students construct knowledge); (vi) Communicating with Parents (parents are influential in student achievement and as such, should be kept informed); (vii) Manipulatives and Technology (these teaching tools enhance student learning); (viii) Students' Mathematical Communication (students should experience oral, written and physical forms of communication); (ix) Assessment (teachers should use a variety of assessment strategies to gain diagnostic, formative and summative data about their students); and (x) Teacher's Attitude and Comfort Mathematics (teachers affect student perception and should project positive attitudes towards mathematics). Although educators may select just one or two dimensions for school-wide focus, the dimensions are not discrete and a focused effort to improve in one area will inevitably improve their teaching practices more globally.

Method

The Collaborative Teacher Inquiry Project (McDougall, Jao, Maguire, Stoilescu, & Gunawardena, 2010) spanned three semesters from January 2009 to May 2010. There were 11 schools from four school boards across the Greater Toronto Area involved with the project. Participants included: teachers who taught Grade 9 Applied Mathematics for at least one semester during the project; mathematics department heads from each of the participating schools and a member of the school's administrative team.

The timeline of the project is as follows:

Semester 1: Introduction to the Collaborative Teacher Inquiry Project, the Ten Dimensions of Mathematics Education, completion of the Attitudes and Beliefs Survey (Ross, Hogaboam-Gray, McDougall, & Le Sage, 2003), selection of dimensions for department and personal foci, Learning Consortium organized professional development workshops focused by dimension, and individual reflection of participation in the project.

Semester 2: Learning Consortium organized professional development in-service sessions, co-planning and collaboration within math implementation teams at each school, and individual interviews with participating teachers.

Semester 3: Learning Consortium organized workshops, individual and team collaboration, and school team and individual reflections on the Collaborative Teacher Inquiry Project. A final celebration with a panel and school presentation was held at the end of the project.

Back at their home schools, participants team-taught classes, observed their colleagues teaching, and had group meetings for program planning. Participants were asked to complete reflections at the end in June 2009 and May 2010 to reflect on their journey throughout the project. Data was collected in two different ways: teacher interviews and the reflection surveys.

Data Collection

Teachers and department head/curriculum leaders were individually interviewed to determine participants' professional background, beliefs, goals and visions for education. These semi-structured interviews were 45-minutes in length, audiotaped and transcribed.

Teachers were asked to complete reflection forms that asked questions to specifically focus on the benefits and challenges of the collaborative process, the affect of the Ten Dimensions framework throughout their journey, future plans, and general reflections about the Collaborative Teacher Inquiry Project.

Data Analysis

A qualitative approach was used to gain a deeper, authentic and descriptive perspective of the issues being explored (Denzin & Lincoln, 2000). Qualitative analysis software, Nvivo9, was used to efficiently organize and perform a multi-faceted data analysis to uncover trends and patterns in the data. The data analysis followed a series of coding cycles. For this study, an open coding format was used where data were examined, compared and categorized (Strauss & Corbin, 1990).

This open coding process involved the reading of transcripts during which time key ideas were highlighted and labeled. The key ideas were grouped by similarity to form sub-categories and sub-categories were further re-grouped by similarity (Strauss & Corbin, 1990). These components were called concepts and categories respectively (Glaser & Strauss, 1967). The categories were considered the over-arching themes extracted from the data.

This study followed a grounded theory approach (Glaser & Strauss, 1967) and as such, the data collected were the source of the major findings of the study, however, categories and subcategories were created with components of existing literature in mind to be able to generate a possible hypothesis that could be relevant to current research and practices (Glaser & Strauss, 1967).

Findings

The data re-iterated that teachers face many challenges. Participants shared that the Collaborative Teacher Inquiry Project was a mode of professional development that allowed teachers to work collaboratively to improve their teaching practice in often a solitary profession.

Participants reported that the project acted as a vehicle for collaboration in several modes: with other teachers within their mathematics department, across departments within their school, with other participants within their school board and with those from other boards involved in the project.

Collaboration within the Department

The Collaborative Teacher Inquiry Project showed that teacher inquiry within the department could take many forms. Some school teams met as a group, scheduling times to meet, plan together, create consistent activities and assessments to use in each of their classes, and discuss challenges that they faced in their classes. Other school teams collaborated by meeting before class to plan their lessons and then engaging in team teaching. Other schools had teachers observe one another teach to learn new strategies and reflect upon their own teaching practice.

One challenge reported by school teams was the change of teaching staff within the school team. Teachers said that school teams would have been more successful had the same teachers been teaching the Grade 9 Applied Mathematics course for each of the three semesters of the project. Teams found that it took time to get the new members of the team involved and would have been able to more efficiently use their time if the members were consistent throughout the project. Although teams wanted to work collaboratively, they were unable to create a cohesive unit with when their group was continuously changing.

Teachers also stressed that, in order for collaboration to be successful, participants need to respect and be respectful of one another. It also helped if all teachers have the same vision for mathematics. This, of course is not always possible, so to facilitate this, the educators appreciated the Ten Dimensions of Mathematics Education as a framework to guide their improvement plan. This ensured that although teachers may have had different professional goals, they could still all work towards the same school-wide goals.

In general, teachers appreciated the change to work together. The following quote from a participant describes how her school collaborated and the positive impact it had on their team: "We established a core team to work together on everything from lesson planning to writing new culminating activities to coordinated EQAO (Provincial testing) preparations. Our new Grade 9 Applied program is more cohesive and purposeful to address student engagement and achievement gaps" (Maria Kovalevskaya School, Team reflection, May 27, 2010).

Collaboration within the School

School teams also collaborated with other educators within their school. This type of collaboration came in two forms: support from the administration and collaboration with other departments.

Teachers shared that a supportive administration encouraged their team to put a positive attitude towards the project. Teachers shared that they appreciated when they felt that their administration valued the work that they were doing and were invested and showed a strong desire to improve their school's mathematics program.

Other departments that got involved with the school teams' efforts include special education and English. Participants reported that these collaborations were especially beneficial as support during the provincial standardized exam organized by the Education Quality and Accountability Office (EQAO). This collaboration also strengthened the professional community at the school. Many of the participating schools have a high number of students with documented learning exceptionalities and school teams attributed part of their increase in EQAO results to this improved relationship.

Collaboration within the School Board

Participants reported that a very useful collaboration, and one that they believed that they should further develop, is with feeder schools. In the Ontario school context, secondary school starts at Grade 9 and therefore educators do not have the natural lines of communication between Grade 8 and 9 that exist with teachers within the same school. One school reported on a board-wide initiative between secondary schools and their feeder schools. It was explained that this program opens the lines of communication between secondary and feeder school teachers to ensure that students have a smooth transition between the two divisions. While this initiative has a student focus, teachers reported that they had a better understanding of the skill level of their students entering Grade 9 and could therefore better frame their Grade 9 Applied Mathematics program to meet their students' needs.

The Learning Consortium organized professional development sessions were the only structured opportunities for teachers within the same school board to meet and share ideas. Teachers appreciated collaborating with teachers from other schools and having the change to learn about the teaching strategies they have tried and to have worked for them. They also appreciated the chance to clarify and find consistency between schools for different board-wide initiatives.

Teachers expressed that it was a challenge to find time to collaborate teachers at other schools, given teachers' busy schedules and the distance that teachers would have to travel to meet one another. An online platform was created for the Collaborative Teacher Inquiry project for this very reason. The wiki was, unfortunately, not used to its full potential. Teachers reported that they liked the idea of a wiki as a platform to share ideas with other participants, however, not many participants posted resources, nor did any indicate why this resource was not used more often. This should be a platform that is further expanded on in future studies as it could overcome many logistically barriers to teacher collaboration.

Collaboration between School Boards

The Collaborative Teacher Inquiry Project allowed teachers to work with teachers from other school boards. The reported benefits of this type of collaboration are similar to those shared about collaboration between schools.

One participant described how this project opened her eyes to the possibility of teacher collaboration. She shared how she wanted more opportunities to collaborate with other educators, discuss ideas, trade resources, share success stories and hear about what is happening in other schools and school boards.

> I wish when we went to [more] meetings with the four school boards, I wish we could do more and see more student work. To invite me to a meeting and get me to do mathematics is not something I find useful. I really wish that we could sit down together and mark students' work together to see if we are all marking fairly and marking - if I am marking fairly. I would like to see the work that other students do in other schools. Because I only have my students to base my evaluations on. I do not ever see the work of other kids, good or bad. Just meeting the teachers from the other boards and hearing that they are dealing with the same types of students that we have that are coming to us without skills and for us to be teaching them curriculum that is often abstract and might be obvious to us as adults but is totally not obvious to the children. (MK2, Interview, November 26, 2009)

Another teacher shared the impact that the Collaborative Teacher Project and the chance to dialogue with teachers across the four school boards has made on their professional practice:

> The Learning Consortium has been a good eye-opener for a lot of us. I did not really know what was going on in other schools, and other schools did not know what was going on with our school. The fact that we had that time to collaborate, and share our resources, and discuss how we are running programs and how we are achieving success in our different courses. I think that is fantastic. For sure I think that was one of the good things about how schools can be more effective in the way they help students be more successful in math. Especially with our EQAO results, we jumped a lot from the year before to last year and again it was most because of collaboration with other schools, other boards, other teachers. Finding out what they are doing to help their kids to be successful, and same thing back, we are providing all the information that we have, sharing assessments, all that stuff, sharing our workbook even. I think the collaboration is what is helping us understand what can make math or how to make math more successful for the kids. (FC3, Interview, November 26, 2009)

Significance of the Study

This paper reports on the challenges and benefits of teacher collaboration on teachers' professional development. As such, the participants were able to improve their teaching practices through this dedicated time to focus on their Grade 9 Applied Mathematics program. Participants shared that their self-efficacy increased and were able to develop their instructional and assessment strategies. Extending out of this study, the findings can help other educators, department heads/curriculum leaders and school administrators who also want to improve their Grade 9 Applied Mathematics program. Although this study specifically focused on teachers of the Grade 9 Applied Mathematics course, similar challenges and benefits will most likely occur in other secondary grade levels and even other subject areas. This study showed that teacher collaboration is a worthy professional development strategy of mathematics educators across four school boards across the Greater Toronto Area.

USING PREDICTION FOR MATHEMATICS TEACHER DEVELOPMEMENT

Ok-Kyeong Kim
Western Michigan University
ok-kyeong.kim@wmich.edu

This study investigated using "prediction" as a means of mathematics teacher professional development. Throughout the study, one middle school classroom teacher developed prediction questions around the main mathematical ideas of each lesson, posed those questions to students at the launch of that lesson, and orchestrated a classroom discussion on students' predictions and reasoning. Developing such prediction questions was a challenging task that required a careful examination of the mathematics being taught as well as students' mathematical thinking. It also facilitated well-planned instruction and teacher reflection on teaching. The results show the teacher's improved understanding of the content and changes in her teaching practice, which supports the use of prediction for mathematics teacher development.

The teaching and learning of mathematics greatly depends on the teacher. Everyday on-site instructional decisions that teachers make influence the quality of mathematics instruction that the students experience. For example, the task a teacher chooses to discuss in the whole group determines the kinds of mathematical strategies and reasoning that are shared. In order to make appropriate instructional decisions, teachers need to know the big ideas of the main instructional task, connections between the task and other tasks before and after, potential difficulties students might have, and useful mathematical representations of the big ideas. It has been widely acknowledged that teacher preparation at the college level is not sufficient to help develop the kinds of teacher knowledge required for effective mathematics teaching, and thus continued teacher professional development is very important (Loucks-Horsley, 1997). Because of this need, various teacher professional development activities have been developed, implemented, and examined. This case study developed, implemented, and examined such activities with an initiative to use prediction as a teacher professional development context for middle school mathematics. What prediction is and why this particular procedure is suggested is described below.

What Is Prediction?

In this paper, *prediction* refers to a type of reasoning, more specifically, reasoning about the mathematical ideas of the lesson at the launch by using prior knowledge, patterns found, or connections made from related concepts (Kim & Kasmer, 2009). Peirce's (1998) notion of abduction supports the importance of prediction in developing human knowledge. According to Peirce, abduction is forming a prediction without any positive assurance, is the only way in which people are introduced to a new idea, and makes a logical connection between deduction and induction.

An example from Kim and Kasmer (2009) further explains what prediction is like in the mathematics classroom. Before exploring a problem on linear relationships, students are asked to predict what effect increasing walking rates will have on the table, the graph, and the equation as they examine the relationship between distance and time. When making such predictions, students have to look back on what they already know (i.e., what walking rates mean, and how those rates are represented in a table, a graph, or an equation) and use that to reason about what will happen when a rate is increased. Even though students' predictions will vary and often will not be accurate, such an opportunity to make a prediction encourages students to check their prior knowledge and concepts in relation to the mathematical ideas embedded in the prediction question and its context. This facilitates thinking about the mathematical ideas in the problem they solve and making connections between what they already know and a new exploration.

Why Is Prediction Used for Professional Development?

Because of the usefulness of prediction, in various disciplines, prediction has been investigated as a means of promoting students' learning. In reading education, for example, students were asked to make a prediction in reading activities using questions such as, "What do you know about this character that helps you predict what he or she will do next?" and "Given the situation in the story, what will possibly happen next?" The results showed that asking students to make such a prediction helped increase their reading comprehension (e.g., Block, Rodgers, & Johnson, 2004). Gunstone and White (1981) incorporated prediction in science teaching and suggested a prediction-observation-explanation model, which was utilized in several other studies (e.g., Lavoie, 1999; Palmer, 1995). Interestingly, de Bruin, Rikers, and Schmidt (2007) asked college students to make a prediction when they learned how to play chess in a computer game setting. They found that students who were asked to predict and explain their predictions learned chess principles better than those who only predicted chess moves and those who observed games without making predictions.

In mathematics education, while exploring students' learning in geometry, Battista (1999) found benefits in having students make predictions. According to him, a discrepancy between predictions and actual answers made students reflect on their strategies and helped build useful mental models for problem solving. Buendía and Cordero (2005) viewed prediction as a social practice that supports the construction of mathematical knowledge, and provided such evidence in the context of periodic functions. In fact, the analysis of state mathematics standards revealed that prediction was the most prevalent reasoning expectation across grades as well as content strands (Kim & Kasmer, 2006). Kim and Kasmer (2007, 2009) and Kasmer and Kim (2011) also investigated the potential of using prediction for the development of students' mathematical understanding and reasoning in the middle school algebra context over years. Using prediction provided an opportunity for students to make connections among mathematical ideas that they learned and to develop the meaning of algebraic concepts. As a result, students who participated in prediction activities developed better mathematical understanding and reasoning around algebraic concepts than those who did not. Moreover, using prediction offered additional classroom benefits, such as promoting classroom discussion on mathematical ideas, helping teachers assess students' thinking informally and formatively during instruction, and encouraging teachers to reflect more often on what they plan and teach.

Even though the advantages of using prediction in the teaching and learning of various subjects including mathematics have been reported, the focus has mainly been on student learning outcomes. Little has been investigated in terms of teaching practice and teacher development. Given the effectiveness of using prediction on student learning and the potential benefits for teachers (e.g., prediction serving as a means to promote classroom discussion rather than direct teaching, and quick informal assessment on student thinking during instruction), further investigation is needed on how utilizing prediction can prompt teacher professional development.

Research Questions and Analytic Framework

Based on the above rationale, this study addresses an overarching question, *How does using prediction promote teacher professional development*? In this study, I define professional development as Therefore, to analyze the impact of using prediction on professional development, two aspects are closely examined: teacher knowledge and teaching practice—whether positive changes occur in each aspect and, if so, what the changes look like. Two research questions are formulated to address each of the two aspects.

1. Does using prediction help increase teacher knowledge? If so, what aspects of knowledge?
2. Does using prediction help improve teaching practice? If so, what aspects of teaching practice?

First, teacher knowledge is accounted for with respect to (1) understanding of big ideas in tasks and lessons, (2) understanding questioning strategies, and (3) content knowledge measured on a standardized exam relative to a norm-referenced group. Second, teaching practice is examined with respect to (1) the characteristics of classroom discussion, and interactions with and among students, (2) kinds of questions asked by the teacher, and (3) ways in which the teacher reflects on her own teaching practices.

Professional Development Procedure

The main procedure of this professional development centers on a middle school teacher's involvement in activities, such as examining the content of the lessons to teach, developing one or multiple prediction questions for each lesson, asking them at the launch of each lesson and organizing discussions on students' predictions and reasoning, and reflecting on teaching. The detailed process is given below.

Teacher Selection

One middle school mathematics teacher was selected based on her interest in the study as well as her teaching and professional development experiences. She taught middle school mathematics for 12 years. Throughout her teaching career, she used Connected Mathematics Program (CMP). At the time of the study, she had been using the second edition of the curriculum (CMP2) for one year. She was an experienced teacher and confident about her teaching. She, however, wanted to identify areas to improve and welcomed an opportunity for professional development. In particular, her decision to participate in this study was based on the fact that she felt that she was losing her initial enthusiasm and settling into routines, as she had taught for many years. It was also based on her desire to discuss the mathematics that she taught and pedagogical strategies that she wanted to be equipped with.

Content Area

Algebra was chosen for the target content area of the mathematics lessons because it is one of the most important and difficult topics in middle school mathematics. Also, algebra units are taught throughout the year. The unit taught during the study was *The Shapes of Algebra* (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2009) from CMP2, which was about linear systems and inequalities. Because of the abstract nature of the content and extensive use of symbols, teaching this unit was very challenging, especially in helping students understand what they were doing and why when they manipulated symbols, and what that meant in the problem context.

Teacher Professional Development Activities Using Prediction

There were three stages of teacher professional development activities using prediction during the study. In the first stage, I provided the teacher with prediction questions of each algebra lesson so she could use them in her teaching. During this stage, the teacher became accustomed to using them in class and examining how prediction questions provoked students' thinking and guided her teaching. In the second stage, the teacher and I developed prediction questions together, and the teacher used them in her teaching. In the final stage, the teacher developed prediction questions on her own to use in her lessons. Before and after each stage, the teacher and I discussed the big ideas across the lessons, how prediction questions would stimulate or stimulated students' thinking, advantages and disadvantages of particular prediction questions, and possible alternatives of the prediction questions proposed or used. Each stage had three lessons, and nine total lessons were taught during a one-month period. (Each lesson often needed more than one day. The teacher also used practice problems for a few days in between lessons to help improve the students' ability of symbol manipulation.)

At the individual lesson level, the following process repeated throughout the professional development:

- Examine mathematical ideas of a lesson and create prediction questions for instruction
- Pose prediction questions at the launch of the lesson and elicit students' responses and their reasoning
- Use information to adjust lesson plan
- Reflect on teaching, plan for next day, and revise prediction questions for future use

Data Collection and Analysis

During the project, data were collected to measure the growth of teacher knowledge and the improvement of teaching practice. Data collection and analysis of each data source are described below.

Paper-and-Pencil Measures

Teacher knowledge was examined by using a paper-and-pencil measure, which was developed and tested by a research group at the University of Michigan (Content Knowledge for Teaching Mathematics [CKTM] measures). The CKTM measures have two forms that measure middle school teachers' knowledge of algebra. One form was used at the beginning of the project and the other at the end of the project. Each form contained about 20 items. Questions about the items were asked during the pre- and post-interviews looking for teacher reasoning and further explanations regarding particular choices made. The two test responses were compared using the reference group provided by the test developers.

Interviews and Discussions

During the study, through interviews (pre- and post-interviews) and discussions (before and after each stage) with the teacher, I had opportunities to clarify the teacher's thinking in terms of teaching and her own understanding of the mathematics being taught. During the interviews and discussions, the teacher was asked about big ideas of tasks and lessons, the purpose of particular prediction questions and advantages and disadvantages of those questions, and her instructional decisions made on site. All the interviews and discussions were audiotaped and transcribed. These transcripts were analyzed for evidence of change in her knowledge and teaching practice.

Classroom Observations

During the project, the teacher's instruction of the unit was videotaped three times, one per stage. Those lessons videotaped were used for the analysis of characteristics of classroom discussion, and interaction with and among students by looking at related teaching actions, such as kinds of questions asked after prediction questions and other main questions, kinds of responses given to students, and ways in which student responses were used in teaching. In particular, the *Coding Rubric for Measuring the Quality of Mathematics in Instruction* (QMI instrument, Learning Mathematics for Teaching, 2006) was used to analyze whole-group discussion periods, for the purpose of looking at kinds of classroom discussion and how the teacher organized discussions. This instrument was designed to measure teacher knowledge revealed in instruction, and therefore it was helpful to account for what kind of teacher knowledge was used in teaching and in what ways. Each coding element required an indication of whether evidence was "present" or "not present" and whether it was "appropriate" or "inappropriate" for every 5-minute segment. Important segments identified during this coding process were transcribed for further analysis. Once every lesson was analyzed, characteristics of each stage were summarized and then the three stages were compared.

Another coding tool used was the *Reformed Teaching Observation Protocol* (RTOP) (Piburn, Sawada, Falconer, Turley, Benford, & Bloom, 2000), which was developed as an observation instrument to provide a standardized means for detecting the degree to which K-20 classroom instruction in mathematics or science is reformed. For the purpose of the study, the coding elements on classroom culture (communicative interactions and student/teacher relationships) were used. Each element was coded by a 5-point Likert-scale (0 being *never occurred* and 4 being *very descriptive*). Once the coding was done, a score for each lesson was assigned by finding the mean of the codes. The scores of the three videotaped lessons were compared to determine any changes in classroom culture.

Lesson Plans

The teacher provided one lesson plan using prediction during each stage. Each lesson plan was provided before the actual lesson took place. The teacher chose the format of the lesson plans. Once the lesson was taught, the teacher provided a reflection on the lesson. These lesson plans were analyzed to account for whether each lesson was formulated to highlight the big ideas of the lesson, whether prediction questions were used to help students make connections between the main ideas of the lesson and previous concepts, whether the overall lesson sequence as well as specific questions and guidance encouraged students to develop the big ideas of the lesson, and what strengths and weaknesses the teacher identified in her lessons and lesson plans.

Teacher Journal Entries

The teacher kept a weekly journal during the study. Although the teacher had the freedom to choose any lesson of the week to write about, each journal entry had specific components: big mathematical ideas of the lessons of the week, prediction questions asked, how prediction questions helped instruction (from the perspectives of teaching and learning, respectively), what went well and what did not and possible reasons, and what she would do differently next time. When analyzing teacher journal entries, patterns of reflections in each of the three stages were searched in terms of ways in which the teacher reflected on her teaching, and the breadth and width of her reflection.

Results

The results are described to answer the two research questions, and highlight the areas in which using prediction positively impacted the teacher's professional development.

Teacher Knowledge

The results indicate that using prediction helped increase teacher knowledge, especially knowledge of the content that she taught and knowledge of questioning in teaching.

Content Knowledge

The teacher and I discussed the content and its representations in-depth throughout the study in order to create good prediction questions to use in instruction. Teacher interviews and discussions show that creating and using prediction questions challenged the teacher's knowledge base. The teacher revealed her strong and weak areas, developed a better understanding in the weak areas, and realized things that she did not think about before. For example, during the first discussion, the teacher talked about the content of three lessons and what she would focus on. She understood the importance of using graphical representations for the solutions of linear inequalities, and yet did not see the connection between "a number-line graph" and "graphs of two linear functions" on the coordinate plane. (The number-line graph is, in fact, shown on the x-axis of the coordinate plane.) Therefore, she focused on the number-line representation of linear inequality solutions and did not plan to spend time on the graphical representation of the coordinate plane. When further examining the latter during the discussion, she saw that the number-line graph was embedded in the graphical representation on the coordinate plane and how the two representations were related, and she gained confidence in using both of them in instruction. As the study progressed, the teacher began to focus more on big ideas and meaning along with symbolic solutions and to make more solid connections. Previously, she was concerned about her students' skills on symbol manipulation ("The biggest priority is, can you solve a linear inequality?") rather than whether they understood what they were doing. Standardized measures, CKTM-middle school algebra, also indicated that her knowledge on the content increased. IRT scores on pre- and post-CKTM were 1.1295 and 1.8781, respectively. Both were high scores according to the norm group, but the latter was the highest, whereas the former was the fourth highest.

Knowledge of Questioning

The teacher explicitly mentioned several times that she tried to improve her questioning skills. In fact, a comparison of the first day and the last day observed as well as a review of the lesson plans shows that, at the end of the study, the teacher demonstrated greater knowledge of what to ask and how to probe students' thinking. By her choice, one of the components in her lesson plans was "questions I will try to ask to extend our discussion." The last lesson plan included a longer list of questions, even with rationale, including: "How does this process (what students just did) relate to the type of process we learned yesterday? Can you do this for all problems of this type? Is it possible to solve this system using x= instead of y=? What happens if you do solve it for x=?" She asked these questions to encourage students to make connections between what they did and previous learning, to make conjectures, and to think about alternatives.

In fact, it is difficult to formulate good prediction questions when the content is very abstract, as in this unit. Nevertheless, she was able to create good prediction questions on her own later in the study. For example, the problem context was as follows: "The eighth graders are selling T-shirts and caps to raise money for their end-of-the-year party. They earn a profit of \$5 per shirt and \$10 per cap." One of the questions she posed was, "What do you predict will be the equation that shows how the profit is related to the number of shirts and caps sold? Explain your reasoning." The students had experienced linear "only in the $y = ax + b$ form" and $ax + by = c$ was new to them. She realized the benefit in using equations for the situation that students came up with to guide her next steps during the lesson. It also would provoke students to think about what they knew already and relate that to this situation—whether the standard form ($y = ax + b$) would work or if they would need a different form to represent the problem context.

Teaching Practice

The results reveal that using prediction was effective in improving classroom practice. The areas positively influenced include classroom culture, questioning skills, and teacher reflection.

Characteristics of Classroom Discussion

First of all, more discussion time was spent during instruction as the study progressed. In the first observation, class discussion lasted for 5 minutes except for discussions on prediction. The lesson in the second stage included 10 minutes of discussion, and in the last lesson observed, more than half of the 50-minute class period was for discussion. Even when checking homework answers, the teacher initiated discussion on important mathematical ideas behind the solutions. Second, she devoted much time to discussing the meaning and reasoning behind the procedures. During teacher interviews and discussions, she repeatedly expressed that she had difficulty juggling between increasing students' symbol manipulation skills and focusing on the big ideas she identified. For example, it took time to help students understand $ax + by = c$ as linear, as opposed to focusing on symbolical problem solving alone. Often students graphed it by putting points and connecting them, not realizing that this new form also represented a linear relationship between x and y. Likewise, students focused on solving for x or y, not understanding what that x- or y-value meant. This year, the teacher spent a great deal of time helping students understand the rationale behind the procedure or symbolic manipulation that they were engaged in. She also helped students to make sense of what they did by connecting back to the problem situations when appropriate. For such purposes, she asked many questions, such as "Why do you solve for x? What does that mean? What's next? Which equation should be used to substitute x? What would happen if the other one is used? What does that mean? Why do they give the same y?"

RTOP results also indicated that her classroom culture slightly changed (first, second, and third stages scored 2.8, 3.0, and 3.1, respectively). In particular, student-teacher relationships remained the same (3.2), and yet communicative interactions changed a bit (2.5, 2.8, 3.0) as the study progressed. Areas that improved include:

- The teacher's questions triggered divergent modes of thinking.
- There was a high proportion of student talk and a significant amount of it occurred between and among students.
- Student questions and comments often determined the focus and direction of classroom discourse.

Questioning Strategies

Lesson plans and classroom videotapes showed improved teacher questioning skills. As shown in earlier examples, the teacher asked more "why" questions along with "how" and more probing questions, and asked more about the meaning behind procedures to help students develop algebraic reasoning with symbols.

Reflection on teaching. The teacher reflected on teaching more often, ranging in topics from fundamental teaching philosophy to specific teaching strategies. Such regular ongoing reflection helped her improve her teaching practice. Some teacher reflections at various points are as follows:

- *It* [using prediction] *helped me revisit and refine my philosophy of mathematics teaching – something that had become a bit dusty from underuse… It strengthened teaching skills.*
- *It forced me to think about their responses, the flow of the lesson, the types of questions I needed to ask if they got or didn't get the question.*
- *It also caused me to reflect more on the lesson before teaching it and, of course, after teaching it, something that I've lost along the way for lack of time to devote to this process.*

Conclusion and Significance

This is a case study involving one teacher. During one month of the study, the teacher had extensive and in-depth discussions with me about the content she taught and prediction questions to use in teaching the content, as well as pedagogical challenges and strategies, such as questioning skills. The results show not only that using prediction for professional development is feasible, but also that such professional development activities are effective. Using prediction provided a significant context for professional development. To create good prediction questions, the teacher had to closely examine lesson content, which led her to focus on big ideas of the lessons and connections among those ideas for her students and to build on her own learning of the content that she was teaching. To use those prediction questions in teaching, she had to think about appropriate probing questions and to organize classroom discussions around meaning of and reasoning about mathematical ideas and procedures. The next step is to design professional development activities for multiple teachers working together over a longer period of time. A group of teachers engaging in this type of professional development would benefit from discussing mathematical ideas, formulating prediction questions, and reflecting on their teaching as a group.

MEASURING THE EFFECTIVENESS OF A HYBRID PROFESSIONAL DEVELOPMENT PROGRAM FOR MATHEMATICS TEACHERS

Hea-Jin Lee
Ohio State University-Lima
lee.1129@osu.edu

This study explores how a hybrid professional development model may support quality and success of mathematics teachers. The primary focus of this study is on the experiences and the opportunities, which on-line discussion and face-to-face workshops provide for mathematics teachers' professional learning. The findings present the impact of the program on teachers' practice, as well as the nature of the virtual interactions including frequency and content of virtual communication. The conceptual discussion includes potentials and limitations to be considered in further dialogue, development, and research in designing and evaluating a hybrid program for teacher success in deep learning and practice.

Purposes of the Study

This study is based on a year-long professional development program for middle school mathematics teachers. Our project program was designed considering the following issues: How should the professional development program be designed to maximize teacher learning and improve instructional practice?; What types of professional learning experiences should teachers experience in the program?; and How should the professional development program foster professional interactions? This paper investigates the nature of participants' interactions in a virtual learning community, as well as the impact of the professional development program on teachers' view about mathematics and their practice.

Conceptual Framework

Studies comparing online and traditional courses report no significant differences between the two programs. The professional development program of this paper was designed under this assumption that there is little difference between these two models. Consideration for a teacher's busy schedule and the need for on-going teacher interaction led the professional development program in this study to adopt a Blended Learning System, which forms a harmonious combination rather than random cost efficiency (Graham, 2005; Heinz & Procter, 2005). "Blended Learning is learning that is facilitated by the effective combination of different modes of delivery, models of teaching and styles of learning, and founded on transparent communication amongst all parties involved with a course" (Heinze & Procter, 2004, p. 12).

Since Dewey, the social nature of all human learning and the role of communication ability/skill in the human development process are the most often discussed concepts in higher education (Feldman, 2000; Heinze & Procter, 2005). Learning in Communities of Practice, networks of practitioners, relies on communication between individuals and occurs as an interaction among practitioners takes place (Heinze & Procter, 2005, Kahan, 2004). Communities of Practice "are creating a Zone of Proximal Development with capable peers. There is no one on the stage who is the knowledge source, but all individuals have an equal right to share their experience, and their stories are valuable contributions to the community" (Heinze & Procter, 2005, ¶ 3).

When we discuss students' learning, our question should not be whether students can or cannot achieve mathematical skills but about whether students will elicit maximum success in mathematics. "Such recommendations call for an approach to mathematics teaching that allows students to communicate, problem solve, and engage in conceptual mathematics. … From a professional development standpoint, this perspective suggests that programs should provide opportunities for teachers to learn mathematics around specific content and teaching situations that may arise in practice." (Brown & Benkenp, 2009, p. 56). The key concerns, therefore, for online professional development are to ensure peer exchange of ideas and information (Hammond, 1998); the creation and assimilation of knowledge (Thomas, 1992); and providing a climate of accelerated change in which participants need to access up-to-date knowledge and apply new skills flexibly in changing circumstances (Hargreaves, 1994). The learning community should be more than a forum for the exchange of information (Chapman & Ramondt, 2003). It must evolve in response to the diverse needs of learners and the communities in which they work.

The project being investigated is developed to provide a blended learning option. The project incorporated a combination of face-to-face and online communication that has the potential of increasing the participants' sense of community (Rovai & Jordan, 2004) and continuation of professional learning. It was recognized that a sense of community was critical for sustaining teacher interest. Participants in the program came from various backgrounds and diverse experiences, which made bonding a challenge. The assumption was that if teachers could form a community in supporting and learning from each other, then they would be more likely to succeed with their learning.

Methods

The professional development program of this study was designed to improve student mathematics knowledge and attitude by (1) increasing teacher content knowledge and (2) improving instructional skills to teach mathematics concepts in an environment rich in context, community, and connections. The major activities of the project consisted of three components: face-to-face workshop courses, implementation, and sustaining a professional community. The online conversations between face-to-face meetings facilitated the building of a professional community among project participants. Desire2Learn was used to sustain the professional network during and after the project period.

Twenty-nine teachers in grades 5 - 9 participated, 22 first year and 7 continuing participants. A team of 2-4 mathematics teachers from each district was recruited. Each participant received 9 graduate credits, and all participants engaged in 73 hours of face-to-face workshop meetings, at least 18 hours of an online workshop course, and co-teaching with project instructors. Teachers explored how algebra is taught at different grade levels, is related to other math content, and applies to our daily life. The workshops were conducted through discussions; collaborative group work; hands-on activities; problem-solving opportunities; and presentations by participants. Assignments included readings in the textbooks; reflecting on activities introduced during the workshop; developing lesson plans; providing critical comments on lesson plans developed by peers; solving mathematical problems using invented ways; employing various technology to solve problems and perform tasks and mentoring; observing peer participants classroom practice and provide productive comment on their practice; on-going communication with colleagues through Carmen (Web-based course tool); and evaluating web-based resources.

In order to answer research questions, pre- and post- surveys, interviews, field observations, and online discussion messages were analyzed. Surveys, interviews, and filed observation notes were analyzed, mean scores compared, and synthesized in the Results section. All 1149 online messages were analyzed and coded. Three coders were trained and checked for inter-rater reliability at the end of training by using a sample set of coding. The Assignment 1) postings (237 messages) were coded by all three coders and checked for inter-rater reliability. For the assignments 2, 3, 4, and 5, each coder was assigned a series of threads to code. Coders and the researcher had regular meetings to discuss issues and questions.

Results

Changes in Teachers' Opinions about Mathematics and Classroom Practices

Teachers had a good understanding of effective questioning techniques and their use in the classroom; the average rating on this item increased significantly (from 1.96 to 1.54); a significant increase in those agreeing that they had the methods necessary to teach math concepts effectively (up from 74% to 96% and the mean went from 2.26 to 1.73); significant improvements on their understanding of authentic assessment methods used to measure student performance (mean went from 2.37 to 2.00) *(Lower mean score indicates a higher level of agreement, as "Strongly Agree" was represented by the value of 1 and "Strongly Disagree" had a value of 5).* Although all started the program saying that they had a good understanding of fundamental core content in their discipline, this dropped slightly by year-end (89%), which may suggest that the course made them aware of some gaps in their knowledge.

The teachers expressed the highest level of agreement with, "Classroom interaction involves a dialogue among teacher and students" (74%), and by year-end, most (92%) confirmed that this was true of their classes; there was a significant movement on the average response (up from 3.96 to 4.46). There was also a significant increase in those saying that the "Student role is to apply inquiry and problem solving skills to discover solutions to problems" (increased from 56% to 81% and average was up from 3.70 to 4.23). Participants were significantly less likely to report that students worked independently (down to 8% from 19% and the average decreased to 2.23 from 2.89) and that instruction emphasized broad coverage of information (down to 4% from 12% and the average decreased to 2.27 from 2.65). Finally, increased use of alternative assessment methods was confirmed in the significant gain on the average use reported (up from 2.37 to 2.77).

Participating teachers showed initial variation in teachers' comfort with some of the listed practices. Significant differences in participants' use of specific instructional practices in math and professional activities are highlighted in Table 1. Teachers' responses pointed to increases in their use of inquiry-based instructional practices and alternative assessment. They had also expanded their professional development activities at their schools and online. Teachers emphasized the changes that they made to their instructional approach. "*I try very hard not to be the primary speaker in the classroom. As often as possible, I have the students working together, explaining to each other and answering each other's questions. I try to stress the importance of being able to explain how an answer was found and the fact that there are many different paths to a correct answer."*

Individual teachers made a lot of change in what they were doing and more teachers choosing more student-centered approaches. The conversation was much deeper and their questioning skills got advanced. Teachers were looking for ways to question and find out now to get the ideas into the classroom. The biggest change is that the project encouraged teachers to do were random responses and encourage all students to be listened to and heard. Instead of responding to students who had their hands raised, they were randomly selecting students and giving opportunities for those students to respond. Every student was given the opportunity to summarize, and if confused, to ultimately resolve that confusion. The teacher was constantly asking the question "why" and not simply accepting an answer but requesting support for that answer. A much higher level of learning was occurring.

Table 1: Changes in Teacher Practices and Professional Activities (Sorted by Mean Difference)

	Percentage Difference			**Mean Difference**[1]		
	Pre-survey	**Post-survey**	**More Frequent**	**Pre-survey**	**Post-survey**	**More Frequent**
I utilize the project website during and after the project.	14.8	32.0	N.S.	2.58	1.88***	-0.70
I encourage students to engage with materials in a more in-depth way for longer periods of time.	7.4	53.8***	46.4	2.11	1.46***	-0.65
I include opportunities for students to engage in active and inquiry-based learning.	29.6	80.8***	51.2	1.78	1.19***	-0.59
I actively participate in classrooms and virtual communications.	14.8	38.5	N.S.	2.40	1.85**	-0.55
I match instructional strategies and materials to identified students' learning experiences.	37.0	61.5**	24.5	1.78	1.42***	-0.36

I use problems for which there is no immediately obvious method or solution.	18.5	46.2**	27.7	1.96	1.65***	-0.31
I monitor student performance in mathematics by applying rubrics and keeping records of alternative assessment tools.	7.4	30.8**	23.4	2.22	1.92*	-0.30
I encourage students to debate ideas or otherwise explain reasoning.	55.6	80.8*	25.2	1.48	1.19*	-0.29
I conduct a team-designed professional development in own school district.	3.7	12.0	N.S.	2.81	2.60*	-0.21
I develop inquiry and problem solving activities to help students associate the subject matter with their own experience and redefine the concepts.	22.2	50.0**	27.8	1.81	1.50	N.S.

[1]Lower mean score indicates a higher level of frequency, as "Frequently" was represented by the value of 1 and "Never" had a value of 3. N.S. = Not Significant

Table 2: Changes in Teacher Opinions about Mathematics (Sorted by Mean Difference)

	Percentage Difference			Mean Difference[1]		
	Pre-survey	Post-survey	Change in Agreement	Pre-survey	Post-survey	Change in Agreement
It is a good use of time to work on mathematics problems that have no precise answers.	66.7	92.3	N.S.	4.26	5.27***	1.01
Strategies help a student learn mathematics.	96.3	100.0	N.S.	5.00	5.31*	0.31
It is a waste of time to work on mathematics problems that have no exact answers.	18.5	0.0*	-18.5	2.00	1.42*	-0.58
Mathematics is primarily a solitary activity, done by individuals in isolation.	14.8	3.8	N.S.	1.93	1.27*	-0.66

[1]Positive difference indicates a higher level of agreement. Negative difference indicates less agreement.
N.S. = Not Significant

Table 2 reveals teachers' opinions about mathematics. Responses on teachers' confidence about their preparation to answer students' questions indicated that teachers were more comfortable about their skills in mathematics at year-end. Teachers' view of math has shifted, particularly with respect to the value of working on problems that do not have a precise answer. They also increasingly view strategies as a way to help students learn math. Finally, they were less likely to view math as a solitary activity. This is consistent with the results with another survey in which participants were significantly more likely to have students working in groups.

The greatest change in the classrooms was the expectation that all students actively participate. One shared, "*I have a better idea of how to get the students involved and know better now how to help the students do more and on their own."* Others stressed how they have made their classes more student-centered. Teachers noted, however, that students were often initially resistant. A participant explained, "*They sometimes have a difficult time accepting the fact that I am not just giving them the answers or telling them exactly how to do the problems*." Encouragingly, by year-end, several revealed that they had succeeded in getting their students to buy-in to the changes.

Virtual Communication Frequency

Three structured online assignment topics were assigned during the academic months from March to May, and two assignments were given from September to November. Online discussion occurred between monthly face-to-face meetings. During the summer, there were intensive face-to-face meetings for a week.

Figures 1 and 2 depict the average number of messages per individual teacher. Approximately 10 of 22 teachers posted more than 8 messages while all 2nd year teachers posted more than 8 messages. Overall, more contributions in online communication were made by 2nd year teachers than 1st year teachers: an average of 8.9 messages by the first year teachers and 12.4 messages by the 2nd year teachers.

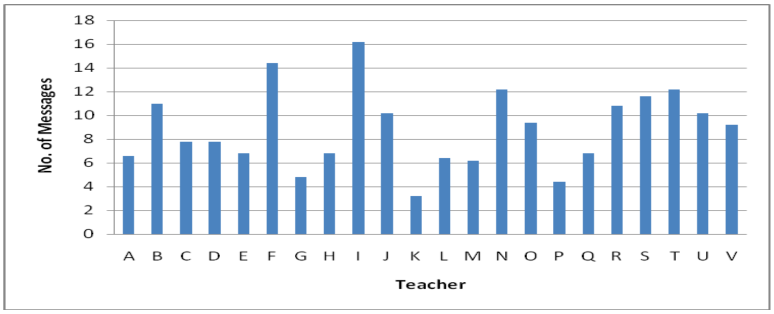

Figure 1. Average No. of Messages Posted by Year 1 Teachers

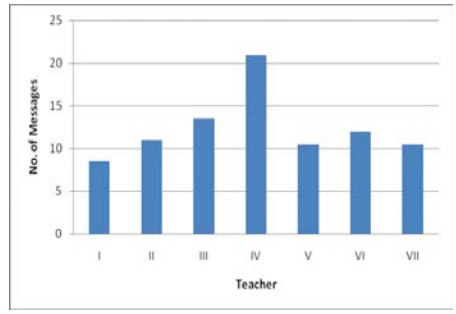

Figure 2. Average No. of Messages Posted by Year 2 Teachers

Figure 3 compares average number of messages posted per assignment. The first year teachers posted the most number of messages for the Assignment 1) Book Reading Discussion and Assignment 2) Video Critique. Compare to the first two assignments, relatively lesser number of messages were posted for three Implementing discovery-based lessons, Assignments 3), 4), & 5), which required creation of lessons and implementation, and commenting peer teachers' work. (*no messages by the 2nd year teachers for the first three assignments, because they joined in the program for the last quarter*). The second year teachers' contribution was much more active and interactive than the first year teachers'.

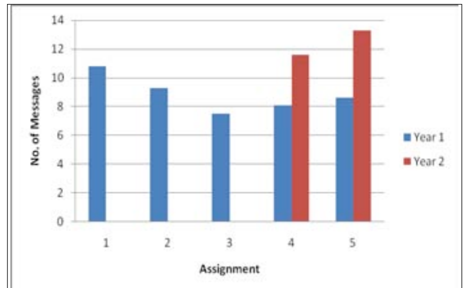

Figure 3. Average No. of Messages per Assignment

Virtual Communication: Purpose and Content

In addition to communication frequency, our study analyzed the data to find the purpose of messages and their content. Our codes were founded in Gareis and Nussbaum-Beach (2007), Interstate New Teacher Assessment and Support Consortium (1992), and Joint Committee on Standards for Educational Evaluation (1988) and finalized after two initial analyses. Table 3 provides final codes and sample messages.

Table 3. Discussion Messages Analysis Codes and Sample Messages

Codes	**Sample messages**
Reflection	I should be more forth coming making sure they hold the spaghetti towards the end of the spaghetti and maybe they would have achieved better results.
Sharing experience	I did this activity with my Algebra class. I found this lesson through the Math Portal site. The lesson took two class periods, which are about 42 minutes in length
Issue/problem	but I always have a few kids who just write one or two words
Question/Suggestion	With all of the variables that prevented a linear graph, was it worth it or would you use a different route?
Instruction (not based on personal exp. but used information from other sources)	Geometry Made Simple (High School Edition), Frank Schaffer Publications – This is where I found the Logic 101 questions. www.printable-puzzles.com – This is where I found the logic puzzle. This is a great website with a lot of different types of puzzles (crosswords, sudoku, cryptograms, word searches, etc.).
Students (extended message about students)	They always want to help so and so add to their answer- no one ever tells another student "No, you're wrong".
Guided Advice	I covered my box with metallic Contact paper, which by the way is dry erase. I

	then used a piece of sparkle craft foam for the screen and white craft foam for the dial. Lastly, I used a pair of old school (large) headphones for the top. Easy and durable!
Simple Agreement	I agree that the number line is a great way to get the year started
Acknowledgement	I am interested in seeing this in action. It does sound like a good activity

Even though the first assignment was reading reflection, the main focus of discussions was not the information presented in the reading chapter. Teachers' interacted discussions were mostly about how to work with certain math concepts, sharing their experience as well as asking questions for instructional delivery including how to relate math concepts to the real world; how well a specific strategy works; games and websites that could help their students with learning concepts; creative ways to demonstrate concepts to their students; the most effective way to use manipulatives in the classroom; how to allow for more student centered time in the classroom; being able to make mistakes in math, not being afraid to do this, and allowing students to help teachers correct them by collaborating with them or turning the mistake into its own mini lesson; the connections made between the different concepts covered in math and all the standards that need to be addressed; the use of vocabulary as a way to help with math communication; and how to overcome time constraints to allow them to teach the "why" as much as they would like to.

Teachers also discussed the growth that they saw in their students, such as asking questions and working more efficiently. They expressed excitement about each student being able to be the "teacher" and also having every student present themselves as a star in the classroom at some point. They discussed the importance of mathematical wording in the classroom, feedback from students on what they think makes a good teacher and also classroom control and how difficult it is for teachers to give that up to allow for a more student directed classroom at times.

Teachers shared struggles that they have faced with math and how they can and have turned that around to help their students. They discussed ways they have made personal connections from their own learning in school and also things that they still want to learn so that they can help the students to hopefully more easily get past the things that they had a lot of difficulty with when they were in school. They also talked about how even teachers are scared about not knowing how to explain the "why" to students, which is the most important part.

Some discussions were about inclusion teachers and general education teachers. They were taught so differently when they were in school that they don't feel comfortable with teaching certain concepts to their own students. They were taught that there is only one way to do problems, but they want to be able to teach their students that there are multiple ways of solving and learning. That was one of the main things they were hoping to gain insight into from this class. They also discussed with interest the similarities teachers share with students in that they all have different ways of learning, such as hands-on, visual, auditory, etc.

There was also a great deal of discussion about how important it is for a teacher to be able to continue to learn and make changes in the classroom, but to try to do this in small amounts (they suggested 10% at a time) to make it easier and more feasible. They also discussed how important it is to find time to talk to and work with your colleagues. (*Quantified results of the content analysis will be shared during the presentation*.)

Discussion

This study investigated the effectiveness of a hybrid professional development program and online communications. Approximately half of the group at the first workshop session revealed they were most comfortable with traditional instructional practices. Nevertheless, teachers overwhelmingly expressed an openness and desire to improve their math instruction in ways that would address the needs of their students. At the end of the summer course, teachers emphasized their appreciation for exposure to additional ideas about how to teach algebra to their students. Participants stressed that they increased their understanding of math content and learned about practical strategies that are applicable to their classrooms. They also valued the sheer number of new hands-on and inquiry-based activities that were covered. By year-end, it was evident that participants had made an effort to make their classrooms more student-centered and inquiry-based. Students were doing more group work and the teachers had learned strategies that resulted in their involving all students in their classrooms. They had begun requiring students to explain their answers and to respond to “why” inquiries if their explanations were not sufficiently clear. They had also begun incorporating more alternative assessments.

Overall, teacher participants increased their math content knowledge and improved their instructional skills. Furthermore, teachers enthusiastically described changes that they have made in their classrooms as part of enriching their students’ math learning. They have made their classes more student-centered, including giving students more opportunities to do inquiry-based, exploratory activities in which they have to present and explain their answers to the class. Teachers also learned additional questioning strategies, which they have applied in their classes. Finally, teachers were more frequently having their students working in groups and using a wider variety of manipulatives than in the past.

With regards to the effectiveness of the online part of the program, there were some trivial findings and unexpected outcomes that can provide an insight into mathematics teacher educators. Most face-to-face discussions centered on the activity or mathematics problems that were presented in class; whereas online discussions reflected on and shared experiences in their own classrooms. The content of online discussions made no distinction between different assignments. The main focus of discussions was sharing their experience about teaching mathematics instead of focusing on what they were required to discuss. It would be important to investigate how different online discussion topics and assignments contribute to teachers’ active learning and participation.

Another interesting finding was the differences in the total number of messages for each assignment. First year teachers had more to share when they were asked to reflect on book readings or video-taped best practices than to exchange their own ideas and experiences about planning and implementing a discovery-based lesson. What teacher educators can learn from this finding is the sequential order of the online professional development program. Practitioners also need plenty time for learning the website and technology that the online PD uses.

SUPPORT FOR PRACTICING TEACHERS IN THEIR USE OF RESEARCH-BASED FRAMEWORKS OF STUDENTS' MEASUREMENT KNOWLEDGE

Jenni K. McCool
University of Wisconsin-La Crosse
mccool.jenn@uwlax.edu

This study investigated the ways in which a teacher developed conceptions of measurement teaching and learning as she collaborated with a researcher to learn and implement a measurement learning trajectory (MLT) (Clements & Sarama, 2009) with two of her students over the course of 18 weeks. The results indicated that several of the components of the professional development program were critical to the teacher's growth from a Level 3 to a Level 4-A on the CGI framework for teacher knowledge developed by Fennema and her colleagues (1996).

Objectives

This study sought to determine which aspects of a professional development experience were most important to an elementary teacher's professional growth by developing accounts of practice for a teacher as she extended her pedagogical content knowledge of measure. More specifically, this study sought to develop a model for a professional development opportunity which incorporates research on student understanding of measurement into a teacher's instructional practices. The researcher sought to offer a unique opportunity involving collaboration, relevant research, teaching sessions with individual students, weekly professional development tasks and reflection to encourage and support a practicing teacher to unpack her own students' conceptual knowledge of measure. A Measurement Learning Trajectory (MLT) for length and area (Clements & Sarama, 2009; Barrett & Clements, 2003) was used as the research-based framework of student knowledge that the teacher used as a lens to view her students' understanding and misconceptions of measure. With a focus on ways of guiding a practicing teacher to understand and students' ways of thinking about mathematics, the Cognitively Guided Instruction theory for professional development provided a model for designing this study within which the measurement learning trajectories served as the researched-based framework for identifying and addressing students' misconceptions (Fennema et al., 1996; Carpenter & Fennema, 1992).

Theoretical Framework

This study combined aspects of both a Teacher Development Experiment (TDE) and a Three-Tiered Teaching Experiment to form a collaborative teaching experiment model for professional development. A TDE (Simon, 1999) is one tool for conducting a professional development program that allows for in-depth analysis of the procedures involved in the professional development experience and the ensuing teacher growth. Because this methodology allows researchers to closely study and foster the development of teachers through cycles of analysis and intervention, the TDE offered a framework that could be used to gain insight into a teacher's developing expertise. In a TDE the focus is not only on the teacher's mathematical development, but also on the generation of models that describe how teachers develop pedagogical knowledge (Simon, 1999). The researcher used the TDE to help determine which aspects of our interaction seemed to be most helpful to the teacher and allowed for the creation of a model for how the teacher grew. This study attended to the teacher's development of pedagogical content knowledge in the area of measurement as she collaborated with a mentor/researcher and as she interacted closely with two students in teaching experiments to develop their measurement knowledge. The teacher's pedagogical content knowledge was developed through the process of learning a measurement trajectory and using it as a tool for guiding tutoring sessions with two of the teacher's students.

In order to attend to the teacher's growth, as well as my own growth as a professional developer I employed a modified Three-Tiered Teaching Experiment model, placing emphasis on the researcher and teacher tiers (Lesh & Kelly, 2000). Teaching experiments (TE) (Steffe, 1988) are the basis of a variety of research designs and "focus on development that occurs within conceptually rich environments that are explicitly designed to optimize the chances that relevant developments will occur in forms that can be observed" (Lesh & Kelly, 2000, p. 192). The Three-Tiered Teaching Experiment allows attention to focus on students' developing knowledge, teachers' developing pedagogical content knowledge, and the researcher's developing understanding of the students' and teachers' developing conceptions. See Table 1.

Tier 3: The Researcher Level	Researchers develop models to make sense of teachers' and students' modeling activities. They reveal their interpretations as they create learning situations for teachers and students and as they describe, explain, and predict teachers' and students' behaviors.
Tier 2: The Teacher Level	As teachers develop shared tools (such as observation forms or guidelines for assessing students' responses) and as they describe, explain, and predict students' behaviors, they construct and refine models to make sense of students' modeling activities.
Tier 1: The Student Level	Three-person teams of students may work on a series of model-eliciting activities, in which the goals include constructing and refining models (descriptions, explanations, justifications) that reveal partly how they are interpreting the situation.

Table 1 Three-Tiered Teaching Experiment (Lesh & Kelly, 2000)

Three-Tiered Teaching Experiment allowed the researcher to focus on hypothesizing about the processes and mechanisms that promoted growth through the collaborative teaching experiment. In a teaching experiment a researcher generates and hypotheses about a student's thinking strategies and then tests those hypotheses in individual interviews (Steffe, 1988). In this study the teacher was encouraged to assume the lead role in this process as she used the measurement learning trajectories for length and area to guide her development of teaching experiments with two students.

The researcher focused the teacher's attention on weekly decision-making activities that involved explanations or justification of predictions that exhibited how the teacher was interpreting situations and problems (Lesh & Kelly, 2000). Through these weekly professional development tasks (PDTs), the researcher hypothesized, tested, and refined my own developing ideas about the mechanisms that were promoting the teacher's growth and adapted a model of her thinking accordingly. An account of the teacher's practice was thus formed in the first three weeks of the collaborative teaching experiment and was used as the benchmark for determining if this initial account of her practice changed throughout the 18 week collaborative teaching experiment (Heinz, Kinzel, Simon, & Tzur, 2000).

The Cognitively Guided Instruction Professional Development framework (Fennema et al., 1996) was used as a tool to guide the decisions made during the process of creating the model of the teacher's measurement instruction. After identifying the major components of instruction and beliefs fundamental to the goals of the CGI program, Fennema et al. (1996) defined four instructional levels. These levels were used in the current study as a lens for viewing teacher change. Although every math lesson was not observed, the four pre- and four post-lessons, as well as the three measurement lessons the teacher invited me to observe were viewed through this lens. This framework identifies four major levels of instruction that are fundamental to the philosophy of Cognitively Guided Instruction (Fennema et al., 1996). See Table 2.

Level	Description
1	Provides few, if any, opportunities for children to engage in measurement problem solving or to share their thinking in measurement.
2	Provides limited opportunities for children to engage in measurement problem solving or to share their thinking in measurement. Elicits or attends to children's measurement thinking or uses what they share in a very limited way.
3	Provides opportunities for children to solve measurement problems and share their measurement thinking. Beginning to elicit and attend to what children share but doesn't use what is shared to make instructional decisions.
4-A	Provides opportunities for children to solve a variety of measurement problems, elicits their thinking, and provides time for sharing their thinking. Instructional decisions are usually driven by general knowledge about his or her students' measurement thinking, but not by individual children's measurement thinking.
4-B	Provides opportunities for children to be involved in a variety of measurement problem-solving activities. Elicits children's measurement thinking, attends to children sharing their thinking, and adapts instruction according to what is shared. Instruction is driven by teacher's knowledge about individual children's measurement thinking in the classroom.

Table 2 Levels of Cognitively Guided Instruction (Adapted from Fennema et al., 1996)

In this study, the researcher blends aspects of the Teacher Development Experiment and the Three-Tiered Teaching Experiment and proposes a different approach to professional development. This trajectory-focused approach is called a Trajectory-Based Collaborative Teaching Experiment (TBCTE). Different from Simon's Teacher Development Experiment, the TCTE is a close collaboration working one-on-one with a teacher as they learn to use learning trajectories specific to the measurement content domain. The CGI levels of professional development were used as a lens for viewing teacher change as the researcher supported the teacher as she developed tasks and assessed two of her students.

Methodology

In order to identify essential aspects of the TBCTE I worked with one, fifth grade teacher from the rural Midwest over the course of 18 weeks. Because the Measurement Learning Trajectory (MLT) was the focus of the professional development experience, the teacher was given opportunities to explore her own concepts of measurement and students' measurement misconceptions prior to learning the MLT. Weekly Professional Development Tasks (PDTs) were used to provide the opportunity for the researcher to hypothesize about the teacher's responses and refine and reorganize conceptions about the mechanisms that were promoting the teacher's growth, ultimately helped the researcher adjust and refine the model of the teacher's thinking. Such mechanisms included: critiquing example problems for strengths and weaknesses, role-playing, presenting her own problems to the entire class, determining which trajectory levels different tasks addressed, and writing performance assessment tasks for her students.

Before the teacher was introduced to the MLT her students were given a measurement assessment. She was also asked to read related literature and reflect on those readings prior to learning about the MLT. The researcher observed two whole class lessons and used these observations to document an initial interpretation of the teacher's CGI Level in an attempt to build an initial model of her thinking. Weekly PDTs were then created and posed to the teacher. The researcher made predictions about how the teacher would respond to the tasks so these predictions could be prepared to the teacher's actual responses. This cyclical process of model building through predictions and examinations using PDTs continued throughout the study as the researcher gradually refined, expanded, or rejected the current interpretations of the teacher's growth (Lesh & Kelly, 2000). Readings, reflections, meetings with the researcher, and PDTs continued throughout the entire 18 weeks of the professional development experience.

In week four the MLT was introduced as a tool for assessing student knowledge of length and area. Two students were chosen based on parent permission and their initial assessments. After the teacher had time to practice using the MLT to analyze other students' thinking strategies and discuss her thoughts with the researcher, they individually reviewed the two focus students' initial assessments in an effort to determine the level at which the two students were operating for the majority of the length and area tasks. Once an initial level of student thinking was identified, the teacher predicted how she thought the student would respond to new tasks that were presented in individual interview sessions. Following each interview the teacher was encouraged to make a claim about the student's length or area knowledge based on the learning trajectory. This cycle of planning, predicting, and checking started in week seven and continued for six sessions per student, requiring 12 weeks to complete this cycle with the pair of students as the teacher gradually reorganized, expanded, or rejected her current interpretations of their thinking level.

Results

Weeks 1-3 CGI Level 3

Based on my observations and the teacher's reflections from the first three weeks, the initial model of the teacher's measurement instruction was at a Level 3 on the CGI professional development framework because she "elicits and attends to what children share but doesn't use what is shared to make instructional decisions." The researcher looked for changes in the teacher's ability to elicit student thinking in the individual interviews and her use of that information to inform whole-class instruction and assessment. Such changes informed decisions to make new models of the teacher's pedagogical content knowledge throughout the remaining fifteen weeks of the professional development program.

Weeks 4-7 Level 4-A

Following these first three weeks, the teacher was given weekly PDTs to assess her use of measurement content knowledge and her knowledge of the measurement learning trajectories to guide instruction and assessment. These tasks were used to predict her responses based on the knowledge the researcher gained in week three. Her actual responses were then used to guide the creation of the next PDT. Along with these tasks the teacher was introduced to the trajectories and began planning and conducting the individual interview sessions with the two focus students. In the following weeks the teacher also shared ways that she had changed whole-class instruction and invited the researcher into her classroom on two occasions to observe measurement lessons she had created. These events form the context for the adaptation and refinement of the model of her thinking at various CGI instructional levels.

During weeks four through seven, the teacher was given many opportunities to use the MLT as a tool for analyzing assessment problems as well as her students' answers to measurement tasks. Also during this time frame, without a prompt from the researcher, the teacher significantly altered a measurement lesson to incorporate the information she had learned through the trajectory use and the measurement articles she had read. At the conclusion of week seven the teacher's actions demonstrated instruction at the 4-A Level because, on more than one occasion, she had provided "opportunities for children to solve a variety of measurement problems and elicited their thinking."

Another indication of Level 4-A was when the teacher explained how she had discovered that her students did not know that a meter stick was comprised of 100 centimeters. She explained that she addressed the meter stick misconceptions the following day by engaging students in a discussion about the units on the meter stick, which indicated that she had based instructional decisions on general knowledge about her students' measurement thinking. Over the course of the next 11 weeks, the teacher continued to read measurement articles, complete weekly PDTs, and began the interviews with the two focus students.

Weeks 8-11 Level 4-A

The teacher's responses to the PDTs for weeks eight through ten indicated that she indeed understood the importance of the problem statement. She changed two problems to better assess her students' knowledge of length. These changes were a result of her knowledge of measurement misconceptions she had learned about from the readings. The model of her thinking was not changed as a result of these three weeks and remained at Level 4-A because she had changed measurement problems to allow "opportunities for children to solve a variety of measurement problems and elicited their thinking."

During week eight the teacher described a change in a task she had done in previous years. She changed this task due to what she had learned about one focus student's difficulties with understanding the difference between area and perimeter when given a rectangular grid instead of labels on the sides of a rectangle. The teacher asked her class to make a rectangle that had a perimeter of 12 units using square tiles. No student was able to correctly do this task. Her findings are consistent with prior findings (Chappell & Thompson, 1999) that illustrate the difficulty students have when asked to produce a drawing to show a specific perimeter. Although the teacher suspected there would be some students who struggled with this task, she was surprised that no student could do this task correctly.

Weeks 12-15 Level 4-A

Over the course of these four weeks, the length and perimeter TEs were completed and work with area began. By this time in the program, the teacher had gained confidence in her measurement knowledge and was taking on more of a lead role in the TE task creation by asking more probing questions during the TEs. For a PDT task, she was asked to find an area problem she typically assigns as homework and change the task to make it a better task for informing her about students' knowledge of area. The problem the teacher chose to change showed a three by four grid made of toothpicks and asked students to determine how many toothpicks formed the perimeter and to find the area of the figure. She changed this task to include the length of the tooth picks as 1 cm long and asked her students to draw a line that would be equal to the length of the perimeter of the rectangle. In addition to having the students find the area, she asked her students to draw a square that was the same size as one of the area units. The teacher explained the rationale for her changes. "I would like to make this into a problem where the student was using construction to help them 'see' or 'understand' the difference between perimeter and area units." Her attention to perimeter and area beyond formula use indicated that she had a better understanding of how to address her students' misconceptions about these formulas.

The changes the teacher made to the homework question indicated that her knowledge of student misconceptions motivated her to focus students' attention on the notion that perimeter was composed of length units and area was composed of square units. There was not substantial evidence to indicate there was a change in the teacher's model for teaching measurement during these four weeks. She had changed measurement problems to "elicit students' thinking" and had used information about Eliza's struggles with an area task to make a decision about how to rewrite the task for the whole-class final assessment. These actions fit with Level 4-A, which is indicated when "Instructional decisions are usually driven by general knowledge about her students' measurement thinking, but not by individual children's measurement thinking."

Weeks 12-15 Level 4-A

During the last TEs the teacher exhibited a great deal of confidence with her knowledge of students' misconceptions and carried out the interviews with little assistance. She made decisions based on her understanding of the role each task played in her quest to assess students' understanding of measurement and move them into higher levels of thinking. The post-questionnaire exhibited the teacher's changing conceptions about measurement teaching and learning. Her responses to the post-questionnaire focused on the role the MLT should play in her teaching practices. She used more specific measurement ideas to explain her understanding of the big ideas of measurement in the post-questionnaire. She wrote, "The importance of equality of length, conserving space and iterating units need to be mastered before I can expect them to understand more advanced ideas. Looking at my questioning techniques from a different angle, not only as a probe, but also as a way to encourage them to cross over into that next level conceptually is something I think about more often." There was no evidence to indicate that the teacher had moved beyond Level 4-A and into Level 4-B which would require her to base instructional decisions on her "knowledge about individual children's measurement thinking in the classroom."

Discussion

The findings of this study indicate that although the teacher's measurement content knowledge changed little, her understanding of students' misconceptions about measurement conceptions improved. The critical aspects of the professional development experience were the measurement readings, the PDTs, the teacher's reflection practices, the MLTs, the cyclical nature of the TEs, and the weekly collaborative meetings. The order in which these components were incorporated into the experience was also important to the manner in which the components impacted each other. For example, the findings indicate that the readings were critical in sparking the teacher's curiosity about her own students' measurement thinking and learning and validated the need for the trajectories. This helped in the teacher's acceptance of the MLTs and prompted her to develop measurement lessons on her own. Later the intense cycles of reading and applying the information in the form of TEs helped the teacher make sense of the MLTs. After the MLTs were introduced, the researcher found that the PDTs served as a means to give the teacher experiences that supported her developing understanding of and use of the MLTs to assess student responses.

Through the teacher's participation in the professional development experience using the MLTs, she shifted on the CGI scale for teacher knowledge from a Level 3 to a Level 4-A. By utilizing both a CGI model for professional development and a learning trajectory for length and area, this study offers unique insight into how this combination might impact a teacher's professional growth. The researcher anticipated that this model of a professional development program would give readers a clear picture of the developmental processes involved when a teacher and a researcher collaborated in an attempt to help the teacher and researcher grow as professionals.

As researchers and professional developers work to determine ways in which practicing teachers might incorporate research into their own classrooms this teacher's incorporation of the ideas she read about into her own classroom, indicate one possible avenue. Also, the research-based learning trajectories were accepted and used by the teacher as a lens to view and make sense of assessment and student learning. The findings indicate that the cyclical nature of the readings and the application of that material into the TEs helped the teacher grow as a professional. This study offers a promising method for incorporating research into teachers' everyday practices.

A PERSPECTIVE OF CHANGE: A TEACHER'S EVOLUTION THROUGH PROFESSIONAL DEVELOPMENT

Melissa M. Soto
University of California, Davis
mmsoto@ucdavis.edu

Rebecca C. Ambrose
University of California, Davis
rcambrose@ucdavis.edu

This study discusses the evolution of one teacher as a result of participating in professional development focused on children's mathematical thinking. Viewing her interactions with students in video-taped problem solving interviews from the beginning and third year of her participation in the professional development, prompted her to reflect on the changes that she had made. She reported that she had begun to capitalize on mathematics as it came up throughout the day, as well as valued student strategies rather than their success at solving problems. These perceptions were consistent with previous research findings even though different student populations were examined.

In an attempt to improve teacher quality in mathematics, the National Council of Teachers of Mathematics (NCTM) developed and set forth their 1991 *Professional Standards for Teaching Mathematics,* which provide goals to guide teachers in continuous learning and improvement. As part of these goals, teachers are encouraged to participate in "appropriate and ongoing professional development" (NCTM, 1991). The rational for encouraging teachers to participate in continuous learning is to enhance their reflective and metacognitive processes. Ideally, they will create opportunities for their students' metacognitive mathematical thinking, as well as share best practices for teaching mathematics with other colleagues (NCTM, 2000).

To have the greatest impact on teacher improvement and student achievement, prior work suggests that professional development programs be rigorous, ongoing, and provide teachers with the opportunity to engage in collegial exchanges (Darling-Hammond, Wei, Andree, Richardson, & Orphanos, 2009). Stigler and Hiebert (cited in NCTM, 2000, p.18) have found that "collaborating with colleagues regularly to observe, analyze, and discuss teaching and students' thinking or to do 'lesson study' is a powerful, yet neglected, form of professional development in American schools". Fortunately, there has been a push to increase the number of reform based professional development programs and investigations of the impact of those programs on teacher practice. This study examined the effects of one such reform based professional development program (PDP) and provides insight into the changes of one teacher's mathematical instruction in an urban school district in northern California.

Theoretical Framework

Our study investigated the effects of a PDP using the principles of Cognitively Guided Instruction (CGI), (Carpenter, Fennema, Peterson, Chiang, & Loef, 1990). In professional development programs using CGI, leaders share "an organized set of frameworks" (Franke & Kazemi, 2001, p. 103) of the different types of mathematical problems children solve and the

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

PME-NA 2011 Proceedings

invented solution strategies they employ. Not only is there a focus on the different invented solution strategies, but also on the explanations students provide to justify those strategies. If teachers are aware of different solution strategies and how students explain their thinking, they can help students verbalize their thinking, make more sense out of what their students are thinking, and more effectively plan instruction and guide classroom discussions (Franke, Carpenter, Levi, & Fennema, 2001).

Research investigating teachers, who have participated in CGI PDPs, and their pedagogical beliefs have shown that by the end of the professional development, teachers had stronger beliefs in students' abilities to solve problems without explicit instruction. These teachers also tended to created environments in which students were encouraged to develop their own solution strategies and share them with others. They also saw their role as a guide who questioned children and supported their thinking when the need arose (Fennema, Carpenter, Franke, Levi, Jacobs, & Empson, 1996). This research is over 15 years old now and conditions for teachers have changed tremendously during that time. This study examines the degree to which CGI continues to foster this kind of change for teachers.

The research questions that guided our investigation were:

- How does one teacher in a CGI PDP perceive that her participation has impacted her teaching?
- What is one teachers' perception of the evolution of her interaction with her students?

In order to investigate these questions, we interviewed a participant from our CGI PDP to gain insights into her evolution as a mathematics teacher. Given the variability between teachers, such as differing personal and professional experiences, levels of education, or previous professional development, we focused on one particular teacher who took advantage of what was offered, a sort of best case scenario. Mrs. K, a first grade teacher who has taught for 12 years and is bilingual, was chosen to be interviewed because she had participated in all three years of our CGI PDP. She often provided thoughtful comments during after school meetings and she implemented many of the strategies discussed in the professional development which was evident from classroom observation and student interviews.

Methods

In the spring of the 2007-2008 school year, professional development began in a small urban school district in northern California with a high percentage of English Language Learners. This three year grant-supported program invited kindergarten through second grade teachers from around the district to join each year. Unlike previous CGI PDPs, our program situated interviews and other professional development material within the district and teachers' classrooms instead of relying on original CGI materials, which depicted homogeneous classrooms quite different than those found within the teachers' district. This is done to change teachers' preconceive notions and promote the idea that children from diverse ability, cultural, economic, and language backgrounds are capable of problem solving without direct instruction.

As part of the professional development, teachers attended monthly after school meetings to discuss students' mathematical thinking by viewing video-clips of their students solving problems; listening to audio-clips of students in classrooms sharing solution strategies; and

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

PME-NA 2011 Proceedings

learning ways to scaffold critical thinking during problem solving. During the after school meetings, teachers were given story problems to present to their students and a member of the professional development team scheduled a time to visit each teacher's classroom to observe and audio-tape student solution strategies. The teachers also selected three students to interview during the fall and spring of each year, which provided them with an opportunity to implement strategies learned in the professional development in a one on one session with their students. These interviews provided teachers with an opportunity to develop elicitation and questioning strategies. Because these interviews were videotaped, they, as well as classroom observations and audio recordings, formed the basis of our instructional material to present during meetings to elicit authentic, meaningful comments and begin dialog amongst the teachers.

In the summer of 2010, we invited Mrs. K to discuss her impressions of the PDP as well as perceived changes in her teaching as a result of her participation in the program. In the summer interview, the two authors of this paper used a semi-structured interview protocol to discuss with Mrs. K her experiences in the professional development (Merriam, 2009). Videos of past interviews with students were also used as artifacts to spark discussions and also to provide a diachronic report, which described phases of development or change that captured her evolution as a teacher (Weiss, 1994). The interview occurred at the university office of one of the authors, which contained the audio/video equipment used to play the student interviews. The interview lasted about two hours, and was audio recorded in order to retain the original data as well as to ensure that our interpretation and analysis was accurately constructed out of the participant's words (Seidman, 2006).

Our goal was to provide an account of one teacher's evolution as a result of participating in a child centered professional development. The interview was transcribed to enable the authors to make judgments about the data without imposing their own reference frame too early in the analytic process (Seidman, 2006). After transcribing, the transcripts were read in more detail but particular attention was devoted to segments when Mrs. K specifically discussed changes in her practice and/or perceived differences in her interactions with children.

Results

Reflecting on Practice

We began our interview with Mrs. K by asking her to reflect on her three years in the PDP, and in particular what changes she had noticed in her instruction. Throughout the interview, Mrs. K described her realization that mathematical concepts and ideas were not only occurring during her math lessons, but that there were opportunities to explore these concepts throughout the school day. She described her process of math instruction before the professional development as, "I got to teach math, let's get our lesson, let's get through it, and then we're moving on to a new subject…The lesson is just one day and we turn the page and move on." Her instructional process was one that focused on efficiency and getting through the material to move on to something different and that by doing this, she believed that her students understood the material.

After participating in the professional development and reflecting on how her math instruction had changed, she stated,

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

PME-NA 2011 Proceedings

> I really have noticed that there are math concept ideas throughout the day, it's not just math time. You look for opportunities to do story problems. I really recognize moments throughout the day where it's just so easy to pose a question…

Mrs. K recognized that although it may seem more efficient to follow a pacing guide or the text book and quickly move through topics, it is insufficient and that to accurately gauge how well her students were making sense of the mathematics, she had to take the time to incorporate the math throughout the day, listen, and observe her students. She also realized that the way she taught previously was underestimating what her students were able to accomplish.

She discussed a previous perception of her role as a classroom teacher indicating, "I pretty much knew everything and I'm going to tell you everything and then you'll walk away knowing things." But after engaging in the PDP, she stated that, "I teach completely differently as a result and I give kids more opportunities. We are learning together. It's kind of exciting. It takes a lot of pressure off." Here we see Mrs. K's shift in perceptions of her role as transmitter of information to facilitator. Where other teachers may find it more difficult to guide students through the problem solving process, Mrs. K found this process to be exhilarating, less stressful, and lead students to anticipate math throughout the day. She explained that her students "are always looking for a way to solve the problems themselves. Before I even know that that's what I want to do, they're already doing the numbers." This process slowly became a classroom norm and children began to anticipate mathematics on a daily basis; without prompting, children began mathematizing for themselves.

Not only did Mrs. K describe the evolution in her teaching but she also mentioned how her students responded in a positive way to her teaching methods. She described her students as becoming more confident in their mathematical abilities and enjoying the process.

> Everything is a way to do math and they love it. It's surprising how much they actually enjoy it. It really surprised me, they look forward to it…I've noticed I can let go and students are learning from each other. And they feel good about it. They look forward to it. They are looking forward for opportunities to show what they know.

With this change in teaching practices and in her role as a teacher, Mrs. K created an environment where student thinking was valued and students were able to take charge of their math learning.

Viewing of Student Interviews

After discussing the perceptions in her practice, we then asked Mrs. K to view video-clips from two sets of her student interviews. One set was recorded after her first year participating in the PDP and the second set was recorded after her third year. We decided to view student interviews that were recorded after her third year of participation first for her to identify potential differences. Each set of interviews were about 15 minutes in length and we watched short segments and asked her to discuss her interpretation of the child's thinking and/or her scaffolding techniques. The following results will focus on a particular type of story problem, a Compare Difference Unknown (CDU) problem, selected because these problems have been found to be especially difficult for children. (Fuson, Carroll, & Landis, 1996)

PME-NA 2011 Proceedings

This first segment, recorded after her third year in the PDP, was with a child Luis, a designated English Language Learner (ELL). Luis struggled at the beginning of the school year but by the end of the year, he had improved academically even though his English language was developing. The first text box describes what occurred in the video-clip as he solved the following story problem:

- Julissa has ten flowers and Brianna has 16 flowers. How many more flowers does Brianna have than Julissa?

[Luis began counting out cubes to represent each set. He made a set of eight which he miscounted as ten and connected them together to make a long stick of cubes and then he made another long stick of 16. He then stopped, reread the problem, and lined up the two sticks next to each other.]

L: They both have one, they both have two, they both have three, they both have four, they both have five, they both have six, they both have seven, they both have eight.

[He realized that he was missing two more cubes on Julissa's row and added two more cubes.]

L: They both have nine, they both have ten. *[He stopped and looked at the remaining cubes.]* Julissa has ten and Brianna has 16.

Mrs. K: Right, how many more does Brianna have than Julissa?

[He reread the problem out loud.]

Mrs. K: She has 16, Julissa has ten, so that means Brianna has more right? How many more does she have? How many more flowers?

L: Two flowers.

Mrs. K: Well, what are you holding in your hand? We are pretending those are what?

L: Flowers

Mrs. K: Ok, show me Julissa's flowers. *[He held up the stick with ten cubes.]* Show me Brianna's flowers. *[He held up the stick with 16 cubes.]* So when you put them next to each other, who has more flowers?

L: Brianna

Mrs. K: How many more flowers does she have?

[He looked at the cubes which were next to each other and counted the ones that were extra.]

L: Six

Teacher-Student Interview: Spring 2010

Mrs. K actively interacted with Luis. She revisited the specifics of the problem with him, asking him to consider the relative size of the quantities. When he gave her the wrong answer, "2" she asked him to consider how his cubes related back to the problem, "what are you holding in your hand?" She then evoked the work that he had previously done ("they both have one, they both have two…" by asking him, "when you put them next to each other, who has more flowers?" Mrs. K's interactions with Luis were not extensive but it is clear from her questions to him that she was actively listening to his comments and closely observing his work. She was

actively supporting him without taking over his thinking. The next text box is Mrs. K's reaction to the previous video-clip.

> **Mrs. K**: He knows how to compare but he just doesn't know. He knows how to set it up but doesn't know where to go from there. He's on his way.
> **Researcher**: He kind of lost his flow. So I think that shows that comparison problem isn't that solid for him yet. You didn't tell him what to do, he figured it out finally.
>
> Researcher-Teacher Interview: Summer 2010

In this reflection of the video, Mrs. K is not being critical of the child and she is noticing that he could build the sets but did not know what to do with them. She also realizes that Luis needs more experience to be facile with this problem type.

In the next segment we examined Mrs. K's reaction to an interview during her first year in the PDP. The student, Daniel, a native English speaker, was solving the following problem:

- Erica has 12 stuffed animals. Melissa has nine stuffed animals. How many more stuffed animals does Erica have than Melissa?

> *[Mrs. K read the problem twice for the student. After hearing the problem the second time Daniel wrote on his paper 12+. Mrs. K then read the problem a third time.]*
> **D**: Ok.
>
> Teacher-Student Interview: Spring 2008

> **Mrs. K**: Me rereading the problem doesn't do anything. Poor kid, oh my gosh!
>
> Researcher-Teacher Interview: Summer 2010

While watching her interview, Mrs. K responded with the above quote which acknowledged that her interaction was not productive. The next text box continues with the teacher and student interview.

> *[He crossed out the plus sign next to the 12 and wrote the number nine under the 12 and then wrote a six under the nine.]*
> **D**: Twelve minus nine is six.
> **Mrs. K**: Is that right? You want to check with the cubes? You can.
> *[He started counting out cubes.]*
> **Mrs. K**: Count out loud so I can hear you.
> **D**: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, *12 [He counted out loud as he connected the cubes together to make a stick. He then started making another stick of six. He lined them up and counted backward starting at 12 and ending at six. He then looked up at Mrs. K.]*
> **Mrs. K**: Would you like me to read it again? *[They read the problem again together and then she reread it two more times.]*
>
> Teacher-Student Interview: Spring 2008

In this episode, Mrs. K only repeated the problem to Daniel as opposed to the first episode with Luis where she questioned and supported him in figuring out the answer. At this point in her

PME-NA 2011 Proceedings

professional development she did not know how to offer support and so took a passive role in her interaction with the student.

> **Mrs. K**: Oh my gosh! I'm torturing him. This is horrid! I'm not even questioning why he's holding on to that six…I'm not giving him any direction you know, there's nothing. He's just out there trying to do something.
>
> Researcher-Teacher Interview: Summer 2010

This observation suggests that she sees other ways she could have supported his thinking rather than just repeating the problem. She recognizes that she could have asked him about his strategy and thinking, especially in the six. At this point in her professional development, she realized that questioning the student's strategy/thinking can inform her interactions with the child. As she noted, "For me I was just looking for the correct answer not the process in getting there."

By observing these two episodes of her student interviews, Mrs. K could see the difference in her interactions. She reported that she was unclear as to what her role was in the interaction, so she chose to restrict her activity to restating the problem. After viewing this second episode, Mrs. K discussed how she was thankful to have seen these two episodes, especially at that point as opposed to after her first year because "if I would have seen it, I wouldn't have known what to compare it to. So I think this is actually effective. For me looking at it, I really see a difference." This suggests that her interpretations of interactions with children had changed significantly from the beginning to the end of the PDP, with her having a much better sense of how to support children in figuring things out for themselves at the end of her three years. She now values students' mathematical thinking rather than looking exclusively at their success in solving problems.

Discussion

In her reflection of the changes she had noticed, Mrs. K mentioned that she had perceived changes in her role as a teacher, especially in the way she approached her mathematical instruction and in the way her students participated in mathematics in the classroom. Two of the most important roles for teachers in reform based classrooms are creating environments where students explore, justify their solutions, and make sense of the mathematics; and guiding activities and discussions while not taking over students' thinking (Hiebert, Carpenter, Fennema, Fuson, Wearne, Murray, et al., 1997). Instead of teaching in a didactic way using algorithms and direct instruction, teachers should encourage students to develop their own solution strategies and help make connections between manipulatives, mental arithmetic, and written methods (Verschaffel, Greer, & DeCorte, 2007; Fuson & Burghardt, 2003). Mrs. K, with the help of the PDP, viewed herself as a facilitator as opposed to a distributor of knowledge and she created an environment in which she and her students were learning together. Her comment "I have taken the time to listen to them…and time to observe the strategies that kids use," highlights this change in her role and the new focus of her instruction.

By examining student interviews from Mrs. K's first and third year of participation in the PDP, we were able to compare and visualize the evolution which she had undergone while in the

PME-NA 2011 Proceedings

program as opposed to relying on self assessment. It is unclear if this evolution would have been evident had we only used the original CGI professional development materials. The CDU problems were of particular interests because research has shown that these problems are one of the most difficult problem types for children to solve, as there is no clear action stated within the problem (Fuson, Carroll, & Landis, 1996). Also, children have limited experience with this type of problem as they are more accustomed to joining, separating, sharing, counting groups of items, and identifying greater/lesser quantities, but rarely do they ever calculate the difference. Because of this lack of action in the problem, teachers too find it difficult to scaffold students without explicitly teaching them how to solve them. In the case of Luis, Mrs. K was able to skillfully question him so that he was able to figure out the solution for himself without her telling him how to do so directly.

Through the interview with Mrs. K, it appears that the PDP was a valuable experience that had a positive effect on her mathematical instruction as well as having beneficial effects on her scaffolding skills and interactions with their students. Although only one teacher's experience was presented here, several other teachers have expressed similar perceptions and experiences in their classrooms and interactions with their students. We have continued our professional development in this school district by incorporating third and fourth grade teachers into the program. We anticipate similar outcomes from this program for developing teachers.

MAKING SENSE OF STUDENT WORK WITH LEARNING TRAJECTORIES

P. Holt Wilson
The University of North Carolina at Greensboro
phwilson@uncg.edu

Jere Confrey
North Carolina State University
jconfrey@ncsu.edu

This paper investigates a group of elementary teachers' uses of a learning trajectory to making sense of children's mathematics during professional development. Teacher learning activities focused on understanding students through observation and analysis of written work, as well as considering next instructional steps in response. Results suggest that mathematics learning trajectories can support teachers in identifying, interpreting, and responding to evidence of student cognition.

As stated by *Principles and Standards for School Mathematics* (NCTM, 2000), assessment "should be an integral part of instruction that informs and guides teachers as they make instructional decisions" (p. 22). Though work to improve large-scale assessment systems and accountability models has received much attention recently, Black and colleagues (2004) remind us of the importance of considering what happens "inside the black box" of classrooms. Informal classroom assessments, such as observing students engaging in mathematical tasks or reviewing their written work, have the potential to improve student learning provided teachers use these assessments to guide instruction.

Some researchers have reported the benefits of having a framework for understanding the mathematics of children to interpret students' mathematical work (e.g. Carpenter, Fennema, Franke, Levi, & Empson, 1999). Such structures for making sense of students' approaches to mathematical concepts assist teachers in identifying likely understandings and misconceptions that may direct teachers' instructional choices and ultimately support greater student achievement (Carpenter et al. 1999). One such structure currently receiving attention is the construct of learning trajectories (LTs). Some have conjectured such positive benefits of LTs (Confrey & Maloney, in press; Corcoran, Mosher, & Rogat, 2009), and early research on the ways in which teachers may use their understandings of LTs in classrooms suggests that they may serve as a framework for understanding students' mathematics (Wilson, Mojica, & Confrey, 2010).

The purpose of this paper is to explore teachers' uses of an LT in identifying, interpreting, and responding to evidence of students' mathematical thinking when observing students and when analyzing written work on instructional tasks. The research reported describes the ways that a group of practicing elementary teachers used their knowledge of an LT to make sense of students' mathematical activity by addressing the following research questions: In what ways do elementary mathematics teachers in a professional development setting use their knowledge of a learning trajectory to understand students through the classroom assessment practices of observation and analysis of written work? In what ways do they respond instructionally?

Perspectives

The current notion of learning trajectories is related to Simon's (1995) seminal work on the Hypothetical Learning Trajectory, the idea that a teacher coordinates his or her knowledge, learning goals, and plans for instructional activities to form a hypothesis about a student's learning process. In recent years, researchers have built upon this idea by synthesizing research and empirically supporting descriptions of the ways student understanding evolves over longer periods of time (Confrey & Maloney, in press). Though multiple definitions exist among researchers, most agree that LTs are descriptions of the varying levels of reasoning sophistication held by students as they refine their informal understandings into more adequate, complex conceptions. This study uses Confrey et al.'s (2009) definition which states that a LT is "a researcher-conjectured, empirically-supported description of the ordered network of constructs a student encounters through instruction (i.e., activities, tasks, tools, forms of interaction, and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time" (p. 347). From this perspective, learning is closely related to students' instructional experiences, highlighting the teacher's role in supporting student learning (Confrey & Maloney, in press).

In *Knowing What Students Know* (NRC, 2001), the authors of the report cite a common principle for all assessment to be *reasoning based on evidence*. Assessments serve various purposes in various contexts, from the large-scale evaluation of programs to the examination of individual student achievement. Of particular relevance to this paper is the report's point concerning classroom assessment. It describes classroom assessments as "informal methods for determining how students are progressing in their learning" that are used by teachers "to inform day-to-day and month-to-month decisions about next steps for instruction"; such assessments include "classroom observations, written work, homework, and conversations with and among students" (pp. 37-38).

The report presents a three-part framework that underlies the assessment process called the Assessment Triangle (figure 1). The framework illustrates how three facets of assessment, one at each vertex of the triangle, are integrally related. The Observation vertex represents the "a set of beliefs about the kinds of observations that will provide evidence of the students' competencies" (p. 44). The Interpretation vertex represents the process by which one makes sense of evidence. The Cognition vertex represents a model of cognition and learning for a particular domain of knowledge. Each of these facets works together for an assessment to draw conclusions about what students know based on their performance.

This paper explores the possibilities of LTs serving as a model for student cognition at the Cognition vertex. It seeks to characterize the observations and interpretations teachers make during classroom assessments when an LT is taken as a model of cognition. As classroom assessments may be made for the purpose of informing and guiding instruction, it also investigates possible steps that teachers might take in response to their assessment of student learning.

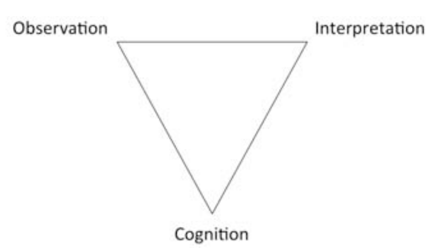

Figure 18. Assessment Triangle (NRC, 2001).

Methods

Design studies methodology was used to investigate the ways in which teachers used their understandings of an LT to observe students and to analyze written work. Design studies seek to engineer learning environments and study the learning that results from them (Confrey, 2006). They are based on the iterative design, implementation, and refinement of conjectures of how a particular form of learning unfolds (Cobb, Confrey, diSessa, Lehrer, and Schauble, 2003; Confrey & Lachance, 2000). For this study, a professional development experience was designed for elementary teachers to support their transition to newly adopted state standards that represented increased content knowledge on rational number by focusing on a single learning trajectory for rational number.

A learning trajectory for equipartitioning (EPLT) (Confrey et al., 2009) was selected as a context for studying the ways teachers might use knowledge of an LT. Confrey and her research group define equipartitioning as the set of cognitive behaviors that have the goal of producing equal-sized groups or parts from collections, single wholes, or multiple wholes such as is typically encountered by children in the context of 'fair sharing' (Confrey et al., 2009). The EPLT describes how children's experiences with fair sharing develop into an understanding of partitive division across the elementary years. Its levels describe the strategies, mathematical practices, emerging relationships, generalizations, and misconceptions that children may encounter as they gain proficiency in an understanding of $a \div b$ as b equal-sized parts of a (Confrey, Maloney, Wilson, & Nguyen, 2010). A central part of the EPLT is a description of the ways that children work to coordinate three equipartitioning criteria. When equipartitioning, students must (1) create the correct number of groups or parts, (2) create equal-sized groups or parts, and (3) exhaust the whole or collection. The EPLT outlines how different parameters, such as the number of parts created (e.g. repeated halving is easier than creating odd numbers of parts) or the type of whole (collections, a single whole, or multiple wholes) affect the level of difficulty of instructional tasks.

Twenty hours of professional development on the EPLT was designed for elementary teachers. In five 2-hour after-school sessions, teachers studied the EPLT as well as engaged in instructional practices focused on elucidating, understanding, and using student thinking in instruction. These practices included observing and conducting clinical interviews with students, selecting and adapting instructional tasks, and analyzing students' written work. The remaining ten hours involved classroom-based activities with students pertaining to these practices (Wilson, 2009).

Thirty-three K-2 teachers from two rural schools in the southeast participated in the study: 11 Kindergarten, 11 First Grade, and 11 Second Grade. Of these 33 participating teachers, 88% received undergraduate training in elementary education and 24% held a master's degree in education. Their average number of undergraduate credit hours was 6.4 hours in mathematics (SD = 4.1 hours) and 4.4 in mathematics methods courses (*SD* = 2.1 hours). Six of the participating teachers were currently enrolled in a graduate program in elementary education. Two of the teachers were certified by the National Board of Professional Teaching Standards in Elementary Education. On average, the teachers had 12.0 years of experience (*SD* = 7.2 year), 9.2 of which were with students in grades K-2 (*SD* = 5.8 years). Upon completion of the professional development, participants earned two continuing education units toward license renewal.

Primary data sources for this investigation are three activities from the professional development. In the Session III Student Work Analysis activity, grade-level groups of teachers analyzed various hypothetical written work samples from students engaged in fairly sharing circles and rectangles among various numbers of people. They were guided by a series of questions about what the students may know or not know about equipartitioning, what kinds of feedback they would provide to the student, and what next instructional moves they might take with the student. Later in the professional development, teachers met in cross-grade groups during their final meeting (Session V) to analyze two samples of written work from a Kindergartener, Emma, who had fairly shared a circle among three and four people. Their discussions were guided by questions similar to those in the previous written work analysis activity. The third source was an Interview Analysis activity that immediately followed the Session V Student Work Analysis activity. Teachers viewed a clinical interview of Emma fairly sharing rectangles and circles among two, four, three, and six people. Before each task, the recording was paused and teachers anticipated how they believed Emma would complete the next task. After viewing the episode, the recording was again paused while teachers summarized what they believed Emma knew about fair sharing and predicted her approach for the next task.

Participants' written responses to the three activities served as data for the analysis. In addition, video and audio recordings of each of the three activities were viewed to identify critical moments (Powell, Francisco, & Maher, 2002) for transcription. Written responses and the transcripts were coded for teachers' observations, interpretations, and conjectured responses. Analysis was conducted using the constant comparison method (Glaser, 1992), allowing for the identification and distillation of patterns within each of these categories.

Results

Observation

An analysis of the instances of observation indicates that experience with the EPLT during the professional development *sensitized* teachers to students' behaviors and verbalizations that were indicative of particular approaches to instructional tasks. In the Session V Student Work Analysis activity for example, the work samples had been inscribed by the student with "1 = 3" on each unequal-sized part when using vertical lines to share among three people and "1 = 4" on each fourth when sharing among four. Some of the teacher groups noticed this inscription and rather than dismissing it as mathematically incorrect, the teachers used this as evidence to further refine their understanding of Emma's thinking about equipartitioning. As one teacher in a group stated, "I think she's trying to say one of the four instead..." The teacher's comment may indicate that she believed that Emma was attempting to meet the three equipartitioning criteria by exhausting the whole and making the correct number of equal-sized parts as described by the EPLT.

Also, the teachers were sensitive to students' verbalizations. Recall that the interview viewed by teachers depicted Emma creating written work for sharing among three that the teachers had just examined. During the Interview Analysis activity, many of the teachers commented on Emma's utterance, "it's bigger than you think," believing that this indicated Emma's understanding of the need for equal-sized parts when sharing among three but her inability to create them on a circle. Drawing on their understanding of the three equipartitioning criteria and the task parameters, one teacher stated, "Odds, such as three, seem to be more difficult and circles seem more difficult than squares. She knew it was thirds, so she understood parts, but she didn't know how to get them equal. Saying 'it is bigger than you think' implies she knew it [one of the parts] wasn't big enough." With the EPLT as a model of student cognition, the teachers were sensitive to evidence in students' work and words when observing students and analyzing written work.

Interpretation

The data also suggest that teachers were able to *locate* a particular student's understanding within a range of understanding described by the EPLT. They used their knowledge of the trajectory to describe the ideas a student was likely to already understand and which ideas were likely to develop next. For example in the Interview Analysis activity, when asked to anticipate how Emma would share a rectangular cake among three people, one teacher recalled the increasing difficulty of splits from the EPLT and stated, "The student is not sure how to divide the cake to make equal parts when there are an odd number of pieces. She understands how to divide the cake if it cut into an even number of pieces." The teacher used the EPLT as a model of how students progressed through increasingly difficult equipartitioning tasks together with her observations to locate Emma's understanding within this range.

In the Session III Student Work Analysis activity, a group of Kindergarten teachers considered a sample of student work on equipartitioning a circle into three parts. They discussed:

T1: The student was asked to share a key lime pie among three people. What do you think the student understands?

T2: They understand a half - they started with the half. They knew they had to have three pieces… so they halved the other one, so…

T3: The evidence is they had a line down the middle. And they have another line to create three pieces.

T1: [writing] "…has a diameter cut and another cut."

T3: What do you think the student does not understand?

T2: Equal parts.

T1: He doesn't understand how to cut a circle into thirds.

The teachers establish that the student can halve and that he or she may understand that there needs to be a one-to-one correspondence between the number of pieces created and the number of people sharing the cakes but is still in the process of coordinating the three equipartitioning criteria when creating thirds. In these and other examples, teachers used the EPLT when interpreting evidence to situate a students' conception in terms of what the student was likely to already know and what the student might learn next.

Response

Suggesting next moves. In many instances, teachers were able to make decisions about their next instructional steps based on their location of student's conceptions along the EPLT. One type of instructional decision involved altering the parameters of a task, such as changing the shape from a circle to a rectangle in order to focus the student on creating a particular number of equal-sized parts. For instance in the Interview Analysis activity, teachers were asked what they would do next with Emma after she did not create equal-sized pieces when sharing a circular cake among three. One teacher wrote, "I would work on fair sharing from the stand point of equal. I would show Emma how to divide for a square, rectangle, then circles." Another teacher suggested, "…have her practice sharing with three and six people – she would catch on to this quickly. She needs other ways to share than just halving."

Similarly in the Session III Student Work Analysis activity, teachers were asked what they would do next with the student based on the work sample. Some of the groups of teachers suggested changing from a circle to a rectangle as their next move or changing the number of people sharing from six to four to decrease the difficulty of the task. For example, when suggesting next moves for the student whose work indicated that he or she made four equidistant cuts on a rectangle (creating five parts) while attempting to share among four people, one group discussed:

> T1: Well, you could ask, "do you have four pieces?" He's going to say, 'No, you have five,' and then…
>
> T1: What are you going to do about that last piece? How are you going to make it equal? How will you divide it fairly?
>
> T2: That kind of answers the next question, too.
>
> T3: What will you do next with the student? Let them eat cake.
>
> T3: Would you? Give him a new cake? Or slab of play dough or whatever
>
> T2: And say try again and see if you can divide this, all of the cake, between four people without a left over piece.

Other teachers suggested revisiting previous proficiency levels of the EPLT when planning follow-up activities. During the Interview Analysis activity, one teacher recommended, "Go back to sharing cookies, gold, etc. [collections] with 3 people." Similarly, another teacher wrote, "I would give her objects like counters and ask her to fair share among different numbers of people." Here, the teachers were recommending that the next instructional task for the student should be aligned with a lower proficiency level of the EPLT. As a model for thinking and learning, the EPLT not only assisted teachers in observing and interpreting but also suggested instructional steps to move a student from their current understanding to the next as described by the trajectory.

Predictability. Also based on how they located a student's understanding along the trajectory, teachers were able to anticipate what evidence they might see within the student's actions, work, or words on subsequent tasks. That is, the EPLT allowed teachers to make predictions as to how a student might approach a new task. For instance, after each segment of the video recording of the Interview Analysis activity, teachers were asked to predict how Emma would solve more difficult equipartitioning tasks, and many of the teachers suggested strategies described by the trajectory; in particular, creating six equal-sized parts of a circle tends to be less difficult than creating three (Confrey et al., 2010). After viewing a clip of Emma unable to share a rectangular cake fairly among three, one teacher wrote, "I believe Emma will be able to share among six people based on the attempts for three. She begins with cuts in half which makes her chances better since six is an even number." Later, after viewing segments of Emma's attempts at sharing a rectangular cake among three, six, and at sharing a circular cake among three, another teacher predicted this about Emma's sharing of a circular cake for six:

> She will cut the cake in half diagonally and then again to create 4 parts. She will then draw a line through the middle to make unequal-sized parts. I think she'll do this because she sees things in halves and only makes cuts that result in halving the section. Emma will make a diagonal cut through the cake and will probably cut though the mid-line again to make six sections. If she can't make six sections (on a rectangle), she probably won't be able to do six (on a circle).

In both examples, the teachers used their observations and interpretations in relation to the ELPT to anticipate the way that Emma would approach the next task. Thus, the sensitivity and ability to locate a student's understanding within the EPLT afforded by the model of cognition also provided teachers with the ability to predict of how students would engage in a task. In turn, these anticipations would likely sensitize teachers to evidence of understanding on subsequent tasks.

Discussion

One promise of learning trajectories for teachers is the "ability to respond appropriately to evidence of their students' differing stages of progress by adapting their instruction to what each student needs in order to stay on track and make progress toward the ultimate learning goals" (Corcoran et al., 2009, p. 19). In this paper, an LT was taken as a model for student cognition and learning using the Assessment Triangle framework to investigate teachers' observations and interpretations of evidence as well as the ways in which they might adapt instruction as a result. As depicted in Figure 2, LTs may sensitize teachers to evidence of particular ways of thinking within a domain of knowledge and assist them in locating a student's understanding within a range of conceptual development through informing their interpretations of evidence. Additionally, these "models" of student thinking (Wilson, Mojica, & Confrey, 2010) inform teachers' instructional adaptations in response to evidence. Two ways that this might happen that are indicated by this study include: (1) the suggestion of targets for subsequent instructional activities believed to help the student move along the trajectory; and (2) the ability to predict a student's approach to a task, supporting the anticipation of more evidence for assessing a student's understanding. Thus, this paper offers an elaboration of the Observation and Interpretation vertices when an LT is taken as the Cognition vertex. Observations are enhanced as the LT brings sensitivity to evidence. Interpretations are informed by the LT in a way that locates a conception along a progression of growing understanding. Moreover, the findings begin to specify what it means to respond to evidence with knowledge of an LT.

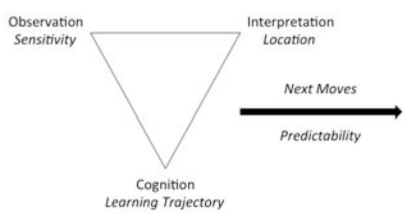

Figure 19. Results in relation to the Assessment Triangle (NRC, 2001).

Classroom assessment, the focus of the teachers' learning activities in this study, when used to guide instruction is one type of formative assessment, a practice widely accepted as a means of increasing student achievement (Black & Wiliam, 1998). In *Learning Progressions: Supporting Instruction and Formative Assessment*, Heritage (2008) describes eliciting evidence as one of several elements of formative assessment for which LTs are "foundational." She states, "When formative assessments arise spontaneously in the course of a lesson, interpretations of how learning is evolving can be made based on the trajectory of learning represented in the progression" (p. 6). This study offers a look at the classroom assessment practices of student observation and analysis of written work as two examples of "spontaneous" formative assessment and describes the role that an LT may play in reasoning about how student learning is progressing based on evidence.

LESSON PLANNING INFLUENCES: TESTING AS A MEDIATING ASPECT

Julie M. Amador
Indiana University
jamador@indiana.edu

Teruni Lamberg
University of Nevada, Reno
terunil@unr.edu

This study investigates how teachers plan lessons and what mediates their lesson planning and ultimately how they teach. Four elementary teachers were observed planning and teaching elementary lessons. In addition, they were interviewed during this process. The findings revealed that standardized testing strongly influenced the lesson planning process and even the teaching style. Three teachers focused on teaching skills and algorithms for the test, as opposed to teaching for conceptual understanding. In this paper, we propose a theory that teachers followed a testing trajectory as opposed to learning or teaching trajectory.

Background

Lesson planning is a component of the cyclical process of teaching (Carlson & Bloom, 2005) that occurs when teachers make decisions about what they will teach and how they will go about delivering the lesson content (John, 2006). This process allows teachers to make decisions about future learning based on past student performance, with the intention of promoting student achievement (Bage et al., 1999). To plan effective lessons, teachers should take time and think about their learning goals and outcomes for students (Morris, Hiebert, & Spitzer, 2009). The process of planning lessons is a key component to delivering effective lessons; however, limited research exists on this topic. As a result, it is important to thoroughly analyze the lesson planning process to gain an understanding of teacher planning practices and to understand how teachers use lesson plans as they teach.

Theoretical Perspectives

The purpose of lesson planning is to support the learning of children (Bage, Grosvenor, & Williams, 1999). Teachers should design lessons that will help students achieve learning goals by utilizing their knowledge of content and pedagogy (Panasuk & Todd, 2005; Morris et al., 2009; Simon, 1995). In the process of designing lessons, teachers decide what will happen during their teaching and they make instructional decisions that influence the lesson that takes place (Bumen, 2007; Gilbert & Musu, 2008; John, 2006; Panasuk & Todd, 2005). All of the decisions teachers make during the lesson planning process have the potential to affect the student learning that takes place in the classroom (Borko, Shavelson, & Stern, 1981). When teachers consider elements of effective teaching strategies as part of the lesson planning process student learning is increased (John, 2006).

Teachers may consider a multitude of issues when planning lessons, but often influences beyond the teacher's control play a role in shaping the lessons that are planned (Regis, 2008; Shavelson & Stern, 1981). These influences can originate at the national or state level; however, many of the influences that affect day-to-day planning are due to decisions made at the district or school level. As a result, teachers' original ideas are influenced by constraints and affordances, often beyond their control. As a result, understanding how teachers plan, the influences they encounter, and why they make specific decisions, provides insight into how lessons are constructed.

This information is important for teacher preparation programs and for administrators seeking to assist teachers in improving student learning. Additionally, this information is important for future student achievement because lesson planning is related to the learning that takes place (Panasuk & Todd, 2005).

Educators should understand how teachers are planning elementary mathematics lessons to know the affordances and constraints in the planning process, and to understand how teachers' considerations are shaping elementary mathematics lesson plans. Additionally, because lesson plans serve as a guide for teaching (Shavelson & Stern, 1981) and teaching influences learning (Franke et al., 2007), it is important to understand how teachers are making decisions in this process. As a result, this study addresses the following question related to lesson planning:

5. How do elementary teachers plan mathematics lessons?

Method

A multiple-case design of case study (Yin, 2009) was used to explain how four, fourth-grade teachers from the same school made decisions in the lesson planning process, why they made these decisions, and to discover the mediating influences of these decisions. This approach allowed for an in-depth study of the participants, their institutional contexts, and their practices. Case study was utilized to optimize the understanding of the situation by providing data to answer the specific research questions (Stake, 2005). The teachers worked at a school that had made Adequate Yearly Progress (AYP), according to state standardized tests, in mathematics for the past three consecutive years. The school district had adopted Everyday Math as the curriculum of use seven years prior to the study. Of the four teachers in the study, Amie was a first year teacher and Bonnie, Carla, and Dana had each been teaching for about twelve years.

Data was collected through interviews, written lesson plans, direct observation, and physical artifacts. All audio recordings were transcribed and data was analyzed using a grounded theory approach with the purpose of describing the practices of teachers and adding to the theory related to the topic (Corbin & Strauss, 2008).

Results

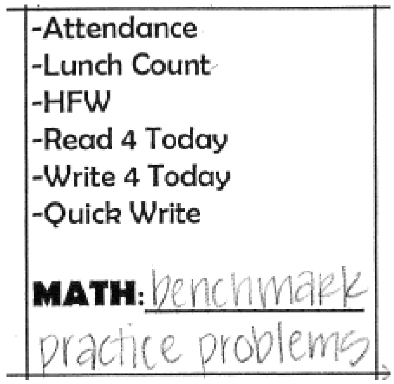
Even though the data for this analysis was collected during the end of the school year after the high stakes state CRT test, teachers continued to consider the high stakes assessments throughout their planning practices. In addition to the state mandated CRT examinations, students in the district where the data was collected annually took three District Benchmark Examinations, often referred to as "Benchmarks." The Benchmark tests were intended as formative assessments for teachers. However, the teachers viewed these exams as a summative assessment. The results from these examinations were entered into data analysis software and administrators and teachers were able to analyze results based on individual teacher, individual student, individual standard, or question type. The CRT and the Benchmarks tests influenced planning and teaching in the ways described below.

District Level Influences

The school district influenced the lesson planning process by publishing district-wide Benchmark assessments, adopting specific curricula, promoting the use of state standards in mathematics, and allocating resources.

Amie

Amie planned lessons to help students do well on the district Benchmark test, by planning to teach content that would be on the district Benchmark test. Her written lesson plan is evidence of this action (see Figure 1).



-Attendance
-Lunch Count
-HFW
-Read 4 Today
-Write 4 Today
-Quick Write

MATH: benchmark practice problems

Figure 1: Amie's written lesson plan for test preparation.

Amie devoted entire lessons to practicing problems similar to the questions that would be asked on the tests.

Carla

Carla was influenced by district standards as she worked to prepare students for the state test. When lesson planning, she focused on the district standards because the content in the standards was the content that would be tested. She was asked about lesson planning influences in mathematics.

> Researcher: District and state and national standards and policies?
>
> Carla: Uh, the, well, the standards, based on the fact that the kids are tested on the standards. So, I do, again, in long-range planning, make sure that those skills, I have covered in the classroom and that they will be tested on them.

Carla considered the standards as a set of skills that must be taught because the students would be tested on the standards. Therefore, the district standards mediated Carla's decision making while planning because she recognized that the plans she made should be based on the skills students would need for the tests.

The planning practices of all of the teachers were influenced by the district adopted standards in mathematics. These standards were used to write the district level Benchmark assessments and teachers were incorporating considerations for these tests into their planning. As a result, decisions made at the district level regarding standards and testing influenced teacher lesson planning.

Levels of Planning and Sequencing

The teachers used the Benchmark to guide their planning on a yearly level, so they were sequencing lessons over the course of a year based on the Benchmark topics. There were three Benchmark exams, so the teachers would spend the first third of the year teaching the content that was on the first Benchmark exam. They spent the second portion of the year teaching content that would be tested on the second Benchmark and the third portion of the year was spent teaching the content that would be on the third Benchmark exam. As a result, the test content determined how teachers planned on a yearly and daily level because the teachers were continually referencing the Benchmarks to determine the sequencing of mathematical topics within the context of the school year.

Carla

Carla looked at specific test questions and made lesson plans that aligned with the specific questions that would be asked, as opposed to following the Everyday Math curriculum.

> Researcher: Okay. How do you determine what in Everyday Math you are going to use or not use?
>
> Carla: Mmm, hmm. I (pause), umm, one, I look to see if it is even an idea that I like. For example, you know, finding the area of your skin. I, forget that. I am just like, "What are you freaking kidding me?" Because that's like, that activity is not how they test area on the test. They need to know the basic formula of a square or a rectangle to do that. So, activities like that, I am like, we, they take so long first of all. We don't have the time to be wasting on an activity that is not relevant to what we are going to be looked upon. Umm, so that's part of it. And, some of it, if it's, yeah, if it's just not what I would consider a worth-while activity—it is going to take forever, I can't see how the activity is going to relate to something that they are going to be tested on, then, it's uh, no. I don't do it. I know it probably develops that higher level thinking, but counting boxes on your hand is, I just, you know, or you measure the distance around your head. And, I know they are trying to get that manipulative, like get up and move, but it's, it's not, it's not worthwhile. It is not worthwhile. You know, there are four lessons in that fourth grade book on compasses. Well, you know, I throw that out as kind of like a center activity. Why am I going to waste four days on compasses when compasses does me no good anywhere else in the whole year?

Carla focused on the exact skills students would need for the test. As a result, when the reformed curriculum included a lesson to build conceptual understanding by measuring area of skin, Carla did not teach the lesson because fourth graders "only have to find the area of rectangles and squares on the state test." She made this decision even though she knew the lesson "develops that higher level thinking" because she considered whether or not the lessons seemed "worthwhile" as they related to the test. Therefore, the CRT examination and Benchmark examinations mediated Carla's curriculum decisions.

Dana

The Benchmark assessments influenced how Dana planned the order of mathematical topics she would teach. She considered the order in which the standards would be tested on the Benchmark Examinations and follow the Everyday Math order for those tested topics.

> Researcher: And how do you determine the exact content of the lesson you will teach?
>
> Dana: The standards. Yeah. I will pull….
>
> Researcher: Is there any specific order?
>
> Dana: I try to follow the standards as they are in the Everyday Math because they follow the Benchmark, the test that the kids take once every trimester, so I do try to stay, umm, up to whatever the standards are in the order they are presented in those tests.

Dana viewed the Benchmark as containing material that was in the standards, and she determined content based on the standards. Therefore, she referenced the Benchmark assessments to determine the order she would follow when sequencing lessons.

Curriculum Use

After the original adoption of Everyday Math, the teachers reported that they used the curriculum with fidelity; however, seven years after the adoption, the teachers were heavily supplementing, replicating lessons from others, and inventing lessons to attempt to have to their students do well on standardized tests. The CRT and Benchmark examinations mediated curriculum use because teachers only taught curriculum content that was tested because they wanted students to do well on the test. Therefore, material in Everyday Math was taught if it aligned with the testing standards. Furthermore, the teachers' desire for students to master test content mediated curriculum use because the teachers would repeat the content of a lesson until students had reached mastery, thus disregarding curricular pacing to continue with subsequent lessons.

Bonnie

Bonnie's fourth grade lesson planning was mediated by the fifth grade teachers' preference for teaching traditional algorithms, so that students would not be confused by multiple solution strategies. The fifth grade teachers at the school requested that Bonnie, a fourth grade teacher, teach traditional algorithms to her students, even though the district adopted Everyday Math taught multiple ways to solve problems, such as the lattice and partial quotients approach.

Researcher: Do you work with anyone when you plan your lessons?

Bonnie: Usually no. I mean sometimes we will discuss what we are doing with math. There was a big thing a couple of years ago where the fifth grade teachers were getting frustrated because the kids were going to them using lattice and like partial quotients and the varying algorithms that are taught in the Everyday Math program and that is not what our fifth grade teachers are teaching them, so the kids have no idea, as to, you know what they were talking about and weren't prepared when they were going there. So, there was kind of a consensus between fourth and fifth grade a couple years ago that we would teach them the traditional methods of multiplication and division as opposed to the other. Now, I know there are a couple teachers who still might teach the partial quotients, but I don't think anybody is still teaching the lattice. But, we try to, we try to listen to what fifth grade needs, as far as what they need to have, you know what their students need to be able to do, and be prepared for coming into fifth grade and we kind of do the same thing for coming into third grade. You know, as far as what those students, what we expect of them when they are coming in to fourth grade. Although, you know, that is not always you know, happening, so….(laughs).

The fifth grade teachers requested that Bonnie discontinue teaching multiple methods for multiplication and division, so that the students would be familiar with the traditional algorithms when they moved up to fifth grade. These teachers were focused on students getting correct answers, as opposed to helping student understand various mathematical processes. As a result, Bonnie reduced the conceptual focus of multiplication and division lessons by eliminating curriculum components at the request of the vertical grade level teachers. She disregarded the reformed curricula and chose to teach traditional algorithms for solving problems so that students would be procedurally sufficient at algorithm use for testing.

Dana

Dana planned for a teaching sequence that would take students from the use of a manipulative to demonstrate a procedure to more abstract representations of the procedure through the use of paper and pencil, while basing her yearly plan on the Benchmark examinations. Dana's knowledge regarding concrete and abstract learning influenced her planning because she considered the sequence of lessons for students along the concrete to abstract continuum.

Researcher: Okay, can you describe what you are teaching today?

Dana: Yep. So, today, moving from, I am taking the area from that irregular object, being their hand print, moving toward the formulas of the squares and the rectangles, and I will show them a model of a square foot, a square inch and a square centimeter and then we will

> pull in different, as a modeling, pull in different sized things to show them which would be the best thing to use for each item. Should we use the square foot for this? Should we use the square inch for this or the centimeter? And then show them, and then I will have lots of square inches cut up and take like a textbook and show them. Well, we can measure that with square inches and then lay them all out and show them how cumbersome that is and how long that takes and then try to guide them toward what would be a better way to do that, a faster way to do that, and then lead them into the measurement and then they will break up into partners again and then go out and measure the area of different squares and rectangles that they find in the classroom.

Dana considered how she would take students from the concrete representation of square manipulatives to determine area, and lead them to constructing the algorithm for area. Her purpose with using the squares was to make the point that finding the area with manipulatives is *cumbersome* and that the algorithm should be used instead. Consequently, the model she used was not conceptually based, but was focused on demonstrating the need for an algorithm to find the area. Dana's conceptualization of taking students from concrete to abstract was a focus on concrete representations that lead to memorized algorithm use, resulting in a skill focus for the context.

On a daily level, Carla and Dana acknowledged the learning process of taking students from manipulative use to paper and pencil practice, so they utilized this focus to sequence their lessons within a topic. However, their purpose of using this format was to lead students to the use of a specific algorithm to solve their problems, so that students would be proficient with skills when tested. The concrete representation was not viewed as a tool for building conceptual understanding, but was rather used to show students how "cumbersome" a model can be, which encouraged students to disregard the model and place their emphasis on the correct algorithm.

The teachers' use of the Everyday Mathematics curriculum decreased over the prior seven years and had been replaced with the incorporation of multiple supplemental materials that the teachers considered to align with the standards and would prepare students for tests. These replacement materials focused on skill mastery through repetitive practice of similar problem types. Bonnie disregarded the suggested use of Everyday Math altogether and incorporated a text that was not reformed based and focused on mastery. The changes the teachers made prioritized skill practice over conceptual understanding and all content was determined and sequenced based on testing content.

Discussion

The institutional context afforded a heightened emphasis on proficient test scores over the past several years. Specifically, in the state where the study took place, administrative pressure focused on increasing student achievement on the CRT examinations. The school district where the study took place published Benchmark examinations that teachers considered to be guidelines for how students would perform on the CRT examinations. As a result, the context of the study gave rise to teacher pressure for students to achieve high scores on both the Benchmarks and CRT examinations.

Due to the testing pressure, the teachers adjusted their teaching practices in an effort to improve student achievement. When reflecting on their individual teaching practices, and their students' achievement, the teachers believed that the adopted curriculum was not meeting the testing demands because a lack of focus on mastery. As a result, the teachers only taught pertinent curricula components, specifically content related to what would be tested. The teachers influenced student learning by focusing on specific curricula components over other curricula components (Remillard, 2005). In this study, teachers completely disregarded curricula components that they considered to be irrelevant for the standardized testing. Even though curricula guides what teachers teach (Remillard, 2005), the testing pressure on the teachers was so extensive that the teachers began to slowly eliminate all use of the adopted curricula.

While the changes in testing emphasis were taking place, teachers were faced with new demands they had not experienced in the past. Throughout this time, the teachers did not have district or school support focusing on using the Everyday Math curriculum to meet the testing demands. The only professional development on the curriculum had been conducted seven years prior, when the curriculum was purchased. As a result, the teachers were not confident in the ability of the curricula to meet the recent testing demands. Therefore, the teachers began using supplements for the majority of their lessons and they relied very little on the adopted Everyday Math curriculum. The elimination of the curriculum brought with it an increased emphasis on skill mastery. The teachers sought to incorporate curricular materials that would prepare students for testing by exposing them to repeated practice of skills that would be necessary for testing.

The supplements the teachers decided to use were focused on skill and practice through repetitive algorithm use. The teachers began using test preparatory practice in their lessons and taught lessons that were based solely on test content. Supplements became the main source of lesson content because teachers considered supplemental programs to better prepare students for the high stakes tests.

All four teachers in the study made decisions when planning that they believed would be the most beneficial for supporting student achievement. They were faced with challenges, such as preparing students for testing, and were forced to make decisions about what they would teach. These challenges were a result of the institutional context (Cobb et al., 2003) that fostered an environment with an emphasis on testing and student achievement on the tests. As a result, the teachers made the decisions they considered would be the most beneficial for the students and worked to prepare students for the assessments. The lesson planning that occurred was a result of the compensation and considerations the teachers made within the institutional context where they taught. These teachers were following a testing trajectory and making decisions based on the examinations, as opposed to following a learning trajectory (Simon, 1995).

Implications

This study highlights the need for professional development to support teaching for conceptual understanding. This means that teachers need to be familiarized with teaching concepts and need specific direction on how to teach for conceptual understanding. Likewise, it is important that teachers understand the benefits of making connections for students between and among concepts (Bransford et al., 2000) with the intention of forming links in student learning.

Additionally, it is important for teachers to understand how to use their curricula to meet the learning goals they have for students. Teachers with reformed curricula need support beyond the initial implementation of the curricula. Furthermore, when faced with changes in the institutional context, such as a heightened testing awareness, it is imperative that administrators are cognizant of the changes and provide teachers with support.

Finally, the study indicates a need for teacher support to prepare students for testing. The teachers made accommodations they considered would be helpful, but they did not have direction or support when making changes. As a result, preservice teachers should be familiarized with the pressures they will face when teaching and should be provided with support so when they begin teaching they are prepared to face the testing challenges. Practicing teachers also need support with how to prepare students for the examinations. This support should not be focused on skill and practice, but should instead highlight the importance of teaching for conceptual understanding.

TOWARD THE IDENTIFICATION OF MATHEMATICAL HORIZON KNOWLEDGE OF PLACE VALUE CONCEPTS

Chantel C. Blackburn
University of Arizona
cblackburn@math.arizona.edu

Horizon knowledge is still a relatively new and unexplored domain of mathematical knowledge for teaching. In preparation for an empirical study to take place in February and March of 2011, this paper will analyze research on student learning and teacher education to identify potential horizon knowledge as it relates to place value concepts.

Introduction

In the 1980s, Lee Schulman (1986) proposed a theoretical framework for conceptualizing the kind of knowledge needed for the practice of teaching. It has not been until the past decade, however, that researchers have empirically observed and designed measures to identify this kind of knowledge in teachers of mathematics (Ball, Thames, & Phelps, 2008). Ball et al. (2008) have identified six domains of subject matter and pedagogical content knowledge that accommodate a wide range of specialized *mathematical knowledge for teaching* (MKT). In their work to refine Schulman's framework for use in mathematics, Ball and colleagues provisionally included a category of *subject matter knowledge* (SMK) specific to the practice of teaching called *horizon knowledge*, that is neither common nor specialized mathematical knowledge (Ball et al., 2008; Ball & Bass, 2009).

At the present time, many important issues regarding horizon knowledge have yet to be addressed by the mathematics education research community (Ball & Bass, 2009). The purpose of this article is to contribute to both the emerging conceptualization of horizon knowledge and the development of a conceptual framework that will support an empirical study of horizon knowledge, specifically as it relates to place value concepts.

Theoretical Framework

Research supports the claim that possession of mathematical knowledge is a fundamental part of MKT (e.g., Ma, 1999). In her study of primary teachers' knowledge of elementary school level mathematics, Ma (1999) described and identified SMK called *profound understanding of fundamental mathematics* (PUFM). She concluded that the elementary teachers in her study possessing PUFM had developed it over the course of their teaching practice and that it was only present in teachers with substantial teaching experience. However, the development of this kind of knowledge does not occur easily nor does it necessarily happen at all, even in the presence of experience (Ball, 1990; Ball & Bass, 2000; Ma, 1999). How to measure and develop this knowledge in teachers, therefore, remains a significant challenge for researchers and educators.

In some cases, especially in studies using the number of university courses taken as a proxy for mathematical knowledge, advanced mathematical knowledge may not even have a significant effect on teaching knowledge (Fennema & Franke, 1992; Huang, Li, Kulm, & Willson, 2010). Only relatively recently have changes in methodology have allowed researchers to observe that teachers' mathematical knowledge does impact pedagogical decisions and by extension, must impact learning, although direct connections between teaching and learning remain unclear (Fennema & Franke, 1992, 149; Fuson et al., 1997).

The framework developed by Ball et al. (2008) has made a significant contribution to our conceptualization of MKT because it emphasizes knowledge of pedagogy, a component of teaching knowledge elevated by Schulman in the 1980s, in addition to SMK. Through empirical observations, Ball et al. (2008) have identified six domains of subject matter and pedagogical content knowledge. Five of these domains, horizon content knowledge, specialized content knowledge, knowledge of content and students, knowledge of content and teaching, and knowledge of content and curriculum, are specific to the practice of teaching while the sixth domain of MKT, common content knowledge, describes mathematical knowledge that is not unique to the practice of teaching but may be used in a variety of professional and/or nonprofessional settings (Ball et al., 2008).

Critics have argued that the MKT framework proposed by Ball and et al. (2008) ignores global mathematical knowledge in favor of isolated content knowledge (Clay, Silverman, & Fischer, 2010). At the time they proposed their framework, however, Ball and colleagues provisionally included a category of SMK specific to the practice of teaching, called horizon knowledge, which they described as "an awareness of how mathematical topics are related over the span of mathematics included in the curriculum" (Ball et al., p. 403). According to Ball and Bass (2009) their most recent conception of horizon knowledge has four constituent elements:

1) A sense of the mathematical environment surrounding the current "location" in instruction.
2) Major disciplinary ideas and structures
3) Key mathematical practices
4) Core mathematical values and sensibilities.

Although horizon knowledge is purely a mathematical domain of MKT, in practice, it is likely to have a significant influence on pedagogical decisions (Ball, 1993; Ball & Bass, 2009; Ball et al., 2008). As a result, no one is sure "how far out or in what direction the pedagogically relevant and useful horizon extends," nor does anyone "know how horizon knowledge can be helpfully acquired and developed" or "have ways to assess or measure it" (Ball & Bass, 2009). The goal of the study presented here, therefore, is to examine the extent to which available research on teaching and learning can guide researchers' conceptualizations of horizon knowledge and then utilize these conceptualizations to measure teacher knowledge.

In particular, a wealth of research on student learning, in addition to recent work on conceptions of prospective teachers, suggests that the area of place value is an important context in which to explore and define horizon knowledge and its pedagogical relevance (Baroody, 1990; Hiebert & Wearne, 1992; Mills & Thanheiser, 2010; Stacey et al., 2001; Thanheiser, 2009). Place value concepts arise in a variety of topics in the K-8 curriculum including reading and writing numbers, rounding and estimation, addition and subtraction of natural numbers, standard algorithms for the four operations, ordering numbers, representations of rational numbers, and scientific notation. Further, place value knowledge is also fairly difficult to construct and takes place over an extended period of time (Kamii, 1986).

Because our notational system is the product of social conventions and logico-mathematical knowledge (the construction of mental relationships), children cannot discover place value concepts (Kamii, 1986; Verschaffel, Greer, DeCorte, 2007). Place value refers to a system of notation in which the relative positions of the symbols is used to encode the value of a number. In the decimal place value system, the value of a numeral is given by the sum of the value of the individual digits; the value of each digit given by the product of its face value with its place value. The symbols 0-9 and the words zero, one, two, … used to represent numbers are social conventions. Similarly, by convention it is determined that the value of each column increases from right to left and adjacent positions are related by ten-for-one trades. Fractional values are represented to the right of the decimal. Making sense of place value notation requires constructing mental relationships such as connecting the column position of a numeral with its value (Kamii, 1986).

Research shows that constructing these mental relationships can be difficult for both children and preservice teachers (e.g. Thanheiser, 2009; Kamii, 1986) Many of these difficulties arise as a consequence of forming a strong unitary conception of number without developing a multi-unit one such as evidenced by a failure to differentiate between the complete value of a number and face value of the digits (Fuson, 1990; Varelas & Becker, 1997). For example, often both children and preservice teachers, while capable of identifying that 16 represents 16 ones, will also indicate that the 1 in the numeral 16 represents 1 one instead of 10 (or 1 ten) (Hiebert & Wearne, 1992; Kamii, 1986; Resnick et al., 1989; Thanheiser, 2009).

In contrast, a multiunit conception would allow for simultaneously viewing 16 in terms of reference units such as 16 ones or 1 ten and 6 ones. Thanheiser (2009), however, found that only 20% of the preservice teachers in her study could reliably conceive of a number in terms of reference units. Further, 67% of the preservice teachers in her study displayed concatenated conceptions of number where most or all digits were conceived of in terms of ones regardless of the position of the digit. These concatenated conceptions of number also appear in research on student learning of operations. For example, expressing the sum 38 + 24 as 512 and sometimes calling the answer "fifty twelve" is a frequent and widespread error (Fuson, 1990; Hiebert, 1992; Hiebert & Wearne, 1992; Kamii, 1986).

Many researchers have suggested that the English named-value spoken system of number words makes it more difficult to learn base 10 place value concepts, especially because a majority of the English number names between 1 and 100 do not correspond directly to the written form of the number (Fuson, 1990; Fuson & Briars, 1990; Miura & Okamoto, 1989; Verschaffel, Greer, DeCorte, 2007). In contrast to verbally expressing the number 40 as "forty," for example, Asian languages would read more like "four-ten," making it more likely for a child to "construct number representations that reflect the Base 10 numeration system" (Fuson et al., 1997; Miura & Okamoto, 1989, p. 109). The irregularity of the decade names may also contribute to the tendency for American children rely on unitary conceptions of two-digit numbers (Fuson, 1990). Unitary conceptions of two-digit numbers appear to be used frequently by adults and children who may use the nonstandard language "twenty ten" to refer to the year 2010 or read 2500 as "twenty-five hundred" (Fuson, 1990).

Studies also show that decimal concepts are difficult for children and preservice teachers (e.g. Hiebert, 1992; Stacey et al., 2001). Sakur-Grisvard and Leonard (1985) found that errors occurred as children utilized three intermediate rules to compare decimals beginning with treating decimals as whole numbers (longer number is larger) and then moving on to rules that take into account the decimal point but still ignore place value. Later, Resnick et al. (1989) showed that these intermediate rules appear to have resulted as students attempted to integrate new material with their prior knowledge of whole numbers, fractions, and zero. Although the use of these intermediate rules declines with age, evidence suggests that errors involving "shorter-is-larger" conceptions may persist in preservice teachers (Stacey et al., 2001). Further, preservice teachers may be unaware of the "shorter-is-larger" conception that children may develop as a result of prior experiences with fractions (Resnick et al., 1989; Sakur-Grisvard & Leonard, 1985; Stacey et al., 2001).

According to Ball and Bass (2000), students may expect symmetry in the place value names about the decimal. However, while there *is* a naming symmetry about the ones place value position, a similar symmetry does *not* exist for value. As stated above, in our base 10 notational system, the value of each column increases from right to left and adjacent positions are related by ten-for-one trades. This is true for both whole numbers and decimal numbers. Resnick et al. (1989) found, however, that children who use whole number rules for comparing decimals (decimal with more digits is larger) also demonstrate errors related to naming symmetry. For example, for "6 tenths and 2 hundredths," children may write 0.026 or 2.6, both of which could correspond to thinking of the positions of the whole values, 6 ten*s* and 2 hundred*s* (Resnick et al., 1989). Finally, preservice teachers in the study by Stacey et al. (2001) displayed errors when comparing decimals with zero suggesting that "many preservice teachers do not understand the relationships among decimals, whole numbers, fractions, zero, and negative numbers" (p. 222).

Place value concepts develop over a long period of time and across a wide range of mathematical content. Further, studies also suggest that teachers and programs/curriculum sequences impact the kinds of strategies children utilize in problem solving (Fuson et al., 1997; Resnick et al., 1989). Therefore, pedagogically useful horizon knowledge should include mathematical connections that can be used to bridge or direct a student's current understanding toward concepts to be acquired in the future. I argue here that it is possible to both gain insight into the kinds of horizon knowledge that is pedagogically useful and devise ways to measure and assess that knowledge in teachers by studying the literature on student learning and teacher knowledge, such as explored above.

Methods

The approach I took to determine potential horizon knowledge involved two phases. In the first phase I conducted a search of the existing literature on the teaching, learning and preservice teacher conceptions of place value. To learn about preservice teacher knowledge I used the recent work by Thanheiser (2009), Mills (Mills & Thanheiser, 2010), and Stacey et al. (2001) who have examined preservice teacher knowledge related to place value and decimals. To locate work on teaching and student learning of place value I used Google Scholar and educational databases such as ERIC to search for keywords, for example "place value" and "place value decimal." Additional works were obtained by repeatedly examining and obtaining literature found in the reference lists and citations within the papers I already possessed, beginning with the above works on preservice teacher knowledge and the results of the database searches.

The second phase involved a mathematical analysis of the literature obtained regarding the teaching and learning of place value concepts. I began by narrowing the literature to areas in which the conceptions of place value for preservice teachers and students were well documented, as outlined in the literature review above. I then analyzed these conceptions for mathematical connections in an effort to determine horizon knowledge that had a potential to impact pedagogical decisions regarding place value across the curriculum.

This mathematical analysis was then used as a basis to design a pilot study to be conducted in February and March of 2011. The participants of the pilot study are approximately 11 preservice teachers enrolled in a mathematics methods course for K-5 offered at a large public university in the southwestern United States. Each preservice teacher was asked to conduct one-on-one problem solving interviews with elementary school children in which the preservice teacher posed various addition/subtraction and multiplication/division problems, assessed the child's strategies, and designed and discussed ways in which they could extend and support the child's mathematical thinking. The resulting paper written by the preservice teachers will be analyzed to determine the extent to which preservice teachers display applicable horizon knowledge in their discussion. The preservice teachers will then be interviewed to further explore the extent of the mathematical connections they can identify as being pedagogically relevant to supporting and extending the mathematical thinking of the child in their interview.

Results/Discussion

In this section, I discuss some mathematical connections between whole numbers and decimal numbers that may comprise pedagogically useful horizon knowledge for place value. One potentially powerful example of horizon knowledge for place value is related to the conventions that allow for making connections between whole numbers and decimals. For example, in the verbal expression "twenty-five hundred," the 25 occupies the hundreds place and violates notational conventions because it indicates that there is more than one digit in the hundreds place value position, as in $\underline{25}00$. A similar problem presents itself if we want to write the decimal representing "one hundred twenty five thousandths" where all three digits can be thought of as occupying the thousands column, as in $0.00\underline{125}$. However, for all decimals we know that the values of each column increase from right to left. Further, each column in the standard decimal representation is related by ten-for-one trades, which is also true of the digits already comprising 25 and 125. Therefore, these conventions together tell us to trade each digit left until they occupy their own column, as in 2,500 and 0.125.

A similar example of horizon knowledge arises out of the meaning of the decimal; the values of the columns appearing to the right of the decimal are fractional. Additionally, we know that the contrapositive of the above must hold true for both whole numbers and decimals, column values decrease from left to right. If we consider 3.5%, we can view it as "three and five tenths of a hundredth." This can be represented as $0.0\underline{3.5}$ using the underline decimal notation introduced above. In this case, the hundredths represented in this decimal contains both whole and fractional parts. According to notational conventions then, we have three whole hundredths and the fractional part is traded to the right of the (original) decimal for five thousandths, giving 0.035. This concept extends naturally to numbers that are represented using decimals along with reference units, as in 12.5 million or similarly, using scientific notation as in 1.25×10^7. In the first case we have $\underline{12.5},000,000$ which has 12 whole millions in addition to a fractional 0.5 (or half) million. In the second case we have $\underline{1.25}0,000,000$ or 1 whole ten million and 25 hundredths of a ten million. In both cases, the notational conventions tell us that wholes trade with larger values to the left and fractional values trade with smaller values to the right, resulting in 12,500,000 in both cases.

The impact of a lack of horizon knowledge such as that described above is illustrated by the observations that children who displayed whole number rule errors while comparing decimals were likely to represent "two tenths and five hundredths" as 0.052 or "three hundredths" as 0.300 (Resnick et al., 1989). This may suggest that the rules utilized by the children in the study emphasized superficial features of whole numbers such as tens are positioned to the right of hundreds or the number three hundred is followed by two zeros (Resnick et al., 1989). The above examples, however, show a variety of connections that have a potential for being pedagogically powerful because they emphasize whole number concepts that are not unique to whole numbers but also carry over to decimals.

In the above examples, common fractions were not considered directly because it is often more efficient to determine a decimal representation using a division algorithm. Now I propose another potential example of horizon knowledge of place value involving connections between division algorithms, decimals, and the interpretation of whole number division as partitioning.

For example, consider 6625 ÷ 53 and 66.25 ÷ 5.3. An inefficient way to partition 6625 is to "deal out" 1 at a time into 53 groups until the 6625 is gone and then count the number of 1s in each group. A more sophisticated way to partition would be to "deal out" to each of the 53 groups 100 at a time, then 10, and so on. As a result we see that 6625 contains *1* set of 53 *hundreds*, *2* sets of 53 *tens*, and *5* sets of 53 *ones*, or 53 sets of 125. Similarly, 66.25 can be partitioned into sets of 5.3. We know that 66.25 can be partitioned into *1* set of 5.3 *tens*, *2* sets of 5.3 *ones*, and *5* sets of 5.3 *tenths*, or 5.3 sets of 12.5.

As with many computational algorithms, division can be described completely in terms of manipulations of symbols and no reference to place value. For example, computing 6625 ÷ 53 might start out like "53 goes into 6 zero times, 53 goes into 66 one time…". Further, when considered purely as symbolic manipulations, the whole number algorithm does not provide any clue as to how the algorithm must be adjusted to accommodate decimals. Instead, long division with decimals may begin by memorizing additional rules such as rewriting 66.25 ÷ 5.3 as 662.5 ÷ 53, placing the decimal in the quotient directly above the decimal in 662.5, then following the procedure for whole numbers. However, mathematical meaning lies not in the rules of symbol manipulation but in the construction of connections between the "quantities and the symbols and rules that represent them" (Hiebert, 1992, p. 297). In the example above, explicit references to place value in both whole number and decimal division illuminates the division algorithm as a sophisticated form of partitioning and eliminates additional rules used to modify whole number division for use with decimals. Therefore, it is conceivable that possession of this horizon knowledge would encourage a teaching approach that helps students construct a conceptual understanding of division of whole numbers as partitioning with respect to reference units that would support a conceptually similar concept of decimal division.

Finally, the last example of horizon knowledge that I propose here is related to the connections between place value and infinite series. Further, this knowledge can also extend to mathematical habits of mind as described by Cuoco, Goldenberg, and Mark (1996) including a disposition toward description and looking for patterns. As we considered the algorithm above, implicitly we realize that the quotient, 12.5, of 66.25 ÷ 5.3 is given by the sum 10 + 2 + 5/10. By using the division algorithm to find the decimal representation of a nonterminating decimal such as 1/3, we can easily recognize its equivalence to the infinite series 3/10 + 3/100 + 3/1000 + …. Further, this example illustrates the power decomposing numbers in various ways can create an awareness of interesting mathematical connections.

For example, solving the standard Towers of Hanoi puzzle gives another glimpse the power obtained by flexibility in the representation of numbers. The standard Towers of Hanoi puzzle uses a playing board with three pegs and n discs with increasing radii stacked on one of the pegs. The goal is to move all n discs from one peg to another, without placing a larger disc on top of a smaller one, in the least amount of moves. Table 2 shows the minimum number of moves, m, to solve the Towers of Hanoi puzzle for $n = 1,\ldots,5$ discs along with several representations of each number of moves.

n	m		
1	1	$2^1 - 1$	2^0
2	3	$2^2 - 1$	$2^0 + 2^1$
3	7	$2^3 - 1$	$2^0 + 2^1 + 2^2$
4	15	$2^4 - 1$	$2^0 + 2^1 + 2^2 + 2^3$
5	31	$2^5 - 1$	$2^0 + 2^1 + 2^2 + 2^3 + 2^4$

Table 2. Minimum number of moves, *m*, to solve Towers of Hanoi with *n* discs.

By representing the number of moves in different forms, we not only illuminate a functional relationship, $m = 2^n - 1$, between the number of moves and the number of discs but we also find that $\sum_{k=0}^{n-1} 2^k = 2^n - 1$, the closed form for the (n – 1)th partial sum of the power series $\sum_{k=0}^{\infty} 2^k$.

In conclusion, the above analysis of research on student learning and teacher knowledge suggest that place value concepts are important across the K-8 curriculum. Further, horizon knowledge of place value that appears to be pedagogically useful may extend quite far, both in terms of central mathematical ideas and practices. However, while the range of horizon knowledge is potentially vast, research on student learning can help narrow our conceptions of what may comprise the core of horizon knowledge we desire to find or develop in those involved in the teaching profession.

ELEMENTARY TEACHERS' MATHEMATICAL CONTENT KNOWLEDGE, EFFICACY, AND PROBLEM SOLVING ABILITIES IN ALTERNATIVE CERTIFICATION

Brian R. Evans
Pace University
bevans@pace.edu

The purpose of this study was to understand teachers' mathematical content knowledge, efficacy, problem solving abilities, and teacher beliefs in an elementary education mathematics methods course for special education teachers in alternative certification programs. Findings revealed a significant increase in mathematical content knowledge and teacher self-efficacy. Additionally, teachers were found to have high self-efficacy at the end of the semester and strong problem solving abilities. Further, teachers generally found that helping students with disabilities learn mathematics was the biggest issue in their teaching, and that the use of technology and manipulatives were the most important topics addressed in their learning.

The purpose of this study is to provide an understanding of teachers' mathematical content knowledge, self-efficacy beliefs, level of problem solving abilities, and teacher beliefs in an elementary education inquiry-based mathematics methods course for special education teachers in the New York City Teaching Fellows (NYCTF) and Teach for America (TFA) programs. Understanding teacher knowledge is important because it is directly related to student achievement (Hill, Rowan, & Ball, 2005). Self-efficacy is a teacher's belief in his or her ability to teach effectively and positively affect student learning outcomes (Bandura, 1986; Enochs, Smith, & Huinker, 2000), and an important component for successful teaching. Further, it is recommended that mathematics should be taught through a problem solving perspective (NCTM, 2000; Schoenfeld, 1985).

Problem solving continues to be of high importance in mathematics education (NCTM, 2000; Posamentier & Krulik, 2008; Posamentier, Smith, & Stepelman, 2006). It is one of the five National Council of Teachers of Mathematics (NCTM) standards (NCTM, 2000), and is critically important in how students best learn mathematics (Posamentier et al., 2006). The National Council of Supervisors of Mathematics (NCSM) has considered problem solving to be the principal reason for studying mathematics (NCSM, 1978).

In order to understand what problem solving is, first it must be understood the definition of a mathematical "problem." Charles and Lester (1982) defined a mathematical problem as task in which (a) The person confronting it wants or needs to find a solution; (b) The person has no readily available procedure for finding the solution; and (c) The person must make an attempt to find a solution. According to Krulik and Rudnick (1989), problem solving is a process in which an individual using previously acquired knowledge, skills, and understanding to satisfy the demands of an unfamiliar situation. Polya (1945), in his seminal work *How to Solve It*, outlined a general problem solving strategy that consisted of (a) Understanding the problem; (b) Making a plan; (c) Carrying out the plan; and (d) Looking back.

Understanding the level of elementary school mathematics teachers' problem solving abilities is critical in supporting them to teach their students from a problem solving perspective. For example, teachers are critically important in developing abstract thinking in students in the problem solving process. However, Cai (2000) has shown that sixth grade U.S. students rarely used abstract strategies in their problem solving. Strong problem solving abilities among teachers are needed if teachers are to teach mathematics well because content knowledge by itself, while being necessary, is not sufficient for good teaching (Ball, Hill, & Bass, 2005; Ma, 1999). The NCTM (2000) said, “Problem solving is not only a goal of learning mathematics but also a major means of doing so” (p. 52). If there is interest in good student problem solving, teachers need to be more than proficient in their own problem solving abilities.

The theoretical framework of this study is based upon the emphasis of the importance of content knowledge for teachers (Ball et al., 2005). Additionally it is founded on Bandura’s (1986) idea that teacher self-efficacy can be subdivided into a teacher’s belief in his or her ability to teach well, and his or her belief in a student’s capacity to learn well from the teacher. Finally, the NCTM (2000) and Schoenfeld (1985) have emphasized problem solving as a way of teaching though an emphasis on problem solving as an important process standard.

Background on New York City Teaching Fellows

The NYCTF program is an alternative certification program developed in 2000 in conjunction with The New Teacher Project and the New York City Department of Education (Boyd, Lankford, Loeb, Rockoff, & Wyckoff, 2007; NYCTF, 2008). The program goal was to recruit professionals from other fields to supply the large teacher shortages in New York City’s public schools with quality teachers. Prior to September 2003, New York State allowed for teachers to obtain temporary teaching licenses to help fill the teacher shortage. Teaching Fellows generally are recruited to teach in high needs schools throughout the city (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2006).

Background on Teach for America

TFA is a non-profit organization formed in 1990 with the intention of sending college graduates to low-income schools to make a difference for the underserved students. Its founder, Wendy Kopp, was herself a new graduate of Princeton University looking to do something more with her life after graduation (Kopp, 2003). She considered that many recent college graduates at America’s top universities would consider teaching low-income students if given the opportunity. The idea was that there should be a teachers’ corps that would allow new graduates at top universities with an interest in teaching to quickly begin teaching students in underserved communities.

Research Questions

1. What differences existed between teachers’ mathematical content knowledge before and after an elementary mathematics methods course?
2. What differences existed between teachers’ concepts of self-efficacy before and after an elementary mathematics methods course? Further, what level of self-efficacy did teachers possess at the end of the semester?
3. What level of problem solving abilities did new teachers have in an elementary mathematics methods course?
4. What were teachers’ beliefs about teaching and learning mathematics?

Methodology

The methodology of this study involved both quantitative and qualitative methods. The sample in this study consisted of 24 new teachers in the NYCTF ($N = 9$) and TFA ($N = 15$) programs. One third was male and two thirds were female. The teachers in this study were selected due to availability and thus represented a convenience sample. Participants were enrolled in an inquiry-based elementary mathematics methods course for special education teachers that involved both pedagogical and content instruction.

Teachers were given mathematics content examinations and self-efficacy questionnaires at the beginning and the end of the semester, and were given a problem solving examination at the end of the semester. The mathematics content examination consisted of 20 multiple choice items that measured knowledge of number sense, fractions, decimals, and percents (6 items); probability and statistics (4 items); measurement and geometry (5 items); and algebra (5 items), and was based on the PRAXIS mathematics examination (ETS, 2005). Possible scores ranged from zero to 20 points.

The self-efficacy questionnaire was the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI) developed by Enochs et al. (2000), and measured concepts of self-efficacy. The MTEBI was a 21-item five-point Likert scale instrument with choices of strongly agree, agree, uncertain, disagree, and strongly disagree, and was grounded in the theoretical framework of Bandura’s self-efficacy theory (1986). The MTEBI contained two subscales: Personal Mathematics Teaching Efficacy (PMTE) and Mathematics Teaching Outcome Expectancy (MTOE) with 13 and 8 items, respectively. Possible scores ranged from 13 to 65 on the PMTE, and 8 to 40 on the MTOE. The PMTE specifically measured a teacher’s self-concept of his or her ability to effectively teach mathematics. The MTOE specifically measured a teacher’s belief in his or her ability to directly affect student learning outcomes. Enochs et al. (2000) found the PMTE and MTOE had Cronbach alpha coefficients of 0.88 and 0.77, respectively.

The problem solving examination consisted of five problem solving situations as adapted from the literature (Krulik & Rudnick, 1989; NCTM, 2000; Posamentier & Krulik, 2008; Posamentier et al., 2006). It is important that students be unfamiliar with the problems because in order to be authentic problem solving students should encounter unfamiliar situations with no immediate solutions available. Each item was worth two points and possible scores ranged from zero to 10 points. Sample problems were as follows.

> A bicycle dealer just put together a shipment of two-wheel bicycles and three-wheel tricycles. He used 50 seats and 130 wheels. How many bicycles and how many tricycles did he make if he used all seats and wheels available?
>
> Jim bought a new camera that cost more than \$30 but less than \$40. He paid for the camera with \$5 bills and \$1 bills. He paid with the same number of each. What did the camera cost?

Teachers were required to keep reflective journals on their teaching and learning over the course of the semester, which provided qualitative data regarding their beliefs about teaching and learning mathematics.

Results

The first research question was answered using the mathematical content knowledge test, and data were analyzed using paired samples *t*-test (see Table 1). The results of the paired samples *t*-test revealed a statistically significant difference between pretest scores and posttest scores for the mathematics content knowledge test, and there was a large effect size.

The second research question was answered using the MTEBI with two subscales: PMTE and MTOE, and data were analyzed using paired samples *t*-tests (see Table 1). The results of the paired samples *t*-test revealed a statistically significant difference between pretest scores and posttest scores for the PMTE, and the effect size was moderate. Further, the results of another paired samples *t*-test revealed no statistically significant difference between pretest scores and posttest scores for the MTOE.

Table 1
Paired Samples t-Test Results for Content Test and Self-Efficacy Test (PMTE and MTOE)

Assessment	Mean	SD	*t*-value	*d*-value
Content Test				
Pretest	75.00	16.151	-3.778**	0.85
Posttest	87.08	11.971		
PMTE				
Pretest	2.70	0.504	-2.575*	0.45
Posttest	2.91	0.478		
MTOE				
Pretest	2.69	0.691	-0.213	
Posttest	2.71	0.666		

$N = 24$, $df = 23$, two-tailed
** $p < 0.01$
* $p < 0.05$

Further, the second part of the second research question was answered using independent samples *t*-tests to determine if the participants had significantly better concepts of self-efficacy at the end of the semester as compared to a neutral value coded as “2” on the survey sheet (see Table 2). For the PMTE and MTOE the results of an independent samples *t*-test revealed a statistically significant difference between efficacy scores and neutral scores, and the effect size was very large.

Table 2
Independent Samples t-Test Results for PMTE and MTOE Scores

Assessment	Mean	SD	*t*-value	*d*-value
PMTE Actual Scores	2.91	0.478	-9.310**	2.69
Neutral Scores	2.00	0.000		
MTOE Actual Scores	2.71	0.666	-5.249**	1.50
Neutral Scores	2.00	0.000		

$N = 24$, $df = 23$, two-tailed
Equal variances not assumed.
** $p < 0.01$

Descriptive statistics were used to answer research question three. At the end of the semester teachers had a mean score of 8.54 out of 10 possible points on the problem solving examination with a standard deviation of 1.615, which represents the teachers' level of problem solving abilities.

The fourth research question was answered using data collected from the teaching and learning journals. The teaching journal was used as a reflection upon the teachers' actual teaching and classroom experiences. As part of the mission of the school of education where this study took place, teachers are encouraged to be reflective practitioners. Similarly, the learning journal was used as a reflection on the learning in the mathematics methods course.

Analysis of the teaching journals revealed that the most commonly addressed topic was special education issues in the classroom. Teachers addressed their struggles and successes of working with students with disabilities. The next most frequently mentioned topic was mathematics anxiety. Teachers not only addressed the anxiety their students experienced, but also the anxiety they themselves held as teachers of mathematics. Teachers also expressed concerns about a lack of conceptual understanding in their students. Teachers lamented the difficulty in helping their students learn mathematics for understanding, as well as the lack of understanding students possessed prior to entering the classroom. Finally, teachers often reflected upon the emphasis placed upon standardized testing in their schools and the need to prepare students for the examinations, and they resented the emphasis on standardized testing. Surprisingly, very few teachers reported difficulty with classroom management.

Analysis of the learning journals revealed that the most commonly addressed topics were the use of technology and manipulatives in the classroom. Teachers appreciated exposure to these learning tools and implemented them in their own classroom. Manipulatives used in class included base ten blocks, Unifix cubes, Cuisenaire rods, and the Tower of Hanoi, among others. Next, teachers most often addressed their conceptual understanding of mathematics content. Teachers in the methods course appreciated the focus on understanding mathematics since many of them lacked conceptual understanding themselves. Recall that the teachers reflected upon their concern that their own students lacked conceptual understanding in their teaching journals. The topic of differentiation and numeracy were frequently mentioned in the journals. Additionally, microteaching was a topic that many teachers thought enhanced their learning in the course. Every teacher was required to present a 10 minute micro lesson that involved a "hook" to get students interested. Many teachers found observing other teachers teach to be a very valuable aspect of this course. Finally, problem solving was often mentioned in the reflective journals. Teachers were given a "problem of the day" problem solving situation that they were to solve in groups at the beginning of each class.

Discussion

It was found that elementary teachers increased their mathematical content knowledge and self-perception of their abilities to teach effectively over the course of a one semester inquiry-based mathematics methods course for special education teachers while teaching in the own classrooms. Further, it was found that at the end of the semester the teachers generally had high concepts of self-efficacy both in terms of their ability to teach well (as measured by the PMTE), as well as their ability to positively affect student outcomes (as measured by the MTOE). Additionally, teachers had relatively high problem solving abilities. Analysis of the reflective journals revealed that teachers revealed that the most commonly addressed topic was special education issues in the classroom. Teachers reflected on their struggles and successes of working with students with disabilities. Teachers found that the use of technology and manipulatives were the most important topics addressed in their learning.

Over the semester there was an increase in mathematics content knowledge, which is attributed to the combination of focus on content and pedagogy in the mathematics methods course, along with the teaching experience the teachers in this study were gaining. Future studies should focus on the contributions to an increase in content knowledge from the coursework and teaching components, separately.

The results of this study are consistent with the finding of Palmer (2006) and Swars, Hart, Smith, Smith, & Tolar (2007), who found that there was an increase in self-efficacy in terms of elementary pre-service teachers' ability to teach well and their ability to positively affect student outcomes. However, Palmer (2006) and Swars et al. (2007) examined preservice elementary school teachers, while in this study teachers were in-service and enrolled in alternative certification programs. Also, Palmer looked at efficacy using the STEBI-B for science, and Swars et al. used the MTEBI for mathematics, as was done in this present study. Soodak and Podell (1997) also found that preservice teachers exhibited higher levels of self-efficacy than when they began teaching in the field, but through experience the level of efficacy rose again. The results of this study were somewhat inconsistent with the results found by Hoy and Woolfolk (1990), who found a significant decline in beliefs to positively affect student learning outcomes during student teaching, which had been attributed to teachers' exposure to the realities of the classroom. However, in this present study teachers had an increase in this belief despite early encounters with the realities of the classroom. Perhaps there is something different about alternative certification preparation that could explain this difference. Change in self-efficacy should be further investigated, especially for alternative certification teachers.

It was found that teachers had relatively high problem solving abilities. This is in contrast to findings in the literature (Ball et al., 2005; Ma, 1999), and commonly held perceptions of teacher problem solving ability (Paulos, 1990). The translation of strong problem solving abilities into the classroom should be further investigated, and it is suggested that alternative certified elementary school teachers be evaluated for their implementation of their problem solving abilities into the classroom.

Since the teachers in this study were special education teachers, it was not surprising that teachers most often reflected upon the challenges and successes they had with their special education students in their teaching journals. It was surprising, however, that very few teachers reflected on classroom management issues. Classroom management is often considered a top concern among new teachers (Costigan, 2004; Cruickshank, Jenkins, & Metcalf, 2006). This should be examined in future studies.

Teachers expressed concern about lack of conceptual understanding in their students and an appreciation for the emphasis on understanding in the methods course. The method course in which these teachers were enrolled had a strong emphasis on teaching for understanding. It has been shown that many U.S. elementary teachers lacked the content understanding needed to teach well (Ma, 1999), and that this should not be a surprise given that these teachers graduated from the same system that researchers wish to improve (Ball et al., 2005). Hence, a cycle of non-understanding persists. Nurturing conceptual understanding in teachers is important given the relationship between teacher knowledge and student achievement (Hill et al., 2005).

Teachers frequently mentioned differentiation and numeracy in their learning journals. The school of education where this study takes place has a strong emphasis on differentiated instruction. It should be noted that teachers in this class had been exposed to differentiation prior to enrolling in the method course. Teachers were required to read Paulos' *Innumeracy: Mathematical Illiteracy and its Consequences* (1990). In this book Paulos addressed what it means to be numerate (i.e. mathematically literate) in a democratic society.

Teachers often discussed problem solving in their learning journals. Problem solving as a way of teaching was thoroughly addressed in the course with considerable time devoted to problem solving in the mathematics classroom as recommended in the literature (NCSM, 1978; NCTM, 2000; Schoenfeld, 1985).

Ball et al. (2005) found that teacher knowledge is an important variable in preventing the achievement gap from growing in high need urban schools. Additionally, self-efficacy impacts student learning (Soodak & Podell, 1997). As earlier referenced, it is possible that beliefs about self-efficacy may be a greater variable in quality teaching than content knowledge alone (Bandura, 1986; Ernest, 1989). Future studies should examine content knowledge, concepts of self-efficacy, and problem solving abilities in the special education context. Considering the high need for special education teachers, schools of education must be careful in determining the abilities and beliefs of special education teaching candidates. Further, considering the large number of alternative certification program candidates who teach in high need schools (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2006; Kopp, 2003), it is extremely important for the sake of these students that educational researchers understand teacher knowledge, concepts of self-efficacy, and problem solving abilities.

A COMPARISON OF TWO ALTERNATIVE PATHWAY PROGRAMS IN SECONDARY MATHEMATICS TEACHER CERTIFICATION

Brian R. Evans
Pace University
bevans@pace.edu

The purpose of this study was to compare the mathematics content knowledge, attitudes, and efficacy held by teachers in two alternative pathways to mathematics teacher certification: New York City Teaching Fellows and Teach for America (TFA). Differences were not found in content, attitudes, and efficacy, but learning and teaching journals revealed several differences between Teaching Fellows and TFA teachers. Particularly, social justice in the classroom was mentioned more often by TFA teachers, and Teaching Fellows found classroom management to not be as much an issue as had been expected.

The purpose of this study was to compare the mathematics content knowledge, attitudes toward mathematics, and concepts of self-efficacy held by teachers in two alternative pathways to mathematics teacher certification: New York City Teaching Fellows (NYCTF) and Teach for America (TFA). Secondly, the purpose was to determine differences in their attitudes toward their own learning and teaching as new mathematics teachers in New York City.

Strong teacher content knowledge is an important factor for teaching mathematics successfully (Ball, Hill, & Bass, 2005). Further, negative teacher attitudes toward mathematics often lead to avoidance of teaching strong mathematical content and affect students' attitudes and behaviors (Amato, 2004). Additionally, poor attitudes toward teaching are directly related to teacher retention issues (Costigan, 2004), and self-efficacy is an important component for successful teaching since self-efficacy is a teacher's belief in his or her ability to teach effectively and positively affect student learning outcomes (Bandura, 1986; Enochs, Smith, & Huinker, 2000).

Backgrounds on the NYCTF and TFA Programs

The NYCTF program is an alternative pathways program developed in 2000 in conjunction with The New Teacher Project and the New York City Department of Education (NYCTF, 2008; Boyd, Lankford, Loeb, Rockoff, & Wyckoff, 2007). The program goal was to recruit professionals from other fields to supply the large teacher shortages in New York City's public schools with quality teachers. Prior to September 2003, New York State allowed teachers to obtain temporary teaching licenses to help fill the teacher shortage. The NYCTF program has grown very quickly since its inception in 2000: "Fellows grew from about 1 percent of newly hired teachers in 2000 to 33 percent of all new teachers in 2005" (Boyd, Lankford, Loeb, Rockoff, & Wyckoff, 2007, p. 10). Teaching Fellows represent 11 percent of all New York City public school teachers, and 26 percent of all mathematics teachers (NYCTF, 2010). NYCTF is the largest alternative pathways program in New York City (Kane, Rockoff, & Staiger, 2006).

TFA is a non-profit organization formed in 1990 with the intention of sending college graduates to low-income schools to make a positive difference for the underserved students. Its founder, Wendy Kopp, was herself a new graduate of Princeton University looking to do something more with her life after graduation (Kopp, 2003). She considered that many recent college graduates at top U.S. universities would consider teaching low-income students if given the opportunity. The idea was that there should be a teachers' corps that would allow new graduates at top universities with an interest in teaching to quickly begin teaching students in underserved communities. Kopp considered that her idea could be a Peace Corps for the 1990s, and that the teachers would either stay in education or go into other sectors and remain advocates for public education.

Literature Review

There have been several studies that compared different pathways to teacher certification with the primary focus on student achievement and teacher retention as measures of success (Boyd, Grossman, Lankford, Loeb, Michelli, & Wyckoff, 2006; Constantine et al., 2009; Rochkind, Ott, Immerwahr, Doble, & Johnson, 2007). Rochkind et al. (2007) documented teacher experiences from TFA, Troops to Teachers, and the New Teacher Project in Baltimore, who described their first year of teaching. However, this study was limited in scope. Recently the National Center for Education Evaluation and Regional Assistance, Institute of Education Sciences, through the U.S. Department of Education, conducted a comparison study of various pathways to teacher certification in elementary reading and mathematics (Constantine et al., 2009). Constantine et al. claimed that despite the rapid growth in alternative pathways programs, little evidence has been gathered to determine their effectiveness. Constantine et al. found that alternatively and traditionally prepared teachers did not have statistically significant content knowledge differences, or statistically significant differences in student achievement levels. The latter finding is in contrast to previous research in which differences were found (Boyd, Grossman, Lankford, Loeb, Michelli, & Wyckoff, 2006; Darling-Hammond, Holtzman, Gatlin, & Heilig, 2005; Laczko-Kerr & Berliner, 2002). Previous studies had indicated that teachers in alternative pathway programs had students who scored about as well as, if not better than, students of traditionally prepared teachers in achievement examinations after the initial certification process (Kane et al., 2006).

Plumer (2010) concluded that while alternative pathway teachers appeared to be slightly more successful in mathematics and science than in reading, the research had come to conflicting and mixed conclusions on the impact of alternative pathways teachers. In New York the NYCTF and TFA programs are two large alternative pathways programs, and this study compared the mathematics content knowledge, attitudes toward mathematics, and concepts of self-efficacy held by teachers in these two programs.

Theoretical Framework

Aiken (1970) was an early pioneer to examine the relationship between mathematical achievement and attitudes toward mathematics, and showed that attitudes and achievement in mathematics are reciprocal. Like Aiken, Ma and Kishor (1997) found a small but positive significant relationship between achievement and attitudes through meta-analysis. This relationship, along with Ball et al.'s (2005) emphasis on the importance of content knowledge for teachers, formed the framework of this study. Ball et al. said, "How well teachers know mathematics is central to their capacity to use instructional materials wisely, to assess students' progress, and to make sound judgments about presentation, emphasis, and sequencing" (p. 14). Further, Ball et al. suggested that teachers with high content knowledge could help narrow the achievement gap in urban schools. Teaching Fellows and TFA teachers are placed in high need urban schools in New York City.

Additionally, Bandura's (1986) construct of self-efficacy theory framed this study's focus on self-efficacy in Teaching Fellows and TFA teachers. Bandura found that teacher self-efficacy can be subdivided into a teacher's belief in his or her ability to teach well, and his or her belief to affect student learning outcomes. Teachers who feel that they cannot effectively teach mathematics and affect student learning are more likely to avoid teaching from an inquiry and student-centered approach with real conceptual understanding (Swars, Daane, & Giesen, 2006).

Research Questions

5. What differences existed between Teaching Fellows and TFA mathematical content knowledge both at the beginning and end of a mathematics methods course?
6. What differences existed between Teaching Fellows and TFA attitudes toward mathematics both at the beginning and end of a mathematics methods course?
7. What differences existed between Teaching Fellows and TFA concepts of teaching self-efficacy?
8. What differences existed between Teaching Fellows and TFA attitudes as measured by learning and teaching journals?

Methodology

The study used both quantitative and qualitative methods, and participants consisted of 42 Teaching Fellows and 22 TFA teachers at a partnering university, a medium-sized urban university located in New York City. Teaching Fellows and TFA teachers were both at the beginning of their teaching careers teaching middle and high school mathematics while taking graduate education courses. For mathematical content knowledge, attitudes toward mathematics, and learning and teaching journals, the sample for TFA is the entire 22 teachers. However, for self-efficacy the sample is reduced to 19 participants because two teachers did not return their self-efficacy instruments, and one teacher left teaching, the partnering university, and the TFA program all together in the second year. All 42 Teaching Fellows were available for all measurements.

The teachers were enrolled in a mathematics methods course that was based upon reformed-based methods and addressed both pedagogy and content from a problem solving perspective. The course was one semester for Teaching Fellows, but it was a year long course for TFA. However, the same content and same amount of time was devoted to the mathematics content and methods in both programs. It was a year long course for TFA teachers because the course was combined with two other courses: assessment and literacy.

Both Teaching Fellows and TFA teachers took the New York State Content Specialty Test (CST) the summer before they began their program, which is required by the State of New York for teacher certification. This test assesses mathematical content knowledge for teacher certification and the scores range from 100 to 300 with a minimum passing score of 220. It consists of multiple choice items and a written assignment, and has six sub-areas: Mathematical Reasoning and Communication; Algebra; Trigonometry and Calculus; Measurement and Geometry; Data Analysis, Probability, Statistics and Discrete Mathematics; and Algebra Constructed Response. Further, both Teaching Fellows and TFA teachers took a mathematics content test at the beginning and end of their mathematics methods course. The mathematics content test consisted of 25 free response items ranging from algebra to calculus, and the test taken at the end of the course was similar in form and content to the one taken at the beginning.

Additionally, both Teaching Fellows and TFA teachers were given a survey instrument that measured attitudes toward mathematics at the beginning and end of the mathematics methods course. The attitudinal questionnaire was adapted from Tapia (1996) and had 39 items that measured attitudes toward mathematics including self-confidence, value, enjoyment, and motivation in mathematics. The instrument used a 5-point Likert scale with items strongly agree, agree, neutral, disagree, and strongly disagree.

Teaching Fellows were given self-efficacy surveys at the beginning and end of their mathematics methods course. However, TFA teachers were given the self-efficacy survey only once in their second year of teaching and enrollment in the graduate education program. The self-efficacy instrument was adapted from the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI) developed by Enochs et al. (2000), and measured concepts of self-efficacy. The MTEBI is a 21-item five-point Likert scale instrument with choices of strongly agree, agree, uncertain, disagree, and strongly disagree, and is grounded in the theoretical framework of Bandura's (1986) self-efficacy theory. The MTEBI contains two subscales: Personal Mathematics Teaching Efficacy (PMTE) and Mathematics Teaching Outcome Expectancy (MTOE) with 13 and 8 items, respectively. Possible scores range from 13 to 65 on the PMTE, and 8 to 40 on the MTOE. The PMTE specifically measured a teacher's self-concept of his or her ability to effectively teach mathematics. The MTOE specifically measured a teacher's belief in his or her ability to directly affect student learning outcomes. Enochs et al. (2000) found the PMTE and MTOE had Cronbach alpha coefficients of 0.88 and 0.77, respectively.

Finally, Teaching Fellows and TFA teachers were required to keep reflective journals on their learning and teaching over the course of the methods course, which provided qualitative data of their attitudes toward learning and teaching mathematics. The learning journal had guiding questions such as: How has this course affected your teaching? What has been helpful? What are the most important concepts you've learned in this class? The teaching journal had guiding questions such as: How are your students learning? What challenges do you face? What successes have you had? Has your attitude toward teaching shifted over the course of the semester?

Results

Research questions one, two, and three were answered using independent samples *t*-tests with significance levels taken at the 0.05 level. For research question one, both pre- and post- mathematics content test scores and mathematics CST scores were used to determine if there were any significant differences between NYCTF and TFA teacher content knowledge. For research question two, both pre- and post- attitudes toward mathematics findings were used to determine if there were any significant differences between NYCTF and TFA teacher attitudes toward mathematics. Finally, for research question three, both pre- and post- MTEBI scores, separated for both PMTE and MTOE subscales, for Teaching Fellows were used with MTEBI scores for TFA teachers to determine if differences existed in teacher self-efficacy between the two programs.

Findings revealed no statistically significant differences between Teaching Fellows and TFA teachers on the mathematical content test, CST scores, attitudes toward mathematics instrument, and the MTEBI for both subscales: PMTE and MTOE. This means there are no differences between NYCTF and TFA mathematics content knowledge, attitudes toward mathematics, and concepts of teaching self-efficacy as measured by the instruments used in this study.

Analysis of the learning and teaching journals revealed similarities and differences between the two programs. For the learning journals it was found that both groups cited problem solving and numeracy in the methods course frequently. Techniques for motivating student learning were discussed in both NYCTF and TFA journals. Both Teaching Fellows and TFA teachers cited reflective teaching and literature critique reviews least often. While social justice was cited most frequently by TFA teachers, it was mentioned very infrequently by Teaching Fellows. While microteaching and learning about motivation techniques were two categories frequently mentioned by Teaching Fellows, TFA teachers rarely mentioned these. In both NYCTF and TFA methods classes teachers were expected to present a brief micro lesson that contained a motivator for the lesson, to their classmates.

For the teaching journals both Teaching Fellows and TFA teachers cited classroom management as the most frequently cited concern. However, it should be noted that while every TFA teacher reference to classroom management was citing a problem with classroom management, several Teaching Fellows mentioned classroom management as not being as problematic as they thought it would be. Also frequently referenced in both NYCTF and TFA journals were student motivation for learning, student attendance, and standardized state examination preparation as emphasized by their administrations. TFA cited unsupportive administration frequently as a concern, whereas NYCTF did not.

Discussion

No statistically significant differences were found between NYCTF and TFA teachers on mathematics content knowledge, attitudes toward mathematics, and concepts of self-efficacy. It is commonly claimed by TFA that their candidates come from the most highly ranked and selective universities in the United States (TFA, 2010; Xu, Hannaway, & Taylor, 2008), and the implication is that those among America's brightest become TFA teachers. However, the findings in this study indicated that NYCTF and TFA teachers are statistically similar in terms of content knowledge, attitudes, and beliefs. These results are quite surprising considering there is a common perception held by those working with the programs in New York that TFA teachers, while not staying in education quite as long at Teaching Fellows, do however have stronger mathematics content knowledge. Moreover, Constantine et al. (2009) claimed that of the various alternative pathways programs, NYCTF and TFA are the more selective of the other alternative pathways program in candidate selection. In 2008 only about 15 percent of NYCTF program applicants were accepted into the program, and over 8 percent of NYCTF applicants actually entered training in the summer before teaching with an additional 1 percent beginning early in the 2007/2008 academic year (NYCTF, 2008). In 2008 approximately 20 percent of TFA applicants were accepted into the program with about 15 percent of applicants actually starting the program (TFA, 2008). The mean grade point average in 2008 for new Teaching Fellows was 3.3 (NYCTF, 2008), while the mean grade point average for new TFA teachers was 3.6 (TFA, 2010). Statistically significant differences in grade point averages had not been examined.

Since the results of this study indicate there are no differences found in several variables that measured teacher quality between the two programs, the implication is that it should not matter in which program teachers are selected based upon content knowledge, attitudes toward mathematics, and concepts of self-efficacy. However, given results from prior studies that focused on teacher retention, perhaps NYCTF maintains an advantage over TFA using retention, a variable important in student success, as an important criterion for success. Sipe and D'Angelo (2006) found when surveying Teaching Fellows that about 70 percent of them intended to stay in education. NYCTF reports that 92 percent of Teaching Fellows completed their first year of teaching, 73 percent completed at least three years of teaching, and half have taught for at least five years (NYCTF, 2010). Boyd, Grossman, Lankford, Michelli, Loeb, and Wyckoff (2006) reported that about 46 percent of Teaching Fellows stayed in teaching after four years as compared to 55 to 63 percent of traditionally prepared teachers. Further, Kane et al. (2006) found that Teaching Fellows and traditionally prepared teachers had similar retention rates. However, Darling-Hammond et al. (2005) reported that upon becoming certified many TFA teachers leaving teaching. This is in contrast to TFA's own report of teacher retention. TFA claimed that about two-thirds of TFA teachers stayed in the field upon completing their time in the program, and half of those remained in teaching (TFA, 2008). This means that about one third stayed in the classroom upon fulfilling their commitment, which generally lasts several years. Another one third maintained non-teaching roles in education, such as in administration or advocacy (TFA, 2008). Lassonde (2010) claimed that only 11 percent of TFA teachers reported planning to teach 10 years or more. As of 2010 there were 17,000 TFA alumni (TFA, 2010), and according to TFA, over 5600 remained teaching in the classroom after their commitment ended (TFA, 2009). These findings indicate that approximately more than twice the percentage of Teaching Fellows stayed in the classroom compared to TFA teachers over a similar time period of several years. However, no statistical analysis had been conducted to determine significant differences.

In the learning journals teachers in both programs cited problem solving and numeracy frequently. However, more interestingly, social justice was cited most frequently by TFA teachers, but it was mentioned very infrequently by Teaching Fellows. This is an interesting finding given the emphasis on social justice in the school of education where this study took place. If social justice issues in the classroom are of high concern, then perhaps TFA teachers have an advantage over Teaching Fellows, in this respect. This should be further investigated.

In the teaching journals teachers in both programs cited, unsurprisingly, classroom management issues as the most frequently cited concern for new teachers, as documented in the literature (Cruickshank, Jenkins, & Metcalf, 2006). It was surprising, however, that NYCTF teachers found classroom management to not be as much of an issue, but TFA teachers found classroom management exclusively problematic.

An interesting finding was that Teaching Fellows cited learning about motivation techniques often in their learning journals, while TFA teachers did not, especially since both groups frequently mentioned student motivation in their teaching journals, a concept related to the microteaching required in the methods class.

Both Teaching Fellows and TFA teachers cited time needed for, and administrative emphasis on, standardized state testing. In the time of No Child Left Behind (NCLB, 2001) much emphasis on accountability means that schools and principals must ensure that teachers are raising standardized state test scores. It is no surprise that both NYCTF and TFA teachers rank this highly among their concerns.

The major implication from this study is that TFA is not stronger than NYCTF in content knowledge, attitudes, or in their confidence of their own teaching efficacy, as is often assumed given the reputation of TFA and caliber of college and university pursued by TFA in candidate recruitment, and it is hoped that this study changes this perception. From the literature it appeared that Teaching Fellows had an advantage in terms of teacher retention, but the results of this study indicated that TFA teachers had an advantage with concern for social justice in the classroom. However, more confirmatory research is needed. Further studies should compare differences between Teaching Fellows and TFA teachers in actual classroom practice in secondary mathematics teaching specifically, given the size of the programs. How does student achievement compare for the two groups among high need students? This study found no differences in content knowledge and beliefs for the two groups of teachers, but it would be beneficial to understand NYCTF and TFA direct impact in urban classrooms.

Educational researchers must continue to investigate the quality of alternative pathway programs. Since students in high need urban schools are often the ones who receive alternative pathways teachers in the classroom, it is imperative that educational researchers, professors of education, administrators, and policy makers ensure that these students are getting the highest level quality teachers they deserve. The question posed to administrators and policy makers is: Would you accept an alternative pathway teacher in your own child's classroom? We must continue to understand and improve alternative pathways until the answer is a resounding "yes."

PROSPECTIVE MIDDLE GRADE MATHEMATICS TEACHERS' MISTAKES IN KNOWLEDGE OF ALGEBRA FOR TEACHING

Rongjin Huang
University of Colorado Denver, USA

Gerald Kulm
Texas A & M University, USA
Hrj318@gmail.com

This study examined prospective middle grade mathematics teachers' mistakes in knowledge of algebra for teaching. 115 prospective teachers participated in a survey. It was found that the participants performed better in expressions and linear equations but revealed numerous mistakes in irrational functions and equations, and relevant advanced mathematics content area. They also showed limited knowledge in selecting appropriate function perspectives and representations.

Introduction

Equipping teachers with appropriate knowledge needed for teaching is the key to high-quality teaching that aims at achieving high student achievement (Conference Board of the Mathematical Sciences [CBMS], 2001; National Mathematics Advisory Panel [NMAP], 2008). Many studies revealed that U.S. teachers do not have adequate content knowledge and pedagogical content knowledge preparations (Kulm, 2008; Ma, 1999; Schmidt et al., 2007). Meanwhile, relevant recommendations for improving teacher preparations have been made (NMAP, 2008; RAND Mathematics Study Panel, 2003; Kilpatrick, Swafford, & Findell, 2001). In particular, CBMS (2001) recommended that prospective middle mathematics teachers should have at least twenty-one semester hours in mathematics, including at least twelve semester hours of fundamental ideas of mathematics appropriate for middles school teachers. Does taking much more mathematics or mathematics education courses matter for preparing qualified teachers? In this study, we examined prospective teachers from a program that meets the requirements (CBMS, 2001) how they responded to the survey which was designed to measure knowledge of algebra for teaching. By focusing on the particular content of algebra, we hope to provide a better understanding of teacher knowledge in the specific area and provide insight into mathematics teacher preparation in general. The purpose of this study is to examine the strengths and weakness of teachers' knowledge for teaching algebra with a particular attention to their mistakes.

Theoretical Framework

Teachers' Knowledge for Teaching Algebra

In the past decades, researchers have focused on conceptualizing and measuring particular mathematical knowledge needed for teaching (MKT) (e.g., Ball, Hill, & Bass, 2005; Hill, 2010; Kilpatrick et al., 2001). Recently, growing attention has been given to define and measure teachers' knowledge needed for teaching specific areas (e.g., Chinnappan & Lawson, 2005; Even, 1993, 1998; Floden & McCrory, 2007). Since algebra is a core component of school mathematics (National Council of Teachers of Mathematics [NCTM], 2000; NMAP, 2008), researchers have proposed different models defining teachers' knowledge for teaching algebra (e.g., Doerr, 2004; Even, 1993; Floden & McCrory, 2007). For example, Floden and McCrory

(2007) have developed a model to guide the development of a measure of teachers' knowledge of algebra for teaching (KAT). According to this model, the knowledge for teaching algebra includes three types of knowledge: school algebra knowledge, advanced algebra knowledge, and teaching algebra knowledge. Moreover, they also developed relevant instrument for measuring KAT. Thus, we developed our own instrument based on Floden and McCrory's (2007) framework and instrument.

Understanding of the Concept of Function

Process-object duality is a generally accepted model of mathematics concept development (Briedenbach, Dubinsky, Hawks, & Nichols, 1992; Schawarz &Yerushalmy, 1992; Sfard, 1991). With regard to the development of function concept, according to the process perspective, a function is perceived as linking x and y values: for each value of x, the function has only one corresponding y value. On the other hand, the object perspective regards functions or relations and any of its representation as entities (Moschkovich, Schoenfeld, & Arcavi, 1993). The term "representation refers both to process and product-to the act of capturing a mathematical concept or relationship in some form and to the form itself'' (NCTM, 2000, p. 67). Hence, representation is an essential part of the mathematical activity and a vehicle for capturing mathematical concepts (e.g., Goldin & Shteingold, 2001). Different representations play different roles in helping students understand the concept of function (e.g., Lesh, Post, & Beher, 1987; Schwarz &Yerushalmy, 1992). For example, while the algebraic representations can help understand a function as a *process*; the graphical representations help understand a function as an *object*. Thus, it is important to have sound understanding of these two perspectives (Clement, 1989; Even, 1998) and use appropriate representations with regard to different contexts (Cuoco 2001; NCTM, 2000, 2009).

Teachers' Knowledge for Teaching the Concept of Function

There are several studies on teachers' knowledge for teaching the concept of function (e.g., Even, 1993, 1998; Hitt, 1998). For example, based on 152 prospective secondary teachers' completion of an open-ended questionnaire concerning their knowledge about function, Even (1993) found that many prospective secondary teachers did not hold a modern conception of a function as univalent correspondence between two sets. These teachers tended to believe that functions are always represented by equations and that their graphs are well-behaved. In summary, teachers have difficulties in (1) understanding the concept of functions as univalent correspondence between two sets (sometimes, it is not presented by a formula, or it is not of discontinuous graph), (2) shifting different representations flexibly, and (3) relating formal function notions to contextual situations which produce the function.

Method

Data Sources

The data used for this study were taken from a comparative study (Huang, 2010) consisting of 115 U.S. prospective middle mathematics teachers' survey on knowledge of algebra for teaching and follow- up interviews with 5 participants (Larry, Jenny, Kerri, Alisa, and Stacy are pseudonym names of the interviewees). The participants were from an interdisciplinary program preparing math and science middle school teaches at a large research public University in South of the United States. Based on Floden and McCrory' (2007) questionnaire, we developed an instrument which included 17 multiple choice items and 8 open-ended items. The interviews were conducted individually during the week after completion of the survey. Each interview lasted about 20 minutes, and was audio recorded. The majority of the participants (87%) were junior and senior students and they had completed an average of 7 mathematics and mathematics courses.

Data Analysis

After quantifying the data, we first analyzed typical mistakes with regard to expressions, equations, and graphs (Items 1-17). Then, we analyzed the performance and typical mistakes in solving open-ended problems (items 18-25) from two perspectives: function perspectives and representations.

Results

Mistakes in Knowledge Related to Expressions, Equations, and Graphs

Some typical mistakes in knowledge of algebra for teaching were identified as follows: (1) neglecting the domain of independent variable when transforming and/solving irrational functions and equations; (2) inappropriate use of graphic representations; and (3) misconceptions in advanced knowledge.

Neglecting the domain of independent variables. In item 4, participants were required to find the equivalent expressions of the function $f(x)=\log_2 x^2$ from: i . $y=2\log_2 x$; ii . $y=2\log_2|x|$; iii. $y=2|\log_2 x|$. Their choices of A (i only), B (ii only), C (iii only), D (i and ii only), and E (i, ii, and iii), were 37%, 15%, 6%, 21%, and 0% respectively. This indicates that 37% of them did not consider the domain of independent variable x when transforming a function and also 21 % of them did not differentiate these four expressions. For another example, participants were asked to comment on the following process of solving the equation: $9^x-3^x-6=0$: "Peter denoted $y=3^x$ and gets the equation $y^2-y-6=0$, which has 2 different roots. He concluded that the given equation also has 2 different roots". 15% of them agreed with Peter's solution, and 54% of them believed the substitution method is wrong, only 18% of them realized the mistake in neglecting the range of y. These results suggest that participants were likely to neglect the domain of an independent variable□or range of a dependent variable□ when transformation irrational functions or expressions.

Inappropriate use of graphic representations. Many participants were not able to appropriately use geometrical representations to present algorithms, algebra relationships, relationship between time and velocity, and root of trigonometry functions. For example, only 30% of the participants realized the following relationships: " i. The equivalence of fractions and percents, e.g. $\frac{3}{5}=60\%$; ii. The distributive property of multiplication over addition: For all real numbers a, b, and c, we have $a(b+c)=ab+ac$; iii. The expansion of the square of a binomial: $(a+b)^2=a^2+2ab+b^2$" can be represented by rectangles. 26%, 22% and 16% of the participants did not realize that the distributive rules of multiplication over addition, the equivalence of fractions and percents, and the formula of square of a binomial can be presented by rectangles respectively. Thus, the participants did not have profound understanding of using geometrical representations to present algorithmic and algebraic relationships.

Misconception in advanced mathematics. We identified some essential mistakes in the operation rules across different number systems, mathematical induction, and slope of tangent line of a curve. For example, one question is to judge the statement that " *For all a and b in S, if ab = 0, then either a = 0 or b = 0"* is true in different number systems (S) such as real numbers (i), complex numbers (ii), and a set of 2 x 2 matrices with real number entries (iii). 44% of the participants selected only (i) (incorrect) and 22 % of selected only (i) and (ii) (correct answers), and 30% of them selected i, ii and iii (incorrect). It means that 44% of them are not able to generalize the rule to complex number system, while 30% of them inappropriately generalize the rule to matrix system. The invariance of operation rules in different number systems is a core concept; however, majority of them were not able to differentiate.

Inflexibilities or Mistakes in Quadratic Equations and Functions

The results are organized into two parts. One is related to the selection of perspectives of function concept. The other is about the flexible use of representations.

Weakness in selecting appropriate perspectives of function concept. Items 18, 24 and 25 are particularly used for measuring knowledge of understanding and applying function concept from different perspectives. Item 18 is in favor of using process perspective; item 24 is easily proved if adopting an object perspective. It is necessary to connect those two perspectives when solving item 25. The score distribution of these three items is shown in Table 1.

Table 1. Score Distribution of Items Related to the Adaption of Function Perspectives

Item	0 point (%)	1 point (%)	2 points (%)	3 points (%)	4 points (%)
Item 18	32.2	17.4	27.8	12.2	10.4
Item 24	98.3	1.7	0	0	0
Item 25	31.3	17.4	33	13	5.2

Take item 18 for example. The item is as follows: On a test a student marked both of the following as non-functions

(i) f: $\boldsymbol{R} \rightarrow \boldsymbol{R}$, $f(x) = 4$, where $\boldsymbol{R}$ is the set of all the real numbers.

(ii) $g(x) = x$ if x is a rational number, and $g(x) = 0$ if x is an irrational number.

(a) For each of (i) and (ii) above, decide whether the relation is a function;

(b) If you think the student was wrong to mark (i) or (ii) as a non-function, decide what he or she might have been thinking that could cause the mistake(s).Write your answer in the Answer Booklet.

About 23 % of the participants got a correct answer (10%) or almost correct answer with minor mistakes (12%). While 32% of them provided nothing or meaningless information about the solution and about 28% of them just gave correct answers without any interpretation or gave one correct answer and relevant explanations. The participants preferred to use diagrams to visualize the function relationship and then make a judgment of these two given relations

The perspectives used in participants' interpretations of the item 18 are listed in Table 2 (The percentages with wrong answers are omitted in the Table).

Table 2. Perspectives Adopted in the Responses to Item 18

Perspective	Description	Percent
Process	Corresponding relationship between domain and range (one-to-one; multiple-to-one)	6
Object	Expression feature (constant value; two expressions) Graphic features (one line, many holes/un-continuous)	9

With regard to this item, it is more appropriate to adopt the process perspective. However, the participants preferred using object perspective (9%), namely, basing on function expressions and graphic features to using essentially corresponding relationship features (6%). In responding to how they made their judgments, except for one Jenny, the others reported they used the vertical line test (Larry, Alisa, and Stacy) or diagrams presenting corresponding relationship between two sets (Kerri). Jenny made her wrong judgment based on visually graphical images. Since she had difficulty drawing the graph of the second relation, she believed it was not a function. However, when asked whether she heard of the vertical line test, she clearly stated that "one x value can only have one corresponding y value; one x value cannot be corresponded to two y-values." Kerri said she "is a visual learner, and likes using diagrams to represent the relationship between two sets (one-to-one or multiple-to-one, but not one-to-multiple)". Larry not only explained the vertical line test rule, but also showed an example ($x=y^2$) which cannot pass the vertical line test. Alisa and Stacy explained the rule by emphasizing "each input [value] should have only one [corresponding] value, but that does not mean that different [input] values cannot have same [corresponding] value". They also attributed students' mistakes to students' superficial understanding of the vertical line test rule (missing multiple x values correspond one y-value) or the confusion with "many holes", or the repeating output.

Inflexibility of Selecting Representations

The items 19, 21, 22, and 23 are deliberately designed for measuring knowledge for understanding and applying quadratic functions/equations/inequalities through flexibly using multiple representations. It is crucial for participants to flexibly use appropriate presentations and shift between different representations in order to solve them effectively. Regarding item 19, it is expected to have algebraic and graphic representations of equation and inequality. With regard to item 21, it is necessary to shift between algebraic and graphic representations in order to solve the problem. To solve the problem of item 22, it is necessary to have ability to translate graphic representations to algebraic representations. To solve the problem of item 23, it is required to use appropriate forms of algebraic expressions and transformations of different algebraic expressions, and translation between graphic and algebraic representations. The scores distribution of these four items is shown in Table 3.

Table 3. Score Distribution of Items Related to Flexible Use of Representations

Item	0 point (%)	1 point (%)	2 points (%)	3 points (%)	4 points (%)
Item 19	31.3	62.6	5.2	0.9	0
Item 21	84.3	14.8	0.9	0	0
Item 22	34.8	24.3	15.7	16.5	8.7
Item 23	80	16.5	0.9	0	2.6

Take item 19 for example. The question is as follows:

Solve the inequality $(x - 3)(x + 4) > 0$ in *two essentially* different ways.

Only one participant gave two essentially different solutions (i.e., algebraic and graphic methods). Around 60% gave an algebraic statement which did not result in a correct answer. In addition, more than one-third (31%) of the participants left it blank or gave some useless statements. Overall, the students performed worst in this problem. Moreover, many mistakes and misconceptions occurred as shown in Table 4.

Table 4. Misconceptions or Mistakes in Solving Inequality in Item 19

Mistake	Explanation	Example	Frequency (%)
1	Misconception: if ab>0, then a>0, b>0	(x-3)(x+4)>0→ x-3>0, x+4>0, then x>3, x>-4.	37
2	Only transforming into standard form	$x^2+x-12>0$ or $x^2+x>12$.	21
3	Transforming into standard form and getting stuck	$x^2+x-12>0$ or x(x+1)>12 or x(x+1)=12.	7.6
4	Working on the standard form with guess and check	$x^2+x-12>0 \rightarrow x(x+1)>12$; →x>12, x+1>12→x>12, x>11.	12
		$x^2+x-12>0$, or (x-3)(x+4)>0 →x_1=3, x_2=-4.	15
5	Drawing a number line	Find partial answer: x>3 or x<-4.	4
6	Using a table	x>3 (x=1, 2, 3, 4... or 0, -1, -2, -3,…).	4

The table shows that 37 % of the participants adopted the inference: if ab>0, then a>0, b>0. None of them realized that *a* and *b* are possibly negative. In addition, none of them care about the logical operations "or" or "and" between two logical propositions (such as a>0 and b>0 or a>0 or b>0). They also were satisfied with the solution "x>3, x>-4" without any intention to further intersect or combine.

In order to find another method to solve the inequality, an automatic alternative is to transform the factor form into standard form: $x^2+x-12>0$. 21% of them stopped with the standard form. 7.6 % of them were stuck with further algebraic operation: x(x+1)>12 or x(x+1)=12. Some of the participants want further with "guess and check strategies":

Mistake 1 (12%): $x^2+x-12>0 \rightarrow x(x+1)>12$; →x>12, x+1>12→x>12, x>11.

Mistake 2 (15%): $x^2+x-12>0$,or (x-3)(x+4)>0 →x_1=3, x_2=-4.

Participants' explanations. In the interview, Larry just simplified the factor form into standard form ($x^2+x-12>0$), and then moved forward by "guess and check" such as "$x^2>x-12$, and then $x>\sqrt{x-12}$" although it did not work. By analogizing the property of equation: (x-3) (x+4)=0 → x-3=0, or x+4=0, the remaining four interviewees made an inference as follows: $(x-3)(x+4)>0 \rightarrow (x-3)>0,\ (x+4)>0 \rightarrow x>3, x>-4$.None of them had intention to work on "x>3, x>-4" further, such as the logical operations "and" or "or" and the operations of intersection and combination of two sets. They seemed to be satisfied with the "solution". When asking if they can use a graphic method to solve equation or inequality, they recalled the graphs of quadratic equation. All the interviewees explained they did not know how to use quadratic function graph to solve inequality, although they knew the graphing method of solving a system of linear equation. They learned quadratic function first (probably late in middle schools or early in high schools) and then inequality late in high schools. These contents were taught separately. They were not taught how to use graphic representation to solve algebraic problems. They appreciated the method of integration of algebraic and graphic representations. The interview showed that participants may have relevant content knowledge but they did not have an interconnected knowledge network; did not have experience in flexibly using different kinds of knowledge and relevant representations

Take Item 21 for another example. The Item 21 is as follows:

If you substitute 1 for x in expression ax^2+bx+c (a, b and c are real numbers), you get a positive number, while substituting 6 gives a negative number. How many real solutions does the equation $ax^2+bx+c=0$ have? One student gives the following answer:

According to the given conditions, we can obtain the following inequalities:

$a+b+c>0$, and $36a+6b+c<0$.

Since it is impossible to find fixed values of a, b and c based on the previous inequalities, the original question is not solvable.

What do you think may be the reason for the students' answers? What are your suggestions to the student?

Only one participant gave a correct explanation and useful suggestions (there are two roots, and a graphic method is suggested). About 84% of the participants agreed with the student's explanation (actually, it is wrong), and they got stuck with the algebraic manipulation to find *a,b* and c, and had no idea about how to help the student get out of their difficulties. 15 % of the participants suggested plugging more value of *a, b*, and *c* (such as *a*=-10, *b*=-9, and *c*= 20) to see whether certain patterns can be found. They did not think to use graphic or geometrical representations to find the answers. Some of them (15%) had the following misconception: if you plug more numbers, you can find some patterns, and then you may find the solutions.

Participants' explanations. Three of the interviewees fully agreed with the student's (wrong) statement, namely "Since it is impossible to find out fixed values of *a, b* and *c* based on the previously given inequalities, the original question is not solvable". They tried to find out *a, b,* and c using algebraic transformation but it did not work. They had no ideas how to help the student find a solution. The other two interviewees felt that the problem may be solved, but they did not have any concrete ideas about how to solve it (Jenny and Stacy). What they could suggest is that the student is to "try different ways, such as plugging more numbers between 1 and 6."(Jenny) or "explore in different ways such as plugging more numbers to see whether they can find certain patterns, rather than being stuck"(Stacy).When asked whether they can try other methods such as graphical methods to solve, they sketched a graph and find possible roots. Four of them were successful in finding the number of roots by examining the intersection points of the quadratic function. All of them said that they had never realized such a way because they had not got such experiences in solving problems, but they realized the usefulness of the graphing method in algebra.

Discussion and Conclusion

This study showed that the participants from the interdisciplinary math and science middle teacher preparation program had relatively weak knowledge of algebra needed for teaching. Moreover, they also revealed their weakness in selecting appropriate perspectives of function and flexibly using of representations of quadratic functions. These findings are in line with other studies on teachers' knowledge for teaching algebra (Even, 1998; Hitt, 1998). The participants had limited advanced algebra knowledge although they had taken advanced courses such as calculus, linear algebra, and abstract algebra. The interviews revealed a lack of experience in using different representations, possibly because courses in mathematics and teaching methods were separately taught. This raises an issue about the curriculum for preparing mathematics teachers for middle and high schools. Equipping prospective teachers with appropriate knowledge for teaching is not a simple issue of adding more mathematics courses. It should include developing coherent curriculum that integrates content and pedagogy to help prospective teachers develop a well-structured algebra knowledge base with flexible use of different perspectives and representations. In order to implement mathematics curriculum that recommends providing middle and high school students with experience in developing connections and representational flexibility, prospective teachers should have the opportunity to develop relevant knowledge and skills needed for organizing classroom activities that promote this type of student learning (NCTM, 2000, 2009). The findings imply that beyond providing adequate number of math and math education courses, it is important to provide focal and coherent curricula from pre-university to university level. It is also important to have coherent teaching to emphasize knowledge development and form a well-structured and interconnected knowledge base.

This study has its own limitations. First, the instrument mainly focused on expression, equation, inequality, and functions which may not reflect a whole picture of algebra. Second, the participants were from a program in a single university, so caution is necessary in generalizing these findings.

MATHEMATICS FOR TEACHING AND LEARNING: DEVELOPING TEACHERS' CONCEPTUAL UNDERSTANDING OF ELEMENTARY MATHEMATICS

Ann Kajander
Lakehead University
ann.kajander@lakeheadu.ca

Jennifer Holm
Lakehead University
jholm@lakeheadu.ca

In this five-year study, 600 preservice teachers' understanding of mathematics as needed for classroom teaching was explored. Data sources included pre/post written open-response mathematics items, and pre/post semi-structured interviews. Results consistently showed that while participants were able to perform standard numeric calculations, conceptual understanding of elementary concepts was initially extremely weak. Moderate progress was made during the one-year program, with stronger growth for those teacher candidates who chose to enroll in the optional course in mathematics-for-teaching. Based on our results, an exam in "mathematics for teaching" is now a graduation requirement.

Objectives

Our previous anecdotal and observational experiences with upper elementary teacher candidates participating in mathematics methods courses were that what appeared to be weak understanding of mathematics concepts impacted preservice teachers' willingness and ability to embrace and develop problem-based lessons, even though participants were generally able to use a procedure to calculate a correct answer. Hence our research questions were: What mathematical understandings, both procedural and conceptual, are demonstrated by preservice teacher candidates at the beginning and end of their (in our case one-year) teacher preparation program?; What factors appear to influence such development?; What beliefs changes are observed?; Does extra course time in related mathematical concepts appear to better support such development?

Perspectives and Framework

This study used the bioecological model of Bronfenbrenner (1999) as a framework. Our research questions around teachers' beliefs and understandings formed the risk and protective factors thought to interact and influence growth.

Substantial literature (for example, Wilkins, 2008) links teacher beliefs with development of teacher knowledge, which in turn influences student achievement (Baumert et al., 2010). In particular, a specialised body of mathematical knowledge, variously dubbed *profound understanding of fundamental mathematics* (Ma, 1999), *mathematics for teaching* (Ball, Thames, & Phelps, 2008), and *pedagogical content knowledge* (Shulman, 1986; Baumert et al., 2010) has been argued as fundamental to the support of problem-based or inquiry-based classroom learning, the mainstay of suggested curriculum reforms over the past few decades (National Council of Teachers of Mathematics, 2000). It has been argued that "teachers' knowledge of mathematics alone is insufficient to support their attempts to teach for understanding" (Silverman & Thompson, 2008, p. 499), and further that such teaching is "predicated on coherent and generative understandings of the big mathematical ideas that make up the curriculum" (p. 501).

In particular, teachers need to understand the connection of appropriate classroom mathematical models to the concepts as well as have a knowledge of the underlying structure of procedures (Hill, 2010), in order to help students construct understanding and methods (including alternate or student-generated methods). Teachers also need to support such learning with appropriate questioning as well as the ability to diagnose student misconceptions and understand alternate methods (Ball et al., 2008). Such a depth of understanding provides significant challenges to new teacher-candidates.

Methods

The study used a mixed-methods design supported both quantitative and qualitative results. Preservice teachers for grades 4 to 10 (approximately 120 per year) were surveyed using a paper and pencil instrument (Kajander, 2007) at the beginning and end of their methods course. Mathematical understanding was measured as "procedural" as well as "conceptual"; questions relating to the former involved asking participants to perform a standard elementary procedure such as "3 x 1.6" or "5 – (-3)" using a method of their choice, while questions relating to the latter involved asking for an explanation, model, contextual example, or alternate method, all thought to be aspects of teachers' needed specialized knowledge (Hill, 2010). We use the term 'conceptual knowledge' to refer to those mathematical understandings that are mathematically specialized, yet may be developed without necessarily making a connection to students and teaching, as described by Hill (2010). As well a number of demographic variables were collected, such as undergraduate background, highest high school mathematics course taken, school curriculum experienced, and years out of university before entering the teacher education program. This same survey was used with several cohorts of in-service teachers during the first two years of the study. These data continue to be analysed statistically.

As well as the quantitative data, pre/post semi-structured interviews (50 pairs) were conducted during each of the most-recent 3 years of the study to support the survey results, and methods classroom artifacts such as assignment work and examination responses were also examined. Semi-structured interviews were conducted with 10 participating classroom teachers during the latter half of the study, and five were observed on at least one occasion while teaching. While all of this data forms the data-sources for the study, the current report focuses on the survey results related to preservice teachers' conceptual knowledge, and the preservice interview data related to beliefs about conceptual knowledge.

The written survey items were directly drawn from the questions used in Ma's (1999) landmark interviews and hence have arguably strong face validity. Reliability was also established during the first three years of the study (Kajander, 2010). Descriptive statistics from the survey are supported by examination of individual responses, as well as the participants' self-reports as drawn from the interview data. A final mandatory examination in "mathematics for teaching" was introduced to the program in year 3 based on the earlier data, and participant scores on this mandatory examination also support the written survey data.

Results

Our results consistently show that conceptual understanding of elementary mathematics concepts was weak to non-existent for teacher candidates at the pretest, which took place at the very beginning of the mathematics methods course. Also, nearly all of the participants interviewed mentioned some form of lack of comfort or insecurity with their mathematical understanding. The few who did feel slightly more comfortable tended to equate 'understanding' with procedural skill. Yet many participants who were almost completely unable to explain why standard numeracy methods worked, were still able to perform them accurately. While literature suggests that it is likely the case that teachers are better able to perform standard procedures than explain them (Hill, 2010), the extent of the problem, when we actually looked at multiple samples of prospective teachers' work, was staggering. According to our evidence, substantive numbers of teacher candidates were initially simply unable to provide *any* explanation, justification, model, or context for the standard algorithms they were generally able to perform. Explanations, if any, generally took the form of "because that is the rule". The mode score on conceptual knowledge on the pretest written survey was 0, with the mean each year hovering around 10%. Yet procedural knowledge on these same items had a much higher mean, over 70% (see Table 1).

Table 1

Initial Written Survey Mean Scores

Response Type	*M*	*SD*	*SE*
Procedural knowledge	7.1361	2.05917	.08602
Conceptual knowledge	1.2670	1.46291	.06111

Note: All knowledge scores are scaled out of 10 possible points. Pretest survey responses, *N*=573. *SE*=standard error of the mean.

The same written survey was re-administered at the end of each year. Substantial growth particularly in conceptual knowledge was shown over each of the five one-year cohorts (see Table 2). Results have been shown as significant for each of the first three years of the study (Kajander, 2010) and analysis for the final two years is underway.

Table 2
Final Written Survey Mean Scores

Response Type	*M*	*SD*	*SE*
Procedural knowledge	8.8586	1.58641	.06627
Conceptual knowledge	5.6021	2.49660	.10430

Note: All knowledge scores are scaled out of 10 possible points. Post-test survey responses, *N*=573. *SE*=standard error of the mean.

Yet the numbers alone fail to bring to light the issues as strongly as examining the actual participant survey responses. Using a semi-random selection process (every fourteenth response in the database was selected from year 5, as space permitted), a selection of specific responses to two of the survey questions is offered.

Two of the seven survey questions are chosen as illustrative. The instructions for each of these questions are the same. For Part a) the participants are asked to

***Answer** the question, showing your steps as needed to illustrate the method you used*

while in Part b) they are asked to

***Explain** what you can about why and how the method you used in a) works, using explanations, diagrams, models, and examples as appropriate. If possible, do the question another way.*

Part a) questions are scored as *procedural knowledge* items, while Part b) questions are scored as *conceptual knowledge*. Figures 1 and 2 show sample pretest responses selected from the year 5 data.

Selected Pretest Survey Responses to Integers Question

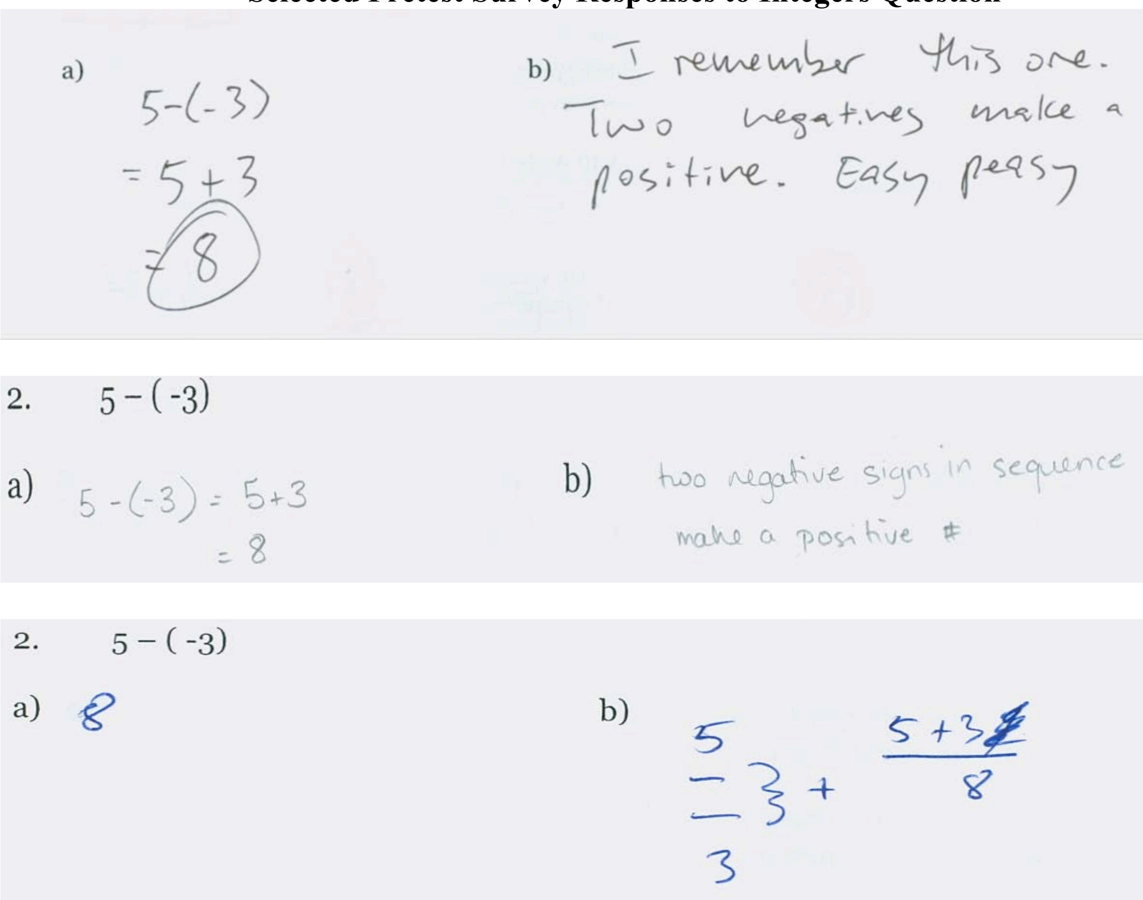

Figure 1. Pretest responses to 5-(-3). Part a) asks for answer and Part b) for explanation.

Selected Pretest Survey Responses to Fractions Question

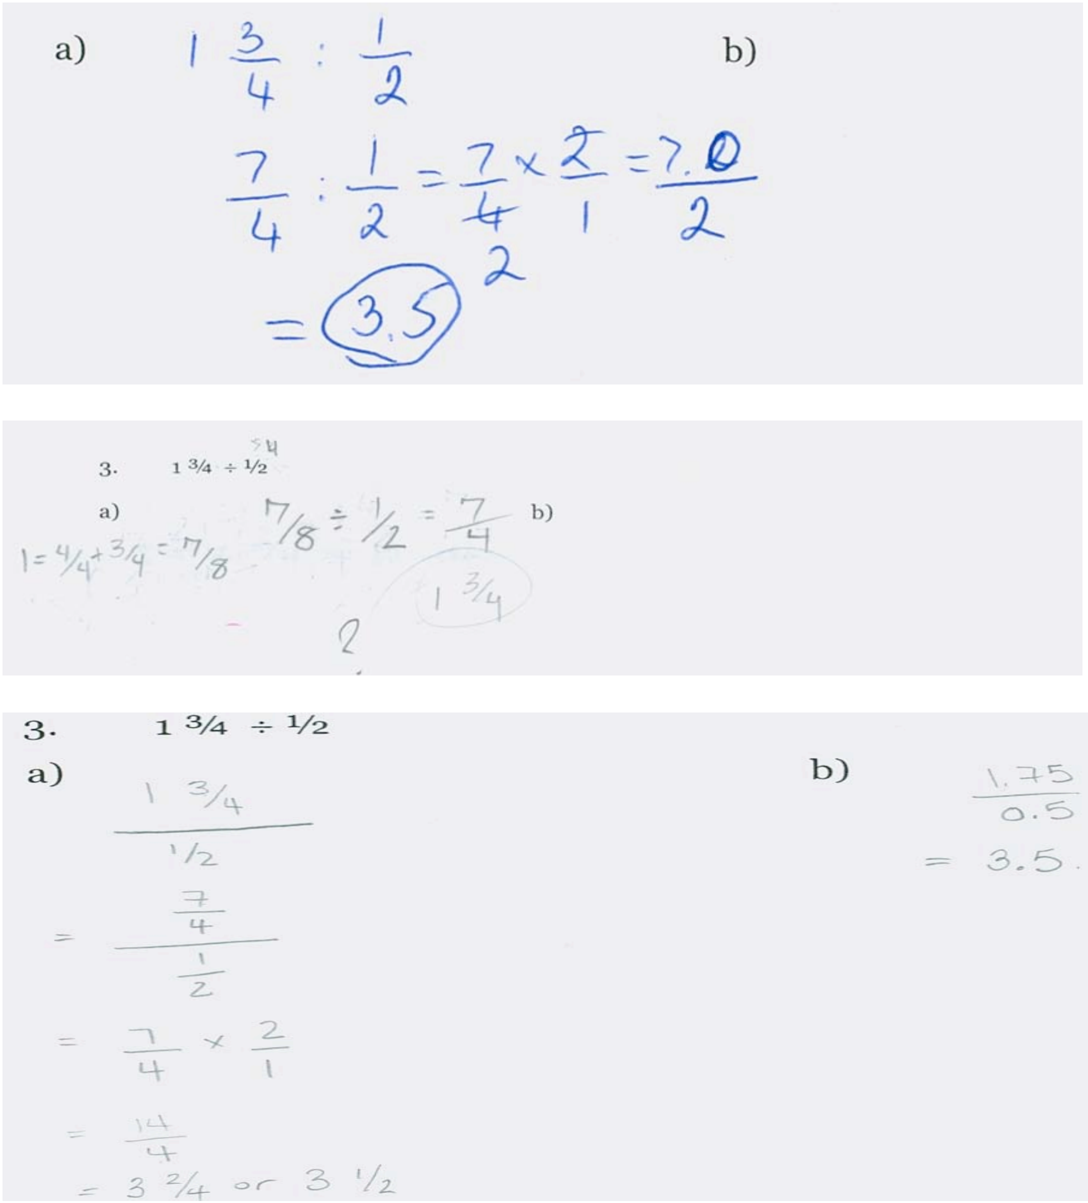

Figure 2. Pretest responses to 1 ¾ ÷ ½. Part a) asks for answer and Part b) for explanation.

The following samples (Figures 3 and 4) are post-test responses from the same respective participants as shown in Figures 1 and 2.

Selected Post-test Survey Responses to Integers Question

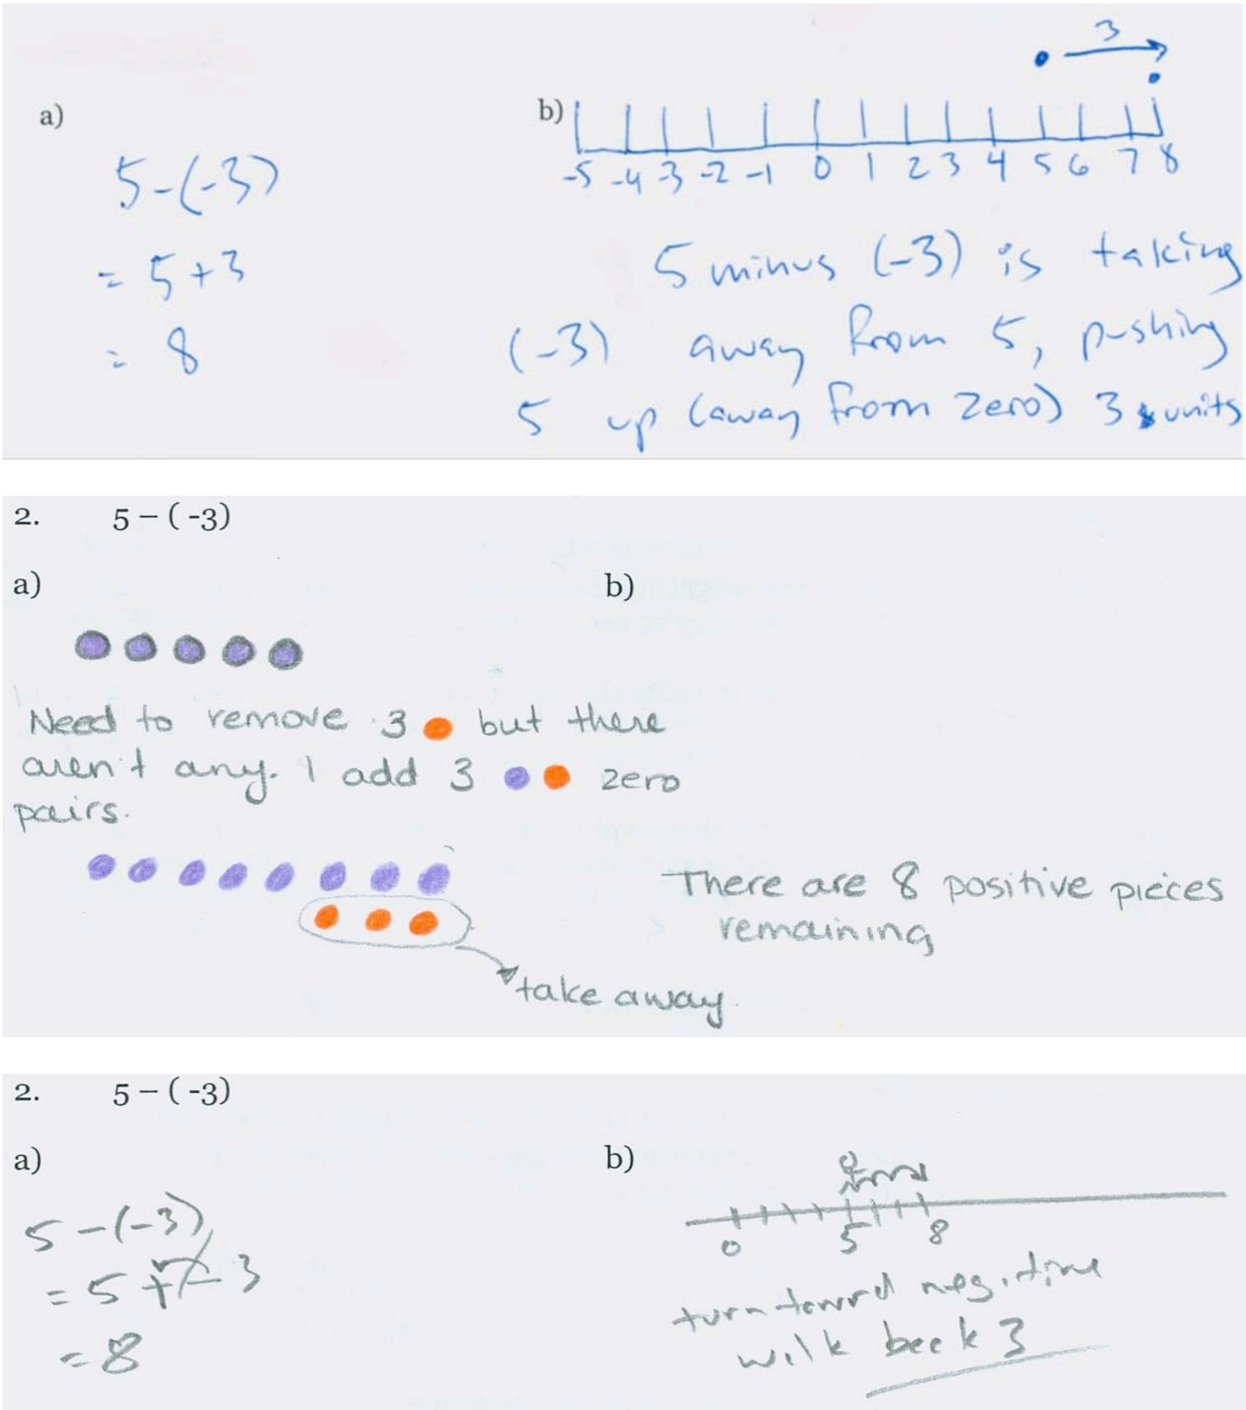

Figure 3. Post-test responses to 5-(-3). Part a) asks for answer and Part b) for explanation.

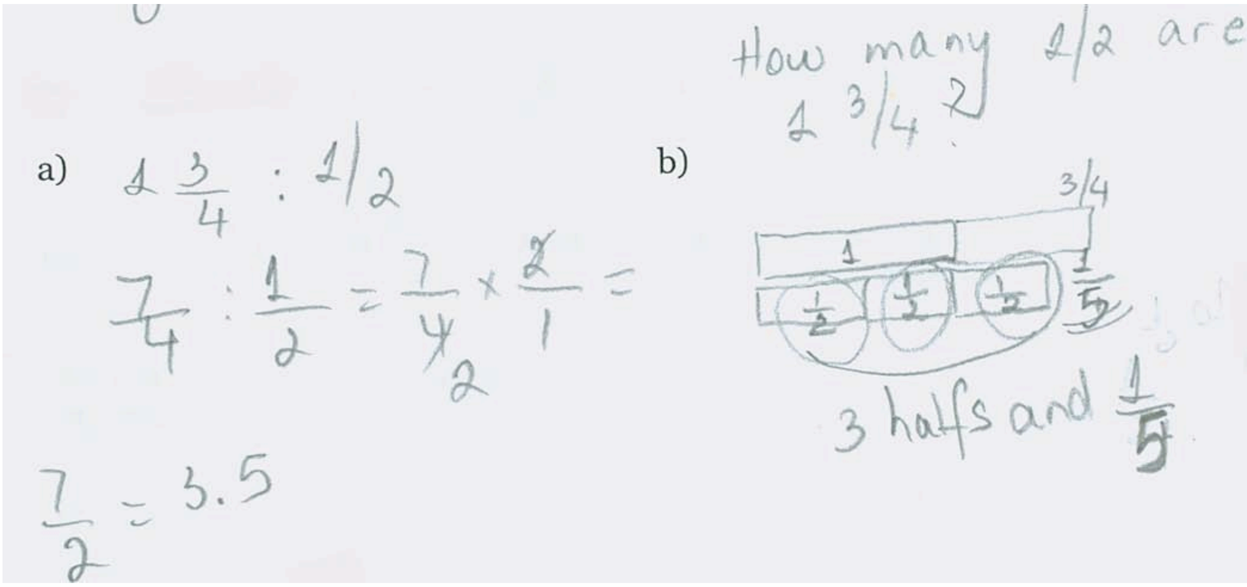
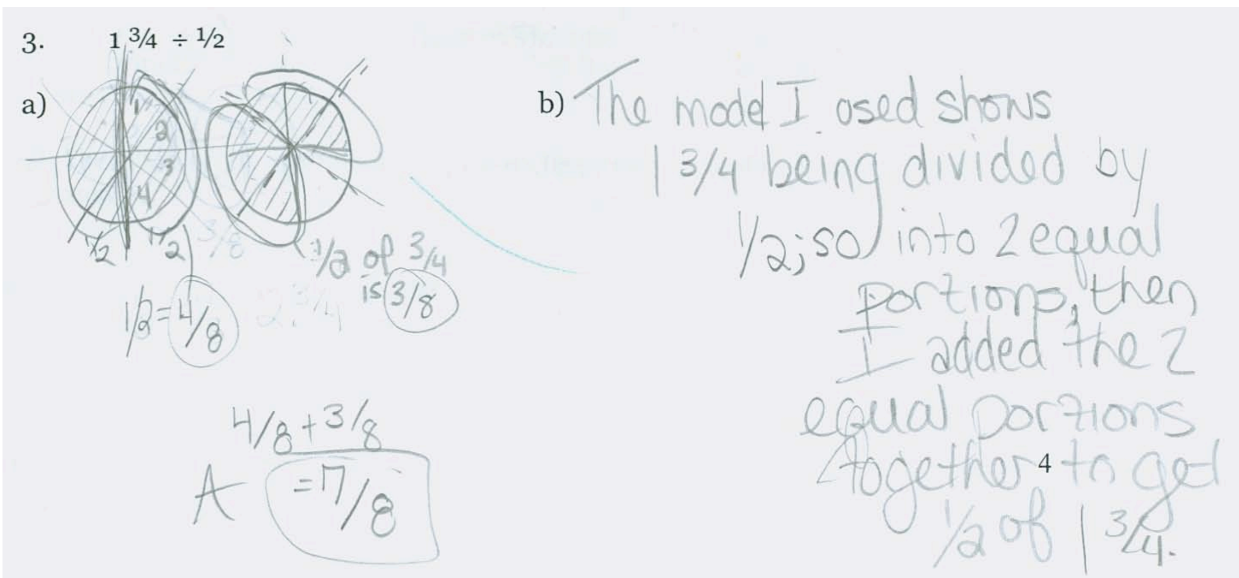
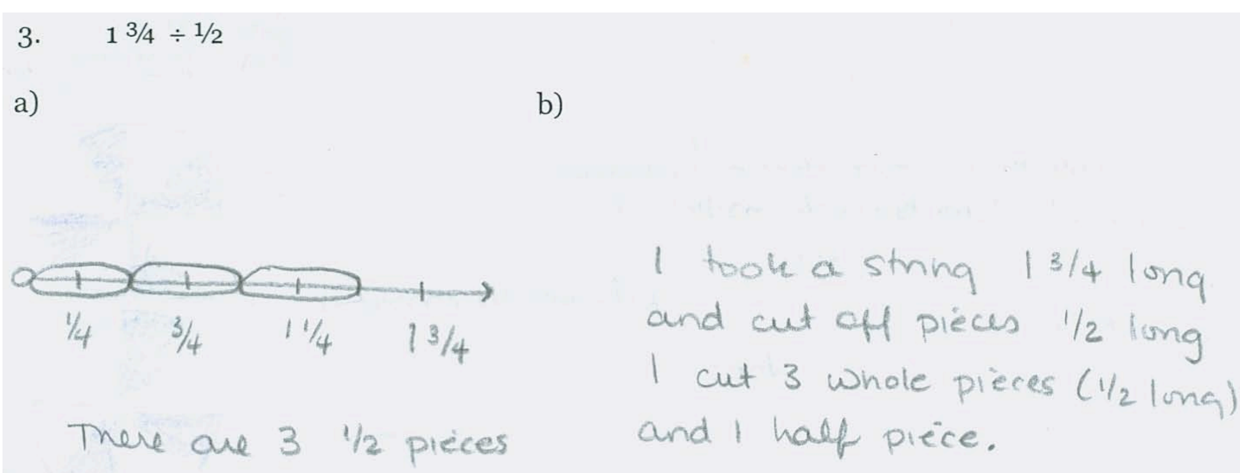
Selected Post-test Survey Responses to Fractions Question



a)
1 3/4 : 1/2
7/4 : 1/2 = 7/4 x 2/1 =
7/2 = 3.5
b)
How many 1/2 are 1 3/4 ?
3/4
1
1/2 1/2 1/2 1/5
3 halfs and 1/5



3. 1 3/4 ÷ 1/2
a)
1/2 of 3/4 is 3/8
1/2 = 4/8
4/8 + 3/8
A = 7/8
b) The model I osed shows 1 3/4 being divided by 1/2; so into 2 equal portions, then I added the 2 equal portions together to get 1/2 of 1 3/4.



3. 1 3/4 ÷ 1/2
a)
1/4 3/4 1 1/4 1 3/4
There are 3 1/2 pieces
b)
I took a string 1 3/4 long and cut off pieces 1/2 long
I cut 3 whole pieces (1/2 long) and 1 half piece.

Figure 4. Post-test Responses to 1 ¾ ÷ ½. Part a) asks for answer and Part b) for explanation.

Interview data indicated that at the pretest nearly all participants viewed mathematics as "something to memorize". Interview responses at the post-test suggest that participants generally felt very good about their deepened understanding, yet there were still indications related to the fragility of the newly developed understanding. Many referred to their newly emerging conceptual understanding as a kind of revelation. For example, one participant stated "I feel like I am learning mathematics for the first time".

Discussion and Implications

An examination of the pretest data, both quantitative and qualitative, suggests to us that most participants were operating with an almost exclusively procedural view and capacity of standard elementary mathematical processes. The vast majority of survey respondents were virtually unable initially to offer any conceptual basis for the calculations they generally quite readily performed. Interview responses indicated that many participants were both aware of, and deeply troubled by, this situation. Significant improvement was noted in many cases by the post-test, even though the number of hours of mathematics coursework was less than ideal. While at times imperfect or incomplete, participants had generally made strong improvements. Even more encouraging was the sense that many participants now had a different view of mathematics, and their role in it.

Our results underscore the on-going and desperate need for specialised and supportive mathematical experiences for preservice teachers. We continue to be astonished that even with curriculum reform in Ontario, teacher candidates are entering education programs with virtually a purely procedural view of the subject and a sense that mathematics is a subject in which you have to follow the "steps" or memorize the "rule". While we had observed preservice teachers' struggles prior to this study, the extent of their initial lack of conceptual understanding was still a surprise. An awareness of the pretest results helped us be more sensitive to the struggle and effort required by participants as they developed so significantly during the one-year program.

Concurrently with the development of recommendations for preservice teachers in the U.S. (National Council on Teacher Quality, 2008), the Canadian *Working Group on Elementary Mathematics for Teaching* (Kajander & Jarvis, 2009) recommends that preservice teachers take a minimum of 100 hours of specialized mathematics courses. Since the mathematics methods course described is of a 36-hour duration, with only about half of the hours concentrated directly on mathematics concepts, we were far short of a desirable situation. Hence in year 3, an optional 20 hour course in "mathematics for teaching" was introduced, taken by about a quarter of the participants each year. As well, a mandatory examination in "mathematics for teaching" was introduced. Initial effects of these program changes seem promising, particularly for low-achieving students (Holm & Kajander, 2009). Further opportunities for participants to strengthen their conceptual mathematical understanding will likely be needed, however, before the full vision of mathematics teaching as is described in the *Standards* (NCTM, 2000) and elsewhere can be realized in their classrooms.

EXPLORING SHIFTS IN A TEACHER'S KEY DEVELOPMENTAL UNDERSTANDINGS AND PEDAGOGICAL ACTIONS

Kevin C. Moore	Dawn Teuscher	Marilyn P. Carlson
University of Georgia	Brigham Young University	Arizona State University
kvcmoore@uga.edu	dawn.teuscher@asu.edu	marilyn.carlson@asu.edu

Research has identified mathematical knowledge for teaching (MKT) as specialized knowledge that contributes to a teacher's ability to teach for understanding. This report discusses one teacher's (Claudia) MKT as she implemented research-based precalculus materials. Claudia initially encountered difficulty implementing the materials in ways that supported her students' learning. As the semester progressed, Claudia's understanding of the central ideas of the course deepened and specific ideas emerged as key for understanding other ideas. Once she became aware of these connections she made more informed pedagogical choices that supported her students' thinking and learning.

Background

It is well established that although content knowledge is an important attribute of a successful teacher, content knowledge alone is not sufficient to support students' learning processes (Shulman, 1986; Silverman & Thompson, 2008). Explorations into relationships between a teacher's content knowledge and her/his practice have identified *mathematical knowledge for teaching* (MKT) as a critical link between content knowledge and supporting students' learning (Ball, 1990; Simon, 2006). Recent studies (Silverman & Thompson, 2008) have emphasized the importance of exploring teachers' ability to transform content knowledge from personal understandings to knowledge that has pedagogical power in the classroom.

Project Pathways is an ongoing initiative with a focus on improving secondary mathematics teachers' practice and secondary students' learning. The project's interventions (e.g., graduate courses, professional learning communities, and workshops) intend to improve teachers' content knowledge and their ability to achieve conceptually oriented classrooms that engage students in problem solving activity. During initial phases (years 1-4) of the project the research team observed gains in teachers' content knowledge, but shifts in the teachers' pedagogical actions lagged behind the content knowledge shifts. When investigating the obstacles preventing the teachers from shifting their practice, project members identified that the mathematical content in their curriculum was incompatible with the mathematical ideas developed during the project's interventions.

In an attempt to better support the teachers in improving the conceptual focus of their teaching, the project shifted the concentration of the summer work and professional learning communities (PLCs) to examining and modifying the teachers' curriculum, but the teachers found revising their curriculum to be a daunting and exhaustive task. The heavy burden of writing curriculum led the project leaders to offer a research-based, conceptually oriented precalculus curriculum (Carlson & Oehrtman, 2010) for use by one precalculus teacher (Claudia). We conjectured that the combination of the *Project Pathways* interventions and curriculum tasks would support Claudia in realizing the desired shifts in her practice and students' learning. Our report discusses the role of Claudia's MKT in her implementation of the curriculum. Claudia's difficulties and successes with the curriculum illustrate the relationship between Claudia's content knowledge, her transformation of this knowledge in ways that inform her practice, and her ability to support her students' learning processes.

Theoretical Perspective

We leverage the construct of *key developmental understanding* (KDU) (Silverman & Thompson, 2008; Simon, 2006) to examine MKT in the context of secondary precalculus mathematics. Like Silverman and Thompson (2008), we believe that a teacher's mathematical conceptions and reasoning abilities influence her/his pedagogical choices and actions. In order to describe understandings that support MKT, Simon (2006) and Silverman and Thompson (2008) characterized KDUs as one's understandings and ways of reasoning that connect various ideas, provide foundations for learning other ideas, and support solving novel but related problems as a consequence of these understandings.

Although KDUs are critical features of a person's mathematical knowledge, Silverman and Thompson (2008) highlighted that a teacher's development of KDUs does not imply these KDUs will inform her/his practice. Silverman and Thompson suggested that MKT is developed when a teacher transforms a KDU in a way that shapes and informs their interactions with students. Specifically, Silverman and Thompson described:

> A teacher has developed knowledge that supports conceptual teaching of a particular mathematical topic when he or she (1) has developed a KDU within which that topic exists, (2) has constructed models of the variety of ways students may understand the content (decentering); (3) has an image of how someone else might come to think of the mathematical idea in a similar way; (4) has an image of the kinds of activities and conversations about those activities that might support another person's development of a similar understanding of the mathematical idea; (5) has an image of how students who have come to think about the mathematical idea in the specified way are empowered to learn other, related mathematical ideas. (p. 508)

As the *Pathways* interventions transitioned to focus more on applying the teachers' content knowledge to their teaching practice through curriculum design, we conjectured that the interventions would better support the teachers in developing KDUs that informed their pedagogical practices. We expected that our providing Claudia with quality curriculum would better position her to construct the MKT necessary to achieve shifts in her practice. Specifically, we conjectured that the use of quality curriculum would lead to Claudia developing KDUs and transforming these understandings in ways that informed her pedagogical actions.

Research Question

How does a teacher's MKT impact her pedagogical choices and ability to support student learning? How does a teacher's MKT impact her ability to successfully implement research-based curriculum?

Methodology

During the semester in which Claudia used the Pathways curriculum, she attended a weekly 50-minute PLC composed of 4-6 trigonometry and precalculus teachers. She also sporadically attended a 3-hour trigonometry PLC after school with two other trigonometry teachers and a project member (the first author of the report) who served as the PLC facilitator. The PLC members primarily examined the knowledge involved in understanding and learning key ideas of their courses. The PLC members also spent time developing conceptually oriented tasks for classroom use.

Three *Project Pathways* members regularly observed Claudia's classroom and worked with Claudia to answer her questions about the curriculum. Claudia's classroom was videotaped two class periods a day and these videos were digitized for analysis. The project members took field notes during Claudia's PLC meetings, when observing Claudia's classroom, and during her meetings with project members. The project members directed the field notes towards Claudia's content knowledge as revealed by her interactions with her colleagues, her students, and the project members. As Claudia interacted with her students during class sessions, her responses and questioning offered insights into her mathematical understandings and thinking. Similarly, her interactions during the PLC meetings offered glimpses into her content knowledge, particularly when the PLC sessions focused on discussing how students learn various topics. Relative to Claudia's meetings with *Pathways* members, she often asked for clarification of the mathematical ideas driving the curriculum. Claudia also discussed questions she had about the solutions and reasoning that her students were providing. Collectively, the project members used these data sources to characterize Claudia's teaching practice by describing her mathematical content knowledge, pedagogical actions, and improvements in her students' learning.

As the semester progressed, the project members who observed Claudia's classroom noted shifts in her practice and her ability to scaffold her students' thinking. In order to characterize shifts in her teaching and her questioning, the research team analyzed her classroom videos to document relationships between her propensity to focus on student thinking and her questioning techniques (Teuscher, Moore, Marfai, Tallman, & Carlson, submitted). After analyzing her classroom sessions, the research team chose three particular sessions that were representative of her shifts over the course of the semester.

The present study extends the aforementioned study (Teuscher et al., submitted) by analyzing Claudia's thinking and MKT during the classroom sessions that the research team deemed to be representative of Claudia's practice (see Teuscher et al. for an explanation of the case selection). Compatible with Thompson's description of a conceptual analysis (Thompson, 2008), we analyzed Claudia's interactions with her students in an attempt to characterize the mental actions driving Claudia's pedagogical actions (e.g., the mathematical content knowledge that informed her questioning and utterances). We then compared the results of this analysis to the project members' field notes that were taken during PLC meetings in which the teachers discussed similar content topics. By comparing these data sources, we characterized information about Claudia's content knowledge and MKT and the influences of these knowledge bases on her pedagogical actions.

Results

In the following section we report the results of Claudia's interactions with her students when they were completing two in-class activities. We also discuss Claudia's meetings with project members and her PLC members in the context of her MKT and ability to support her students' learning.

During the first week of class Claudia's students completed The Diving Task (Figure 1) while working in groups of 3 or 4. The task asked the students to compare and contrast the meaning of average rate of change and average as an arithmetic mean. The previous lesson developed a meaning of average rate of change in the context of average speed (e.g., the constant rate of change needed to cover the same distance in the same amount of time). *Excerpt 1* presents Claudia's interactions with one group of students.

In a diving competition, a diver received the following scores from 4 judges after making a dive.

Judge 1	Judge 2	Judge 3	Judge 4
8.7	9.3	8.0	8.2

How does the meaning of the word *average* when computing a diver's average score compare with the meaning of the word *average* when computing a diver's average speed?

Figure 1 – The Diving Task

Excerpt 1.

S1:	Do you know the meaning of average in this problem?
C:	Tell me what you have so far.
S2:	If the average is 8.55…
C:	Okay, so…
S1:	I said that 8.55 would mean average would be like the constant or the, I don't want to say constant.
S2:	You said approximate.
S1:	The approximate score.
C:	Keep going.
S3:	Can we use mean to describe average?
C:	(*laughs*) No.
S1:	The approximate score to get your score.
S4:	No, cause…
C:	Your…
S4:	…the approximate score given by the judges for that dive…
C:	Keep going, the approximate score by the judges, what…
S4:	…for the dive.
C:	Okay, for what dive?
S2:	For the diver's dive.
C:	For just one dive?
S:	Yeah (*students in unison*).
S2:	They only did one dive.
S1:	If each, if one judge per dive or isn't it…
C:	Four judges for the one dive, okay, alright. Okay so tell me again what you said.
S4:	The approximate score given by the judges for the one dive.
C:	Okay, by which judges?
S1:	By the four judges.
C:	By what?
S2:	By the four judges. (*Claudia confirming the student's answer and moving on)*

During this interaction, Claudia's questioning did not result in her students making explicit connections between average as an arithmetic mean and average rate of change. For instance, she failed to leverage a student's reference to "constant" (lines 5-6) and she did not ask the students to expand on their meaning of "approximate" (lines 7-8, 12, & 15), nor did she ask them to compare and contrast their thinking with the outcomes of previous tasks. Additionally, Claudia's questions were mathematically shallow and she allowed the interaction to end with the students failing to develop the understandings as intended by the curriculum.

Claudia approached a project member after this class session and expressed an uncertainty of the ideas driving the diver task. She also expressed confusion about the tasks relation to previous tasks and claimed that her confusion about the intent of the questions prevented her from determining how to guide and support her students' thinking. Claudia's interactions with the project members, in combination with her interactions with her students in *Excerpt 1*, suggest that Claudia did not understand the content in ways compatible with the curriculum's intent. In lieu of her lacking the understandings necessary to make appropriate sense of the activity, she did not have the foundational knowledge necessary to identify ways to support her students in learning the key ideas of the lesson. Furthermore, Claudia's actions indicate that her understanding of arithmetic average consisted of a vague connection to an approximate value and that she had not cognitively distinguished notions of average rate of change and an arithmetic average in a way that she could support her students in making similar comparisons.

As the semester progressed, the project members observed an increase in the mathematical depth of Claudia's questioning in both her classroom and during her meetings with project members. During a lesson on linearity, during which the students created a graph, Claudia questioned her students in an attempt to draw their attention to determining changes of output for equal changes of input. The shifts the project members observed near the middle of the semester indicated that Claudia was developing understandings that enabled her to interpret the curriculum tasks in ways consistent with the curriculum's design. However, our analysis of Claudia's classroom also revealed that she was having difficulty engendering these understandings in her students (Teuscher et al., submitted). Such a finding suggests that Claudia had not transformed her understandings into mathematical knowledge that was useful in her teaching (e.g., MKT).

As the semester progressed the project members observed Claudia continuing to improve her content knowledge. The project members also observed a transition in Claudia's ability to support her students' learning. The concluding module of the precalculus curriculum introduces trigonometric functions, beginning with a lesson on angle measure. Following the lesson on angle measure, a lesson introduces the sine and cosine functions. Specifically, the curriculum introduces these two trigonometric functions using a circular motion context (e.g., a bug on the tip of a fan blade) and asks the students to determine how the bug's vertical distance above the center of the fan varies as the fan rotates. When beginning this problem, Claudia posed the following question: Does the angle measure change if the radius of the fan is changed, but the distance the bug travels (measured in radians) is not changed? *Excerpt 2* presents Claudia and two students discussing their response to this question.

Excerpt 2

S1:	How does the angle change if the radius changes? The angle stays the same.
S2:	Yeah, but if the distance traveled around stays the same, but the radius changes then it will be a different amount of radians.
S1:	Oh yeah.
S2:	It will be inversely proportional.
C:	It will be a different amount of radians?
S2:	The angle measure.
S1:	Well the distance the bug travels.
S2:	Because as the radius gets bigger, the arc length will be a lesser portion of the circle meaning a lesser angle.
C:	Ok, so draw, ok so let's take any two circles, if you were to cut out a 90 degree angle, actually, draw a circle inside of a circle for me.
S2:	The arc length is…
C:	Now draw another circle - yeah.
C:	Ok, now do you have a Wikki Stix, does anyone, you do?
C:	Ok, first for the inside circle I want you to mark off one radian of the

	circumference.
S2:	Can we just take a Wikki measure, do I have to use radians?
C:	She is trying to find the center of her circle though, is what she is doing. Here let me get you a smaller Wikki Stix. Here is a skinner one it might be easier to use.
S1:	It is two and half so it would be like in the middle
C:	Yeah so for the small circle mark off one radian of the circumference. Ok do the same thing for the bigger circle.
S2:	One radian?
C:	Yeah one radian
S2:	But the radian of an angle measure is not arc measure, the radian and arc measure are the same. No, the angle measure is the same…
S1:	One radian is the same…
C:	What is the same about one radian?
S1:	The same angle.
C:	Yes, what is the not the same about one radian?
S1:	The arc length.
C:	Yes, do you see that S2?
S1:	But then what is distance traveled? Is that the arc length?
S2:	Yes.

Claudia first asked the students to clarify their claim that the radian measure changes when the radius changes (line 6). Student 2 made an incorrect claim (lines 9-10) and in order to support the student in confronting his misconception, Claudia focused the students' attention on the idea of measuring arcs in radii (lines 11-29). Claudia's line of questioning led the students to realize that an arc of one radian, regardless of the size of the circle, corresponds to an angle with the same amount of openness (lines 28-34). As their interactions continued, Claudia probed her students to elaborate on the implications of measuring arcs relative to the radius, with Student 1 concluding, "The angle measure doesn't change if the radius is changed."

Later in the class session, the same group of students attempted to graph the bug's vertical distance above the center of the fan in relation to the bug's distance traveled around the fan. The students were experiencing difficulty relating the two quantities when Claudia joined their discussion (*Excerpt 3*).

Excerpt 3.

C:	Let's back up a step…Your bug's going to start moving. Now what's going to happen to the total distance?
S1:	It's going to increase.
C:	Ok, alright. And what's happening to the vertical distance, in general?
S1:	It's increasing at a decreasing rate.
C:	Ok, it's going to increase, and then, why did you say it's going to increase and then decrease (*referring to a student's statement given previous to this interaction*)?
S1:	'Cause once it gets to 12 o'clock, then it's going to, the vertical distance is going to decrease back to zero.
C:	Ok, what is the vertical distance at 12 o'clock.
S1:	About 2.6 feet.
C:	And how do you know that?
S1:	Because that's the radius.
C:	Ok, so, you know here (*pointing to the top of the fan*) that your vertical distance is

15		2.6 feet. And then what does it do?
16	S1:	It decreases.
17	C:	So, at a total of distance of zero, your vertical distance is zero, right?
18	S1:	(*nodding yes*)
19	C:	Now, what is your…
20	S1:	Then your total distance is 2.6 and your vertical distance is 2.6 as well.
21	C:	So when you get to the top of the circle, when you get to here (*pointing to the top*
22		*of the circle*), have you traveled one radian?
23	S1:	Ya.
24	C:	How many radians are there in a half circle?
25	S1:	Oh, um, pi.
26	C:	So how many radians have you traveled to here?
27	S1:	Pi over two.
28	C:	Ok, so what is that?
29	S1:	That is 1.57 (*identifying values on graph*).

In order to support the students in determining the graph, Claudia prompted the students to reason about variations in the total distance (lines 1-2). As the discussion progressed, Student 1 identified that the vertical distance increased and then decreased as the total distance increased (lines 5-16). Claudia then asked the student to describe specific pairs of values and Student 1 incorrectly identified that the bug travels an arc length of 2.6 feet from the starting position to the top of the circle (lines 17-20). In response, Claudia returned the student to reasoning about measuring the arc length in terms of a number of radii (lines 21-29), which supported the student in correcting her graph and creating the sine graph by the completion of this activity.

Claudia's continued focus (*Excerpts 2-3*) on measuring arcs in radii (which was covered in a previous lesson) suggests that she found this to be an important idea for understanding the sine and cosine functions. Claudia probed her students in ways that supported their measuring arcs in radii when determining the graph of a trigonometric function. These actions suggest that Claudia had developed an understanding of angle measure that she considered developmentally key for learning trigonometric functions (e.g., a KDU), and that she had transformed this understanding in a way that influenced her pedagogical actions and ability to support her students' learning (e.g., she developed MKT).Claudia's interactions with her trigonometry PLC further illustrated that her understanding of angle measure informed her pedagogical actions when teaching the sine and cosine functions. During the year prior to Claudia's use of the curriculum, it did not occur to her or her PLC members that reasoning about measuring arcs in radii is foundational for constructing understandings of the sine and cosine functions. After Claudia's use of the curriculum, her PLC returned to the topic of trigonometry and the PLC members chose to design a lesson exploring applications of trigonometric functions. Claudia became troubled about the topic choice and explained that she did not believe that they could teach applications of trigonometric functions conceptually without teaching angle measure in a way that supported students' understanding of trigonometric functions. Claudia's justification for her decision is consistent with our claim that Claudia's understanding of angle measure as measuring arc lengths in units of radii was key for the way she had come to conceptualize trigonometric functions, and that this understanding provided a basis for her pedagogical decisions.

Discussion and Conclusions

Claudia exhibited content knowledge shifts during the early phases of implementing the curriculum, but she had difficulty supporting her students' learning. At these early stages, her improved understandings did not include connections that supported her re-conceptualizing her teaching in terms of how her students may form similar understandings. However, Claudia's sustained focus on her students' thinking, along with the support she received from the project members, resulted in her building connections that she leveraged to support her students' learning. Specifically, as she developed and transformed KDUs to MKT, the research team observed Claudia scaffolding her students' learning by drawing connections between ideas. Future research should examine the supports (e.g., conceptual curriculum) necessary to help teachers transform their understandings to knowledge that has pedagogical power.

The findings from this study reveal that the nature of a teacher's understanding of an idea is key to her/his conceptualization of teaching that idea and her/his interactions with students when teaching that idea. Claudia's transitions over the course of the semester suggest that a teacher transforming her/his content knowledge in ways that inform her/his practice (e.g., developing MKT) is a complex process. As Stigler and Hiebert (1999) have noted, a majority of pedagogical shifts are superficial. However, Claudia's knowledge and pedagogical transitions were substantive. These shifts that we observed are consistent with Silverman and Thompson's (2008) claim that significant changes in teaching practices result from "pedagogical conceptualizations of the mathematics: both the sense they have made about the mathematics and their awareness of its conceptual development" (p. 507). Claudia was unable to support her students' learning in profound ways until she had acquired key developmental understandings (e.g., measuring arcs in radii to develop trigonometric functions) and used these understandings to scaffold her students' learning (e.g., she transformed these KDUs to MKT). The findings presented illustrate the necessity of future studies that explore the role of KDUs in teaching and the process by which teachers' transform KDUs to understandings (e.g., MKT) that improve their ability to scaffold and build upon their students' learning.

This study utilized a qualitative design of naturalistic inquiry to deeper and better understanding three preservice teachers' (PTs) knowledge on unit and unitizing of fractions. Findings demonstrated PTs had difficulties profoundly conceptualizing the unit whole and their unitizing abilities were limited. When responding to students' work, PTs identified their own misconceptions and were able to provide some basic instructional strategies for correcting students' misconceptions.

Introduction

For decades, a large percentage of studies have shown that teaching and learning fraction concepts is difficult (e.g., Ball, 1990, 1993; Lamon, 1996, 1999; Ma, 1999; Newton, 2008). Recent results of fourth graders' mathematics performance on the National Assessment of Educational Progress (NAEP, 2009) showed that only 25% of the participants could identify the fraction, 5/8 as the closest value to 1/2 when comparing it to other given values. In contrast, a majority (73%) chose incorrect multiple-choice answers of 1/6, 2/2, and 1/5 demonstrating participants' lack of fraction number sense. The results demonstrated many students did not acquire a strong understanding of fractional concepts during classrooms instruction. Additionally, this may reflect that teachers have failed to provide essential fractional knowledge for children.

Literature has documented that the problem of learning fractions was not limited to young children but adults as well. For instance, Ball (1990) and Ma (1999) acknowledged numerous inservice and preservice teachers (PTs) had insufficient knowledge of fractions necessary for classroom instruction. As a teacher plays a significant role in teaching and learning a particular concept, it is important for the teacher to have profound knowledge of basic concepts. Studying teachers' knowledge for teaching fractions is indeed important as the nature of the topic is complex to learn and teach. However, many past and current researchers were limited in their focus and overemphasized division of fractions (e.g., Ball, 1990, 1993; Li, 2008; Ma, 1999; Rizvi & Lawson, 2007; Tirosh, 2000). Much remains to be explored concerning other fractional concepts that are equally important for students' learning.

The concept of unit is important when a teacher first introduces fractions to students, however it has frequently been neglected in classroom discussions (Lamon, 1999). When teachers and textbook authors placed more emphasis on using the same unit such as one pizza, students assumed that a unit was always a single pizza (Lamon, 1999). Lamon further claimed that teachers' instruction failed to address the important concept of units during the teaching and learning of fractions possibly creating confusion for students. For example, Ball (1993) illustrated a 9-year-old student's misconceptions of the idea of unit when comparing 4/4 and 4/8. The student drew two rectangles (Figure 1) with unequal unit wholes and these models showed the values, 4/4 and 4/8 were equal.

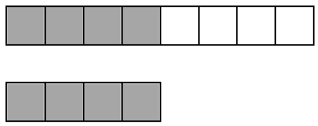

Figure 1. A representational model by a 9-year-old in Ball (1993).

Based on this representation, it appeared the student was not able to connect the concept of unit whole and role of a common unit when comparing two fractions. The student and classmates struggled to identify which one was a larger value from the drawing failing to understand that the rectangles must be the same size (same unit wholes) before making any comparisons. Ball's research findings supported Lamon's argument that many children tended to refer to a unit (one) as a single item (e.g., a single pizza). Most of them are not aware the unit may include more than one item or may consist of items packaged as one known as a composite unit. For example, a package (the unit) may contain two pizzas with the same or different kinds. In this case, it is called a one two-unit and not two one-unit pizzas. Children should be able to differentiate between these two types of units: simple and composite units.

Unitizing is another fundamental topic in teaching and learning fractions that is related to the concept of unit. Lamon (1996) defined unitizing as "The cognitive assignment of a unit of measurement to a given quantity; it refers to the size chunk one constructs in terms of which to think about a given commodity" (pg. 170). For instance, a case of cola can be referred to as a unit of 24 cans, 2 units of 12-cans, or 4 units of six-cans (Lamon, 1999). Lamon also found that the ability to think flexibly with different-sized units is largely dependent on understanding of simple and composite unit concepts. These two concepts were considered basic knowledge for teaching and learning fractions and have long been misinterpreted during classroom instruction. Teachers should first understand unit and unitizing concepts deeply and know how to teach the topics effectively to students.

Theoretical Framework

As fractions are difficult and complex concepts to teach, it is essential for teachers to have a profound mathematical knowledge to teach them effectively to ensure student understanding. The present study focused on PTs' knowledge for teaching and learning units and unitizing of fractions utilizing Ball, Thames, and Phelps' (2008) mathematical knowledge for teaching (MKT) framework emphasizing specialized content knowledge (SCK), knowledge of content and students (KCS), and knowledge of content and teaching (KCT). According to Ball et al. (2008), SCK is the knowledge and skill specifically necessary for teaching mathematics and not necessary in other settings. It involves the understanding of different interpretations of mathematical operations, languages, representations, and models. KCS combines teachers' knowledge about mathematical content and students' knowledge concurrently. A teacher must always consider student thinking, conceptions, and misconceptions of a particular mathematical topic to make wise instructional decisions (Cooper, 2009). On the other hand, KCT is related to the interaction between teachers' understanding of mathematical content and pedagogical issues contributing to students' learning. For example, teachers need to evaluate which instructional representations are effective in teaching and learning fractions.

The purpose of this study was to examine prospective teachers' (PTs) understanding of unit and unitizing based on Ball et al.'s (2008) categories of teaching knowledge: SCK, KCS and KCT. The findings will provide some evidences of PTs' mathematical knowledge for teaching these concepts. Teacher educators may use this evidence to plan appropriate instructional strategies to improve PTs' learning so that they can acquire the knowledge of unit and unitizing in depth for use in their future classroom instruction.

Method

This study was guided by Lincoln and Guba's (1985) naturalistic-constructivist model of inquiry. Specifically, the qualitative data were gathered through a collective case study (Merriam, 2009) to gain a deeper and better understanding on the selected PTs' knowledge of units and unitizing of fractions. The research questions guiding this study were:
1) What knowledge did selected PTs possess about units and unitizing of fractions?
2) How did selected PTs respond to students' solutions of task-based problems on unit and unitizing of fractions?
3) What instructional strategies did selected PTs recommend for correcting students' misconceptions based on the solutions of task-based problems on unit and unitizing of fractions?

Initially, four female PTs at a southwestern public university were invited through email to participate in this qualitative research. Only, three PTs, Alisa, Talima, and Monica (pseudonyms) volunteered to be part of the study. These three cases were *particularistic* and *heuristic* in nature (Merriam, 2009). According to Merriam, particularistic means "case studies focus on a particular situation, event, program, or phenomenon" (p. 43) whereas heuristic provides readers with meaningful understanding of the context under study. Specifically, the present study focused on understanding PTs' conceptions and misconceptions of units and unitizing (SCK), ability to analyze students' responses (KCS), and PTs' teaching strategies for fraction instruction (KCT). All participants were undertaking a bachelor's degree in education and seeking Texas teacher certification. Alisa and Monica are in the elementary education (PreK-6) major with specialization in language arts and early childhood respectively. On the other hand, Talima is an international student with an emphasis in Grades 4-8 Math/Science. These three PTs completed most of their required coursework, will do their student teaching in the Fall, and graduate the following semester.

The selected fractional tasks were adapted from Lamon (1999) and were expected to disclose the context under investigation, the PTs' knowledge of unit and unitizing. A pilot test was administered to examine the tasks in terms of reliability and validity for assessing PTs' knowledge. All the tasks involved questions such as "how much?" versus "how many?" It was important to capture an individual's understanding of two kinds of questions that examined similar but different mathematical concepts (Sowder, Philipp, Armstrong, & Schappelle, 1998). Specifically, Task 1 focused on the concept of unit wholes in which the participants were expected to find the shaded part of a pizza that was eaten. Task 2, 3, and 4 investigated the knowledge of unitizing. Participants were required to verbalize their reasoning while solving the tasks. In addition, they were asked to analyze three to four children's responses to the same problems they had answered earlier (i.e., subsection 1b and 2b). Based on the children's responses, the participants were required to provide some instructional practices that may be used for teaching the concepts effectively.

The data were collected during Spring 2010 through a semi-structured, open-ended interview session based on task-based problems of fractions. Two participants agreed to be audio-taped, whereas notes were taken during a session with another PT who did not want to be audio-taped because of personal reason. Each session lasted about 30 to 40 minutes depending on the interviewee's responses when they were presented with fractional task-based problems. During the interview, the participants' behaviors and their working papers were noted for analysis as well. The audio-tapes and notes were transcribed and were sent to participants for member check. Also, PTs' working papers were used to triangulate the observation notes and the transcripts of the audio recording and note taking for the one who was not audio-taped. Then, the transcriptions were unitized and analyzed into smaller significant parts or ideas that developed during the examination of data using the constant comparison analysis (Leech & Onwuegbuzie, 2007). Common patterns in participants' responses were grouped into interpretable themes (i.e., SCK, KCS, KCT) in order to answer the research questions.

Results

As noted earlier, the findings were presented in terms of PTs' conceptions and misconceptions of unit and unitizing concepts (SCK), ability to analyze students' responses (KCS), and teaching strategies for fraction instruction (KCT). Specifically, the researchers used responses under category SCK to answer the first research questions. The remaining responses were grouped into categories KCS and KCT and were interpreted to support the final two research questions.

Knowledge of the Units and Unitizing (SCK)

The study showed participants had insufficient SCK about the units and unitizing. They could not distinguish between simple and composite units as defined by Lamon (1999). Specifically, the PTs were not able to recognize that the unit can be a group of objects. For example, in Task 1a the PTs were presented two pizzas using two similar size circles, which were divided into four parts and the shaded part denoted the amount of pizza eaten. All PTs agreed that the first shaded circle was one whole pizza and one of the four parts shaded denoted ¼ of another pizza. Monica indicated 1¼ units of pizza were eaten in contrast to Talima who wrote it in the form of an improper fraction, 5/4. Monica believed the two pizzas were two separate and could not see how the pizzas could be a whole unit or a composite unit. Interestingly, Alisa and Talima mentioned 5/8 (simple unit) as an alternative answer for this task demonstrating that their knowledge was not profoundly sufficient because they ultimately confused the value (5/8). Alisa believed that the pizza contained eight total parts and there were only five parts shaded. However, she canceled 5/8 and argued 1¼ was the best one after considering the case of two pizzas. A week later Alisa contacted the interviewer through an email and said, "I thought about the first math problem right after I left there. It was 5/8 of the pizza, because 'the pizza' refers to all the pizza". Based on Alisa's latter response, she seemed able to reflect on her own thinking about the concept of unit fraction - a group of two pizzas.

In addition, the PTs were presented Task 1c, which related two different sizes of pizza (i.e., small cheese pizza and medium pepperoni pizza) that were cut into eight equal-size pieces. Also, the participants were informed that two and three slices of the cheese and pepperoni pizzas were eaten respectively. When they were asked how much pizza was eaten, Alisa and Talima were able to identify the different sizes of the wholes (small versus medium) and to obtain the correct answer (i.e., 2/8 small pizza and 3/8 medium pizza). These same PTs said the sizes were not equal, therefore, one could not add both parts together to get 5/16. In this case, it seemed that they could understand the concept of common unit as discussed by Ball (1993). Alisa further argued that it was impossible to add two different sizes of pizza similar to adding apples and oranges. In contrast, Monica counted all the number of pieces eaten from two different sizes of pizza and provided 5/16 of the total pizza as the answer. Monica's latter response was contradictory with her earlier session for Task 1a in which she said that two items could not be put together to become a larger one unit. It showed that Monica had misconceptions about the concept of units because she could not associate the different sizes of pizza meaning unequal unit wholes. The select PTs' specialized content knowledge (SCK) of a unit-whole was inconsistent; they did not understand that a group of items of similar sizes could be one-unit whole.

On the other hand, in Task 3a the PTs' responses revealed their unitizing abilities were different. The task required PTs to decide which one was a better buy between two cereal boxes: 16 ounces ($3.36) or 12 ounces ($2.64). Alisa simply thought that the bigger one would be cheaper per ounce and upon this based her generalization even though she admitted that this may be applied 80% of the time. Talima unitized the number of ounces with the rounded price ($3) to obtain an estimated cost per dollar. She chose the larger box because she could get more ounces per dollar. Monica calculated the difference of prices ($0.70) and amount of cereal (4 ounces) between the two boxes. She estimated $0.60 and $0.80 per ounce for each box respectively deciding to choose the cheaper box if the calculation was correct. In contrast to Task 3a, PTs possessed a similar understanding of how they unitized a case of cola in Task 2a. The participants were provided a scenario, "Steve took a case of cola to Marcia's party, but it turned out that many of his friends drank water. He ended up taking three quarters of the cola home a. How much cola did he take home?"Alisa, Talima, and Monica agreed that the answer was ¾ of whatever the unit whole was. In addition, Alisa visualized her thinking of the case of cola by using a standard case of 12 cans, then multiplied ¾ with 12 and got 9 cans of cola as the answer. However, she still believed that ¾ of the case of cola was still the best answer as the task did not indicate the actual cans of cola in a case.

The "how many" question was quite easy for the PTs even though only Alisa got the answer correct during her first attempt. Alisa explained her working algorithmically,

> I just look at the total [writing 7⅓], how many ⅓ [writing ⅓ under "a second super piece free"] are in there? So, ok 21/3 plus 1/3, 21..7 times 3 [writing 7x3 on the left side of 21/3] equals 22/3 [writing 21/3 + 1/3 = 22/3]. Then 22 divided by 2 equals 11 [writing 22/2=11], 2 is what each customer can get....each customer will get [writing each customer will get] because there is buy one get one free [writing buy 1 get one free]. Ok, so 11 [circle 11] customers [writing customers as the label and underlining the word].

On the other hand, Monica and Talima used pictorial representation to answer this task. They drew eight circles, divided each into three pieces and shaded 7⅓ circles. Then, they paired every two parts and counted the number of pairs together which gave them 12 at first. Talima counted back and realized that she made a 'silly mistake' when adding the number. Although Monica did not check the final answer, she, Talima and Alisa had a clear understanding of 'how many' as compared to 'how much' in Task 1a, 1c, and 2a. When they were asked about the difference, Alisa mentioned the 'how many' question was easier to solve compared to the 'how much' question. Talima argued that 'how much' was related to measurement and 'how many' was for counting items. On the other hand, Monica thought that when a question asked 'how much pizza', it would mean number of slices and 'how many pizzas' referred to how many whole pizzas were involved. The select participants' responses were similar to results found by Sowder et al. (1998).

Knowledge of Content and Students' Responses (KCS)

The select PTs were able to analyze the children's responses by providing brief descriptions supporting their arguments albeit they had some difficulties on their own. The PTs could identify from the children's responses that they failed to label the final answer for Task 2b. For this reason, the PTs had difficulties interpreting what size chunks the children considered as a case of cola. At some points, the PTs were not sure what the children were thinking and how hard it was for them to predict the figures based on the children's unlabelled responses. In general, Monica explained,

> It seems like that they all assume something to be a whole, maybe I would ask them what they consider the whole to be..try to find out why and how they are getting these answers because it just give me numbers. I would ask them maybe to show their work, go back and show their work and then resubmit it or I will ask them to maybe verbally explain to me what they were thinking, what their thinking process was…to try to find out.

In contrast, Alisa and Talima were able to consider students' thinking, conceptions, and misconceptions when responding to this task. Specifically, they focused in much detail, on the number that children provided. Alisa and Talima tried to predict children's thinking with some drawings and working backward to solve the problem.

Through the observations, the interviewer noticed that Alisa and Monica slowly realized their own mistakes to their previous answer while they spoke aloud their reasoning about the children's responses in Task 1b. It showed they were able to make connections to what they already knew. Specifically, Alisa was able to detect her own misconceptions when reading Joe's response:

> Alisa: Ok, Kristin did 5/4 because 5 little ¼ pieces are shaded. She was thinking in the right direction that she forgot that it's ¼ of each pizza but there two pizzas so there 8 total pieces [I: Ok]. So 5 little one ¼ pieces, but what's the total? She..she put the total 4 but the total 8 of ¼ little pieces [I: Ok]. So, not correct, sorry Kristin [laughing and put a wrong sign beside Kristin's answer]. And then Jean…Jean got it correct 5/8 because there is eight pieces and 5 are colored. That's correct Jean. They got the total number and little pieces number. Tom, 1 and a bite. I guess that's correct but a bite is not as you know descriptive, that's a big bite I think. But guess you could call it correct because a bite could be ¼ of a pizza [writing ¼ denotes a bite]. Joe, it must be 5/8 because 5/4 is impossible. Ohhh..5/4 is [speak slowly]....[both were laughing]…now I think 5/4 is correct. Sorry 5/8 is not. [I: That's ok. That's ok] Oh my God I just realized that. I feel fall down [laughing]. Ok.
>
> I: Are you sure that Joe is correct? Yeah. Just..Just..yeah [Alisa: I know, it was difficult]. Just explain your….
>
> Alisa: Not I could think of it [drawing a big circle with 8 parts]. 5/8 is like..they could..I don't know... that will be like 8 and [shaded 5 parts] then 5 parts shaded, right. Now when I think of it 5/4, he's right because 4/4 equals 1 [writing it besides the big circle] and then the 1 left over will be the 1/4 [writing ¼ equals ¼ below 4/4=1]. So, may be 5/8 is not correct [laughing].
>
> I: 5/8 is not correct?
>
> Alisa: This is…this is confusing! [both were laughing]

These findings demonstrated that Alisa and Monica's thinking was easily influenced by the children's responses. They admitted that they were confused with their own answers after analyzing the responses supporting the notion of PTs' limited understanding of unit fractions. For example in Task 1b, Alisa and Monica believed the children's responses varied because the unit whole could be one object or more objects in the same context. They stated the children made choices about the unit they wanted to use. However, Lamon (1999) argued that deciding on the unit was not a personal choice and teachers should make sure students are aware that the unit may vary in every new context. Unfortunately, Talima was not aware of her own misconceptions while she was analyzing the responses. She strongly believed all the children did not understand the units and unitizing of fractions based on their responses.

Knowledge of Content and Teaching (KCT)

As mentioned earlier, KCT is related to the interaction between teachers' understanding of mathematical content and pedagogical issues contributing to students' learning. The findings found that the participants were able to suggest a number of basic instructional strategies that may be used in a classroom. As Monica, Alisa, and Talima acknowledged that the concept of unit and unitizing was important for teaching and learning fractions, they agreed with the use of concrete manipulatives, real-life application, and multiple representations such as pizzas and cake for learning fractions. Specifically, Talima strongly believed real-life examples made mathematical learning interesting for students when they shared ideas with their family. On the other hand, Alisa argued that teachers should use the same representations for basic fraction instruction so students can grasp the concept clearly.

Similarly, Monica thought pizza was a good representation because teachers could use it consistently in the classroom. However, she admitted that any representation would create problems and confuse the students if the concept was not taught clearly by the teacher. Monica made a connection to the students' responses explaining why the children considered using a different unit whole. She argued this might be due to a teacher's pedagogical style that children had gotten accustomed to. In terms of teaching, Monica further stated that a lesson "reteach" (Cooper, 2009) would be needed if students in her class could not understand the concept of unit wholes. She believed Task 1a was a great example for students to strengthen their understanding of whether to consider one or two pizzas as a unit.

Discussion

In conclusion the findings reveal the participants' knowledge (SCK, KCS, KCT) of teaching units and unitizing of fractions is limited. In regard to the first research question, the findings showed that PTs could not differentiate between 'how much' and 'how many' questions. This affirmed Lamon's (1999) argument that PTs' profound knowledge of the fractional unit was not clear. Even though the selected PTs seemed to slightly understand the concept, they had difficulty thinking during the interview session about the composite unit or unit that contained more than one same size objects. In contrast, the select PTs could unitize the items into different groups; however the strategies they used were mathematically inefficient and not flexible. They could not reconceptualize or reunitize the ounces into easier, faster, and more reasonably sized chunks (Lamon, 1996). Units and unitizing are essential concepts and important for teaching and learning of fractions; therefore, PTs must have adequate mathematical knowledge for teaching that should be developed during their teacher preparation program (Ball et al., 2008; Newton, 2008).

In relation to the final two research questions, the findings demonstrated that the PTs' knowledge of units and unitizing (SCK) might have an effect on their understanding KCS and KCT. Specifically, the select PTs' limited understanding of these concepts influenced their ability to identify students' misconceptions. Surprisingly, they were able to notice their own misconceptions while analyzing students' responses. Also, they offered some instructional strategies to help children limited to basic representational models such as pizza and cake. The select PTs appeared to have limited experiences with children, therefore, more exposure working directly and engaging in classroom teaching and learning is needed. This kind of experience will enhance and develop PTs' understanding of educational and mathematical theories into practice. Teacher educators are accountable for preparing prospective teachers with sufficient profound knowledge and experience necessary for teaching mathematics effectively. Future studies are needed to examine PTs' knowledge of fractions in more extensive and broad perspectives with these concepts, including quantitative data.

MOVING BEYOND THE TRADITIONAL STRATEGY: PRESERVICE TEACHERS' RESPONSES TO STUDENTS' CORRECT AND INCORRECT STRATEGIES IN WHOLE NUBMER SUBTRACTION

Ji-Won Son
The University of Tennessee
sonjiwon@utk.edu

Recognizing meaning in students' mathematical ideas is challenging, especially when such ideas are different from standard mathematics. This study examined, through a teaching scenario task, the reasoning and responses of preservice elementary and secondary teachers to students' correct and incorrect strategies for whole number subtraction along with the standard algorithm. Findings revealed that although a large portion of the preservice teachers recognized the validity and generalizability of the student methods correctly, they justified it from the procedural aspect of each method. When they were asked to provide interventions and connect the student method to the standard method, a majority of preservice teachers tended to use what is called 'show-tell' responses.

Introduction

The idea of interpreting and responding to student thinking is highlighted as one of the central tasks of reform-minded mathematics teaching (NCTM, 2000). Yet, recognizing meanings in students' mathematical ideas is not easy task for teachers, especially when such ideas are different from standard mathematics. Van de Walle, Karp, and Bay-Williams (2010) assert that students who invent strategies or adopt them from classmates are involved intimately in the process of making sense of mathematics and gain confidence in their abilities. Along the same line, NCTM (2000) also stresses that teachers need to spend a significant amount of time and effort on student invented methods or their informal strategies that arise in a typical mathematics classroom and think about how to help students build on them before introducing the standard algorithms.

In this study I set out to investigate preservice elementary and secondary teachers' interpretation of and responses to students' correct and incorrect strategies involving whole number subtraction, and their teaching approaches in connecting student strategies and the standard algorithm. Although a growing body of researchers explored teachers' knowledge and their teaching strategies in whole number computation (e.g., Hill, Ball, & Schilling, 2008; Thanheiser, 2009), preservice teachers' responses and their strategies to student-invented methods has received limited attention in the research literature. In particular, we know little about how preservice teachers connect student-invented strategies to traditional algorithms. Whole number subtraction is known to be one of the most challenging operations in both calculation and justification of changes made to numbers in elementary school mathematics (Flowers, Kline, & Rubenstein, 2003). Not only children experience difficulty in understanding the reasons for different subtraction strategies, but also teachers (e.g., Huinker et al., 2003). It is important to examine how preservice teachers interpret different ideas that may emerge in the classroom and prepare them to deal with such ideas in connection with the standard algorithm.

In this study, I used a student-invented strategy reported by Carroll and Porter (1997) in which the difference is recorded as a deficit or a negative number (e.g., 40-70= -30) so that no "borrowing" or regrouping is necessary where the subtrahend is larger. According to the literature (Campbell, Rowan, & Suarez, 1998; Carroll & Porter, 1997), students often invent this method on their own with little difficulty. Nonetheless, this method may become cumbersome and difficult to use as the numbers get larger, which requires a need for a more efficient method (e.g., the traditional method). Thus, this study examined preservice elementary and secondary teachers' reasoning and responses to the correct and incorrect student-invented strategy and how they attempt to connect such a strategy to the traditional method. The research questions for the study were formulated as follows:

1. How do preservice teachers interpret and respond to student-invented strategies with whole number subtraction along with the traditional method?
2. How do preservice teachers connect the student-invented strategy to the traditional strategy?

Conceptual Framework

Research on Students' Invented Strategies in Whole Number Subtraction

Understanding flexible methods of computation with whole number subtraction requires sound understanding of (1) place value, which involves being able to group by tens and treating the groups as units, (2) properties pertaining to operations such as the associative of addition, commutative, and distributive property, and (3) the relationship between addition and subtraction. Table 1 shows the student-invented strategies for whole number subtraction reported from the literature with the example problem 41 – 25 (e.g., Huinker et al., 2003).

Strategies (subtracting by)	Characteristics	Examples (e.g., 41-25)
1. Adding up	Focus on the meaning of subtraction as the inverse of addition (think-addition strategies). Add up from the subtrahend to the minuend in groups of numbers by answering what I need to add to 25 to get 41.	25+<u>10</u> is 35; 35+*5* is 40; <u>1</u> more is 45. The difference between the two numbers is the sum of the numbers added: 5+10+1=16
2. Taking away	Break the subtrahend apart and taking each part away	41-25= 41- (20+5) 41-20→21-5=16
3. Compensating	Change either subtrahend or minuend as compatible number and then compensate	41-25→45-25=20→20- 4 =16 (add 4 to the minuend and then subtract 4)
4. *Partial differences*	Decompose the numbers based on the place value, subtract each part separately without regrouping, and add the partial differences.	41-25→ (40 +1) – (20+5)→ (40-20) + (1-5)=20-4=16

Table 1. Student-Invented Strategies for Whole Number Subtraction

The *subtracting by partial differences* strategy was chosen for the study since the method requires students to use negative numbers. This method allows students to subtract separately in each column without requiring regrouping, which lead students to use a negative number. Carroll and Porter (1997) point out that it is not important whether students actually think of these partial differences as negative and positive numbers and students may simply consider the negative as "being in the hole" or having a deficit of that quantity. However, this method would be become cumbersome and difficult to apply when applied to a problem involving larger numbers (e.g., 642-489). In addition, some students tend to express the negative number as '0' while using this method (see, video clip from the *Developing Mathematical Ideas*). For these reasons, I was curious about how preservice teachers interpret and respond to a student who used this method and help her/him connect this alternative strategy to the traditional algorithm.

Research on Teacher Knowledge and Approaches with Whole Number Subtraction

A growing body of researchers has explored teachers' knowledge and their teaching strategies in whole number computation. Flowers, Kline, and Rubenstein (2003), for example, investigated elementary school teachers' understanding of whole number subtraction problems. They reported that although most teachers could explain how they perform a procedure, the teachers had difficulty justifying why it works. Some teachers tried to use rules they did not fully understand or that did not apply to the situation to describe the reasons behind their procedures. In addition, Flowers et al. revealed that although teachers recognized the value in developing children's informal strategies, most of the teachers did not fully explain why it worked. Similarly, Thanheiser (2009) reported preservice teachers' lack of understanding about standard algorithms for multi-digit whole numbers and their inability to help the child develop conceptual understanding of regrouping in whole number subtraction. She suggested that teacher educators must be able to build on preservice teachers' initial conceptions and help them move beyond their misconceptions and be able to clearly explain the mathematics behind it. Although these studies have helped us gather important data on preservice teachers' understanding of whole numbers and computation, much research needs to be done concerning how preservice teachers interpret and respond to student-invented strategies and how they connect student-invented strategies to traditional algorithms.

Methods

This study investigated preservice elementary and secondary teachers' interpretation of and responses to student-invented strategies through a classroom scenario in which two hypothetical students come up with different solution methods to a two-digit whole number subtraction problem, as addressed in Figure 1. This task was modified based on an actual elementary student who appeared on a video clip from the *Developing Mathematical Ideas* professional development curriculum (Schifter, Bastable, & Russell, 1999). The first student, Tommy, used a student-invented (*subtracting by partial differences)* strategy and produced the correct answer. Sally, the second student, tried a method similar to Tommy's, but did not understand and failed to execute the procedure correctly.

<table>
<tr><td colspan="2">You are teaching whole number subtraction problem 62-25 to third graders. You asked students to solve it. After a few minutes, two students came to the board and explained their methods in a following way</td></tr>
<tr><td>Tommy's strategy

62
- 25
- 3
40
37

Tommy said:
You have 62 and 25. Take 5 away from the 2</td><td>Sally's strategy

62
-25
0
40
40
Sally said:
Well, I have a different answer from Tommy. The answer is 40. I put 0 in the ones place since I</td></tr>
</table>

and you get ⁻3. Now you take 20 away from 60. That leaves 40. Then take away 3 from the 40, and that's 37. The answer is 37.	can't subtract 5 from the 2 because 5 is bigger than 2. And then I take 20 away from 60 and get 40. Since there is nothing to take away from the 40, the answer is 40.

Figure 1. Pedagogical Task: "How would you respond to Tommy and Sally?"

Three questions were developed in order to assess preservice teachers' understanding of and teaching strategies to these two students' strategies as well as the traditional method for whole number subtraction. In the first question, preservice teachers were asked to determine whether each method worked for all whole numbers and then were asked to explain their reasoning. Preservice teachers were then asked to respond to Tommy and Sally (intervention). In the third, they were asked to provide interventions for Tommy in order to develop the traditional algorithm for subtraction.

One hundred-eleven preservice teachers participated in the study from three mathematics methods classes. Ninety-six preservice teachers were in their pre-internship year of elementary teacher preparation program and fifteen were math majors seeking middle and secondary certification at a large southwest university in the United States. Preservice teachers in elementary and secondary programs were included in order to obtain a broad range of responses to the study's task. The task went through multiple layers of development which included pilot testing with two volunteers who were interviewed in order to check for possible misunderstandings. The task was then administered as a survey to the entire class in three mathematics methods course sections towards the end of the semester. I only report on the data of the preservice teachers who signed the study's consent form.

In analyzing preservice teachers' interpretation and approaches to these student-invented strategies and the traditional method, I was guided by studies such as Rittle-Johnson and Alibali (1999), which distinguish between the use of procedural and conceptual knowledge. I also referred to three criteria articulated by Campbell, Rowan, and Suarez (1998)—validity, generalizability, and efficiency—that teachers should consider to support various student-invented strategies in teaching situations. In particular, I analyzed based on two broad categories developed from Kuhs and Ball's (1986) models of mathematics teaching—'show and tell' and 'give and ask'. After that, their teaching strategies were further analyzed by looking at the patterns apparent. More detailed examples of these categories and the criteria used will follow as I discuss the findings.

Summary of Results

1. How Do Preservice Teachers Interpret Tommy's and Sally's Method?

I mention briefly the findings from preservice teachers' interpretation of Tommy who invented a correct strategy and Sally with an incorrect strategy, as they were helpful in providing an initial framework for analyzing their responses to student-invented strategies. In the first problem, preservice teachers were asked to determine whether Tommy's method works for all whole number subtraction problems and justify why it works. All preservice secondary teachers answered that Tommy's method was correct and generalizable whereas 77% of preservice elementary teachers did so. 23% of the preservice elementary teachers (22 out of 96) answered that Tommy's answer was correct but did not work for all whole number subtraction problems. Preservice teachers' explanations to Tommy's method were further analyzed by looking at whether they pointed out the underpinning ideas of Tommy's method, e.g., place value and distributive/ commutative properties while referring to negative numbers.

Table 2 shows a four-point rubric developed based on the sophistication of preservice teachers' justification, ranging from four, being mostly conceptual, to one, being incorrect or ambiguous. More than half in both groups fell in level two, indicating that both preservice elementary and secondary teachers tend to provide procedural-oriented explanation. However, notice the different tendency between preservice elementary and secondary teachers. While more than half preservice secondary teachers fell in levels 4 and 3, similar percent of preservice elementary teachers fell in levels 1 and 2 (see Table 2).

	Description	Participant Example	Elem. (N=96)	Second. (N=15)	Total (N=111)
4	Describe both the use of property (e.g., distributive/ commutative) and flexible use of place value (decomposing) while making reference to negative numbers.	*The distributive property always works well with whole numbers. Because subtracting is really adding a negative, (60 + 2) - (20 + 5) = (60 + 2) + -1(20+5). Distributive=> 60 + 2 + -20 + -5 Because of the commutative property of the whole numbers with addition this = 60 - 20 + 2 - 5 = 40 + -3 = 37.*	2%	20%	5%
3	Demonstrates somewhat conceptual understanding with use of negative numbers instead of regrouping and/or vague understanding of place value.	*As long as he keeps his place values correct, he can subtract 60 - 20 or any of the tens numbers. Also, because he understands negatives the problem will work every time.*	33%	33%	33%
2	Mention place value, but response is mostly based on procedure or slightly ambiguous.	*I believe Tommy's strategy will work for all whole numbers because he subtracted the one's first and the ten's next.*	40%	47%	41%
1	Provide irrelevant, or incorrect information	*Because he cannot invert the numbers because it changes the value.*	25%	0%	22%

Table 2. Rubric describing the nature of explanation about Tommy's method

As for Sally's strategy, all preservice teachers answered that Sally's method was incorrect and were not generalizable. Table 3 shows a four-point rubric describing the different levels of preservice teachers' justification to Sally's method. In general, overall scoring for responses to Sally were lower than Tommy. The majority of participants scored level 2 in which preservice teachers just restate Sally's procedure without further explanation. When comparing elementary and secondary teachers, similar portions scored level one where preservice teachers were correct in their thinking of the strategy, but provide too ambiguous or incomplete explanation.

	Description	Participant Example	Elem. (N=96)	Second. (N=15)	Total (N=111)
4	Describe limited concept of place value and regrouping by Sally while describing the relationship between tens and ones in place value.	*Sally's strategy does not work because not only does she not understand the concept of place value, she does not understand the concept of regrouping. She does a good job at taking away in the 10s place. It is important for subtracting problems to take both the 1s and 10s place values into account by knowing 10 ones make 1 tens.*	1%	7%	2%
3	Mention limited concept of place value or limited concept of regrouping by Sally but do not fully explain the relationship between tens and ones in place value	*Sally doesn't have a concept of how tens relate to ones with subtraction. In this case, she would need to realize that 62-25 is not the same as 62-22. Her assumption does not work here, and it will not work for all whole number pairs.*	12%	20%	13%
2	Describes Sally's procedure by pointing out the use of '0' and vaguely mention place value or lack of understanding with negative numbers.	*Sally's strategy will not work for all whole numbers because when working with multidigit problems and the bottom number is larger than the top you cannot simply place a zero in its place and move to the next digit.*	71%	61%	70%
1	Did not provide justification, or provide irrelevant or incorrect information	*It won't work because it is logically incorrect and didn't even work when she did it for this problem.*	16%	13%	15%

Table 3. Rubric describing the nature of explanation about Sally's method

2. How Do Preservice Teachers Respond to Tommy's Method?

In the second question, preservice teachers were asked to respond to Tommy and Sally. As previously mentioned, in analyzing the responses of the participants, two categories were identified first—'show and tell' and 'give and ask'—and then their responses were further analyzed by looking at the patterns apparent under each category. In a 'show-tell' approach, the preservice teacher tells, explains or shows whether each method works and provides direct information about the two strategies. The 'give-ask' approach in this study is evident when a preservice teacher provides students opportunities to explain and justify their strategy, and would guide students as they figure out when each method is or is not efficient. Preservice teachers who concluded that Tommy's method was not generalizable were also analyzed to see how they responded to Tommy as categorized into 'incorrect'. Shown below is the various responses in each approach and the percentage of responses. The data dispersion for secondary and elementary preservice teachers was consistently about the same for all categories. A large portion of the preservice teachers was categorized into the 'show-tell' approaches by confirming or rephrasing Tommy's procedure (44% in the 'show-tell' approach) and/or showing Tommy the traditional method as Tommy was assumed to be incorrect (20% in the incorrect). Only around 40% asked Tommy to explain his thinking. About sixteen percent of the participants gave what we would consider fairly ideal responses through student involvement and connecting or building on strategies.

Show and Tell (44% in total): Conformation only (7%), Confirms and reminds of negative numbers (7%), Rephrases Tommy's strategy (17%), Confirms and shows another (traditional) method (6%), Points out the usefulness of Tommy's strategy (5%), and Recognizes Tommy's strategy is inefficient for larger numbers (2%)
Give and Ask (36% in total): Asks Tommy to explain thinking (14%), Asks Tommy to solve another problem (7%), Asks Tommy to show other students to help them understand his strategy (8%), Asks Tommy to come up with another strategy (5%), Get Tommy to recognize the inefficiency with larger numbers (1%), and Asks other students to show strategies to connect (2%)
Incorrect (20% in total): Show and tell proving counterexamples without reason (4%) or tell Tommy his strategy does not work and ask to find another way without negatives (3%), No explanation and shows another method (traditional) (7%), Asks Tommy to apply method where top number is greater (2%), Asks Tommy to explain use of negatives (1%), and Asks Tommy to explain and solve another problem (3%)

3. How Do Preservice Teachers Respond to Sally's Method?

Preservice teachers' replies to Sally were overwhelmingly "show and tell" based. About 77 percent of all participants explained Sally's errors or showed her the traditional method. Only about ten percent of the participants, all being elementary level, attempted to have Sally recognize her error without being directly told. Only around 23% asked Sally to explain her thinking and used it in correcting her mistake. Shown below is the various responses in categories of 'show and tell' and 'give and ask' and the percentage of responses.

Show and Tell (77% in total): Tell or explain errors to Sally (28%), Tell or explain errors and strengths (5%), Tell Sally to use traditional method (20%), Tell Sally to use Tommy's (with negative numbers), or other strategy (16%), and Use concrete model to show errors with place value and or address the traditional method (9%)
Give and Ask (23% in total): Point out the source of Sally's errors and have her rework the problem to correct (12%), Ask her to explain her strategy and teacher shows traditional method (1%), Ask Sally to explain her method and to try another method (4%), Ask Sally to use manipulatives to find her error and see the traditional method (3%), and Have Sally recognize her error by comparing to other methods (3%).

4. How Do Preservice Teachers Connect Tommy's Method to the Traditional Method?

The third question, referring to Tommy, asked participants to explain the traditional method by making a connection to his invented strategy. In analyzing the responses of the participants, two categories—'show and tell' and 'give and ask'—were utilized first. And then two additional categories were identified separately depending on whether preservice teachers provided the connection between Tommy's method and the traditional method. Then their responses were further analyzed by looking at the patterns apparent under each category. Below shows the various responses in each approach and the percentage of responses. Even though participants were asked to connect Tommy's method to the traditional strategy, only 28% of the preservice teachers attempted to show the connection between two methods. 42 % relied on solely explaining the traditional method without any models or using any type of questioning with Tommy.

No Connection (71% in total): Explains traditional method (without manipulatives) with regrouping (38%), Explains traditional method (without manipulatives) with compensation (5%), and Explains traditional method with manipulatives or pictorial model (28%).
Connection (28% in total): Has Tommy explain place value/his method and explore regrouping (5%), Points out inefficiency with negative numbers and explains traditional method (11%), Points out inefficiency with negative numbers and explains traditional method with manipulatives (5%), and Shows both methods and how they relate (5%).

Discussion and Implications

The findings of this study shed light upon preservice teachers' mathematical understandings and their teaching approaches to student-invented strategies for whole number subtraction. While all preservice secondary teachers in this study determined the validity and the generalizability of the student-invented method correctly, a large portion of preservice elementary teachers did not initially recognize Tommy's strategy as a legitimate method for subtracting. However, such differences became less distinct when it came to justifying the reasons behind the procedure and providing good intervention. Preservice teachers in our study, both secondary and elementary, gave mostly procedural explanations for Tommy's strategy. They also showed a tendency to use 'show and tell' approaches rather than 'give and ask' when trying to help students construct their own knowledge. In particular, procedural-oriented responses were more evident when student methods were assumed to be incorrect and when preservice teachers were asked to respond to students, in particular to Sally who provided an incorrect method. This result is consistent with the findings from the Son and Crespo' study (2009). Based on the findings from this study, I propose that preservice teachers' insufficiently developed knowledge of students and teaching strategies would be a reason for creating a procedurally oriented instruction. Despite the limitations of this study (e.g., the small ration of secondary to elementary preservice teachers), this study has implications for teacher educators and future studies. For example, teacher educators must provide opportunities for preservice teachers to explore student-invented strategies and be able to clearly explain the mathematics behind it. Additional research is needed to provide substantiation in how we can help teachers prepare for the multiple student strategies that arise in a typical mathematics classroom.

TEACHERS' KNOWLEDGE IS BUILT AROUND THEIR GOALS

Matt Webb
University of Northern Iowa
matthew.webb@uni.edu

Teachers' goals are an understudied link in the chain from teachers' knowledge, beliefs, and decisions to students' learning and opportunities to learn. Whereas the domains of teacher knowledge, beliefs, and behavior have received much research attention recently, teachers' goals—a critical link between these areas—remain understudied. The reasoning teachers engaged in related to their goals provided a window into their knowledge and beliefs and how their knowledge and beliefs developed around their goals. This information indicates that teachers' goals can be very useful to uncover teacher knowledge and highlights how influential teacher goals are in the overall learning environment.

Purpose

High on the radar of education researchers is the special amalgam of content and pedagogy known as pedagogical content knowledge [pck] (Shulman, 1986). And while much effort is being made to define and measure pck, equal effort is being made to develop it. And yet, often overlooked is how pck develops organically in the ordinary course of teachers' experiences. The research question guiding this research is: How do teachers' goals of instruction contribute to their development of pck?

The findings reported in this paper were derived from original research that broadly examined the nature of five secondary mathematics teachers' goals of instruction. Hiebert and Grouws (2007) defined teaching as consisting of "classroom interactions among teachers and students around content directed toward facilitating students' achievement of learning goals" (p. 372). Learning goals are at the core of the educational enterprise and research on teaching toward specific learning goals in intervention settings claims robust results. Hiebert (2003) wrote, "When extra attention is paid to designing classroom instruction with specific learning goals in mind, students usually improve their achievement of these goals (Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Cobb et al., 1991; Cognition & Technology Group at Vanderbilt [CTGV], 1997; Fawcett, 1938; Good, Grouws, & Ebmeier, 1983; Griffin et al., 1994; Heid, 1988; Hiebert & Wearne, 1993; Markovits & Sowder, 1994; Stein & Lane, 1996; Wearne & Hiebert, 1989; Wood & Sellers, 1996)" (p. 14). Echoing and extending Heibert's assertion here, I contend that when extra attention is paid to designing various aspects of classroom instruction with specific goals in mind, the teacher develops greater knowledge and power in that area to achieve the recognized goals.

Theoretical Considerations

Goals are integral to the cognitive aspects of teaching. In Schoenfeld's (1998) efforts to develop a theory of teaching that enables one to "explain how and why teachers do what they do *while engaged in the act of teaching*" (p. 6, emphasis in original), he generated a cognitive model of teaching, where knowledge, goals, and beliefs activated in context affect and influence teachers' decision making and actions. These components are influenced by one's historical knowledge of past experiences with the students, the mathematics they have learned, and the plans and routines that have previously been enacted. Schoenfeld's model advances the cognitive research on teaching and brings goals onto equal footing with knowledge and beliefs.

Goals are defined as "cognitive representations of what individuals are trying to accomplish and their purposes or reasons for doing the task" (Pintrich, 2000, p. 96). Goals direct action toward desired end states and come with recognition that the present state is lacking. To have a goal is to recognize the difference between an ideal state and one's perception of present reality. This recognized difference creates "a state of tension that [is] maintained until reduced by the performance or completion of the intended activity or a substitute activity" (Locke & Latham, 1990, p. 13).

Knowledge plays a special role in attaining goals. When a goal is chosen, related knowledge is activated to the attainment of the goal. For example, if a teacher chooses the goal that students understand equivalent fractions, the teacher's knowledge of representations and classroom sequences are drawn upon to meet the goal. But if a goal is chosen that one does not have the knowledge to attain, and if one is committed to the goal, the teacher will search for and build knowledge necessary to meet the goal. This explains Ball's (1993) efforts to develop meaningful representations of negative numbers for her 3rd grade students, an effort prompted by her dilemmas that arose "directly from [her] explicit goals" (p. 377). Locke and Latham (2002) reported that challenging "goals… [can lead] to the arousal, discovery, and/or use of task-relevant knowledge and strategies (Wood & Locke, 1990)" (p. 707). In other words, the motivation to develop specific knowledge arises through dilemmas related directly to our goals.

Method

Case study methodology provided direction in conducting this research. As little research has been done to link and describe the connection between teachers' goals and their pck, I chose teachers who were likely to be information rich by virtue of their experience and expertise. The two teachers in this study held master's degrees in curriculum and instruction and were recognized by their administration and university faculty as leaders in the school.

Natalie (as with all participants, a pseudonym) was in her 11th year as a teacher when I observed her. The majority of her experience was in teaching from the *Core-Plus* curriculum. However, in her ninth year she moved to a new school where she principally taught Algebra 1. The year in which the observation was made she was teaching Algebra 1 for the second time.

Sarah was in her fourth year teaching high school mathematics. Sarah has since been accepted into a PhD program in mathematics education. Sarah had taught only integrated courses using the Core-Plus curriculum until the year of observation in which she also taught Geometry using a traditional textbook.

Data Collection and Analysis

In keeping with the case study research tradition, this study drew upon "multiple sources of information such as observations, interviews, documents, and audiovisual materials" (Creswell, 1998, p. 62). Each teacher was observed at least four times and was interviewed after second, fourth, and sixth classroom observations. Classroom teaching sessions were video recorded and used for purposes of stimulated-recall interviews. These interviews were semi-structured and were designed to allow investigation of teachers' goals around significant components of their instruction.

The focus of the data analysis was to find and describe how teachers' goals contributed to their development of pck. Analysis proceeded by identifying dilemmas the teachers were struggling with, then examining how their efforts led to development of pck.

Findings

To illustrate the findings for each teacher, I describe a broad mathematical pedagogy dilemma followed by a more narrowly focused mathematical pedagogy dilemma and the resulting efforts and development of pck. I begin with Natalie. Natalie struggled with getting her Algebra 1 students to share their thinking and to keep them engaged. These two dilemmas turned into broad goals that she spent a great deal of time thinking about. This thinking led to her reasoning about the dilemmas and experimenting with solutions. Natalie recognized a strong contrast between teaching Algebra 1 and Core-Plus courses. Indeed, in her interview she lamented that students were not used to having to discuss ideas. She explained, “When I taught with the core-plus curriculum it had more of the questions there for me. The questions were just embedded in the students work….[My Algebra 1 students] haven’t had to do that. Their way of learning hasn’t been that style” (Natalie, Interview 1).

This challenge to engage students and provide them an environment in which they would feel comfortable sharing their thinking was an issue that Natalie brought up in two of our three interviews. In the last interview she said:

> One of my goals is to get closer to 100 percent of my students engaged and involved. The kids don’t want to go up to the front they don’t want to write on my board. They don’t want to answer out in class even when they probably have the right answer. I just want more of my kids to feel comfortable about sharing in class. (Natalie, Interview 3)

So Natalie experimented with different strategies searching for something that helped. She said:

> Something I’ve been thinking about this year is different ways, what can I do to get the kids engaged more? More of them on task and doing the problems. So I’ve tried the clickers, I’ve tried working in partners more. Thursday and Friday the learning specialist is going to let me use her white boards. So a lot this year I’ve been thinking about what are different ways to present my lesson so that I can get more kids involved. (Natalie, Interview 2)

In order to get students engaged she experimented with different strategies and formats for her lessons.

Natalie also wanted to create a classroom where students felt comfortable participating and discussing mathematics, but found that she needed to find and enact strategies in which students could become prepared to participate in whole-class discussion. She used strategies such as pairing, and wait-time, She said:

> I don’t like to [randomly] call on a kid. I don’t like to say ok “Mike would you do this problem?” because if Mike doesn’t know how to do it then that’s going to make him less likely to answer later. So I don’t want to call on a kid who doesn’t want to offer. So finding a way so that, if they do check with a partner, check your answer, or somebody and then be able to answer my question, then I should be able to call on anyone. (Natalie, Interview 1)

Natalie avoided calling on students unprepared to respond, to overcome this she found ways to ensure they had opportunities to think and discuss the problems. Because of her goal to get them engaged and willing to contribute to class discussion (broad mathematical pedagogy goals) she developed strategies to successfully meet these goals. She developed pck specific to the area of general mathematical instruction.

Natalie: Teaching Equation Solving—Where To Start and Why Do We Do That?

In a more topic-focused area of mathematical instruction, a goal Natalie consistently identified was to get students to engage in mathematical reasoning and justification. She was teaching equation solving. On the first day Natalie began the class with two warm-up problems. One of the problems was "$-(2/5)x - 7 = 11$." After students had a few minutes to work both problems she asked the students: "I need three reasons, why did I add sevens to both sides?" (Natalie, Video Observation 1). In the interview I asked Natalie why she asked this question. She said:

> First of all to the students that look at that problem and see a fraction and then they don't know where to go from there. They don't know where to start. And kind of an order of operations thing. Do I add seven first or do I multiply first, or do I distribute first? You know, what's my first step and why is that my first step. So to kind of give them somewhere to go, because I heard it today I think. "I don't even know where to start." "I don't know what to do." For other ones just to make them think about, because there are the ones that can just do these problems because that's the way we've done them forever. They just probably never have been asked: "Why are we doing that?" It's just Ok we're supposed to add 7 so let's add 7. "That's just how we were taught." So what's the math behind it? (Natalie, Interview 1).

Based on her knowledge of students past and present she realized they struggled to get started, afraid perhaps of making a wrong step. She was also aware that her students typically did not know why they were doing certain processes. Her goals here reflected students' learning needs and her strategies were developed to meet these goals. In addition to her students' learning needs, however, her push for reasoning and justification also came from teaching Core-Plus, and her knowledge that students would have to justify steps in Geometry. She said:

> I guess I saw that a lot in *Core-Plus*. And also leading up to proofs in geometry. I used to teach stuff with proofs, not the two-column format proof, but more of a paragraph of this is the first thing I noticed and giving reasons why. (Natalie, Interview 1)

Natalie's goals related here stemmed from her experience with another curriculum, her knowledge of students future mathematical demands, and her knowledge that students were not confident in the steps to take to solve the problems. With these goals in mind, she developed or adapted previous strategies to her current context to promote the reasoning that explains traditional equation solving. She held class discussions with many participating in sharing justifications for certain steps. She also learned to ask for different ways to begin a problem.

Sarah

Sarah taught Honors Integrated 4. When she first began teaching this class she initially used a strategy she had used previously—holding whole class discussions frequently to summarize the mathematics and clear up misconceptions. But when she held these discussions in the Honors Integrated 4 class she observed and perceived that the students already understood the mathematics. Therefore she was led to ponder how to reduce these unnecessary stops, and at the same time ensure learning. These were her broad pedagogical goals in the context of a senior-level honors, problems-based mathematics class. She said:

> I was used to, they work on the investigation for a while then we stop to kind of clear up some misconceptions some groups are having. It was very sectioned off.
>
> I realize there were times that I thought we needed to stop and talk as a class, and everyone would just kind of stare at me like we already know that.
>
> They worked so hard together, and they worked so well together, that if there's anyone that had it off, the rest of the group helped them figure it out, and they had it corrected.

> I realized that I was standing in their way by saying ok I want you to stop after this problem. I [realized I] need to get out of their way. We don't need to stop at certain points. (Sarah, Interview 1, emphasis added)

At first, she *thought* that she needed to hold frequent whole class discussions for her students' sake, but when she did, she observed student expressions that indicated they already knew the mathematics she was intending to discuss. She perceived these discussions as unnecessary. Her goal was to optimize learning and this meant she needed to get out of the way, to do away with unnecessary discussions so students could learn.

So Sarah developed a plan where the students were given dates for quizzes and tests and were instructed to develop group plans to learn the mathematics for those tests and quizzes. This was the second year she implemented this idea. She said:

> So I just started it with them this week. However, I'm really struggling with the way they're grouped. They're not working at the same pace in their group. So we're going to have a quiz next week, and I'm sure that I will put the kids who are working faster together, and the kids who work a little slower together, because I think they'll work more together.
>
> I don't want everyone to take the same amount of time of time on every problem. That's not the way they learn or have to think through problems. There has to be that point where they thought about it before I'm going to give them an answer. (Sarah, Interview 1)

After initiating the strategy to let the groups work more freely with targeted quiz and test dates she ran into a new dilemma—students working at different paces within groups—this led to her thinking about grouping students in pace-alike groups. In other words, her goal to optimize the learning organization in her classroom continued to prompt her to analyze her efforts and devise new strategies to further enhance the classroom experience. Her goal prompted pck in this context.

Sarah: Teaching Function Notation for Horizontal Translations

In this final example, Sarah held a narrower content goal—to help students learn and understand the relationship between horizontal translations of functions and the corresponding function notation. In the following example students were struggling to formulate where in the function notation this shift would be represented. She explained:

> In the book, the very first problem has them make a table for $f(x)$, $f(x + 3)$, and $f(x-3)$. And they call them $f(x)$, $g(x)$, and $h(x)$. So they actually found the y-values, and they made this table so it had four rows: the x-values then 3 sets of y-values. Then they were supposed to talk about the coordinate rule. It looks like when you looked at the table, weren't the y-values just going up each time? This is your set x-value and the y-values were what were changing. So yeah, if you look at the table, that sure is what's happening. You're x-values went up and your y-values went down. So then I thought, wow, that was almost like a bad thing to do right there because now they're thinking it's a change in the y not a change on the x-axis. So I didn't want her to look at that for a minute, so I was like let me think of some other things she could look at. So I was trying to hurry and come up with something, because I had just realized what a problem that was for two groups.
>
> And did you hear me say let's do y equals x. And I said, "Nope, let's not do that one." And I said let's look at y equals x squared. Well then I was getting the other side of the parabola's outputs. So then it was deceiving again now the left side was crossing over

> when I moved it over. I was like "Ok this is another bad example, let me come up with something where we can look at it." So I came up with $y = 2x$, so we graphed some points, and then we graphed some points on $y = 2(x - 3)$.

In this excerpt so far, it is clear that Sarah was struggling to find a way to make the notation of horizontal translations clear. She was aware that others were similarly confused. So with the goal to help these students make sense of the idea, she is searching for examples. If not the best examples, she is searching for better examples to use to make this particular content more understandable and accessible to her students. She went on to relate an idea she had found in a previous class that she intended to use.

> An Integrated 4 Honors student last year explained it to class this way that made sense to the rest of the students, so that's why I've been trying to say it this way a little bit. "If you have *x* minus 3 in the function, like you're *x*-values have to be 3 higher to get that same output you got on the original function". And he said, "So the whole graph has to happen 3 later on the *x*-axis." And that helped the students understand it more than anything that I had done. So I'm like ok I'm using that one, I wrote it down in my book and I looked at it last week and I was like ok I got to remember to explain it the way he did. That's what I was trying to get her to see. We had to put in an *x*-value that was 3 higher into this new function, than we did the original function to get that same output. So we had to move everything 3 higher on the *x*-axis. We had to go over further on the *x*-axis to get that same output.

In this example Sarah explained her challenge to provide a clarifying example to teach about horizontal translations. Her goal to teach this content led her to searching for and collecting clarifying examples and powerful phrases that would enable her students to understand. In this example her goal led to her development of pck in this area.

Natalie and Sarah were both working on engaging students and optimizing learning formats and routines in the classroom. Their goals in these areas led to their exploration and experimentation with various strategies. In this process they developed pck broadly in their contexts of facilitating mathematics classes. Then, in content specific ways their content goals prompted a search for and development of pck narrower topic areas.

Discussion and Conclusion

Hiebert and colleagues (Hiebert, Morris, Berk, & Jansen, 2007; Hiebert, Morris, & Glass, 2003) have delineated the process of learning to teach as a process of monitoring and revision. In their 2007 paper they identified four skills for teachers to hold and a process to engage in for learning to teach. Those skills are: "Skill 1: Specify the learning goal(s) for the instructional episode (What are students supposed to learn?)" (p. 51). "Skill 2: Conduct empirical observations of teaching and learning (What did students learn?)" (p. 51). "Skill 3: Construct hypotheses about the effects of teaching on students' learning (How did teaching help [or not] students learn?)" (p. 54). "Skill 4: Use analysis to propose improvements in teaching (How could teaching more effectively help students learn?)" (p. 55). Findings in this research indicate that teachers naturally engaged in this process based on the goals they held in the classroom and in doing so developed pck in specific areas.

In this study, teachers' goals led to their sensitized observations, evaluations, and reasoning about teaching mathematics that in turn led to their development of pck. It is clear that they developed pedagogical content knowledge as they learned "ways of representing and formulating subject matter that make it comprehensible to others" and "the conceptions and preconceptions that students… bring with them to the learning of… topics and lessons" (Shulman, 1986, p. 9). However, my interest here is not that teachers developed pedagogical content knowledge; rather it is how this knowledge developed by reasoning about how to achieve their goals. This process is called pedagogical reasoning, "the *process* of transforming content knowledge into forms that are pedagogically powerful and adaptive to particular groups of students" (Brown & Borko, 1992, p. 221). Elsewhere Cooney (1994) used the words adaptation and pedagogical power to describe this effort to transform "what we are able to do to what we want to do" (p. 9).

Teachers' own interests, contexts and teaching philosophies sensitize them to enhancing instruction in unique and idiosyncratic ways. Shulman and Shulman (2004) discussed this issue in their development of a framework for teacher learning. In essence, they asserted that the teachers' vision of teaching, their goals, served as a sort of gatekeeper for teacher development and learning. They said, "A highly developed and articulated vision serves as a goal toward which teacher development is directed, as well as a standard against which one's own and others' thoughts and actions are evaluated" (p. 261). Having this vision, they argued, prepares teachers to learn things necessary to enact it.

Learning because of goals is not a new idea. Locke and Latham (2002) stated, "goals affect action indirectly by leading to the arousal, discovery, and/or use of task relevant knowledge and strategies (Wood & Locke, 1990)" (p. 707). But having a goal is not the whole of the process. Goals sensitize and prompt teachers to observe, to think about, to hypothesize, and to experiment in order to meet them. Consequently, teachers' goals and interests lead them to monitor and reflect on aspects of the classroom related to these goals.

In this section I have made the assertion that teacher growth and development is built around their goals. Locke (2000) made the assertion about the links between knowledge and goals in these words:

> Once the individual decides to act to achieve a goal, spurred on or not by emotion, both conscious and subconscious knowledge come into play. Consciously one has to ask: how will I go about reaching this goal? How does it tie into my other goals: How long will it take: How much effort will be required: Can I do it: What resources will I need: Some of these questions will pull relevant subconscious knowledge into awareness and some will require more thinking and information search. (p. 412)

Still, teachers' goals have not received the attention they should in our quest to understand teacher thinking.

Implications

Teachers' goals lie at the heart of educational activities. In terms of teacher knowledge, goals become a highly accessible avenue to explore teachers' knowledge, as teachers are highly able to explain their reasoning as it relates to specific goals that they hold. In the area of teacher learning or learning to teach, goals form a basis for all that follows. Further research in both of these areas will be enhanced by increased attention to the role and meaning of teacher goals. Additionally, research on beginning teachers' goals and the sources they cite for their goals would shed additional light on the trajectory and challenges beginning teachers face as they develop their own expertise. Research on expert or veteran teachers might help us distil those goals we would desire for all teachers.

Teacher development programs and professional development programs can be strengthened and more powerfully serve teachers by targeting instruction and support to help them develop on the basis of their own goals of instruction. To the extent that teachers' goals are ignored, the learning process will be limited. Interested parties may voice concern that basing teacher development programs on teachers' goals may unnecessarily limit the potential value added by programs constrained in this way. But if teachers are likely to develop competencies according to their own goals then organizing this way can actually accelerate the pace at which teachers come to realize the limits of their typical practice. By building on teachers' deeply held teaching goals and helping them think about and achieve them, professional development schools could quicken the rate of teacher development in positive ways. This effort could help teachers more quickly develop strategies to meet their goals, or help teachers more quickly see the limitations of their strategies and conceptions of teaching. Research should explore these possibilities.

Goals serve as the lynchpin between teacher knowledge and beliefs, and behavior. While much research has been focused on these three areas, goals have been studied to a much lesser extent. I have asserted that goals support the investigation of teacher learning and knowledge. If much of learning to teach and teacher's knowledge is bundled and built around teachers' goals then research in these areas must do better to take this critical area into account. Doing so will enhance these research areas. Afterall, goals are the vehicle and path of teacher growth and the basis of students' learning opportunities.

PATTERNS OF KNOWLEDGE INTERACTIONS DURING INSTRUCTION

Matthew S. Winsor
Illinois State University
mwinsor@ilstu.edu

David Barker
Illinois State University
dbarker@ilstu.edu

This study used stimulated recall interviews to investigate the patterns of knowledge interactions that were exhibited by two fifth-grade teachers during the act of teaching. Schematics were developed to describe the flow of knowledge interactions and were subsequently examined for patterns. During the interviews, the teachers primarily focused on their knowledge of learners and curriculum and instructional strategies, with mathematics being used mainly to justify claims about learners and instruction. In addition, several patterns of knowledge integration were observed and described.

A focal point of mathematics teacher education is to prepare preservice teachers to make effective instructional decisions. Since teachers' actions are based on their integrated knowledge of mathematics, pedagogy, and student thinking, developing integrated knowledge is an important component of mathematics teacher preparation.

Brown and Borko (1992) wrote, "an individual's knowledge structures and mental representations of the world play a central role in that individual's perceptions, thoughts, and actions" (p. 211). In order to plan effective experiences for preservice teachers, teacher educators must understand the structure and organization of the various forms of teacher knowledge, and how teacher knowledge functions in instructional settings. Teacher educators must also understand the connections teachers make between the different types of knowledge and the patterns of knowledge interactions that lead to effective instructional decisions.

The research conducted in this study focused on the interaction among three components of teacher knowledge—knowledge of mathematics, knowledge of learners, and knowledge of curriculum and instructional strategies. Because of the limited research on teacher knowledge integration, we sought to answer the following research question: What were the patterns of knowledge integration that were exhibited by two fifth-grade teachers while making decisions in the classroom?

Literature review

In recent years, research has been conducted on teachers' mathematical knowledge (Ball, Thames, and Phelps, 2008; Winsor, 2003). The aim of the research has been to classify the different types of mathematical knowledge that teachers possess or need (e.g. Hill, Rowan, and Ball, 2005). Unfortunately, there is still little known on how teachers use their mathematical knowledge in conjunction with other types of knowledge in the decision-making process.

Bishop (1976) noted, "Decision making is therefore an activity which seems to me to be at the heart of the teaching process. If I can discover how teachers go about making their decisions then I shall understand better how teachers are able to teach" (p.42). Bishop and Whitefield (1972) propose that decisions are made using a framework or schema. Marshall (1995) examined student schema with respect to problem solving in mathematics. Given that teaching is similar to problem solving, Marshall's treatment of schema theory serves as a foundation for this study. Marshall posits that:

> A schema is a vehicle of memory, allowing organization of an individual's similar experiences in such a way that the individual:
>
> - can easily recognize additional experiences that are also similar, discriminating between these and ones that are also dissimilar;
> - can access a generic framework that contains the essential elements of all of these similar experiences, including verbal and nonverbal components;
> - can draw inferences, make estimates, create goals, and develop plans using the framework; and
> - can utilize skills, procedures, or rules as needed when faced with a problem (or teaching episode) for which this particular framework is relevant. (p. 39).

Understanding the structure of schema and how teachers draw upon their schema when making decisions will aid teach educators in preparing meaningful experiences for preservice teachers. The main operation of a schema is to store knowledge through a network of connected pieces of knowledge called "elements"(Marshall, 1995, p. 43). The more connections that exist within a teacher's schema, the stronger and more useful the schema will be.

Theoretical Framework

In order to investigate the research question of this study it was necessary to construct a model that reflects how teachers use their knowledge in the act of decision-making and how they learn from their experiences. The model is based on Marshall's (1995) work on schema theory. As teachers encounter opportunities to make teaching decisions, connected schemata are activated in order for the teacher to make decisions.

The knowledge structures used for decision-making are shaped and adjusted as teachers make decisions reflect on instruction. In essence, reflection can be seen as a process that allows teachers to build and adapt connected knowledge structures that are then used in decision-making. Barrett and Green state that, "through this process of reflection, teachers transform their inert knowledge into active, classroom practice that continually evolves as they encounter new situations and reconsider past experiences in light of more recent experiences" (2009, p. 19). A researcher-developed model for the knowledge structure used in decision-making, and the role of reflection in that process is provided in Figure 1. The ellipse represents the set of knowledge that the teacher has acquired. The arrow entering the ellipse represents reflection on a teaching incident that promotes connections between different knowledge elements (the knowledge of mathematics (M), of learners (L), and of curriculum and instructional strategies (CI)). Note the connections among the different knowledge elements that result from the process of reflection. The arrow exiting the ellipse represents the connections among various knowledge elements were needed to make an instructional decision.

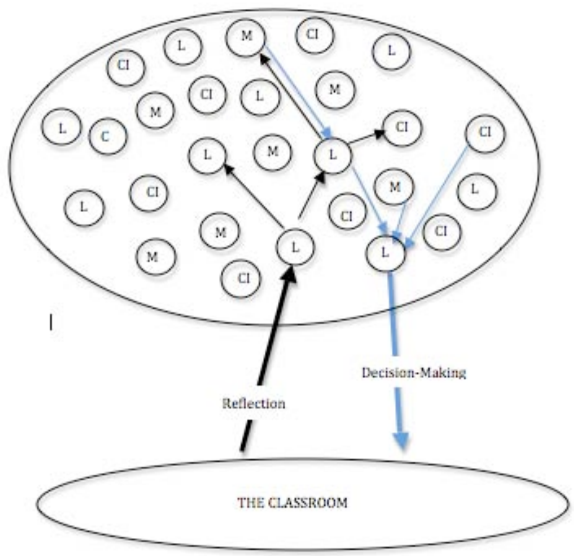

Figure 1: Model of Integrated Knowledge

Methods

A case study methodology was used to investigate how two fifth-grade teachers—Amanda and Emily--drew upon their knowledge of curriculum and instructional strategies, mathematics, and learners while teaching. Each teacher was observed and videotaped as they taught a series of three lessons from the *Patterns of Change* unit of *Investigations in Number, Data, and Space* Curriculum (Tierney, Nemirovsky, Noble, & Clements, 1998). Following each observation, stimulated recall interviews were conducted to obtain the teachers' reactions to the videotaped lessons. As they watched the videos, the teachers were prompted to reflect on what occurred in the classroom and to comment on the thought processes used to make their instructional decisions. The transcripts from these interviews served as the primary data source for analysis.

Following data collection and transcription, the data were retrospectively analyzed using a data reduction approach (Miles & Huberman, 1994). The analysis occurred in several phases. The transcripts were initially coded in terms of the type of knowledge discussed: mathematics (M), learners (L), or curriculum and instructional strategies (CI). At this point, the research team coded portions of the transcripts to develop and test the viability of these definitions. Discrepancies in coding were discussed, and definitions adjusted, until all disagreements were resolved.

The data for each interview were divided into individual episodes, defined to be sections of the transcript where the teacher was discussing a single thought. An initial analysis of these episodes found that one knowledge type was often the primary focus of the episode (primary knowledge type), with a second or third knowledge form (secondary knowledge type) being used in a supportive role. This support was found to occur in one of two ways: (a) the second knowledge type was used to support or justify what was being stated about the primary knowledge type, or (b) a discussion of the primary knowledge type led to an implication or investigation of the secondary knowledge type. In other words, there was a temporary shift in focus to the secondary form of knowledge. Given these initial findings the data were translated into schematics that illustrated knowledge interactions, including which knowledge form was primary and the purpose of interaction. These mappings were then analyzed to characterize

L 2 CICI
L
1 M

patterns among the interactions and are the basis of the findings that follow. An example mapping is provided below.

In the following excerpt Amanda used her knowledge of curriculum and instructional strategies to support a comment she made about one of her students.

> *Amanda:* I was surprised that Kate raised her hand and was giving answers. She usually does not participate. It was like a reversal.
> *Researcher:* Why do you think she was participating?
> *Amanda*: I think it is because we are using a context, we are using blocks, we are showing it, we are showing it in two different formats so we are including two totally different types of thinkers.

In this case, the knowledge of learners (L) is the primary knowledge form, represented by the bold box, and the knowledge of curriculum and instructional strategies is the secondary knowledge type. In this episode Amanda used a statement involving curriculum and instructional strategies to justify her original comment about one of her students. An arrow was drawn from the secondary knowledge type to the primary knowledge type to signify that the secondary knowledge type was used to justify the primary. Figure 2 illustrates this notion.

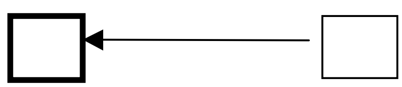

***Figure 2*: CI used to clarify L**

Each episode was then mapped out using this notation; an example mapping is provided in Figure 3.

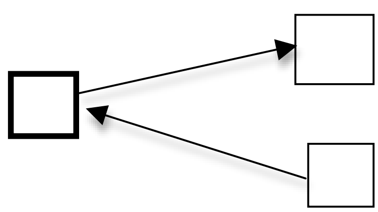

***Figure 3*: Example Mapping**

In this example, the arrow from the primary knowledge type (L) to the secondary knowledge type (CI) represents the second type of interaction, where a discussion of the primary knowledge type led to an implication for the secondary knowledge type. In addition, numbers were added to the arrows to indicate the order in which the interactions occurred. So in this example M was initially used to justify a statement about L, which then led to an implication regarding CI.

Findings

Mathematics' Place in Teacher Knowledge Integration

Researchers such as Ma (2000) and Ball (e.g. Ball, D.L., Thames, M.H., & Phelps, G., 2008) have focused on the type of mathematics teachers need to know to be successful. Kahan, Cooper, and Bethea, (2003) report that knowledge of subject matter alone does not ensure effective teaching performance. This study reveals how mathematics knowledge is used in conjunction with the knowledge of learners and the knowledge of curriculum and instruction in order to make instructional decisions. Table 1 depicts the ways in which Amanda and Emily used their knowledge of mathematics. The direction of the arrow depicts the role of interaction as described earlier.

Summary of Amanda and Emily's Knowledge Use					
	Primary Focus	Support/ Implication	Amanda	Emily	Total
M & L	M →	L	0	6	6
	M ←	L	1	1	2
	L →	M	5	5	10
	L ←	M	38	10	48
M & CI	M →	CI	1	2	3
	M ←	CI	0	0	0
	CI →	M	0	1	1
	CI ←	M	8	8	16

Table 1: The role of Mathematics

Of the 86 interactions that involved mathematics, only 11 had mathematics as the primary focus of conversation. Of these 11 interactions, 9 of them led to an implication or investigation involving mathematics, and only two used CI or L to support a claim about mathematics. In other words, mathematics was not the main focus of conversation for Amanda and Emily as they were making decisions in the classroom. There were 75 interactions that had mathematics as the secondary knowledge type; 11 of these interactions involved a shift of focus from knowledge of learners or knowledge of curriculum and instruction to an implication about mathematics. In other words as the participants talked about their knowledge of learners or curriculum and instruction, their attention was re-directed to investigate or think about mathematics. The main use of mathematics was to either justify a claim about learners (48 interactions) or to justify a claim about curriculum and instructional strategies (16 interactions). From the data, mathematics appears to primarily play a supportive role in teaching for Amanda and Emily, with more than half of the interactions utilizing mathematics to justify a claim about learners. In addition, of the 86 interactions involving mathematics, 66 integrated knowledge of mathematics with learners, and only 20 integrated knowledge of mathematics with curriculum and instructional strategies.

Structures of Teacher Knowledge Interactions

The structure of the knowledge interactions also sheds light on how teachers' use their knowledge while teaching. The following table describes the frequency of interactions where each type of knowledge was the primary focus of conversation (see table 2).

Primary Focus	Amanda	Emily	Total
M	2 (1.6%)	9 (10.2%)	11 (5.1%)
L	88 (68.8%)	43 (48.9%)	131 (60.6%)
CI	38 (29.7%)	36 (40.9%)	74 (34.3%)
Total	128	88	216

Table 2: Frequency of M, L or CI as primary knowledge

Knowledge of learners received the most attention from Amanda and Emily. Emily was more balanced between knowledge of learners and knowledge of curriculum and instruction. Amanda, on the other hand, relied more heavily on her knowledge of learners.

When knowledge of learners was the primary knowledge type, two prominent patterns of interactions occurred. The first pattern observed was that both CI and M were used to justify L or M→**L**←CI (note that the letter in bold represents the primary knowledge type). This pattern occurred in 14 of the 24 episodes that involved L as the primary knowledge type. The other pattern that occurred was M→**L**→CI, which was observed in 11 of the 24 episodes that involved L as the primary knowledge type. In this pattern, mathematics was used to support the knowledge of learners, which in turn had implications for knowledge of curriculum and instruction. There was one episode that simultaneously contained both patterns. One might say that the knowledge of learners was a linking knowledge between the knowledge of mathematics and the knowledge of curriculum and instructional strategies. More complicated connections involving L as the primary focus were not observed.

When knowledge of curriculum and instruction was the primary knowledge type, there are several different patterns that occur. There are two patterns that are similar to the patterns for when L is the main focus. The first pattern is M→**CI**→L and the second pattern is M→**CI**←L, both of which occurred in 4 of the 12 episodes where CI was the primary focus. In other words, CI can serve as a linking element between M and L, but not as frequently as L serving as a linking element. There are also more complicated interactions when CI is the main focus. An example is L→**CI**↔L←M. It seems that in the previous example, starting with CI as the primary focus can promote many connections between L and M.

As noted previously, based on the data, mathematics seems to be used more to justify or support CI or L; therefore, mathematics was rarely the primary focus of conversation. For the two episodes where M was the main focus of conversation the interactions are as follows: CI←**M**←L and **M**→**L**↔CI. In the second mapping, mathematics is the focus at the beginning of the episode but the focus then shifts to the knowledge of learners.

Discussion

From the findings, it is evident that Amanda and Emily employed their knowledge of learners frequently. Moreover, their knowledge of learners appeared to play a linking role between their knowledge of mathematics and their knowledge of curriculum and instructional strategies. In addition, Amanda and Emily rarely had mathematics as a primary focus; instead they used Mathematics primarily in support of the other types of knowledge. However, it must be noted that the results are based on two teachers that were high regarded by colleagues and administration and may not be representative of all teachers.

Mathematics role as a support knowledge seems to be counterintuitive to the emphasis in recent research. This study does not discount the importance of mathematical knowledge, because mathematical knowledge is an important foundation for the other forms of knowledge. However, it raises the issue of how much focus should be placed on acquiring mathematical knowledge without the opportunity to make connections to knowledge of learners and knowledge of curriculum and instruction. This study raises questions regarding the role of the knowledge of mathematics in teaching elementary mathematics, and subsequently how the knowledge of mathematics, learners, and curriculum and instructional strategies are provided during teacher preparation. In addition, the common patterns of knowledge interaction demonstrated by Amanda and Emily may provide insight into how we can structure learning opportunities for pre-service teachers to better encode the connections necessary to become successful teachers.

○ PRESERVICE MATHEMATICS TEACHERS' VISUALIZATION OF POLYNOMIAL-RATIONAL INEQUALITIES, EXPO-LOG FUNCTIONS & DERIVATIVE-INTEGRAL FUNCTIONS ON GEOGEBRA

Günhan Caglayan
Columbus State University
Sezen@ColumbusState.edu

This study investigates mathematics secondary preservice teachers' visual representations of selected precalculus and calculus tasks (polynomial and rational inequalities, graphs of exponential and logarithmic functions, derivative and integral functions) using GeoGebra. Seven students who already completed precalculus and calculus classes were asked to use GeoGebra to solve selected precalculus and calculus problems. For each problem, they were asked to indicate their problem solving procedure on GeoGebra, and to write and explain their reasoning for each step in detail with reference to GeoGebra work. I situate my research within a framework of visual representations in calculus. The main result is that though teachers were successful in obtaining an algebraic solution (using an interval notation, correctly executing derivative and integral calculations), in none of them was there a clear indication of a solution set (intervals of x) constructed where it should be – on the x-axis. Another result is that geometry plays a crucial role as a prerequisite not only in calculus, but in the sense-making of precalculus explorations as well.

Theoretical Background

Visual representations play a crucial role in understanding and making sense of mathematics. Students' favorite mathematics textbooks and teachers are often the ones that use a variety of colorful figures, diagrams, pictures and graphs. Visualizing is also a very important step in understanding and attempting to solve a problem (Polya, 1957). Even when a visual representation is vague or missing, producing a meaningful one is an indispensable route leading to a meaningful solution to the problem (Larkin, 1989; Polya, 1957; Schoenfeld, 1985; Simon & Larkin, 1987).

Just as is valuable to create an algebraic formalism along with its symbols and notation, so is the case for creating a visual representation and connecting the two models (Caglayan & Olive, 2010). As stated by the Principles and Standards for School Mathematics (NCTM, 2000): *Representation is central to the study of mathematics. Students can develop and deepen their understanding of mathematical concepts and relationships as they create, compare, and use various representations. Representations – such as physical objects, drawings, charts, graphs, and symbols – also help students communicate their thinking* (p. 280). Being able to represent mathematical ideas in various ways is as important as relating those representations and connecting them meaningfully.

The theoretical framework of this study is inspired from Zimmerman, who postulated that successful solutions to calculus problems are the ones that are accompanied by meaningful visual representations and graphs (1991). He also reported excellence in geometry as one of the main prerequisites of visual thinking in calculus. Though a calculus instructor may take it for granted, college students may not always be as proficient in visualizing as they are assumed to be (Eisenberg & Dreyfus, 1991). In what follows, I focus on mathematics preservice teachers' visual representations of selected precalculus and calculus tasks modeled on GeoGebra, and on their abilities to connect their visual and algebraic formalism.

○ Context and Methodology

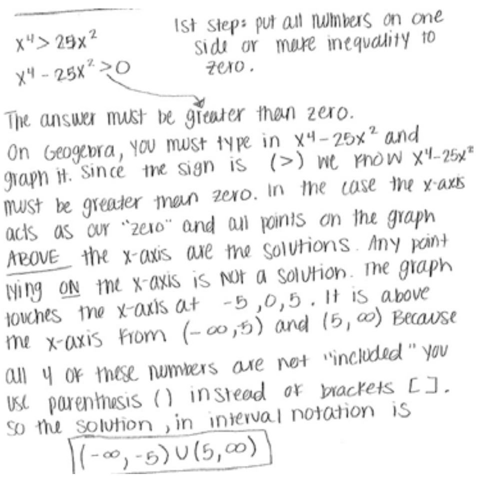
This study investigates mathematics secondary preservice teachers' investigation of selected precalculus and calculus tasks (polynomial and rational inequalities, graphs of exponential and logarithmic functions, derivative and integral functions) using GeoGebra, a free mathematics software that intertwines geometry, algebra, and spreadsheets. Seven students who already completed precalculus and calculus classes were asked to use GeoGebra to solve selected precalculus and calculus problems. For each problem, they were asked to indicate their problem solving procedure on GeoGebra, and to write and explain their reasoning for each step in detail with reference to their work on GeoGebra.

This project included seven mathematics secondary preservice teachers whom I met weekly for three weeks in three-hour sessions. My data consists of these research participants' detailed written algebraic solutions and comments, and work saved on GeoGebra. I then created scanned version of their work and conducted an in-retrospect preliminary thematic analysis of the whole data to generate possible themes for a more detailed analysis. The dataset has then been revisited multiple times in order to generate a thematic analysis (with constant comparison) from which the following results emerged.

Results

The first set of tasks to be modeled using GeoGebra was the following: *Use GeoGebra to solve the polynomial and rational inequalities given at Pearson's MyMathLab tech environment. For each problem, indicate the solution set on GeoGebra (Find a way to make your solution set visible on GeoGebra). Also enter your answer to Pearson's MyMathLab tech environment. For each problem, explain your reasoning for each step in detail with reference to your work on GeoGebra*.

For the first set of tasks, all students except Ashley wrote their comments in outline form. In this format, students basically described each inequality leading to the solution set of the original inequality via a set of phrases, rather than prose format. Only one student, Ashley, was able to relate her reasoning with reference to her work in GeoGebra completely. The other students seemingly treated the algebraic and graphical solutions as independent tasks. Figure 1 depicts Ashley's solution on GeoGebra and written work for the polynomial inequality $x^4 > 25x^2$.



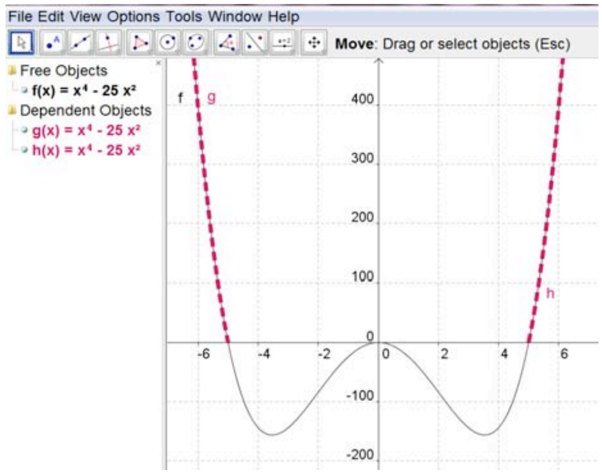


Figure 1 - Ashley's Written Work (left) and GeoGebra (right) Solutions to Polynomial Inequality $x^4 > 25x^2$

Ashley clearly understands the polynomial inequality problem and addresses problem solving steps meaningfully (Polya, 1957). She also finds her own way of representing the "solution set" on her GeoGebra work, using the two pink dashed subsets of the induced function $f(x) = x^4 - 25x^2$ she defines and makes use of[1]. Her comment "all points on the graph above the *x*-axis are the solutions" corroborates the fact that her interpretation of a solution set to a polynomial inequality is actually a set of points on the graph of the induced function; rather than the union of the two rays $(-\infty,-5)$ and $(5,\infty)$ on the *x*-axis.

In his written work for the rational inequality problem $\frac{4x-5}{x+2} \le 3$, Norman first "*breaks down the equation*," by which he obtains the equivalent inequality $\frac{x-11}{x+2} \le 0$. He then goes on to state "*There is a vertical asymptote at* $x = -2$. *I proved this in GeoGebra by graphing* $x = -2$ *along with* $\frac{x-11}{x+2}$ *and the result was undefined meaning that it cannot exist due to the denominator being equal to 0*." Figure 2 depicts Norman's solution on GeoGebra and the concluding parts of his written work for the rational inequality $\frac{4x-5}{x+2} \le 3$.

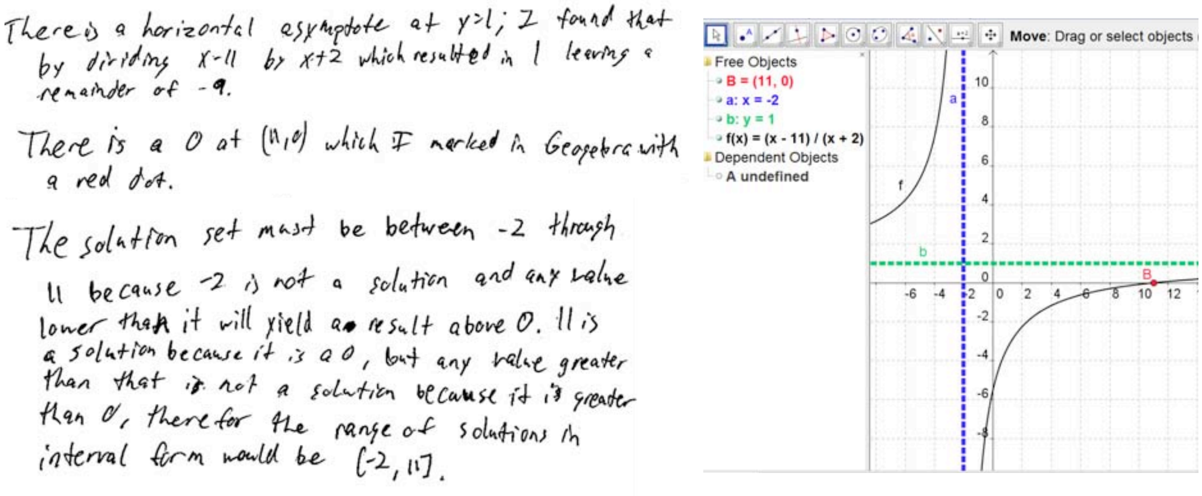

Figure 2 – Norman's Written Work (left) and GeoGebra (right) Solutions to Rational Inequality $\frac{4x-5}{x+2} \leq 3$

Norman clearly uses his GeoGebra work as a check to his algebraic solutions, as evident from his written comments. Rather than indicating the solution set on the graph, he relies on the traditional rational inequality solving procedure algebraically. Though he graphs the vertical asymptote $x = -2$ and point $B(11,0)$ on GeoGebra, he fails to construct the line segment $(-2,11]$, which is the actual visual representation of his solution in "*interval form*."

The second set of tasks to be modeled was about graphing an exponential function and constructing its inverse (the logarithmic function) on GeoGebra. Students were also asked to find a way to make everything (e.g., the domain and the range of the functions, asymptotes, visual proof that the two functions are inverse functions of each other) visible on GeoGebra. The instructions once again asked for a detailed explanation with reference to work on GeoGebra. Mary first graphed the given exponential equation, $f(x) = e^{x-3} + 4$, on GeoGebra and stated that the domain of *f* would be the interval $(-\infty, \infty)$, which she showed as *black dashes* in function graph (Figure 3a). She obtained the horizontal asymptote of *f*, $y = 4$, by "*just looking at the graph. If you zoom in on the graph in geogebra you would see that the line y=4, horizontal asymptote, does not touch the function* $e^{x-3} + 4$. *This is shown as the blue dashed line*."

Mary then used the conversion formula to obtain the equation of the inverse function as $f^{-1}(x) = \ln(x-4) + 3$ algebraically. She also states that she found the range of *f* by looking at the graph. "*The y-values run from 4 to ∞. In interval notation the range is* $(4, \infty)$, *which is shown as black dots in the function graph of f.*" She then explains that she graphed the inverse function by typing its equation, which she obtained algebraically, in GeoGebra's input bar (Figure 3a).

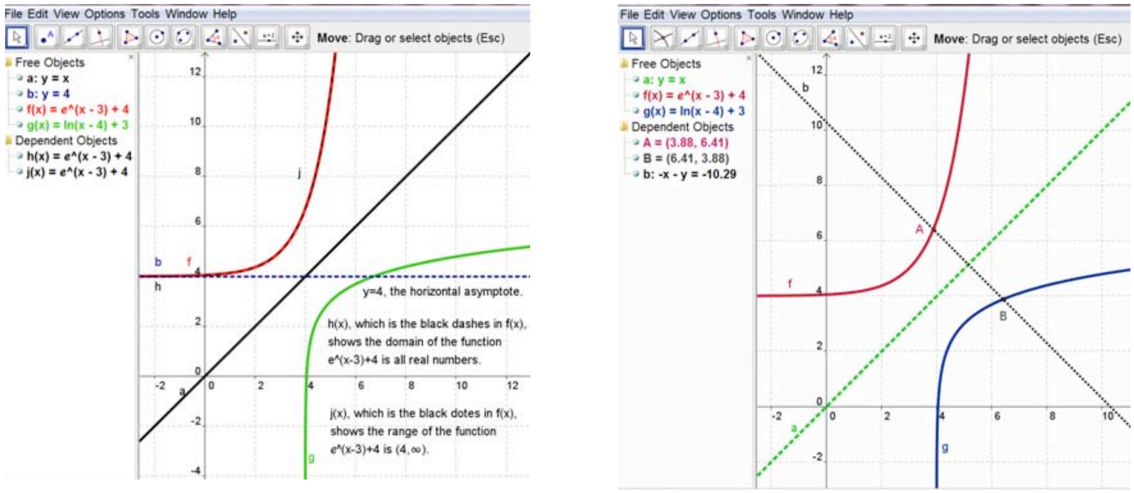

Figure 3 – Mary's (left) and Norman's (right) Exponential and Logarithmic Function Graphs on GeoGebra

We can say that Mary follows a reasoning, similar to Ashley's, in that she represents both the domain and the range of the exponential function as subsets of the exponential function[2]. Mary's interpretation of domain and range is actually a set of points on the graph of the original function *f*; rather than the line $(-\infty,\infty)$ and the ray $(4,\infty)$, respectively, on the *x*-axis. Mary is satisfied with the fact that the graphs of the two functions are reflections of each other with respect to the $y = x$ axis, visually. Norman, on the other hand, not only graphs the two functions, but he verifies that the two functions are inverse functions of each other by constructing a line perpendicular to the $y = x$ axis of reflection. For that purpose, he first constructs an arbitrary point, *A*, on the exponential function graph. He then selects Point *A* and the line $y = x$, which then enables him to construct the perpendicular line. Consequently, he constructs Point *B*, the intersection of line *b* and the logarithmic function graph, using GeoGebra's built-in *Intersect Two Objects* tool. He explains that *"Point A of the exponential function graph becomes Point B of the logarithmic function graph… They simply interchange their x and y coordinates*." The findings stated in this paragraph could be considered as evidence of how geometry plays a crucial role as a prerequisite not only in calculus (Zimmerman, 1991), but in the sense-making of precalculus tasks as well.

The final set of tasks to be modeled was about graphing a function along with its derivative and integral functions. The instructions were similar to the ones for the previous tasks (detailed explanations, request for construction of geometric objects to be determined by the research participants). All participants came up with almost identical constructions on GeoGebra, so in what follows, I focus on Sally's work on the derivative and integral function constructions, without loss of generality.

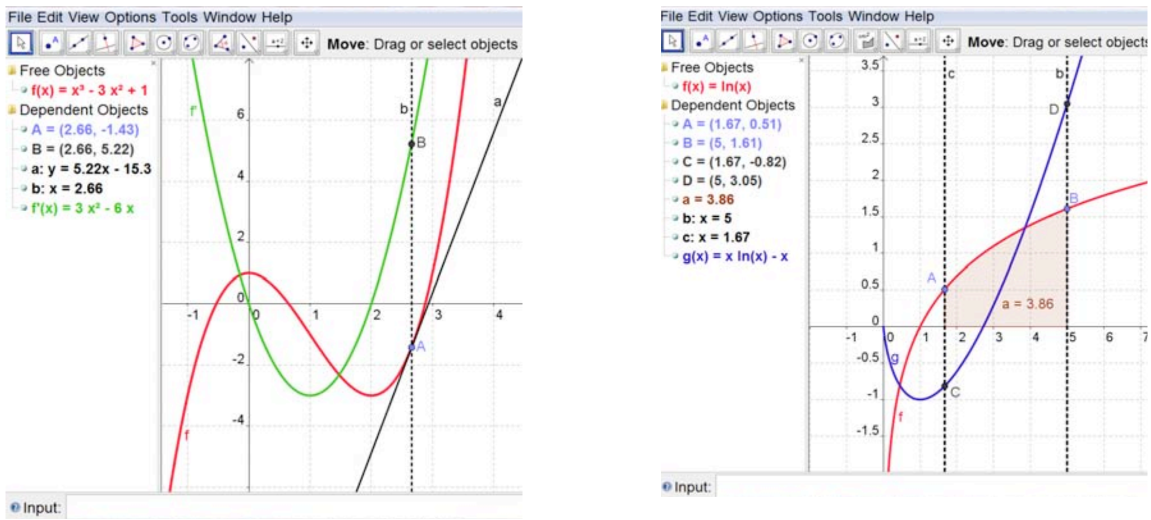

Figure 4 – Sally's Sketches for the Derivative Function (left) and Integral Function (right)

Sally starts by writing that she finds GeoGebra easy to manipulate and very helpful in understanding the derivative of a function. She first created the graph of the polynomial function $f(x) = x^3 - 3x^2 + 1$ by simply typing the function into the input bar. She then used GeoGebra's built-in *Tangents* tool to create the line tangent to the curve *f* at Point *A*. She states "*Being able to see the equation of this tangent line helped me evaluate the slope of the line very quickly*." She then used the syntax Derivative[f] to graph the derivative function. The next task, constructing a geometric object in order to create Point *B* on the graph of f' that should always have the same *x*- coordinate as Point *A*, was challenging for everyone. Sally immediately thought of using a rectangle because the vertical line from Point *A* would intersect f' at some Point *B*, and they would have the same *x*-coordinate. She then thought that if she drags Point *A* down a point where the slope of the tangent line was 0, she could easily create a perpendicular line to the tangent through Point *A* and it would intersect f' at the same *x*- coordinate. This approach did not work because any movement of *A* changed the slope of the tangent line and the resulting perpendicular line was not guaranteed to intersect f' at the same *x*- coordinate. She then decided to use GeoGebra to construct a vertical line through A by typing the equation of the vertical line, $x = x(A)$, into the input box. By using the *Intersect Two Objects* tool, she then was able to construct Point *B* from the intersection of the vertical line and f' (Figure 4a).

Although Sally claimed that GeoGebra was very useful and easy to understand while doing this problem, there was no clear indication of how Point *B* was related to the equation of the tangent line. Sally just mentioned that the slope of the tangent line was very easy to evaluate, but there was no mention of the fact that the *y*- coordinate of Point *B* would be equal to the slope of the tangent line. In fact, a similar disconnect happened in the task on the exploration of a function and its integral function. Sally first constructed the graph of the given function $f(x) = \ln x$ and two arbitrary points *A* and *B* on the curve. She then used the syntax Integral[f, x(A), x(B)] to evaluate the integral $\int_{x(A)}^{x(B)} f(x)dx$. She commented that she was able to see the area under the curve between these two *x*-values had the same value as the expression $\int_{x(A)}^{x(B)} f(x)dx$. She then constructed the graph of the integral function using the syntax Integral[f]. The next task was to construct a geometric object in order to create Points *C* and *D* on the graph of *g* that should always have the same *x*- coordinates as Points *A* and *B*, respectively. This time, everyone easily figured out that what needed to be constructed were two vertical lines (Figure 4b). Sally then evaluated the difference $y(D)-y(C)$ algebraically, using the traditional integration procedure, instead of working it out just by typing the expression into the input bar. Participants failed to relate the difference $y(D)-y(C)$ to the area under the curve between $x(A)$ and $x(B)$.

Conclusions and Discussion

This study aimed to depict visual representations of polynomial and rational inequalities, graphs of exponential and logarithmic functions, derivative and integral functions exposed by secondary mathematics preservice teachers on GeoGebra. Analysis of these participants' visual representations, accompanied by their algebraic formalism and thorough reasoning, has a crucial impact to determine important insights into their sense-making of the mathematics they are exploring. This has direct implications for the teaching of precalculus and calculus in a technology based environment. Mathematics teachers should be more conscious and explicit in modeling problems because otherwise this may be prone to a misinterpretation of the problem situation, or even the solution to the problem, as depicted in this present study. For example, although students were confident with their algebraic solutions (in interval notation) to the polynomial and rational inequality problems, their interpretation of the "solution set" concept differed ostensibly from their algebraic formalism when they were asked to represent this "solution set" on GeoGebra: A function graph, or a subset of the function graph is not the same thing as an interval on the *x*-axis, therefore, an appropriate distinction of these two fundamentally different objects is necessary.

Constant comparison of Mary and Norman's work for the problem of creating an exponential function and its inverse function and Sally's work on the derivative and integral functions on GeoGebra yielded that proficiency in a variety of geometric entities (e.g., transformations, symmetry, constructions of points, lines, line segments, rays, parallel and perpendicular lines) is an undeniable prerequisite in the sense making of not only calculus (Zimmerman, 1991) but precalculus tasks as well. College geometry is often offered as an upper division class that many mathematics and mathematics education majors enroll in long time after they complete the precalculus and calculus sequence. In many universities, Calculus II or III are listed as prerequisites for College Geometry. In fact, therein lies the dilemma: How could we expect our students to master precalculus and calculus while these two being listed as prerequisites for college geometry? Some of the participants of this study overcame this obstacle thanks to their overexcellence in manipulating the GeoGebra software, however, excellence in a geometry software such as Geometer's Sketchpad or GeoGebra does not necessarily implies excellence in geometry.

This study focused directly on the visual representations and written comments and algebraic formalism that the research participants produced. Ferrini-Mundy (1987) found that calculus students made more mistakes in the process of just writing a definite integral than in the process of calculating the definite integral itself. This finding corroborates my theories concerning Sally, for instance, who failed to relate the difference $y(D)-y(C)$ to the area under the curve between $x(A)$ and $x(B)$ in dealing with integral function task (Figure 4b). While she was able to carry out the derivation and integration procedures, and the construction of the derivative and integral functions on GeoGebra perfectly, she failed to *relate* the slope of tangent line to the value of the derivative function at the corresponding *x*-value. She also failed to relate the area under the curve of the original function to the difference of the *y*-values of the integral function on GeoGebra. Bremigan (2005) postulated that mathematically strong students often modified and reconstructed their visual representations in solving calculus problems. The participants of this present study showed a similar behavior. For instance, Sally was very creative and determined to modify and make changes (e.g., in the task on derivative function, for the construction of Point *B* on the graph of f' that should always have the same *x*- coordinate as Point *A*) as opposed to claims by Eisenberg and Dreyfus (1991), who reported a general reluctance on the part of calculus students to visualize in mathematics.

Endnotes

1. She creates those using the piecewise defined function syntax of GeoGebra.
2. Mary too creates those using the piecewise defined function syntax of GeoGebra

CHARACTERIZING DISCOURSE IN TWO TECHNOLOGY-INTENSIVE HIGH SCHOOL GEOMETRY CLASSROOMS

Two different teachers implementing The Geometer's Sketchpad in high school geometry classes were analyzed to examine how the patterns, types, and modes of mathematical discourse differed when technology was used. The patterns, types, and modes of mathematical discourse differed between the two teachers when they were and were not using technology. For each teacher, the mathematical discourse modes appeared to shift when technology was used but the types of mathematical discourse did not.

In 1991, the National Council of Teachers of Mathematics (NCTM) published the *Professional Standards for Teaching Mathematics* in which they emphasized the importance of discourse in the teaching and learning of mathematics. They state:

> Like a piece of music, the classroom discourse has themes that pull together to create a whole that has meaning. The teacher has a central role in orchestrating the oral and written discourse in ways that contribute to students' understanding of mathematics.

While many acknowledge the important role discourse plays in the teaching and learning of mathematics, transforming the classroom to one in which students are active participants in classroom discussions does not occur automatically (Hufferd-Ackles, Fuson, & Sherin, 2004; Nathan & Knuth, 2003). The teacher needs to choose worthwhile mathematical tasks, identify appropriate tools to use, anticipate, monitor, select and sequence student work on those tasks, and then bring the class to an appropriate close (e.g., Stein, Engle, Smith, & Hughes, 2008). They need to be able to orchestrate the communicational processes (who is speaking, when, and how) as well as focus on the mathematical content of the conversations.

One method of examining discourse processes is to consider the sequence of activities involved in an interaction. Cazden (2001) defines "traditional" classrooms as classrooms in which discourse follows a typical initiation, response, evaluation/feedback pattern (I-R-E/F) pattern. In contrast, discourse in "non-traditional" classrooms more closely resemble a conversation two people might have. Discourse in "non-traditional" classrooms do not typically follow the I-R-E/F pattern.

Although it is important to know how discourse transpires in a classroom, to support mathematics learning, the content of discourse is also critical to consider. Students providing a single answer response to a low-cognitive demand question is different from students discussing different solution strategies to a high-cognitive demand mathematical task (Stein, Smith, Henningsen & Silver, 2000). How students participate in conversations as well as the types of responses they may provide may both be influenced by the norms established in the classroom (Yackel & Cobb, 1996).

Because technology supports students' conjecturing, problem solving, and exploration of mathematical tasks that can be of high cognitive-demand, and may also serve as an agent disruptive of current norms and practice (Rochelle, Pea, Hoadley, Gordin, & Means, 2000), this may affect the nature of the content of the discourse in which students engage. Also, since students are interacting with a computer as well as one or more students as they work on problems in pairs or small groups they may pose more questions to each other and to the teacher. A question that guided this study was, "In what ways does the inclusion of technology in a mathematics class influence the nature of mathematical discourse?" The purpose of this study was to characterize the nature of mathematical discourse when students were using technology and to contrast this to discourse that was typical in the class when technology was not used.

Methods

During the summer of 2010, twenty teachers from four different schools districts attended a one-week professional development workshop. The school districts were in different stages of implementing 1:1 laptop initiatives. One school district had been using laptops for seven years while another was planning on distributing laptops to their students for the first time during the 2010-2011 school year. The professional development workshop focused on assisting teachers in using a dynamic geometry software program, *The Geometer's Sketchpad* ver. 5.0, to teach particular topics in the high school geometry curriculum (e.g., triangles, quadrilaterals, transformations). The summer workshop was followed by an online course that was taught during the 2010-2011 school year. These experiences are part of a larger 2-year professional development project. The data reported here were collected during the early stages of the teachers' participation in the professional development experience[1].

During the first semester of the school year, twelve of the twenty teachers from the summer institute were assigned to teach a high school geometry class. All four school districts were on a 4 by 4 block schedule. Students took four classes in the first semester and four different classes in the second semester. Each class met for 90 minutes. Thus, the typical year long geometry course was taught in one semester. Each of the twelve teachers was observed and video-recorded three times during the semester.

The Oregon Mathematics Leadership Initiative (OMLI) Classroom Observation Protocol (RMC Research Corporation) was modified and used to gather more detailed information about discourse in the classroom when technology was and was not used. This instrument identifies the modes and types of mathematical discourse and the tools that were used. However, the purpose of this instrument was to focus on student discourse and it did not attend to discourse that was initiated by the teacher. Thus, the instrument was modified to allow researchers to code both student discourse as well as teacher discourse. The mode was used to identify who was participating in the discourse (e.g., teacher to student, student to student) and the type of discourse was used to identify the nature of the response or question during the interaction (e.g., explanation, prediction, justification, answer). The OMLI project assigned a number to each of the different types of discourse to suggest a ranking similar to the categorization of lower and higher-level questions identified by other researchers (e.g., Hollebrands & Heid, 2005; Moyer & Milewicz, 2002). Especially for this study, the tools that were used for the discourse were important to also note. Computers and calculators were assigned different codes rather than the same code as was indicated in the original observation protocol. Tools refer to what was used during the discursive interaction (e..g, actions, written or spoken words, computers/calculators, graphs). The codes that were used for the analysis are shown in Figures 1, 2, and 3.

Figure 3. Tools for Discourse.

From the twelve teachers, two teachers were initially selected for more in-depth analysis based on teaching experience and technology usage. Mrs. Adams and Mr. Smith represented teachers at both ends of the teaching continuum and demonstrated facile use of various types of technology. The researchers assumed their technological aptitude would eliminate many obstacles related to implementing technology in their classrooms; therefore the analytic focus would shift mainly to discourse. A training session was conducted with a consultant who was part of the original OMLI team. Then a training session with three coders was conducted to check for agreement on the number of episodes and the coding of those episodes. An iterative process was carried out on two of the six video-recordings until an agreement rate greater than 70% on the codes was reached. Then two coders analyzed the remaining four video-recordings individually. The codes were then tabulated to identify themes and trends in the data.

Mrs. Adams

Mrs. Adams has taught high school mathematics for 4-7 years at a small rural high school. There are 728 students enrolled in this school: 59% of the students are classified as economically disadvantaged, 64% of the students are African American, and 6% are Hispanic. Mrs. Adams reported using *The Geometer's Sketchpad* for about two years, and she rated her confidence in using the software as a 2 on a 5-point scale (5 being very confident). She reported using laptops for 1.5 years and demonstrated facile use of technology. She taught an honors level geometry course with 30 freshman students.

Patterns of Mathematical Discourse

A statement, question, answer, statement cycle was predominant in the analysis of Mrs. Adams' teaching when facilitating classroom discourse both with and without technology. Generally, she would initiate discourse with a statement that lead into a question for either the whole class or a particular student. Student(s) would answer the question posed at which time Mrs. Adams would confirm/revise their response with another statement, often initiating the pattern again. The following episode provides an example.

Mrs. Adams: Today we are going to look at the other two pieces of our quadrilateral tree. (S)
Mrs. Adams: What were our other two pieces of the quadrilateral tree that we talked about? (Q)
Student A: Trapezoids and uh…(A)
Mrs. Adams: Trapezoids and…(S)
Student B: Rhombuses…(A)
Mrs. Adams: Rhombus we talked about with parallelograms (S)
Student C: Kites (A)
Mrs. Adams: Kites. We are going to look at our trapezoid and our kites today and those properties that you need to know. (S)

This pattern is similar to the I-R-E/F pattern typical of "traditional" classrooms. In this instance, Mrs. Adams initiates with a question about the quadrilateral tree, students respond and the teacher provides feedback about their responses to her question by correcting or restating what the student said. While this example is taken from a portion of class in which students did not use technology. Similar instances were noted when technology was used.

Modes of Mathematical Discourse

In addition to examining the patterns of discourse, knowing who is participating in classroom discussions is important to consider. By analyzing the modes of discourse, the actors involved in the discussion become more explicit. For Mrs. Adams, a significant shift in discourse can be seen in the reduction of discourse initiated by or directed to the teacher in favor of more student-to-student discourse when technology was employed (Figure 4a & 4b).

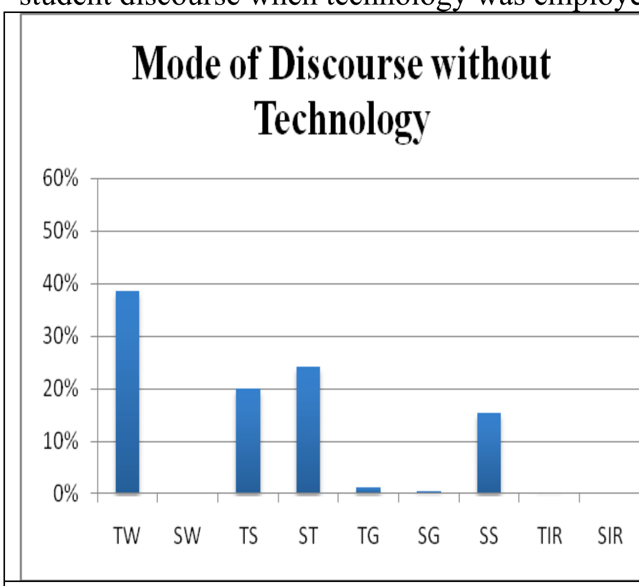

Figure 4a. A chart summarizing the percent of

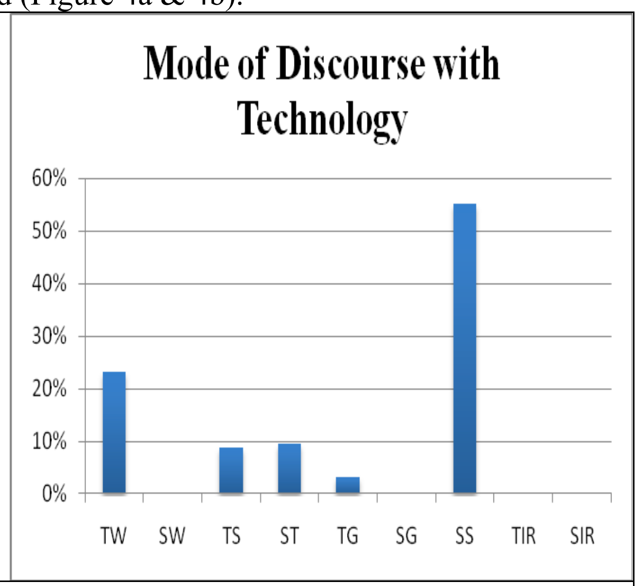

Figure 4b. A chart summarizing the percent of

each mode of discourse recorded in Mrs. Adams' classes when technology was not used.	each mode of discourse recorded in Mrs. Adams' classes when technology was used.

It should be noted that when students were working with the technology they were generally in pairs or small groups and the teacher often allowed them to work for extended periods of time on their own. Although she circulated around the room while students were working, she generally did not interrupt their work and encouraged students to direct questions toward their partner or group.

Types of Mathematical Discourse

Although a marked shift was noted in the mode of discourse, changes in the type of mathematical discourse when technology was used were minimal. The types of discursive exchanges between teachers and students remained approximately the same whether students were using technology or not (Figure 5a and 5b).

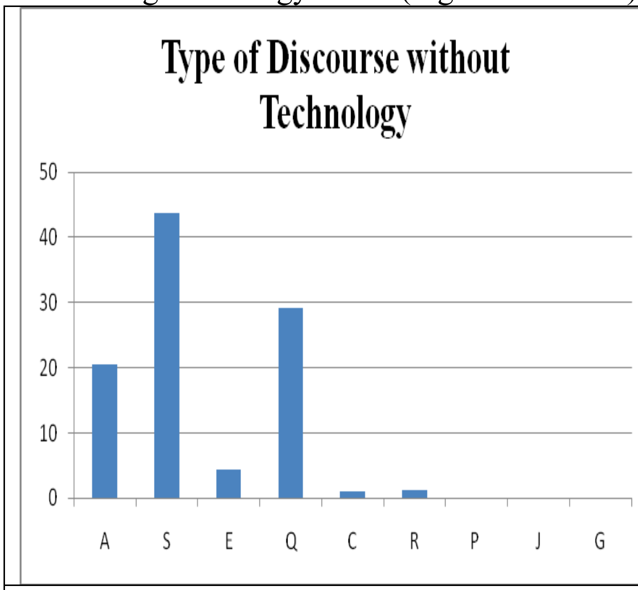

Figure 5a. The percent of each type of discourse recorded in Mrs. Adams' classes when technology was not used.

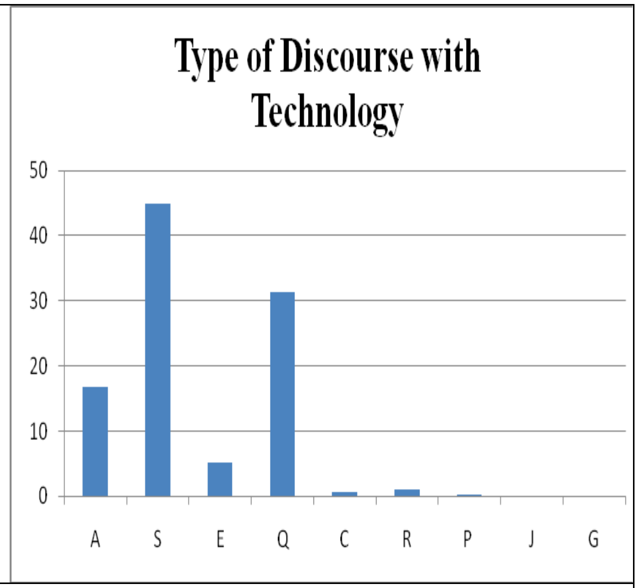

Figure 5b. The percent of each type of discourse recorded in Mrs. Adams' classes when technology was not used.

One might expect that if the participants in the discourse change then the nature of that discourse change also. However, this was not noted in our observations of Mrs. Adams.

Mr. Jones

Mr. Jones has taught high school mathematics for 11-14 years and is the chairperson of the mathematics department at a medium-sized suburban high school. There are 948 students enrolled in this school: 23% of the students are classified as economically disadvantaged, 18.8% of the students are African American, and 8.9% are Hispanic. Mr. Jones reported using *The Geometer's Sketchpad* for about 6 years and he rated his confidence in using the software as a 4 on a 5-point scale (5 being very confident). He was named "Teacher of the Year" for the school district seven years ago. The class he was observed teaching was a regular geometry class that contained 22 students. This school district was beginning the first year of a 1:1 laptop initiative.

Patterns of Mathematical Discourse

Mr. Jones made a determined effort to foster discourse in his classroom. He posed many questions to students and provided an appropriate amount of time for students to think about the question before requesting an answer. Some of the patterns that were observed when technology was and was not used could be described as following a typical I-R-E/F sequence. However, there was another discourse pattern that was prevalent when technology was and was not used that differed from this traditional pattern. Often the pattern would begin with the posing of a question from a student, the teacher would respond with a question, a student would answer, and the teacher would follow with a statement. For example, during the first observation students were working on the computer on an activity, which required them to identify rotational symmetry for a pattern that was provided in a pre-constructed sketch.

Student:	I don't get it. (S)
Mr. Jones:	Okay. Look at the small purple triangles on the outside. These ones. What is the smallest angle of rotation? (Q) Did you rotate that one? (Q) I see that you have it highlighted. Did you rotate that one? (Q)
Student:	Yes. (A)
Mr. Jones:	What are your answer choices? (Q)
Student:	(student reads answer choices) (S)
Teacher:	Okay. Hold on a second. Did you tell it where the center of rotation was? (Q) You always have to tell it this is the center of rotation is and then this is the thing that I am trying to rotate. You've got to put a center of rotation on the picture. Use the arrow tool to double click. (S) Good. (Student performs a rotation) Does that look exactly like the other one? (Q) (Teacher walks toward another group in the class)

In this interchange the teacher posed a sequence of questions to assist the student in using the technology so that she is able to respond to the question on her own. These series of questions are different from the typical I-R-E/F pattern. In particular, the question about whether the image under the rotation looks exactly like the original focused the student on what it means for two figures to be the same under a rotation. This enabled the student to use the technology to determine the rotational symmetry of the original pattern.

Modes of Mathematical Discourse

During the observations when technology was not used, Mr. Jones engaged the class in whole-class discussions during which time he generally addressed the entire class (TW). Students also responded to the teacher (ST) and the teacher addressed particular students either during a whole class discussion or when students were working individually or in small groups (TS, TG). There were also instances of students speaking to their group members (SG). The percent of episodes that were coded for each of the modes when technology was not used is shown in Figure 6a.

	Figure 6a. The percent of each mode of discourse recorded in Mr. Jones' classes when technology was not used.	Figure 6b. The percent of each mode of discourse recorded in Mr. Jones' classes when technology was used.

When technology was used, the percent of discursive interactions between the teacher and whole-class decreased (TW) while the teacher-individual student interactions increased (TS). The number of interactions with the teacher that were initiated by the student (ST) remained about the same and there was a slight increase in the number of interactions the teacher initiated with small groups (TG). There were no instances of student-group interactions or student-student interactions.

The lack of student-to-student interactions was a bit surprising. One might expect that when students worked in groups with or without technology there would be an increase in the mathematical discourse that was exchanged. However, it is important to note that non-mathematical discourse was not coded. So there were times when students would ask each other about directions or how to complete a task with the technology, but these instances were not counted. Also, when students were working in pairs or small groups, Mr. Jones would often interject questions to individuals and groups about the task on which they were working and students would frequently ask questions of him. This was different from the interactions that were observed in Mrs. Adams classroom.

Types of Mathematical Discourse

While the mode of discourse allows examination of who is participating and initiating discourse in the classroom, it does not provide a clear picture of the content of the discourse. To better understand what was discussed when technology was and was not used, the type of discourse was analyzed. Figures 7a and 7b depict a summary of the different types of discourse identified from all three video-recorded observations of Mr. Jones' class.

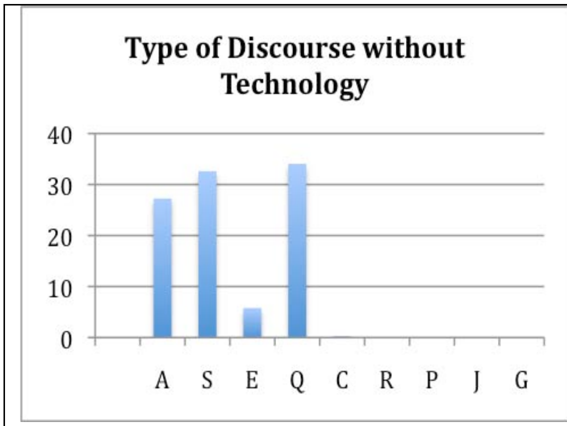

Figure 7a. The percent of each type of discourse recorded in Mr. Jones' classes when technology was not used.

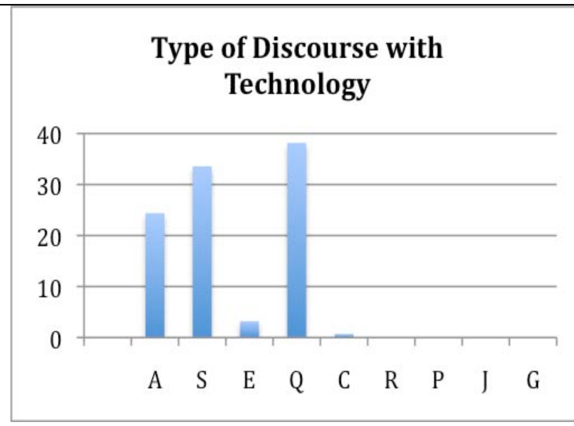

Figure 7b. The percent of each type of discourse recorded in Mr. Jones' classes when technology was not used.

There were approximately the same percentage of answers and statements provided with and without technology. There was a slight decrease in the number of explanations provided when using technology and a slight increase in the number of questions and challenges noted when technology was used.

Conclusions

The purpose of this study was to characterize the nature of mathematical discourse when students were using technology and to contrast this to discourse that was typical in the class when technology was not used. The analysis of the patterns, modes, and types of discourse that occurred in three video-recorded classes of two teachers provides us with a glimpse of those differences. For both Mrs. Adams and Mr. Jones the mode of discourse shifted when technology was used. For Mr. Jones there was less teacher-to-whole class discourse and more teacher-student and student-teacher discourse. For Mrs. Adams there was a striking increase in the number of student-to-student discursive interactions when technology was used. However, it is important to note that while students were using technology they were also working in small groups or in pairs. It is possible that similar changes in the modes of discourse would be observed in non-technological settings when students are working in pairs or small groups. This is a question that could be further examined. And while changes in discourse modes were noted, changes in discourse types were not. While many have suggested that technology has the potential to support reasoning and sense-making activities that could foster justification and generalization discourse types, this was not observed. Research in non-technological learning environments suggests that teachers first build an environment that students feel comfortable interacting (modes) and then turn their focus to mathematics (types) (Silver & Smith, 1996; Wood, Cobb, & Yackel, 1991). It is also important to note that the first year of the professional development did not focus teachers on classroom discourse. As teachers transition into the second year and this becomes a more explicit focus for them it would be interesting to see if more dramatic changes become evident in the type of discourse that occurs within their classrooms.

This study is designed to measure students' perceptions of classrooms using a Classroom Communication Systems (CCS). Drawing on the work of Bransford, Brown, and Cocking (1999), the study is designed to investigate the extent to which CCS classrooms facilitate environments which students experience as learner-centered, knowledge-centered, assessment-centered, and community-centered. Results suggest that students perceive that CCS technology gives teachers more information on what they are thinking, gives them more information on what other students are thinking, gives them more information on their own progress, and supports sharing of information to facilitate collaborative learning.

Introduction

More than two decades and of research and experience supports the idea that advanced digital technologies can have an important role to play in supporting student learning (Heid, 1988; Kaput, 1992; Kutzler, 1996; Papert, 1980; Waits and Demana, 1999). The development of Classroom Communication Systems (CCS) is providing new possibilities for the role technologies play in creating and supporting effective learning environments. The TI-Navigator™, from Texas Instruments, is a wireless CCS designed for K-12 classrooms. The pedagogical potential of CCS technology is still in its early stages but research suggests benefits to active student participation in class and collaborative inquiry in the classroom (Abrahamson, Davidian & Lippai, 2000; Bransford, Brophy, & Williams, 2000; Dufresne, Gerace, Leonard, Mestre, & Wenk, 1996; Pape, Irving, Owens & Abrahamson 2005; Wenk, Dufresne, Gerace, Leonard, & Mestre, 1997). This study is designed to measure students' perceptions of the extent to which CCS classrooms facilitate effective teaching and learning environments.

The research question driving the analysis presented below was:

Does the use of CCS result in an environment which students experience as more learner-centered, knowledge-centered, assessment-centered, and community-centered?

Theoretical Framework

Bransford, Cocking and Brown (1999) developed a framework for designing effective learning environments. The design of such environments is based on three principles:

"To develop competence in an area of inquiry, students must:

- (a) have a deep foundation of factual knowledge,
- (b) understand facts and ideas in the context of a conceptual framework, and
- (c) organise knowledge in ways that facilitate retrieval and application." (p 18)

Furthermore the framework proceeds from the premise that “Students come to the classroom with preconceptions about how the world works. If their initial understanding is not engaged, they may fail to grasp the new concepts and information that are taught, or they may learn them for the purposes of a test but revert to their preconceptions outside the classroom.” (p.14).

These principles form the basis for a model for describing learning environments with specific implications for teaching called How People Learn (HPL). Consequent to these principles Bransford et al. propose that effective learning environments should be learner-centered, knowledge-centered, assessment-centered, and community-centered.

Aspects of a teacher taking a learner-centered approach include using questions, tasks, and activities to show existing conceptions that students bring to the classroom, and exerting an appropriate amount of demand on students to think through issues and establish positions. A knowledge-centered approach manifests itself in a focus on conceptual understanding, and the diagnosis and remedy of misconceptions. Assessment-centered instruction concentrates on formative assessment to provide feedback to students and to teachers on student conceptions. Finally, a community-centered approach is reflected in, for example, class discussion, peer interaction, and non-confrontational competition. (Bransford et al., 1999).

Description of the Technology

Since the late-80s CCS have been an evolving technology. This genre of classroom tools began with hard-wired multiple-choice “response' systems, but is now being transformed by high speed wireless networks, handheld devices, and programmable control by a computer.

Modern CCS consist of five parts: (a) a computer, operated by a teacher, running a software package displaying information to only the teacher; (b) a projection panel which displays public information; (c) student devices which may be calculators, laptops, etc.; (d) a network which connects student devices to the teacher's computer, interprets communication protocols, and sends tasks to and from students and the teacher; and, (e) software which allows the whole system to function as an integrated classroom tool. Using CCS students can send in answers to multiple choice questions, alpha numeric answers, or lists of numbers based on measurements. The TI-Navigator™ is a modern CCS which possesses the unique characteristic of being almost totally programmable. That is, a Navigator™ “activity” or “task” may be designed to accept teacher-authored questions or other specific curricular materials, and also whole new activities written by third-party developers or technically sophisticated teachers.

The following is an example of how a Quick Poll activity might work: The teacher sends students a set of multiple choice questions to be answered including the question “What is –3^2?” with possible answers “A. 3; B. 9; C. –9; D. –3; E. 0”. Students’ progress on the questions can be tracked on the teacher console as they send in their answers. The particular question “What is –3^2?” is a question that students answer incorrectly due to misunderstanding or misremembering the order of operations necessary to get a correct answer. When all students have sent in answers to the set of questions, the teacher can display histograms of the students’ answers. In a class of 25 students the histogram for the question might look like Figure 1:

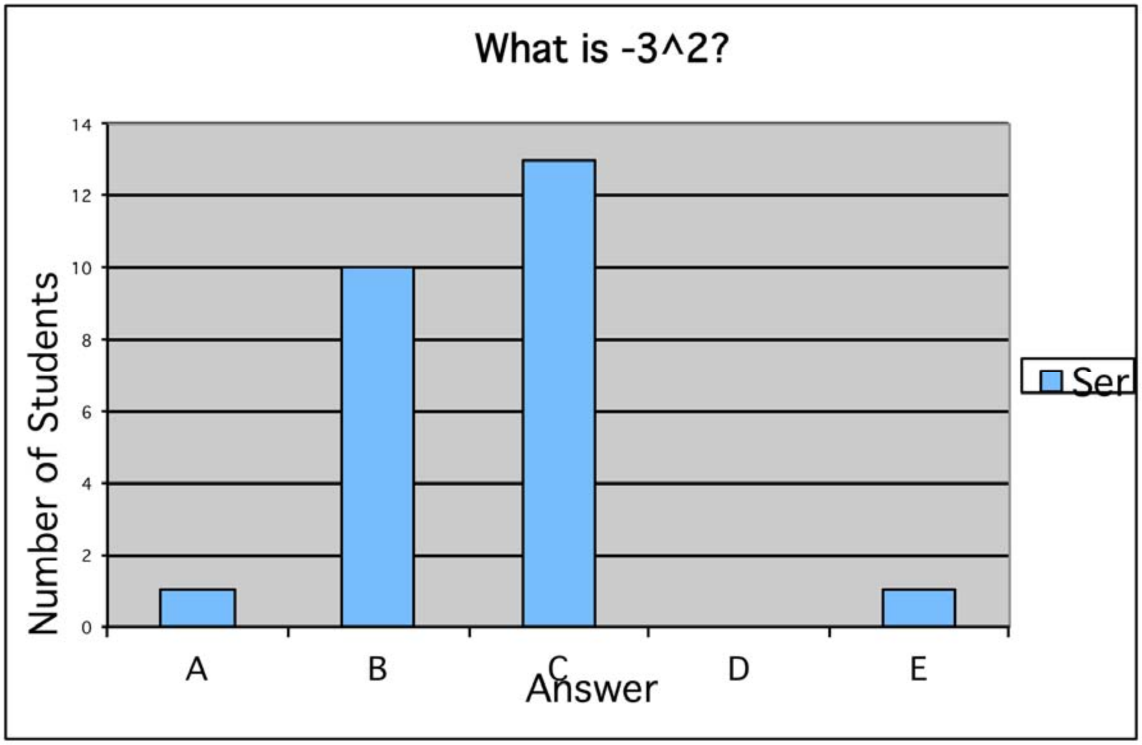

Fig 1 An example of CCS use for polling a class

There are several consequences of using the TI-Navigator™ worth noting here: (a) every student has had to choose and send in an answer to the question (they cannot just wait for someone else to answer), (b) the teacher knows that almost half of the students have a misconception as to how to simplify this arithmetic expression, (c) students know that probably at least half of them answered incorrectly, (d) students know that if they were one of those who answered incorrectly they are not alone, (e) misconceptions about how to answer this question have come into the open without any student having to risk the embarrassment of declaring an incorrect answer (although the teacher can know which students answered correctly).

Methods and Methodology

The participants in this study were eight high school mathematics and science teachers and their students (n=389). The teachers were experienced in teaching with graphics display calculators and took part in a professional development on the technical aspects of operating the TI-Navigator™ system as well as pedagogical techniques and possibilities in a networked classroom. Before the training teachers were surveyed in open question format about their pedagogical practices and were surveyed at the end of the school year about possible changes in their practice. A series of visits was undertaken to their classrooms where the TI-Navigator™ system was being used.

Shortly before classroom visits, teachers and students took Likert-style surveys designed to elicit their views on the extent to which TI-Navigator™ classrooms reflect the HPL model i.e. the extent to which CCS classrooms are learner-centered, knowledge-centered, assessment-centered and community-centered. Responses to the Likert-style surveys were used as the basis for teacher interviews focus group interviews with students.

The Focus Group interviews were transcribed and coded independently by at least two of the research team for instances of each of the centrednesses. The relevant passages were then organised by centredness and further analysed to provide both exemplary and consistent instances of manifestations of students' experiences of the centredness in the CCS environment. Finally the data were coded for themes beyond the centerednesses.

Student Survey Items and HPL Centeredness

The Likert-style student surveys we wrote two statements representing key aspects of each centeredness. Each statement was then also expressed in a negative sense, to give a total of four statements per centeredness. Thus, for the student survey, we presented statements such as:

Learner Centeredness

- Doing activities with the TI-Navigator™ helps me relate new material to things I already know
- I am equally on task in TI-Navigator™ classes and other classes

Knowledge Centeredness

- Doing activities with the TI-Navigator™ helps me get a better understanding of concepts
- Some TI-Navigator™ questions make me try really hard to answer them

Assessment Centeredness

- Using the TI-Navigator™ I can quickly tell whether or not I am right or wrong
- The teacher knows just as much about my understanding without the TI-Navigator™ as with it.

Community Centeredness

- Class dynamics are not affected by the use of the TI-Navigator™
- There is a greater sense of community in a TI-Navigator™ class than in other classes

Student Focus Group Interviews

Student focus group interviews took place after the observed classes. The starting point of the interviews was analysis of the student surveys which had been filled out prior to the visit. Thus, a typical question was: One of the survey questions asked you respond to the statement "The TI-Navigator™ helps me tell if the students understand a concept." Most students said they Strongly Agreed (SA). Why did you think they responded in this way? The purpose of this approach was to retain the focus on the centerednesses in order to directly address the research question.

Data Analysis

The analysis presented in this paper is focuses on the student surveys and student interviews (with occasional quotes from Teacher interviews) in order to answer the research question:

Does the use of a CCS result in an environment which students experience as more learner-centered, knowledge-centered, assessment-centered, and community-centered?

Student Surveys

The student surveys were constructed from eight pairs of confirming and disconfirming statements designed to reflect aspects of each of the four centerednesses. These results are based surveys of all twenty-two classes from eight schools.

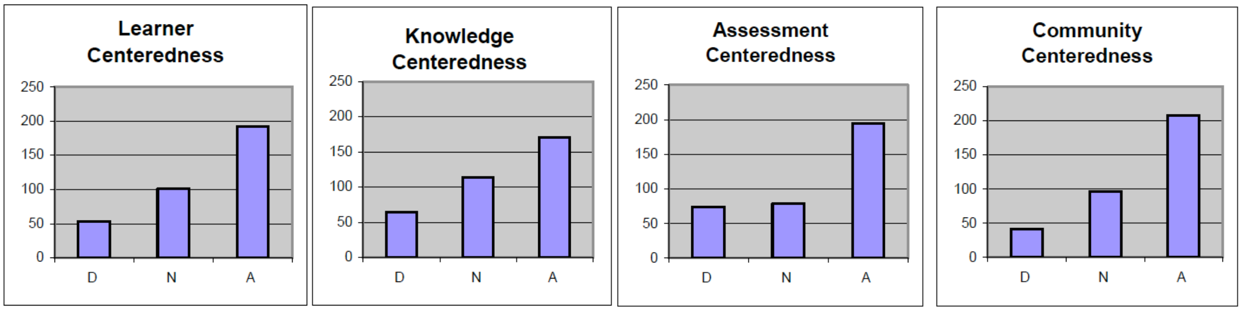

Figure 2. Composite Results from Student Surveys of Classes Listed

Each of the four centeredness plots (in Figure 2) above are composite tallies of responses to four statements. (Student responses were tallied with 'D' and 'A' merged for each survey statement to gives totals for SD + D, N, A + SA. The resultant four component items for each centeredness were summed and normalize (i.e. divide by 4) so totals reflect composite numbers of students).

The results are generally positive especially in the area of assessment-centeredness and community-centredness suggesting students are experiencing the benefit of formative assessment made possible in a CCS classroom, and that class dynamics are improved in a CCS classroom. In the interviews reported below we see some of the reasons behind these student perceptions.

Interviews

Focus Group interviews took place at each school after the surveys had been analysed and a class at that school observed. The analysis, in keeping with addressing the research question, deals separately with each of the centrednesses in turn.

Learner Centeredness

"The learner-centered perspective focuses on the knowledge, skills, goals, and cultural beliefs that each person brings to the learning situation" (Bransford, et al., 2000, p.72). In a TI-Navigator™ class this is facilitated through the possibility of the work that students are doing being available for discussion much more readily than in a non-CCS classroom. The display of results, while it is anonymous, has the effect on students that "because they know it's going to be showing on the [panel], they're trying a little bit harder to get a right answer." (Teacher 1) and "the fact that everybody got it and I didn't get it makes me think, 'Ok, I'm doing something wrong.' and it makes me want to go back and see what am I doing, because everybody else got it right and I didn't do it right." (Focus Group 1, Student 1).

From the students' point of view it seems to be apparent that the TI-Navigator™ helps them to build constructively on prior knowledge. They attribute this partly to the fact that it also helps the teacher to know if they understand knowledge needed to gain further understanding:

Int: *"Doing activities in class with TI Navigator™ helps me relate new material to the things that I already know"?*

FG2 Student 4: I think it's because … we like to see how … where we stand in the class; by doing it they get to know if they understand past material. So you have past material and then you lead up into the new material when we use the TI Navigator™.

Int.: Do you think that's the way her lesson worked today?

FG2 S4: Yeah, I think it was because she gave us a problem on finding just the derivative first, of the equation, and then we worked on the anti-derivative. So it was like going back to make sure if we know

In many interviews students brought up the topic of active engagement. In the following, students discuss the group conversations that are generated by TI-Navigator™ activities:

FG3 S1: If other people are attentive that keeps me attentive as well.

FG3 S2: No one is really goofing off and stuff.

FG3 S4: I think it keeps your mind moving because when one person asks the question it can spark another person's mind and they're gonna have a question and it just keeps going and going. I think you're learning a lot. Always thinking.

Students also feel a more direct connection with the teacher:

FG3 S5: Especially with classes getting bigger like they are now. It gives you more of a feeling of you're more like one on one with the teacher.

The quotes above illustrate that many students experienced the CCS classroom as more learner-centred than their regular classes confirming the possibility, in the CCS, class of an experience where the knowledge each student brings to class can be used in a lesson.

Knowledge Centeredness

A knowledge-centered environment is one in which transferable skills and knowledge in context are both developed (Bransford et al., 1999). A major aspect of a knowledge-centered approach is, therefore, the building of connections between concepts, between different representations of the same concept, and between previously learned concepts and new concepts.

In Teacher 1's classroom, visualization and a focus on the essential characteristics of graphs allowed students "to see how the equation was similar to the other equations that we had seen and where we might start with that picking up with what the vertex was" (Teacher 1).

In the following excerpt, the discussion began with "grades" but quickly turned to issues of effort, understanding, and receiving feedback in a timely manner:

Int.: If you had been using it all year would it have made a difference to your grades?

FG3 S2: I would have understood a lot more. I mean, it couldn't hurt my grade, obviously, because I would have stayed awake, and really paid attention.

FG3 S3: So many times, I would think I had the concept at the end of the chapter, and I would take the test and completely bomb it. So I had *no idea* that I didn't get it. And, if I had [the Navigator™] all year I would probably like been able to tell if I had.

FG3 S4: I do too. It allows you to know at the time when you're studying the topic, what you know and what you don't know, and why, and he can explain it to you better.

However, the process of sense-making and understanding requires sustained effort. Using the TI-Navigator™ system, students are seen to be excited and to want to get things right. The fact that on some activities they can get immediate feedback "gets them more to the level of thinking, 'What was it that I did wrong?' instead of just glazing over the fact that, 'Oh. It's not correct and I don't want to ask about it.' " (Teacher 1). The public nature of information and answers in a TI-Navigator™ classroom leads to them try harder to get a right answer, "I think it makes you try harder because you don't want everybody else to see that you don't know what you're doing" (FG5, S2). Also, the element of immediacy seems to play an important part for some students and this has positive effects on the effort that they apply:

Int.: Do you think having to do something with the calculator makes you think through things that you wouldn't have put the effort into thinking through?

FG4 S2: Yeah and you think, "Oh my gosh, am I ready to send?" and, …

FG4 S4: It makes you think twice about your answer.

However, it appears that this hesitation, does not result in adverse feelings about the system:

FG2 S2: It's like a hands-on activity kind of thing, and it makes it easier.

FG2 S3: And it makes it more interesting.
FG2 S1: Yeah, if we do worksheets, and go to the board. I don't find that much fun.
Int.: So you think generally you're working a bit harder doing it like this?
FG2 S 1, 2, 3, 4: Yeah. … Yeah...

Using the system also seems to provide a level of demand on students to think more and try harder. However, they tend to view this in a positive light:

FG2 S1: Yeah, because on homework, a lot of us will leave it blank if we don't understand, but by having to enter an answer it makes you really try and figure it out because you want to see if you were right or wrong compared with the rest of the class.
FG2 S3: Yeah, it makes you try to think on the answer harder.

Sometimes students had didn't make connections or see the value of an activity: "I think [the simulation] was meant to be more of a fun activity than teaching us anything" (FG1, S3).

The fact that the TI-Navigator™ system can run simulations and allow multiple sets of data generated by students to be compiled and displayed, allowed students the opportunity to make connections between the experiments they have done themselves and aggregated results of the whole class's experiments. Data gathered from many students can be compiled, visualized and understood as a physical process. "Plugging in numbers and seeing what happens … and see[ing] why what you plugged in does what it does or means helps me," (FG1, S3).

Assessment Centeredness

"Effective learning environments also require frequent opportunities to make students' thinking visible to see what they are learning" (Bransford et al., 2000, p.69). It is vital to the learning process that students have feedback on whether they are learning concepts, and vital for teachers to have feedback on how well students are learning concepts. Certain TI-Navigator™ activities allow students to find out immediately if they have an answer correct; whereas, without the technology "if they're doing their regular homework, they didn't necessarily know that they didn't get it correct, so they're still just doing the same thing and not really asking you, because they're not really thinking that they're making a mistake." (Teacher 1). The advantages of this feedback are clear to the students: "… it was quicker, more efficient … we like that you automatically find out what you made on the quiz." (FG1, S5).

The fact that students send answers to a computer means the teacher can see whether they are active or not and whether they are successful or not. Teachers noted that "you get more honest answers with the Navigator™. It is anonymous so it's not threatening." (Teacher 5).

Advantages of both types of feedback (i.e. to students *and* teacher) are clear to the students:
I: "Using the TI Navigator™ does not help in letting me know where I stand on a question?"
FG3 S3: I disagree.
FG3 S2: I would disagree a lot on that, because you get instant results right up on the board, and it tells you if you got it wrong or right, and if enough people got it wrong, he'll know that he needs to go over that, and you'll know you need to go over that - instantly.
FG3 S1: And I think it's easier on the teacher too, because instead of passing out the papers, having to pass them back and him go through it, and then passing them back out and going over it he knows right away as a class where everyone stands, instantaneously.
FG3 S5: And you're able to fix things at the moment. You know, instead of 2 or 3 days.
FG3 S1: By that time you forgot even more. You forgot what the question even *was*.

Similarly, in the following, from a different teacher's classroom:

FG2 S3: If we're all wrong, or the majority is wrong, she'll go over the concept again.

FG2 S1: I think it gives her an idea of where everybody stands in the class, so she knows what we need to review more, … or you know, we can move on, or not.

A problematic area with this feedback is that, for some activities, it can focus on right/wrong answers and doesn't give a physical record of students making their thinking processes visible.

It can be argued that the presence of new types of feedback from systems like TI-Navigator™, means that teachers have to learn to listen in ways that they did not have to before. Teachers have a great deal more information but still need to investigate the cause of misconceptions, and devise ways to rectify them.

Community Centeredness

The effect of the TI-Navigator™ system on the classroom environment and dynamics we visited was quite dramatic. There was a strong sense of students working harder and working towards a common goal: "It's more closely knit, the class. Because in a normal class you have people that are sleeping and here you don't have room for that." (FG5, S3) and, "When we used it, everyone was doing it and everybody was interacting and it made everybody work and I think the class participation went up a lot" (FG1, S4). The public nature of the knowledge state of the class, visible in results on screen, gave rise to discussions of the provenance of answers and provided many "teachable moments" because misconceptions are made visible: "we're all connected to the same system so we can see each other's mistakes, where before we would just do [our work] individually," (FG1, S2). Furthermore, students are less afraid to admit mistakes because of the more free flowing nature of information in the class. Some students felt that the sense of community arose from the novelty of the system and did not impact their learning: "I think the sense of community comes just from being something that's experimental but I haven't felt like I've learned very much" (FG1, S3). Others felt that technical problems with the system and efforts to overcome those were the source of the community feeling, "Everyone was helping everyone else figure out what to do but if it worked properly, then I don't think that everyone's community would be going on." (FG1, S3).

The TI-Navigator™ classroom is a very interactive environment. Students are presented with multiple representations such as symbolic, visual, and simulated. The TI-Navigator™ classroom is one in which there are class discussions arising out of shared information as well as collaboration and a feeling that something novel has happened: "It's more student based. You're not just looking at chalk boards" (FG1, S2)

Int: Class dynamics are not affected by the use of TI Navigator™?

FG2 S4: I guess that's why everyone disagreed, cause I think it does change the dynamics of how our class is. More interaction …we're all connected … and if we don't have the TI Navigator™ we're just sort of in our separate note-taking little world, but with this … we're actually working together. It's just a different way of learning. This is something where we can talk about it and understand it.

Conclusion

This study sought to address the research question:

Does the use of CCS result in an environment which students experience as more learner-centered, knowledge-centered, assessment-centered, and community-centered?

The analysis of the surveys and focus group interviews presented above present compelling evidence that a significant level of transformation occurs in students' experiences of classes when CCS technology is deployed. The data are self-reported by the students but reflect accurately and consistently their experience of the CCS environment and their perceptions are consistent with the teacher and researcher observations of the classrooms.

Clearly much research remains to be done on the impact of CCS on classrooms but we believe that the work done on this project shows that:

1. The role that CCS technology has to play in implementing HPL principles in the design of an effective learning environment centres on the free flow of information in the classroom. That is, CCS technology gives teachers more information on what students are thinking, gives students more information on what other students are thinking, gives students more information on their progress, and supports sharing of information to facilitate collaborative learning.

2.The accumulation of effects of the use of the TI-Navigator™ on student feeling, motivation, behaviour and classroom dynamics suggest that the TI-Navigator™ can have a positive influence on student learning.

We examined the representations used by the teachers in connected classrooms and whether changes occurred in their discourse about multiple representations of functions over time and as the result of access to technology. Analysis of videotapes of 6 teachers' practices when teaching a unit of instruction on functions revealed three major patterns. First, teachers' approaches to teaching functions and their representations were influenced by whether they maintained a calculational or conceptual orientation to teaching. Second, their choices of representations were closely linked to their view of functions as either a process or an object. Third, as the teachers' technical knowledge of technology increased they illustrated various representations more often, however their discourse did not address connections among different representations.

Introduction

Principles and Standards for School Mathematics (NCTM 2000) place tremendous emphasis on the importance of children learning about and using representations when solving problems, communicating mathematics, and representing real life situations. Representations can be taken to be the external representations produced to help think, communicate and interpret mathematical concepts. They may also be considered the internal representations a student might possess. Representation(s) refer to both the act of representing as well as the external, noun form of representation. In mathematics, internal representations can be considered to be abstractions of mathematical ideas or a structured way of thinking that are developed by and are internal to a learner (Pape & Tchoshanov, 2001). External representations typically have a sign or configuration of signs, characters, or objects that can stand for something else, such as graphs, pictures, diagrams, words, symbols, and manipulatives. Internal and external representations are believed to mutually influence each other. However, the literature (Cunningham, 2005; Even, 1998; Galbraith & Haines, 2000; Hitt, 1998; Knuth, 2000; Sfard, 1991) points to the difficulty for students to transfer among the various types of representations while preserving meaning. In addressing this challenge, scholars have argued that the use of technology can facilitate both the development of knowledge of multiple representations and the ability to transition among them (Manouchehri, 2004). A particularly promising tool for doing so is TI-Navigator™. Several features of the TI-Navigator™ have the potential to increase discussion or student use of representations. Quick Poll (QP), Activity Center (AC), Screen Capture (SC), and Learning Check (LC) all can invite all students to participate in activities and practice using representations. Through AC and SC, students can see their own representations as well as other students' representations allowing for reflection on and discussion of the representations. AC has the ability to move among three major representations of the same object, algebraic, graphical. With several students participating, alternative representations are likely to occur. Pursuing explanations and justifications of why are or are not particular representations reasonable can aid students to see representations as tools.

The purpose of the current study was to investigate the nature of teachers' use of representations in classrooms where connected classroom technology (CCT) was used. This report is a part of a much larger research project in which we investigated the relationship between teacher use of CCT

Wiest, L. R., & Lamberg, T. (Eds.). (2011). Proceedings of the 33rd Annual Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Reno, NV: University of Nevada, Reno.

in algebra classrooms and the growth of teacher and student choice of representations of linear functions as manifested in the classroom discourse were investigated directed by Classroom Connectivity in Promoting Mathematics and Science Achievement (CCMS) research project (Irving et al., 2010). In focusing the current study, we considered the topic of linear equations as the context for analysis of teachers' use of and discourse about representations of functions and their connections. Two specific questions guided the data collection and analysis:

a. What representational modes are used by teachers when discussing linear functions?
b. How is the quality of teachers' discourse about representations of functions influenced by the presence of technology?

Theoretical framework

In studying classroom use of representations of functions we grounded our work in the three major perspectives on representations of functions as described by Moschovich, Schoenfeld, and Arcavi (1993) including algebraic, graphical, and tabular. Functions have a dual nature. Functions can be seen as a process, acting on a set of inputs to obtain outputs. They can also be seen as objects that can be manipulated as a whole. Although not specifically discussed by Moschovich and colleagues, the process perspective and object perspective of functions can be thought of as part of the internal representation of functions, since they are the primary ways to think about functions. This framework excludes a major representation particularly vital in classroom interactions, the verbal representation. For example, the function f(x) = 3x+5 can be verbally represented as "the function that multiplies the input by 3 and then adds 5," which is describing a process. The same function could be represented as "a line with a slope of 3 and a y intercept of 5," which describes an object. The different combinations of external representations and perspectives are captured in table 1. Here, the four main representations can be used in conjunction with either the process or object perspective.

	Tabular	Verbal	Algebraic	Graphical
Process	<table><tr><td>x</td><td>y=f(x)</td></tr><tr><td>-2</td><td>4</td></tr><tr><td>-1</td><td>1</td></tr><tr><td>0</td><td>-2</td></tr><tr><td>1</td><td>-5</td></tr><tr><td>2</td><td>-8</td></tr></table> Given these x's find the corresponding y's	The function that multiplies the input by -3 and then subtracts 2.	f(x)= -3x-2 The function multiplies a number by -3 and subtracts 2.	 Plot each point of the line.
Object	<table><tr><td>x</td><td>y=f(x)</td></tr><tr><td>-2</td><td>4</td></tr><tr><td>-1</td><td>1</td></tr><tr><td>0</td><td>-2</td></tr><tr><td>1</td><td>-5</td></tr><tr><td>2</td><td>-8</td></tr></table> The function is the set of ordered pairs.	A line with a slope of -3 and a y intercept of -2.	f(x)= -3x-2. The function is a static relationship between x and f(x).	 The function is the line.

Table 1. Different representations and perspectives of lines.

The process-object framework (Moschkovich, Schoenfeld, & Arcavi, 1993) merged with the external-internal representations interaction framework (Pape & Tchoshanov, 2001) allowed us to suggest a model for how representations may interact within a learning environment. The four main representations of a line, algebraic, graphical, tabular, and verbal representations (Moschkovich et al., 1993) can be considered to interact with a student's internal representations and perspectives via practice, negotiation, reflection, interaction (Pape & Tchoshanov, 2001).

Developing student representational thinking requires not only the use of multiple representations but also discussing the connections among them. This relates closely to how multiple representations are addressed and elaborated in the social context of the classroom, as evidenced in teachers' and students' discourse. Certainly, the more elaborate the discussions of connections among representations, the greater opportunities for students' development occur (Manouchehri, 2004). To capture the quality of teachers' discussions of representations we used the Complex Mathematical Discourse Network CMDN (Manouchehri, 2004) to rank the level of complexity of teacher talk surrounding the usage of different representations of functions.

Methodology

Participants

In the larger project, Algebra 1 teachers from 28 states and 2 Canadian provinces and their students participated. Initially, "a total 127 teachers (66 control, 61 treatment; 74% female) were randomly assigned to either control or treatment groups" (Irving et al., 2010, p. 8). The student participants were students of the teachers from both cohorts during year 1 to year 4 of the study. Fifty-five of the teachers in the CCMS study had videotaped classroom observations in at least one of the four years of the study. Since the purpose of the study was to describe the types of linear representations used, only teachers who were videotaped giving lessons on linear functions for more than one year of the study were considered for investigation. The six teachers who met these criteria were used for analysis in the current report.

Data Sources

Quantitative and qualitative data were gathered by the CCMS project. This study uses the video data. Classroom observation videos were typically two consecutive days of class. Linear function topics ranged from slopes of lines, properties of lines, systems of equations to finding best fit lines. Only the video data and verbatim transcripts of these six teachers were used in the study reported here.

Data Analysis

Observational notes were taken during the first viewing of the video data. The videos, transcripts and observation notes were uploaded into Nvivo, a data analysis software.

Classroom instruction was coded using three different techniques. First, teachers' utterances in each lesson were catalogued according to 4 criteria: the level of cognitive load of questions asked and their mathematical significance (mathematics), the mode of response elicited from the students (closed/dichotomous vs. open/explanatory), the quality of explanations offered to the group (conceptual vs. algorithmic), and the quality of discussions regarding the representational choice used or analyzed. Additionally, we coded the number of times technology generated representations were used by the teacher and whether this choice seemed appropriate to the goals of the lesson.

To describe the types of representations used in the classroom and the quality of discourse surrounding the use of representations by teachers and students in CCT classrooms, we traced the number of each representation used or elicited in class, as well as the number of connecting statements that teachers made to link these representations in their instruction.

The quality of the discourse either about or using representation were coded using the Complex Mathematical Discourse Network (CMDN) (Manouchehri, 2004). Manoucherhi (2004) created a holistic scoring procedure that assigned scores from 0 to 4 depending on how complex the representational discourse might be. *Simple representational discourse* can be characterized by an individual using one aspect of a single representation as a solution without support or multiple representations or aspects of one representation are present but are not connected. Discourse involving only one aspect of one representation without support could be scored 0 and discourse involving multiple representations or aspects but no connections or elaborations could be scored 1. *Intermediate representational discourse* can be characterized by individuals explaining, justifying or reasoning with or about representation(s) of lines or aspect(s) of one representation. Discourse explaining, justifying, or reasoning with or about one representation or multiple representations or aspects of one representation without statements connecting them could be scored a 2. Discourse with these characteristics but where the connections among multiple representations are discussed could be scored 3. Other evidence of intermediate discourse would include reflective behavior such as modifying one's own representation because of the presence of another representation. *Complex representational discourse* can be categorized by intermediate discourse that is used to make generalizations about the connections among different representations. Complex representational discourse could be scored a 4.

Individual case studies are created for each of the six teachers describing their practices. Combining these individual cases we searched for themes that described common and unique instructional approaches among data.

Findings

The primary goals of our research project was to examine the type of representations used by the teachers in connected classrooms and whether changes occurred in their discourse about multiple representation over time and as the result of access to facilities provided by technology which could have enhanced children's thinking. Analysis of videotapes of teachers revealed three major patterns.

First, teachers' particular approaches to teaching, what they chose to include in instruction and their expectations for mathematical work of children in the context of representations of functions, were influenced by their particular orientations to teaching (A. G. Thompson, Philipp, T. W. Thompson, & Boyd, 1994). Teachers' orientations motivated how they used technology and which of its capabilities they chose to capitalize in instruction. A majority of the teachers exhibited an algorithmic orientation to teaching mathematics; instructional emphasis when talking about functions and representation was on production of these models as opposed to connections among them. Technology was used primarily for completion of calculational and procedural tasks and not to advance children's understanding of how to allow access to a deep understanding of multiple representations of functions and their connections.

Second, the teachers' choices of representations in instruction were closely linked to their view of functions as either a process or an object. The questions they asked in class, comments and illustrations they used and ways in which they utilized technology were influenced by this basic mathematical understanding. Data indicated that teachers used and motivated the view of functions and processes and rarely attempted to draw from functions as objects to help children develop an understanding of connections among various representations. The preferred representational mode when talking about functions was symbolic.

Third, as the teachers' technical knowledge of technology increased, they tended to use it to illustrate various representations, even simultaneously at times. However their discourse did not address connections among different representations and ways in which information obtained from these various representations could be used to extract additional information about the behaviors of functions. This disconnect was most prominent in places where the primary focus of instruction was on symbolic competency.

Teachers' orientation and teaching of function concept

Thompson and colleagues (1994) offered two sharply contrasting orientations to teaching characterized referred to as *calculation* and *conceptual*. In elaborating on the substantive differences between these two orientations, authors characterized a teacher with a conceptual orientation to teaching as one who focuses students' attention away from application of procedures and towards a rich conception of ideas, conceptual coherence. In further elaborating on this construct the authors suggested that the conceptually oriented teachers tend to move students towards non-calculational contexts and their actions are driven by a system of ideas and ways of thinking that she intends for students to develop; an image of how these ideas and ways of thinking can develop; … a productive way of thinking that generates a method that generalizes to other situations (A. G. Thompson et al., 1994, p. 86). In contrast, the calcualtionally oriented teachers show, among many: "A disposition to cast solving problems as producing a numerical solution; An emphasis on identifying and performing procedures; a tendency to do calculations whenever an occasion to calculate presents itself; … A narrow view of mathematical patterns as limited to finding patterns in numerical sequences" (pg. 87). The impact of these orientations became visible in the instructional practices of the teachers, what they emphasized in their lessons, tasks they assigned in class and ways in which they used technology to discuss functions and their multiple representations. That is, the teachers with greater tendency towards a conceptual orientation to teaching tended to refrain from being the locus of authority in class and allowed students to generate different representations of functions and insisted on children using technology to examine patterns and relationships. Those with a calculational/algorithmic orientation to teaching, even in the presence of technology, continued to emphasize procedural productions. Consider the following episode as an illustration of such practices. Prior to this particular episode, the teacher had plotted 5 points of the line y=-x/4 and asked students to send in their predictions of other possible points using the CCT.

T: Look at the point (-26,7). It looks really close, but is it correct? What's neg. 26/4? Aren't we dividing by 4 each time?

S: No. Oh, yes.

T: Does that divide evenly?

S: No.

T: No, so it can't come out to 7. So that one was very close, but not quite. And you can tell it's just slightly off, isn't it? And what about this one? Neg. 24, 6. If you divide neg. 24/4 you will get…

S: 6.

T: 6. That one's correct. How about this one? A couple people did that one. Neg. 20,5. neg. 20/4 is…

S: 5.

T: All these are correct. What about this one? It's 22, 6.

S: No.

T: What's 22/4? Adele? What's 22/6? Is it a nice number?

SS: No. No, it's not.

T: No. It's 22/4; I'm sorry. It's not going to be 6, is it?

A similar vignette from another class is presented below. In this vignette the teacher left the graph of y=x+1 displayed on the screen, while students calculated and sent in points for the function y=2x. The teacher then prompted a discussion asking students to compare the two lines, one green, and one red.

S: They meet at (1, 1). They intersect. SS: (1, 2)

T: (1, 2); you're right, it is, (1, 2). So let me just talk about that for one second. Look, that means that the first one which was X + 1; right? 1 + 1 is 2, and the second one is 2 times 1 and 2 times 1 is 2, and that's why because they both make that equation true. Something else? Anything else you want to say?

S: There's a positive trend. T: There's a positive trend, awesome. Anything else? Something else? S: They're all real numbers? T: Yeah, they do, they're all real numbers, um hum.

S: It's a straight line.

T: It is a straight line. Anything else? And that's important because pretty soon we might not see a straight line. Anything else? …

S: They all increase.

T: They all increase, and I think somebody said positive.

S: The green line is like closer in to the Y.

T: Yeah, it is, it's closer in to the Y. How can you say the same thing? How else can we talk about that?

S: The Y axis, the angle is smaller?

The teacher interprets and verifies what the student is saying by placing her fingers on the two lines and measuring the angles. She agrees with the student and moves on to the next problem.

Note that in the first vignette the calculational orientation of the teacher is evidenced in criteria and methods she used and suggested for testing points. Relying on computational procedures for testing values remained a consistent part of her lessons. The teacher in the second vignette, which might appear less calculational, maintains the same orientation. This is apparent partially in the quality of explanation she offered students on why the two lines intersect at (1,2). With computation not being the primary focus, different questions can be asked, such as having students to compare the graphs of lines. The resulting discourse led naturally to the notion of slope, even though it was not taken advantage of at this time. The teacher *appears* to not to be the locus of authority as she uses statements such as, "I'm looking for observations about those two lines; anything you want to say about them." However, the resulting discourse is limited to short answers directed back to the teacher for verification. Students are not pressed for elaboration, explanations, or to comment on peers' statements.

Teachers' Knowledge of Functions: Functions as Objects vs. Processes

As previously discussed by Moschkovich, Schoenfeld, & Arcavi (1993), functions can be seen as a process acting on a set of inputs to obtain outputs. Functions can also be seen as objects that can be manipulated as a whole. In mathematics classrooms, when functions are viewed as processes, the primary focus is on computational production of their representations. For instance, children may be provided with a symbolic representation of a function and asked to generate a table of values, graph the function findings specific points, and moving from one to other in a one directional motion. In contrast, when the view of functions as objects is advocated, the instructional tendency is to focus students' attention to the general behaviors of the functions as a whole. As such, learners might explore for instance, families of functions, the impact of various parameters on the behavior of parent functions, and describe movements of functions as transformations relying on graphs, numerical data, and symbolic forms simultaneously.

Data indicated that the primary view emphasized in classrooms by teachers was that of function as a process. The teachers' discourse regarding the representations of the function and what they expected of children to do thus was influenced by this view. Teachers spent a majority of their instructional time on production of multiple representations, as the main goal of activity, without elaborating on connection among them and ways in which these different representations could be used to make and verify conjectures regarding the behaviors of functions. Such discussions were absent even when ample opportunities were present due to either un-expected results provided by technology or children's own questions and comments. This is most illustrative in the episodes described below.

During one lesson, a teacher had given 5 points that were on the line y=6x. The students were asked to send using the CCT their predictions of another point on the line. When the result of the collection was displayed almost all the points followed the pattern of the line, except for the point (6,6) that was far away from any of the other points. An interesting discussion could have occurred if the teacher had asked, "Is it still possible to have a line, or a function with all the points displayed including (6,6)?" reinforcing the notion of what makes a line a line or a function a function. What if the student legitimately thought (6,6) was a viable prediction of the pattern? Can a line go from (5,30) to (6,6) then to (7, 42)? Rather, the teacher immediately dismissed the point as being wrong, "That's the point (6,6). What do you think happened there? Just a typo? If you plug in 6 are you going to get out 6?" The teacher asked the class what may have been wrong with the point, but the question was answered by the teacher herself who concluded the most likely error was a typo. To identify the correct point, the teacher appealed to the process definition of the line to state the point should have been (6,36).

Technical Confidence and Content Presentation

Previous studies regarding the teachers' use of technology present the view that with increased technical knowledge about technology teachers tended to show the tendency to use it more frequently in teaching. The same was true among the range of data we examined. It also became evident, that while teachers successfully offered children a greater number of illustrations of various representations in their instruction, the quality of their discourse regarding functions or representations was not substantially different. Typical practice is described below.

A teacher put torn pieces of paper with a number written on each and passed them to the students and asked the students to evaluate several functions, such as y=-3x, y=x+1, y=2x, and $y=x^2+1$ using the number they were given. Students submitted their single point on the curve to the teacher using the CCT. The CCT allowed the teacher to collect and display all the students' points. This activity allowed students to see the tabular, algebraic and graphical representations of three different functions as well as a small sample of other students' representations. After collecting the data points for the quadratic, the teacher quickly identified two points as being wrong. By appealing to computation, the teacher asked the two students to correct their points. A student noticed that the quadratic was "crooked. Not crooked, but curvy," and another student mentioned it looked like a skateboard half pipe when asked to compare the four functions. A discussion after the teacher prompted with "What was alike in the other three that's different on this one? I mean because something's making that one curve where all the others are going straight," hinted at the notion of the square being the reason but was not fully realized and explored. Three main representations of functions were present as well as the notion of function as process due to the teachers appeal to computation to correct errors. The notion of function of object did not explicitly appear. However, it seemed students noticed object like properties of functions, i.e. this one is curvy, the others are straight. Two years earlier this teacher frequently used a calculator program to generate graphical and numerical representation of different functions and asked students to guess the slope and y-intercept. The program did not include a connection back to the algebraic representation of the line; neither did the teacher mention the connection. A maximum of two different representations from the process perspective of function were used during the lessons this year.

Final comments

The study of multiple representations in general and those particular to functions are among the most notable goals of current visions for Algebra I curriculum. The assumptions surrounding the utility of graphing technologies within connected learning environments for advancing the learning and teaching of these objectives are certainly valid. However, as our data indicated using technology in ways to substantially impact learning depends largely on teachers' knowledge about the mathematical goals, content specific knowledge regarding concepts taught and their orientations to teaching. These are in line with findings of other studies which have examined the interactions between teachers' resources, instructional motivations and choices they make during instruction (Silverman & Thompson, 2008), confirming Thompson's (2002) view that teachers' pedagogical actions must be viewed as manifestations of their current understandings and visions for and of student learning. Placing new technologies in classrooms without providing them the space to engage in reflective abstractions about learning and teaching, which can lead to the institution of key developmental understandings (Silverman & P. W. Thompson, 2008) central to transformative practice, would have little utility for enhancement of knowledge. Professional development programs designed for teachers need to focus not just on increasing teachers' technical knowledge about the tools but also alternative ways that mathematical ideas might be interpreted or taught using them; that is, using technology as a vehicle for establishing deep personal and pedagogical understanding of the subject matter.

VIEWS OF TURKISH AND U.S. PRESEVICE MATHEMATICS TEACHERS ON THE USE OF GRAPHING CALCULATORS

S. Aslı Özgün-Koca
Wayne State University
aokoca@wayne.edu

This study utilized two conceptual frameworks to investigate the views of Turkish and American preservice mathematics teachers on the use of graphing calculators in mathematics instruction. An open-ended survey questionnaire and group interviews were the main data collection methods. Results revealed that both Turkish and U.S. participants worried about calculator dependency but they both thought that calculators could transform the teaching and learning environment positively. However, some differences in their views were also detected.

Introduction

In the age of technology, mathematics teachers must decide whether to use technology in their classes. If so, more decisions must be made, such as which technology to use, and how, in order to create an effective teaching and learning environment. While making these decisions, teachers' knowledge and beliefs influence their decisions. (Ball et al. 2001; Stipek, Givvin, Salmon, & MacGyvers, 2001). Teachers' differing views and beliefs about the use of technology in mathematics instruction could lead to different levels of use of graphing calculators in mathematics instruction. Researchers encourage conducting studies about teachers' beliefs about the benefits/weaknesses of using graphing calculators in mathematics instruction to learn why and how teachers come to adopt or reject the use of graphing calculators (Burrill et al. 2002; Kastberg & Leatham, 2005). Moreover, the beliefs of teachers about the use and roles of graphing calculators influence the use and roles of those calculators in mathematics classrooms (Burrill et al., 2002; Doerr & Zangor, 2000; Fleener, 1995; Kastberg & Leatham, 2005).

There is limited research comparing the views of teachers from different countries about the use of technology in mathematics instruction. Wagner, Lee and Özgün-Koca (1999) compared American, Korean and Turkish preservice teachers' views on many different subjects, including the use of technology. They concluded that American teachers were more open to the use of both computer and especially calculator technologies in mathematics classes. Turkish preservice teachers had more worries about the negative effects of the use of graphing calculators on teaching and learning. Other such comparative studies mainly refer to international studies such as TIMSS (Antonijevic, 2007; Özgün-Koca & Şen, 2002) with considerably varying calculator use in different countries, including an especially dramatic difference between the U.S. and Turkey.

Research Questions

The current study investigates views on the use of graphing calculators in mathematics instruction held by Turkish preservice mathematics teachers with very limited experience with graphing calculators and views held by more experienced American preservice mathematics teachers. The research questions are:

- What are their views, and underlying reasoning, on using graphing calculators in mathematics instruction?
- What are the similarities and differences between the views of Turkish and American participants?
-

Conceptual Framework

This study employs two conceptual frameworks —the possible roles of graphing calculators in mathematics teaching and learning, as well as technological, pedagogical, and content knowledge (TPACK). The aim is to see the general perspective with the TPACK framework and then tease out the specific perspective on the use of graphing calculators with the framework for the possible roles of graphing calculators in mathematics education.

The Possible Roles of Calculators

The first conceptual framework emphasizes the five overlapping roles of graphing calculators described by Doerr and Zangor (2000): (1) computational tool, (2) transformational tool, (3) data collection and analysis tool, (4) visualizing tool, and (5) checking tool. These roles are interconnected and several roles could occur simultaneously (see Figure 1).

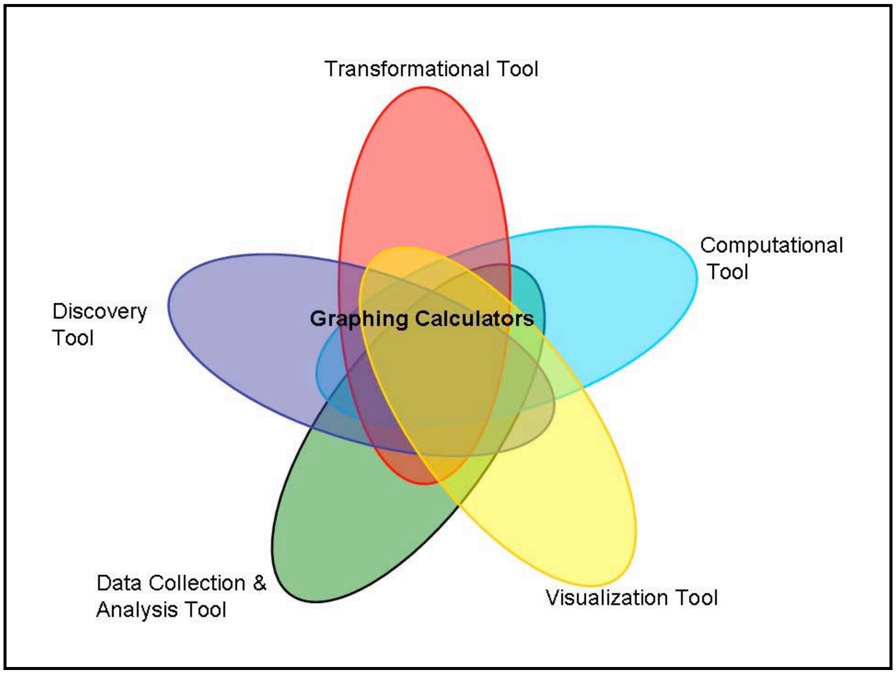

Figure 1. The Use of Graphing Calculators in Mathematics Classrooms

Among these different uses, calculators as a visualization tool and as a computational tool have been emphasized in many mathematics classrooms. Doerr and Zangor described the role of graphing calculators as a checking tool "when it was used to check conjectures made by students as they engaged with the problem investigation" (p. 156). Because checking could be used when students are checking conjectures and/or computational work, this role of graphing calculators is renamed as a discovery tool when calculators are used to support inquiry. When calculators are used as data collection and analysis tools, they make it possible for students to collect and analyze data, and when they are used as transformational tools they change the nature of the teaching and learning environment.

Technological Pedagogical Content Knowledge

The introduction of pedagogical content knowledge by Shulman (1986) was ground-breaking and the research on teachers' knowledge thereby gained a framework. With Mishra and Koehler's (2006, Koehler & Mishra, 2005) and Niess' (2005) introduction of the concept of the teachers' TPACK (see Figure 2), technology-related research in the teacher education and professional development has gained a conceptual framework. TPACK involves content knowledge (CK), pedagogical knowledge (PK), technological knowledge (TK), and their combinations. Looking at these combinations, Pedagogical Content Knowledge (PCK) focuses on the mutual relationship between content and pedagogy, Technological Content Knowledge (TCK), focuses on how the content can be affected as a result of use of technology, and Technological Pedagogical Knowledge (TPK) focuses on how teaching could be affected by the use of technology. TPACK is at the heart of all of this knowledge and takes all of these factors and combinations into consideration.

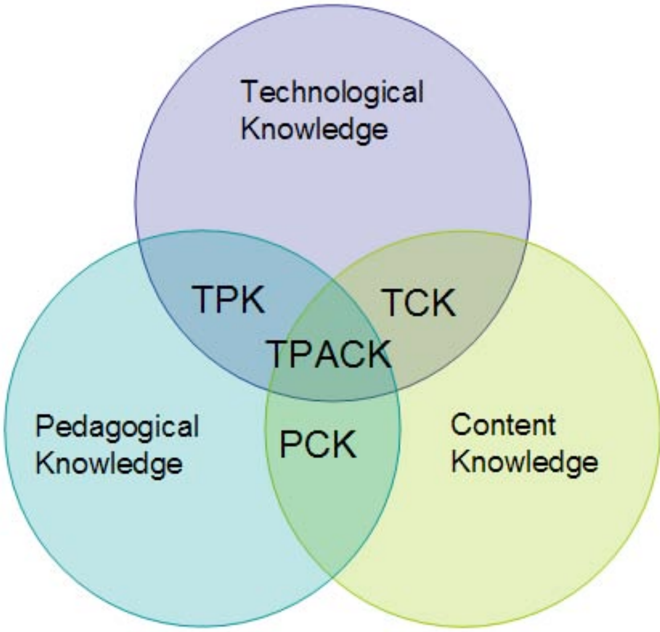

Figure 2. Re-creation of Mishra and Koehler's TPACK Model

Data Collection Methods and Analysis

There were two settings for this study. One was a 5- year teacher education program in Ankara, Turkey. The other was in a university in the Midwestern United States. Turkish participants in this study were 27 preservice secondary mathematics teachers. Even though these participants had no prior experience with graphing calculators in their K-12 schooling, they experienced some graphing activities with TI-92 calculators in their methods courses. They did not have a chance to use these calculators in their field studies or student teaching. One can wonder that if these participants did not have any extensive experience with these technologies, why their opinions would be worth investigating. As mentioned above, some of the instructional decisions that we make are based on the views and beliefs that we hold. Even though one does not have an extensive knowledge about the use of calculators in mathematics instruction, one still has an initial view of graphing calculators. U.S. participants included 23 preservice teachers. Most of the U.S. participants categorized themselves as intermediate level users of graphing calculators. Many of them mentioned that they used graphing calculators in their 9-12 or college education as learners of mathematics.

Data collection involved group interviews and a survey that included open-ended questions. The participants were asked to write about their beliefs on the use of graphing calculators in mathematics instruction in general. Some of the questions were of a general nature to see what different parts of their TPACK participants would bring in to their discussion. However, other questions aimed to reveal different parts of the TPACK model. For instance, one asked the effects of calculators on the teaching and learning environment and process with the aim of revealing participants' TPK. All participants engaged in taped group interviews in which their writings were discussed. The researcher facilitated the group interviews. In these semi-structured group interviews, the same questions from the writing portion were discussed with follow up questions: How should graphing calculators be used for better learning in mathematics classrooms? When are the appropriate times? [As a response to a participant saying that the teacher needs to decide appropriate times.]

Due to the nature of qualitative data, the analysis was based on categorizing in order to investigate emerging themes. First, participants' individual writings were analyzed for common codes to create patterns. At this point, the two conceptual frameworks guided code and pattern recognition in the data. Common codes and patterns were tallied in checklist matrices (Miles & Huberman, 1994). Checklist matrices were created in order to analyze participants' views on the use of calculators in mathematics instruction. According to Miles and Huberman (1994), "the basic principle is that the matrix includes several components of a single, coherent variable" (p.105). Therefore, several elements of the participants' views on the advantages, disadvantages, and possible roles of calculators were analyzed more thoroughly. Percentages of participants sharing similar views were calculated from those tallies. Taking these codes and patterns into account, group interviews were analyzed. Data triangulation and member checks were used to ensure the trustworthiness of the study. Although writings guaranteed that the participants had sufficient private time to respond without pressure, interviews were added to provide an environment where group communication and interaction could be observed. Thus, the two forms of data collection with different encounter levels provided rich sources of data for this study. Member check questions during the interviews were used in order to ensure correct understanding of what the participants meant.

Results

The Roles of Graphing Calculators

When Doerr and Zangor's (2000) framework for the roles for graphing calculators in mathematics classrooms was used to analyze the data, four roles of graphing calculators were mentioned by the participants—computational, visual, transformational, and discovery tools. In general, graphing calculators as computational, visualization or transformational tools and their two and three combinations were mentioned by a majority of the participants. Eighty-eight percent of Turkish and 74% of U.S. participants see graphing calculators as a way to divert time from drudgery and cumbersome work. The time that can be saved from graphing or calculating by hand was one of the points brought up by many participants: "[Graphing calculators] could save time and energy for the graphs that are hard to draw and require detailed calculations" (Writing—Turkish participant). However, most did not mention what they would do with the time saved. That is why their data was coded as computational use of graphing calculators. Nevertheless, one could still argue that these comments might be a sign of the beginning of a change in mathematics classrooms and a signal of the birth of transformational use of graphing calculators by these participants (Özgün-Koca, 2009). However, in this analysis, an emphasis on change was sought in order to code the data as transformational tool. Approximately half of the Turkish and U.S. participants clearly discussed the role of graphing calculators in transforming the nature of the teaching and learning environment: "Teachers are able to spend more time on concepts not facts so students are actually learning, not just memorizing" (Writing—U.S. Participant). Seventy percent of the Turkish and 48% of the U.S. participants stated that one of the advantageous uses of graphing calculators was being able to help students to visualize mathematical concepts. One-third of the Turkish and 22% of the U.S. participants emphasized that graphing calculators could be used as discovery tools: "Calculators, especially in the learning environments that are designed according to the discovery approach or constructivist theory, could be used to enable students to practice [using their previous knowledge], relate different concepts, discover or construct the knowledge [by themselves]" (Writing—Turkish participant).

No participant in this study mentioned the use of graphing calculators as data experimental tools. Since Turkish participants did not experience or observe the use of graphing calculators with Calculator Based Laboratories (CBL) or similar technology, it is not surprising that they would not discuss this use of graphing calculators. The U.S. participants, on the other hand, did not discuss this use, either. During the interviews, the researcher did not intentionally bring up each use of graphing calculators with the aim of observing the roles that participants discuss freely. This situation emphasizes the importance of the experiences that teachers obtain (or not) in their teacher education programs.

Technological Pedagogical and Content Knowledge

When many participants discussed their views about graphing calculators, they mainly focused on the teaching and learning issues of TPACK. Participants' main discussions focused on how graphing calculators might help or hinder students' learning. A major issue in this category of TPACK was the fear of calculator dependency where participants were using their TPK by discussing how the availability of technology might affect students' learning. Approximately sixty percent of the U.S. participants and half of the Turkish participants shared their worries about students becoming dependent on calculators: "Some students may rely on the calculator to an extreme level. This may cause them to be handicapped when doing things by hand" (Writing—U.S. participant). One interesting discussion by U.S. participants was whether to use calculators with a group of students who lack basic skills. One group said that they would allow such students to use calculators to catch up. The other group emphasized that students should be able to compute by hand. At the end of the discussion, participants came to the conclusion that they would like their students to have both computational proficiency and higher-level skills. Another main topic in this category, especially for Turkish participants, was being able to get students' attention and interest with graphing calculators. Seventy-five percent of the Turkish and 48% of U.S. participants stated that teachers can engage students when graphing calculators are used, which could be a positive benefit for students' learning: "The main superiority of using graphing calculators in teaching is that they would attract the students' attention and students get interested more in the lesson" (Writing—Turkish participant).

When participants discussed their TPK from a teaching perspective, according to 15% of Turkish and 56% of U.S. participants, instructional use of graphing calculators in mathematics classrooms should come after students master the skills: "Advanced calculators should start to be used by the students after the topics are well understood and exercises are done with paper-and-pencil" (Writing—Turkish participant) and "I've always been not a proponent of calculators until they [students] have totally mastered it" (U.S. Interview). Almost half of the Turkish participants but only one U.S. participant discussed their worries about classroom management: "I believe there is the possibility that a student could sit at a corner during the whole class session without doing anything" (Turkish Interview).

Turkish participants had no experience using graphing calculators as students, nor had they any experience teaching with them during student teaching. Their technological knowledge was very limited compared to their U.S. counterparts. Thus, 44% of the Turkish participants said that the teacher needs to have technical knowledge of graphing calculators: "[Another disadvantage] could be that the teacher would not be competent in, i.e. s/he doesn't know how to use the calculator" (Writing—Turkish participant). Forty percent of Turkish and 35% U.S. participants discussed that teachers should have necessary TPK about how to use graphing calculators effectively in the classroom: "It is the teacher's role to use discretion for when calculators should be used. Calculators are most beneficial, any kind, when used for learning not as an answer-giving black box" (Writing—U.S. participant).

Content related discussions in participants' writings were very scarce. Participants were referring to their TCK when discussing appropriate subjects to address with graphing calculators in mathematics education. Algebra and graphs of functions were mentioned often in these discussions. Geometry was the next most-mentioned topic for Turkish participants and statistics, data analysis and probability was for U.S. participants. Mainly advanced topics were listed as appropriate to use graphing calculators, possibly due to the fear of calculator dependency.

Relationship between the Two Frameworks

When the two frameworks—the roles of the graphing calculators and TPACK—were taken into consideration concurrently, an emergent theme evolved. The main part that was discussed by all participants in the TPACK framework was TPK. While doing that, different roles of the calculators came into play. When some participants discussed the role of calculators as discovery tools, then tended to discuss how this role helps students' understanding: "It helps students internalize the 'why' behind a process, rather than what to do…They can also be used to verify experimental ideas. 'What do you think would happen if…?'" (Writing—U.S. participant). Conversely, when calculators are used as computational tools, some participants mentioned that this might hinder students' learning: "I do not think that students should use calculators for basic computations/operations…the student should do that mentally in order to gain more basic computational practice" (Writing—Turkish participant).

Summary of the Views of U.S. and Turkish Participants

Turkish and U.S. participants had similar views regarding the use of graphing calculators in mathematics education. Both worried about calculator dependency but thought that calculators could transform the teaching and learning environment, carrying the mathematics experienced in classrooms to new levels. Both groups saw graphing calculators as computational tools. Turkish participants brought the visualization aspect more into play, while calculator dependency was the main discussion topic in U.S. interviews. More U.S. participants than Turkish participants thought graphing calculator use was more appropriate after students have mastered basic skills, and they focused on more practical issues. More Turkish than U.S. participants worried about classroom management and cited their need for technical knowledge. Significantly more Turkish participants discussed the motivational aspect of graphing calculators as an advantage. This could be the result of the novelty of graphing calculators for Turkish participants.

Discussion and Conclusions

Even though Turkish and U.S. participants had different experience levels with graphing calculators, the main role given to them by both groups was doing fast and accurate computations and creating complicated graphs in a short period of time without drudgery—a computational tool according to the Doerr and Zangor (2000) typology—without discussing how they would use the time saved. This is a superficial use of TPK. Some of the roles that participants assigned to the graphing calculators were due to many advantages they saw in using them. Here the use of two frameworks was beneficial, because when participants reflected on the advantages/disadvantages, they were referring back to their TPACK. One implication of these results is to provide environments where preservice teachers experience the potential and effective use of different technologies in mathematics education in order to help them develop more informed views. That Turkish and American participants held similar views about the use of graphing calculators is both encouraging and questionable. How were Turkish participants able to have more positive views in some categories compared to U.S. participants? When half of both Turkish and U.S. participants agree that the use of graphing calculators could transform the nature of their classrooms so that concepts are more valued, we can see a universal trend where understanding is more valued than computation, but one can still wonder what U.S. participants have learned from having graphing calculators in use for the last decades (e.g. seeing students reaching for calculators for basic calculations) and how this might have affected their TPACK as teachers.

One implication of the results of this study is the need to help teachers develop and reflect on a cohesive TPACK (Thompson & Mishra, 2007), rather than a set of disconnected knowledge types (TK, PK, CK, TPK, or TCK). The activities and practices that teachers experience frame the knowledge and beliefs they construct and develop. For example, if the participants had more experience with calculators as data collection tools, they might have discussed it in their writings or in the group discussions. Moreover, group interviews helped participants reflect on, confront, and defend their own beliefs. Listening to others' views might have helped many of them to reconsider not only their beliefs, but also their knowledge, or to expand their viewpoints to include other possibilities. Teacher education offers teachers the knowledge and experience they will require. During their education, teachers not only acquire knowledge, but also form their beliefs about pedagogy which may affect their future instructional decisions (Ball et al. 2001; Stipek, Givvin, Salmon, & MacGyvers, 2001). Therefore, it is critical to identify and study teachers' beliefs in order to advance teacher education to an evolving entity presenting opportunities for teachers to reflect on those beliefs.

We define mathematical performance as the process of communicating mathematics using the performance arts. By highlighting the role of technologies in shaping mathematical thinking, we present two episodes of a qualitative case study. First, considering the use of songs, lyrics, video clip, manipulative blocks, and online applet, we illustrate how thinking collectives of students-teacher-media investigated the L Patterns (sequence and series of odd and even numbers) and conjectured a new sequence of numbers called F pattern. Then, we describe how these collectives created a digital math performance for the Math Performance Festival based on their conjecture. We believe that digital media and the performance arts are helping to create transformative means of mathematical communication and learning.

Traditionally, "mathematical performance" is conceptualized as pertaining to the domain of assessment and evaluation. However, we see *mathematical performance* as the process of communicating mathematics using the performance arts (Gadanidis & Borba, 2008). "Exploring mathematical ideas through performance can offer a way to challenge some of the most limiting stereotypes around mathematics learning" (Gadanidis, Gerofsky & Hughes, 2008 p. 19). By creating music or movies, math performers can provide surprises to audiences and communicate mathematical ideas in an imaginative way. Moreover, *digital mathematical performances* are digital media (e.g., video and audio files, flash animations, and virtual objects) used to communicate math through music, cinema, theatre, poetry, storytelling, etc. We do not suggest all mathematics should be taught using performance arts. However, thinking about mathematics as performance may lead to new ways for (a) student to produce knowledge with technologies and (b) sharing mathematics beyond classrooms (Gadanidis, Gerofsky & Hughes, 2008).

Since 2008, students and teachers have been submitting digital mathematical performances to the Math Performance Festival (MPF) (Gadanidis, Borba, Gerofsky & Jardine, 2008). The MPF is based on a virtual environment where digital performances are published. Every year, Canadian celebrities (e.g., musicians, poets, TV presenters) and mathematicians select their favourite performances in terms of: (a) depth of the mathematical ideas; (b) creativity and imagination; and (c) quality of the performance. The participants of these performances are awarded with medals. Gadanidis and Geiger (2010) have referred to the MPF as "one example that helps bring the mathematical ideas of students into public forums where it can be shared and critiqued and which then provides opportunity for the continued development of knowledge and understanding within a supportive community of learners" (p. 102).

In this paper, we present a qualitative case study to illustrate how Brazilian students investigated and created a digital mathematical performance for the MPF. We suggest math performance can offer ways for transformative teaching and learning mathematics.

Theoretical Framework

Vygotsky (1978) investigated children's development and how development is conditioned by the role of culture and language. According to Vygotsky, higher mental functions are historically developed within particular cultural groups, through social interactions with significant people of children's life, particularly parents and teachers. Through these interactions, children learn the habits of the culture, including patterns of speech, verbal and written language, and other symbolic representations. Thus, Vygotsky emphasized (a) the social interaction with more knowledgeable others in the zone of proximal development and (b) the role of culturally developed sign systems and languages as psychological tools of thinking (Cobb, 1994). In this sense, socioculturalism highlights the role of activity in mathematical learning and development, by linking activity to participation in cultural practices, taking the *individual-in-social-action* as their unit of analysis (Cobb, 1994). Thinking develops from practical and object-oriented activity, that is, "human action is mediated by cultural tools and is fundamentally transformed in the process" (Goos, Galbraith, Renshaw & Geiger, 2000, p. 306).

Tikhomirov (1981) claims that computers reorganize human activities in diverse levels. Tikhomirov suggests computers do not replace, substitute, or merely complement humans in their intellectual activities. Processes mediated by computers *reorganize* thinking. According to Tikhomirov, computers play a mediating role as language does in Vygotsky's theory. Considering the nature of human-computer interaction in terms of feedback, the dimensions involving computational mediation provide new insights for learning and development.

Levy (1998) claims "as humans we never think alone or without tools. Institutions, languages, sign systems, technologies of communication, representation, and recording all form our cognitive activities in a profound manner" (p. 121). Levy uses the term *thinking collectives* to discuss the collaboration between human and non-human actors in the cognitive ecology.

Borba and Villarreal (2005) argue the notion of regulation by computers is qualitatively different when compared to the mediation by verbal and written languages. Borba and Villarreal argue (a) humans-with-media are thinking collectives in constant reorganization of mathematical thinking and (b) media transform mathematics. That is, mathematics produced with paper and pencil is qualitatively different from the mathematics produced with computers.

Therefore, we notice that our research interest is focused on how students-teacher-media form thinking collectives when they create digital math performances. Regarding notions within socioculturalism, we are interested in understanding the role of technologies in shaping students' thinking and learning when they communicate mathematics using the performance arts.

Methodology

Stake (2003) argues qualitative case studies are specific and bounded, they have patterns, and the focus is on the understanding of the complexity of the case. Yin (2006) claims "the strength of the case study method is its ability to examine, in-depth, a case, within its 'real-life' context" (p. 111). Case study "is best applied when research addresses descriptive or exploratory questions and aims to produce a firsthand understanding of people and events" (p. 112).

In this paper, we analyze data produced through the Students as Performance Mathematicians project (Gadanidis, Borba, Gerofsky, Hoogland & Hughes, 2008). Over a period of two years, part of the research team of this project worked in partnership with a state public school in Rio Claro, Sao Paulo, Brazil. These activities engaged middle school students (and some teachers) in a number of activities with the goal of producing digital mathematical performances. These performances were submitted and published at the MPF. Thus, our data consists of several resources produced from these activities. These resources are: (a) field notes; (b) students' writings; (c) video recordings of semi-structured interviews with students and teachers; (d) video recordings of teaching and learning sessions with students; and (e) digital mathematical performances. We use data resources from 4 learning sessions (4 hours each). Eight students participated in the first, second, and third sessions. Four students participated in the fourth session. The first author of this paper played a role as a teacher. In this paper, we first highlight how students-teacher-media conjectured their own sequence of numbers, based on an initial investigation. Then, we describe how this thinking collective created a new digital mathematical performance for the MPF.

Results

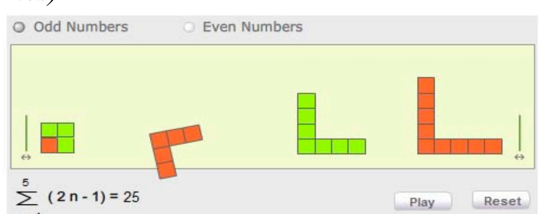
Barton (2008) states "mathematics is created in the act of communication … An educational perspective asks whether this implies that mathematics is learned through communication. This perspective also focuses on the nature of the communication, and the role played by different people in it" (p. 144). That is our focus in describing the episodes, that is, our focus on mathematical thinking emerges through our analysis of how communication through performance happened and how media were non-human actors in this scenario.

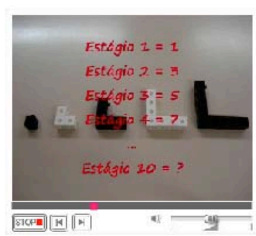
Episode One

At the beginning of the first learning session, the teacher engaged all students in investigating the "L patterns" using several materials as such as songs, lyrics, video clip, manipulative blocks, and online applets. The L patterns (see Figure 1) refer to the study of sequence and series of odd and even numbers. L patterns have the potential to offer surprise in generalizing patterns. Working with manipulative and applets, students can construct sequences of numbers and they can connect blocks (or simulate the connection) to have a geometrical representation for the series which works as a visual proof. Playing with L patterns becomes a surprising and visceral experience when students connect L's forming squares (odd numbers) and rectangles (even numbers).

Figure 1. *L Patterns (Applet, video clip, and lyrics)*

L-Patterns
Playing with blocks, making L-Patterns.
What is going to happen?
I started with a single block,
And I was adding two at each stage.
Playing with blocks, making L-Patterns.
Odd numbers at each stage
1, 3, 5, 7, 9, 11 ... I pose the question:
How many blocks do we need at the tenth stage?
My mind pops up, I understand everything suddenly.
Fitting each L then another pattern emerges.
Playing with blocks, making L-Patterns.
4, 2 by 2, 9. 3 by 3
Adding at each stage, one at a time
Playing with blocks, making L-Patterns.
10, 10 x 10, 100, then I see.
The sum each stage is a perfect square!
Playing with blocks, making L-Patterns
The N x N pattern seems consistent
N odd, N squared.
Playing with blocks, making L-Patterns
What is going to happen?





From the humans-with-media perspective (Borba & Villarreal, 2005), experimentation-with-technologies and visualization play fundamental roles in mathematical thinking. Students-teacher-media were involved in figuring out a generalization for $S_n = 1 + 3 + 5 + \ldots + (2n - 1)$. By investigating the algebraic sum at each stage (writing, singing, and watching a video) and articulating it to the connections of Ls forming a square (constructing with blocks and simulating with an applet), the students-teachers-media identified a new pattern together, as thinking collectives. They also worked with algebraic representations.

At the second session, students conducted an investigation in pairs. They were focused on the use of both manipulative blocks and online applet, but they were also regarding links with other materials as such as the lyrics. By instructing the pairs of students, the teacher was interested in hearing conjectures from them. The teacher proposed to students to speak their ideas and/or write them all on their paper-notes. From the analysis of the video recording and field notes, we highlight that Student 3 came up with an interesting conjecture asking: "*But, if we think about it, there are even numbers in rectangles, are there not?*" The teacher said: "*Perfect. What is the shape related to the series of even numbers?*" Student 3 then argued: *"A rectangle, right? I can see it with the applet."* With the intention of negotiating the meaning of this idea with all students, the teacher brought Student 3's conjecture to the whole class. However, no further discussion happened at this moment involving all students collaboratively. Students were focused on their investigation in pairs. Even though students did not engage in a collective meaning negotiation, we suggest Student 3 did an important articulation involving several representations and media in investigating the L Patterns. Thinking-with-Applet-song-lyric-video-blocks-and-other-media, Student 3 was able to conjecture a visual representation for both the sequences and series of odd and even numbers. Students did not have developed an investigation about even numbers until that moment, but Student 3 was able to visualize and manipulate the applet and the blocks, relate it to the lyrics, images and sounds, recognize an approach on even numbers, relate it to the investigation of odd numbers, and communicate that the series of even numbers can be geometrically represented by rectangles. This moment revealed a significant role of information technology in shaping student's thinking and learning. Other students came up with interesting ideas along the first session as well, but these students' conjectures and ideas toward odd and even numbers will be addressed in other papers.

At the third session, students were still working in pairs. Based on the investigation of the L patterns, Student 1 and Student 8 decided to create a new sequence of numbers using the manipulative blocks. These students created a first F using 6 blocks. They discussed the growth of the sequence and they decided to add 3 blocks each stage, forming the sequence (6, 9, 12, 15,…) (see Figure 2). The teacher brought up this discussion of F pattern to all students. He praised students' conjecture and imagination in creating a new pattern. He proposed that they could develop a similar investigation on the F pattern as they had made to *L patterns*. "*What could be a generalization for the sequence? What would be the series? Would be possible to connect the blocks and create a visual proof to the series? Could we create a performance about F pattern?*" Student 8 said they were trying to figure out the series, but they did not find a regular shape (as a rectangle) to express an algebraic formula for the series. Figure 3 shows students' tentative of creating a visual proof for the *F pattern* series. The teacher asked them if they had already found a formula to the sequence. After fifteen minutes of dialogue between Students 1 and Student 8, where they used blocks, and paper and pencil, Student 1 said: "*I found it! It is n times 3 plus 3*." The teacher said the generalization $3n + 3$ seemed to be a good candidate. Focusing on negotiating that meaning collectively, the teacher proposed to the class to test it for several stages, and they confirmed students' conjecture. Student 1 and Student 8 celebrated the confirmation of their conjectures greeting each other. This moment revealed students' pleasure in thinking mathematics. It shows the beauty of mathematics as an emotional, visceral, and surprising experience in learning (Gadanidis, Hughes & Borba, 2008).

Student 1: The F pattern is composed by 6, 9, 12, 15, 18, and so on. We are adding three blocks each stage. So, what would be the n stage? Here, at the first stage, we have 1 times 3 plus 3 equals 6. At the second stage, 2 times 3 plus 3 equals 9. At the third stage, 3 times 3 plus 3 equals 9. And so on. So, at the n^{th} stage, we have n times 3 plus 3.

Teacher: Great! Congratulations for your discovery!

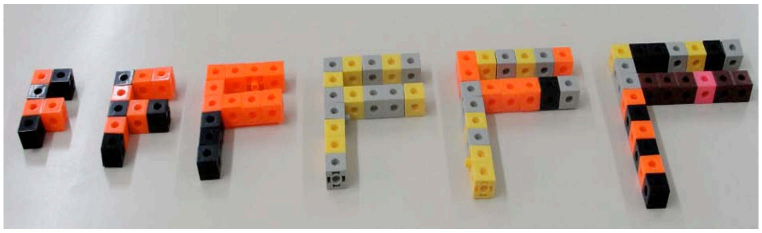


Figure 2: The F-Pattern constructed with blocks by the students

Figure 3: Students' visual proof with blocks.

Episode Two

Four students participated in the fourth session. After a teacher's suggestion, Student 1 and Student 8 came up with the idea of creating a new performance based on the theme of TV News. Their idea was: to present an interview with a mathematician who had discovered the *F pattern*. That was nicely accepted by the other two students, who indicated important suggestions to the script as such as provide humour, use specific songs and sound effects, what kind of images we should portray about reporters and mathematicians, how to explain the series of numbers, and so forth. "Biased" by his interests as a researcher, the teacher tried to create a parallel between the students' conjecture on *F pattern* and a performance about a new math discovery. This parallel was intentionally related on the performative dimension of students creating identities as performance mathematicians (Gadanidis, Hughes & Borba, 2008). Student 1 and Student 8 wrote the words they would like to say. Student 3 wrote a description of each scene as a draft of a script. Student 5 collaborated with script suggestions and technical support. Students-teacher-media recorded the scenes at the same order they would like to present it. The process of playing and recording involved students' speech repetition and improvisation through many takes of scenes. These actions revealed a significant aspect of improving communication and imagination in learning mathematics trough creating a digital skit performance.

After the recordings, based on other students' suggestions, the teacher edited the video called *The F Pattern News* (see Figure 4). A theoretical lens on cinema was fundamental to create the video. It refers to Boorstin's (1990) categories about the pleasures we have when we watch a film. Here, there is an emphasis on the audiences' feelings, which in fundamental in terms of narrative and identity. Boorstin argues about three different categories: *voyeur*, *vicarious*, and *visceral*. The *voyeur pleasure* refers to the mind's eye and not the heart. It is a more rational aspect about the reality or the consistency of the world that is portrayed, but it involves surprise and *making-sense-of-something*. The *vicarious pleasure* puts our heart into the body of the actors. It is when we feel what the actors feel. While the voyeur's eye requires a more opened-close, the vicarious requires a close-up on the actors' faces. The *visceral pleasure* is when we fail to feel what the actors are feeling and began to feel our own emotions.

The *F Pattern News* video plays a lot with voyeur's and vicarious' pleasures. The close parallel with TV News creates a good sense of reality. It involves a lot of surprise in terms of a "new mathematical discovery" and making-sense-of the mathematical ideas presented: sequence of numbers, use of manipulative materials, explanation on the board, experimentation and test of hypothesis, generalization, etc. The sense of humour, the sound effects and music used, the reporters' and mathematician's actions and speeches allow us to fell a vicarious pleasure. If you feel your own feelings in watching this video, if you feel you want to enjoy creating your own digital math performance, it means that the F pattern News also works at the visceral level.

Moreover, the teacher worked with Portuguese/English translations to create subtitles and some students were interested in learning how to speak in English the words they said in the video. Students agreed that the mathematical idea was been communicated clearly. Then, the thinking collective created a final draft at the school's Lab and one of the administrators of the school submitted the video to the MPF. It is available at www.edu.uwo.ca/mpc/mpf2010/mpf2010-134.html. We suggest that by creating a digital mathematical performance, students can talk about mathematics using multiple modes of communication and languages as such as the arts, gestures, sounds, words, visual and symbolic elements, and others (Kress, 2003).

Following, we present a transcription of the video:

Reporter 1: We are interrupting the TV show to tell you terrific news! One just discovered that beyond the L patterns, there is an F pattern!

Figure 4: The F Pattern News

Report 2: F pattern? What are you talking about?

Reporter 1: Our reporter has more information about it.

Reporter 2: Hey, can you hear us?

Reporter 3: Yes. I am here with Hypotenuse. She knows everything about math.

Reporter 2: What is this story about F pattern?

Hypotenuse: The F pattern is here represented by blocks

Reporter 1: Could you please ask her what would be the sequences?

Reporter 3: Sure. What would be the sequence for the F pattern?

Hypotenuse: As we can see, the sequences increase three blocks each stage.

Reporter 3: Look, at the first stage you used 6 six blocks. At the second stage you used nine blocks. At the third, twelve blocks. And so on. What about the hundredth stage? How many blocks do you need to construct the hundredth stage?

Hypotenuse [using the whiteboard and the blocks]: We have a simple formula to figure it out. You can notice the result each stage is equal the index of the stage times three plus three. That is, 3N + 3. At the one hundredth stage we have one hundred times three plus three. It is equal three hundred and three.

Report 2 [with a surprising sound on the background]: I am getting the information that the series was discovered. What would it be?

Reporter 1: In other words, what would be six plus nine plus twelve and so on?

Reporter 3: Hypotenuse, what would be the series?

Hypotenuse [in fast motion and using the whiteboard]: I am going to use Gauss's ideas. The series would be the sum of these numbers. Gauss did it twice. Once from the beginning to the end, that is, $S = 6 + 9 + 12 + \ldots + 3n\text{-}3 + 3n + 3n\text{+}3$. *And once from the end to the beginning,*

> *that is, S = 3n+3 + 3n + 3n-3 + … + 12 + 9 +6. Then, we can add these two expressions. So, we have 2S = (3n+9) + (3n+9) + (3n+9) + … + (3n+9). Therefore, we have 2S = n times (3n+9). It gives us the following formula… [Showing it on the board]. With this formula we can calculate the total number of blocks we need until the stage we wish.*
> *Reporter 1: Last time we talked about the L patterns. Today, we talked about the F pattern. What about you? Which one is your favourite pattern?*
> *Reporter 2: Which one will be our next pattern?*
> *Report 1: Your local show is coming up next.*
> *Reporter 2: Good night… have a good day… good afternoon.*

Conclusions

This paper deals with the learning of mathematics and how students can use both digital technologies and the performance to communicate mathematics. We suggest mathematical performance offers ways for transformative teaching and learning mathematics. Students interacted with could be called a new ‘language”, that is, by using multiple modes of communication that emerge from the digital world in which videos, pictures, drawings, songs and animations are linked to usual printed-based text. In discussing this, we believe that our paper is relevant for some of the main topic of the PME-NA 2011 discussion.

Noss, Hoyles, Geraniou, Gutierrez-Santos, and Pearce (2009) clarify that the difficulties that mathematical generalization and algebraic expression pose for students have been thoroughly studied. For these authors, the difficulties students face when dealing with generalization activities are in some measure due to the way in which they are presented and the constraints of the teaching approaches used. Usually, teachers tend to teach the techniques isolated from all context to help their students find the rule. There is a need to introduce students to different approaches involving generalization of patterns (Noss et al., 2009).

We do see mathematical performance as one more pedagogical tool to address this need. Two students who participated in the creation of the *F patterns News* were interviewed. They said:

> *Student 1: I was learning doing something that I love: theatre. To create a performance we have to know the content, you have to understand it. If you don’t, it doesn’t work very well. It also makes things different. You have to know what you are talking about to create something natural. There are interesting things and with performance I realized it is not so hard. I love the performance about F pattern. To figure out the formula is something big. It is cool because you visualize something and you have to figure out the generalization to know the number for any stage, and what is going to happen. You have a set of numbers and the formula shows how it is growing up. There is a pattern in this process and I realized that by using blocks and seeing the applet. It was a way to learn enjoying. We can use performance to make this transformation.*

> *Student 8: Many colleagues asked me what math performance is or what we do to perform math. First, they said they did not what to do that, because they hated math. They already have too much math classes, and do a drama about math sounded wired. But I started to explain to them exactly what we were doing and the purpose of it. Then, they started to change their opinion, seeing math performance as something different. I tried to convince and encourage them saying that I was playing what I was learning.*

Finally, we highlight that, even though meddle-grade students explored different representations for the sequence and series of numbers they created (e.g., $\sum_{i=1}^{n}(3i+3)=\frac{3n^2+9n}{2}$), we do recognize the mathematics explored in the learning sessions could have gone further. For example, the F pattern (6,9,12,15...) can also be seen as the sum of natural numbers (3,4,5,6,...) and odd numbers (3,5,7,9,...) (that is, 3+3, 4+5, 5+7, 6+9, ...). This could be represented as two separate visual patterns to get a visual picture of the series in a similar way as the L-patterns. On the other hand, by *creating* a digital math performance, we did see interesting ways for mathematical exploration. "Mathematical exploration and play is always possible, at any level. Within the environment of existing mathematics there are (have always been) educational resources full of wonderful open questions … It is nearly always possible to change some basic assumption of mathematics, and to genuinely explore or play in a new environment" (Barton, 2008, p. 150).

We report on research conducted with six seventh-grade mathematics teachers who participated in a two-year professional development research study on implementing formative assessment in networked classrooms. While the full study used a variety of both quantitative and qualitative data sources, this report focuses on data from the semi-structured interviews conducted at the end of the project. We describe three of the categories that emerged from the coding (Strauss & Corbin, 1998) and relate these to teachers' use of the technology.

There are few studies that examine teacher learning and practice for more than a year, especially looking at the impact of technology-focused professional development (Mouza, 2009). In this paper, the impact of two years of professional development on teachers' implementation of formative assessment in a connected classroom is analyzed through the lens of the interactive relationship between practices and beliefs. Analysis is based on case study data collected from six of 30 teachers who participated in Project FANC[1], a research study of implementing formative assessment in a networked classroom using the TI-Navigator System[2] and graphing calculators. The goal of the research in Project FANC was to investigate the use of formative assessment in a networked classroom as it affects middle grades student learning of algebra concepts. In particular, Project FANC studied the effects of one-half of the 30 teachers using formative assessment with the TI-Navigator System for two years and compared them to the effects of the other half using formative assessment with the TI-Navigator System for one year after receiving professional development in formative assessment the first year. Detailed descriptions of the two different models of professional development can be found in Olson et al. (2010).

In *How People Learn* (NRC, 1999), classroom networks were suggested as one of the most promising technology-based education innovations for transforming the classroom environment. Wiliam's (2007) description of a pedagogy of contingency, in which the essence of formative assessment is instruction contingent on what students have learned, can be accomplished through the use of technology that has potential to overcome the major hurdle to utilizing formative classroom assessment: the collection, management and analysis of data. While feedback loops in the regular classroom are very slow, classroom networked technology has the capability to provide rapid cycles of feedback to improve ongoing activity in real time (Roschelle, Penuel, & Abrahamson, 2004). Using the TI-Navigator System, what students know and can do is easily assessed and anonymously displayed. Students can enter and send their responses to the teacher computer and teachers can easily send questions, and receive, organize, and display students' answers, so that the interaction between the teacher and students and among students is greatly facilitated. Four functions of TI-Navigator System particularly helpful for formative assessment implementation are: (a) Quick Poll—allowing teachers to immediately collect and display all students' responses to a question; (b) Screen Capture—allowing teachers to monitor individual students' progress at anytime; (c) Learn Check—allowing teachers to administer quick and frequent formative assessments and provide timely feedback; and (d) Activity Center—allowing students to work collaboratively to contribute individual data to a class activity.

Although teachers may obtain information about student's knowledge, they do not necessarily change their instructional procedure based on the information obtained. Researchers at Ohio State found stronger evidence for technology implementation than for change in instruction. Even with technology tools available to assist with implementation of formative assessment instructional strategies, not all teachers who make significant changes in using of technology necessarily make full use of the potential of the connected classroom for formative assessment (Owens, Pape, Irving, Sanalan, Boscardin, & Abrahamson, 2008). Each teacher will have unique ways of incorporating effective formative assessment practices into her or his classroom using connected classroom technology.

Substantial evidence suggests there is a complex relationship among teachers' classroom practices and the interconnected knowledge and perceptions of mathematics, technology, learning, and teaching. The integration of technology in classroom practices is influenced by teachers' background knowledge and experiences, and conceptions of technology, mathematics, and learning (Zbiek & Hollebrands, 2008). Teachers' disposition towards mathematics and its pedagogies have been highlighted as a major factor in determining the way teachers make sense of technological tools and integrate technology in the classrooms (Ruthven, Deaney, & Hennessy, 2004; Mousley, Lambdin, & Koc, 2003). Mouza (2009) found that teacher change was highly dependent on the continual interaction between practices and beliefs and that teachers went back and forth between implementation of practices from professional development experiences and previous practices. If teachers are to effectively use technology, changes in their knowledge, practice and beliefs are needed. Mouza also reported that teachers' beliefs about their students constituted a critical variable influencing their decision to use technology.

Research shows that technology may change the nature of mathematical activity in the classroom and consequently the teaching and learning of mathematics (Laborde, 2007). Laborde described two levels of teachers using technology: 1) teachers who master the use of technology to do an activity and 2) teachers who used the technology for organizing instruction and learning to take advantage of the specificities of the technology in relation to the meaning of the mathematical content (p.88).

Methodology

The 30 teachers in Project FANC were equally divided into two groups, called FA and NAV, to study the effects of two different models of professional development on student learning of algebraic concepts. All teachers were provided with laptop computers, LCD projectors, Elmos, and a classroom set of TI-73 calculators at the beginning of the project. During the first summer, the participants in the NAV group received TI-Navigator Systems and received professional development using the TI-Navigator for formative assessment while the FA participants received professional development in formative assessment only. Each group participated in five follow-up sessions during the first school year as well as received coaching visits from project staff. During the second summer, the NAV participants received continued professional development in using TI-Navigator with more of a focus on formative assessment, while the FA participants received TI-Navigator Systems and professional development on using the TI-Navigator for formative assessment. Five follow-up sessions for the combined groups were conducted during the second year and coaching continued as well.

It was expected the implementation of the ideas presented in the professional development would vary by teacher and the teacher's beliefs and perceptions about mathematics teaching and learning, efficacy in using formative assessment and networked technology, and support within the school community. To study the implementation process, we conducted case studies on ten of the teachers, five in each group. Data sources for the case studies were background information provided by teachers, classroom observation field notes, notes from coaching visits, focus group and individual interview videos, writing prompts, and the Learning Mathematics for Teaching assessment.

While case study data were collected for 10 participants, this paper focuses on six of the teachers. The focus is on issues of implementation of formative assessment in a networked classroom and not on individual teachers. A brief description of each teacher, by pseudonym, is included.

Kate was in her late 20s and sixth year of teaching when she entered Project FANC. She has secondary mathematics certification and received her degree in mathematics education from Northern Colorado. Kate was interested in Project FANC because of the technology. She teaches in a middle school that has a significant variety of technology available for student and teacher use and was somewhat disappointed that she was not selected for the NAV group. The middle school where she teaches has approximately 900 students. Ethnicities of the diverse student body include 29% Filipino, 22% part Hawaiian, 15% White, and 11% Japanese. Thirty-five per cent of the students receive free and reduced lunch, 6% have limited English proficiency, and 9% are in special education.

Sharon is in her mid 40s and was in her 9th year of teaching when she entered Project FANC, although she served as a long-term substitute for several years prior to that. She has secondary mathematics certification and a major in mathematics education. Sharon does not consider herself a 'genius' in mathematics but loves working hard. She teaches at a combined intermediate and high school in a rural area with about 1650 students. Ethnicities of the diverse student body include 40% part Hawaiian, 21% White, 17% Filipino, and 13% Samoan. Forty-five per cent of the students receive free and reduced lunch, 5% have limited English proficiency, and 12% are in special education.

Yaz is in his 30s and had three years of teaching experience in middle grades mathematics when he became a participant in Project FANC. Both of his parents were teachers. He attended K-12 schools in the Pacific islands but received his undergraduate degree, with certification in elementary and middle school education, in Hawai'i. Prior to participation in Project FANC, he was in his current teaching position for one year. His colleagues view him as the 'tech' person. Yaz teaches at the same school as Kate.

Denby is in her 30s and was in her eleventh year of teaching when she entered Project FANC. She received a bachelor's degree in mathematics and one year later received her secondary mathematics certification. She recently received National Board Certification. Always looking to learn more, she has been a voracious participant in professional development experiences to which she has had access. Denby teaches at an intermediate school in a rural area with about 925 students. Ethnicities of the diverse student body include 40% part Hawaiian, 16% Hawaiian, 10% Filipino, and 7% Samoan. Seventy-five per cent of the students receive free and reduced lunch, 5% have limited English proficiency, and 17% are in special education. Although a participant for two years, she was not able to participate in the activities of the first summer.

Clarise is in her 30s and had one year of teaching experience in middle grades mathematics when she became a participant in Project FANC. She began teaching after Teach for America training to teach third grade. With no elementary teaching positions available in Hawai'i, she was asked if she wanted to teach mathematics or English. Clarise chose mathematics and became an eighth grade teacher at a middle school five days before the start of school. She moved to seventh grade her second year because the school loops with teachers following students from seventh grade to eighth grade. She teaches in a middle school with approximately 900 students. Ethnicities of the diverse student body include 64%

Filipino, 8% part Hawaiian, and 6% Samoan. Sixty-three per cent of the students receive free and reduced lunch, 25% have limited English proficiency, and 10% are in special education.

Iris is in her 30s and was in her 10th year of teaching when she entered Project FANC. She has a degree in mathematics education and both middle school and secondary mathematics certification. She teaches at a large middle school with about 1750 students where only three-fourths of the students are on campus at any one time. Ethnicities of the diverse student body include 26% Japanese, 21% White, 16% part Hawaiian, and 6% Filipino. Thirteen per cent of the students receive free and reduced lunch, 2% have limited English proficiency, and 11% are in special education. While she has considerable experience with technology, she felt she was volunteered for Project FANC.

Results

In this paper, we report on interviews with six of ten teachers who were part of the larger case study. These six were chosen because they represented a wide range of uses of technology, differed in their definitions and implementation of formative assessment, have a range of years of teaching experience, and were from schools representing a wide-range of ethnic diversity and background. While other data were collected, this report focuses on data from the semi-structured interviews conducted at the end of the project. Our report concentrates on three of the categories that emerged from the data analysis (see Olson et al., 2011). We focus on categories that involve teachers' views of formative assessment, pedagogy, and the role of students. In the complexity of classroom life, we believe that these aspects are interrelated in numerous ways. However, we discuss each category separately before looking at how they are manifested in teachers' use of technology in the classroom.

Formative Assessment

All teachers in the case study had been familiar with the term formative assessment before entering the FANC project. Some had participated in professional development sessions about formative assessment given by the state department of education. Two phenomena are of interest here: 1) the variation in teachers' views about formative assessment and 2) whether teachers reported on having changed their views of formative assessment as a result of their participation in FANC.

While all teachers believed formative assessment yielded valuable information, the range of views extended from conceiving of formative assessment as a series of mini-summative assessments to a view of formative assessment tasks indistinguishable from tasks of the ongoing lesson. At one end of the spectrum, teachers used questions and check-ups as one would use quizzes to monitor students. The information from students' responses helped them to find out who was following the lesson, which students 'got it,' and it provided guidance for pacing the lesson. These teachers tended to use Quick Poll and Learn Check more than any other of the Navigator features. Moreover, they interpreted students' responses in terms of correct or incorrect answers. Denby's comment represents this viewpoint. "I use it more just…to assess, Where are they? How many of them got this? Can I move on? Or do I have to still wait and go back and check?"

Other teachers used students' responses to Quick Polls and Learn Checks to focus on misconceptions. Displaying these results provided opportunities for the whole class to discuss misunderstandings. Such discussions helped teachers better understand student thinking, and by making incorrect answers public, students and teacher were able to jointly learn from and address incorrect responses.

In Clarise's classroom, formative assessment was woven into all teaching and learning activities. Clarise had made a major change in her grading policy by no longer grading assignments, including homework. "Homework…is more like a discussion point rather than something to grade." (Clarise) In this way, the homework responses, collected on Quick Poll, became part of the dynamic of teaching and learning, so that both students and teacher could make formative assessments in the course of the lesson.

Almost all teachers reported that their participation in the project had broadened their view of formative assessment. Most teachers had previously thought that formative assessments were those based on a smaller amount of material, such as a quiz, and summative assessments were those that covered a larger body of material, such as a test. They now realized that there are many formats for conducting formative assessment, and it can be a daily occurrence. Yaz expressed his new understanding,

> …formative assessment is more than just a quiz and seeing where kids are and what I need to re-teach. It goes into depth on misconceptions and why kids think this way, how can we address it….

Pedagogy

Among the pedagogical issues that arose in the interviews, two key topics were questioning and planning. Both of these are important aspects of formative assessment (Ayala & Brandon, 2008) and both are integral to using the Navigator features. In their interviews, most teachers focused on the importance of questioning, but not all used questions in the same way. Iris was representative of teachers who used questions to guide students.

> I try to direct them in the way I want them to go, so to speak. With the equations, where they had to put their own equations, I ask them, "What is the coefficient?" And using that vocabulary, trying to get them used to the vocabulary….

Other teachers tried to learn more about students' thinking through questioning. They focused on how their students might solve a problem and created questions to expose misconceptions and provide interventions as needed. They spoke about "thinking as a student yourself" (Yaz) and the importance of knowing the students when introducing new concepts, "what might they have a hard time with, what might they misunderstand or misinterpret…" (Kate). Kate characterizes herself as a 'questioner' and not as a 'teller.'

> I like to ask kids questions, rather than direct them to an answer or tell them their answer is correct. I like to know more about why they think they are right or wrong….

Teachers varied in how they planned lessons. The teachers who were focused on student thinking tried to anticipate what problems and misunderstandings students would have. Yaz and Kate, who collaborate in their planning like to have students' misconceptions in mind as they plan, "…then we are ready for the discussion…." (Kate). Clarise also focused on how her students are thinking about the mathematics. Since participating in the FANC project, she has reorganized her classroom, including getting different furniture, to enable students to work in groups. In her efforts to be responsive to student thinking, her approach to teaching has become more spontaneous. "…Sometimes it's [referring to a Quick Poll question] planned ahead of time, but most of the time it's just right in the moment…." (Clarise)

The goal of Denby's planning was to create a lesson that maximized students successfully completing the tasks she intended for them. Here she carefully broke tasks down into smaller pieces so she could assess if students understood before moving on. She used this approach when introducing the Navigator technology and for introducing mathematics content. Using this approach, Denby felt she was both addressing the mathematics goals of her lessons as well as how effectively the students were learning what she hoped they would learn.

Student Role

The Navigator system is connected to a projector enabling everyone to see student responses. While it is possible for these responses to be anonymous, students usually know and identify which response belongs to them. Teachers commented that the public nature of the display made the students more accountable for their participation in the lesson activities.

> With the Navigator, it holds them a little more accountable. 'Cause they know if they are the one student who is not responding, they know they are the one the class is waiting for…. With the "Are You On the Line," they know if they are the one on or off the line because they weren't paying attention. You know, so, it holds them a lot more accountable to participate. To be engaged. (Kate)

> …having the Navigator…they put in the equation and [they] could immediately see who is getting it right or wrong, and we could help them make the corrections right away. (Iris)

Besides contributing their own responses, the Navigator features enable students to provide feedback for others. In this way, students become sources of knowledge for the class and thereby assume some of the responsibility for the group's learning, both to prompt thinking about the tasks and to assess understanding. "My kids have picked up on my questioning… they make their peers think about it…." (Kate) Not all teachers promoted a shared locus of control to the same degree, but all teachers reported on an increase in student discourse and using that discourse to guide their teaching.

> …it's a whole lot better when they're talking with each other. They teach each other stuff, and then there [are] ten teachers in the room instead of just one. (Clarise)

Discussion: Integration of Technology

Over the course of the FANC project, teachers used the Navigator system in a variety of ways in their lessons. Some examples include using Quick Poll or Learn Check at beginning of a lesson as a warm up; posing problems in Activity Center to which all students contributed data; and displaying student work on Screen Capture so students could compare work in progress. All teachers used the various Navigator features to get feedback about students' progress at critical points during the lesson. Most teachers used Quick Poll and Learn Check more often than activity Center or Screen Capture. They reported taking longer to become comfortable with Activity Center, and they viewed its applicability mainly to algebra topics, especially graphing of data or exploring features of equations.

Teachers believed that the immediate feedback from all of the Navigator features significantly supported teaching and learning in their classrooms. Yet, there was a subtle difference in viewpoint about how that support was utilized that relates to their approaches to formative assessment, pedagogy and the role of their students. Some teachers primarily used the feedback as assessment for how the students were doing. These tended to be the same teachers who viewed formative assessment as measures of correctness or incorrectness, whose questioning was designed to direct the lesson, and who viewed students primarily as receivers of information.

> Class, why do you think so-and-so got this answer? Oh, because they did the wrong step…they multiply first instead of doing power first, whatever…So that's very valuable…you have instantaneous, it's formative assessment and I can check it and see who's got [it] and who doesn't; that's huge. (Sharon)

Another group of teachers viewed the use of the Navigator system as affording greater learning opportunities for their students. These teachers also utilized the feedback from student responses to inform their teaching, but this assessment occurs via the learning activity.

> When…we are going over the answers and I see two different set-up proportions…as being correct, I would use that as a discussion on why these two look different…and are still being considered as correct answers. And then we had a discussion with the kids. (Yaz)

In summary, not only were we able to determine different levels of use of technology and formative assessment, we found this use corresponded to teachers' beliefs and perceptions related to their views of formative assessment, classroom pedagogy, and students' role in the teaching and learning process. These views then had an impact on how they used technology for implementing formative assessment in a networked classroom.

Endnotes

1. The research reported in this paper was generated by the grant, *The Effects of Formative Assessment in a Networked Classroom on Student Learning of Algebraic Concepts (DRL – 0723953)* funded by National Science Foundation Research and Evaluation on Education in Science and Engineering (REESE) program. The views expressed in this paper are the views of the authors and do not necessarily represent the views of the National Science Foundation.

2. TI-Navigator™ is a networking system developed by Texas Instruments that wirelessly connects each student's graphing calculator to a classroom computer.

TECHNOLOGICAL, PEDAGOGICAL, AND CONTENT KNOWLEDGE (TPACK) FOR MATHEMATICS TEACHERS

Dorian Stoilescu
University of Toronto
dstoilescu@yahoo.ca

Douglas McDougall
University of Toronto

This study explores the Technological, Pedagogical, and Content Knowledge (TPACK) of three experienced secondary mathematics teachers and describes ways of using technology. Analyzing their TPACK, we noticed that teachers integrated technology to: a) give students opportunities to learn and experiment with their mathematical knowledge; b) help pass the content to the students in the process of teaching mathematics; and c) assess and evaluate student work, and give them feedback.

Introduction and Methods

This research aims to explore the integration of technology in secondary school mathematics classrooms by using the Technological Pedagogical and Content framework (Mishra & Koehler, 2008)**.** The goals are: to understand existent pedagogical ideas in the context of integration of technology into mathematics education by experienced teachers; and to document and analyze secondary school mathematics teachers' choices in integrating technology. The research question was: How do mathematics teachers describe their ways of integrating technology? Three teachers from a Toronto school agreed to participate. Data was collected from observations, document analysis, and interviews. Data was grouped according to the categories proposed by Niess (2008). We structured the findings of this paper based on Niess's four layers of integrating technology for the TPACK framework: 1) overall conceptions of integrating technology, 2) knowledge of instructional strategies, 3) knowledge of students, and 4) knowledge of curriculum and curricular materials.

Findings

First Layer

Overall, the three teachers displayed high competence in teaching the mathematics curriculum. They knew the mathematics content required for the secondary school curriculum, the students and the context of the school. They were able to acknowledge the difficulties that might appear when their students started to learn these mathematical curricular units and were willing to use technology in order to let students have their own ways of exploring mathematics.

Second Layer

Teachers used technology for various purposes in their teaching and for assessments. Therefore, we might conclude that the teachers were individuals with a sound Technological, Pedagogical, and Content Knowledge, and the administrators supported them to implement computer technology in mathematics instruction.

Third Layer

Each teacher had knowledge about the students' background, academic performance, and possible difficulties. Based on students' skills, the teacher devised his or her methods that would be deemed successful.

Fourth Layer

The teachers had a good knowledge of mathematics curriculum and knowledge of how to adapt their curriculum material for their students. For computer technology, they gave students the opportunity to experiment with their mathematical ideas and test their knowledge through computer technology.

Final Comments

The teachers were able to make technology available as a support for investigation and to establish connections with pedagogy and content. By collaborating and receiving technical support from each other helped the teachers to cope with difficulties of integrating technology in classrooms. The technology was also used for assessing student knowledge, a fact that tremendously reduced the time for feedback of the teachers.

EMERGENT ONTOLOGY IN EMBODIED INTERACTION: AUTOMATED FEEDBACK AS CONCEPTUAL PLACEHOLDER

Dragan Trninic

dor@berkeley.edu

Recent theories of cognition model human reasoning as tacit simulated action. Implications for the philosophy, design, and practice of mathematics instruction may be momentous. We report on findings from a pioneering design-based research study into the embodied roots of proportional reasoning that also explored the pedagogical potential of embodied-interaction (EI), a form of technology-enabled immersive activity. 22 Grade 4-6 individual/paired interviewees remote-controlled virtual objects in a non-symbolic space to solve a problem, then progressively mathematized their strategy using symbolic artifacts interpolated into the space. Drawing on qualitative analyses of the filmed work, we build a sociocognitive account of the role of automated feedback in the mediated construction of perceptuomotor schemes that undergird conceptual development, and we offer a heuristic EI design framework.

Introduction

Over the recent decades, cognitive scientists, psychologists, and philosophers have begun to increasingly question theories of cognition that model the mind as a symbol processor. Alternative "embodied" or "enactive" theories suggest that sensorimotor interaction in the natural and sociocultural ecology deeply shapes the mind—even thinking with or about "abstract" ideas is in fact the mental simulation and coordination of multimodal schematic image schemas (for a recent survey, see Barsalou, 2010). In particular, embodied cognition has been presented as a useful framework for both theorizing mathematical reasoning and designing pedagogically effective learning environments (Abrahamson, 2009; Nemirovsky & Ferrara, 2009; Núñez, Edwards, & Matos, 1999).

Parallel to the rise in popularity of theories of embodiment is the dramatic recent progress in technological affordances for embodied interaction (e.g., Nintendo Wii and Playstation Move, iPhone 4, and Xbox Kinect). Innovative designers tuned to this progress are constantly devising ways of utilizing this commercial technology in novel ways that serve a diverse audience of researchers and practitioners (e.g., Lee, 2008). As such, media that only recently appeared as esoteric instructional equipment will imminently be at the fingertips of billions of prospective learners. And yet, *What forms should "embodied" learning take? How should we theorize such learning? What are best design principles for fostering embodied interaction?*

In what follows, we discuss embodied interaction (EI) as bearing unique affordances for mathematics teaching and learning as well as research on this process. We then demonstrate these affordances by presenting an EI design for proportions as well as vignettes from implementing this design. The vignettes were selected so as to contextualize a proposed sociocognitive view on EI design: educators use EI first to foster student development of a targeted perceptuomotor scheme, then to guide student appropriation of mathematical forms as means of redescribing this scheme in accord with disciplinary practice and parlance. Finally, we offer an emerging heuristic design framework for EI mathematics instruction.

Embodied Interaction in the Research and Practice of Mathematical Learning

EI is a form of technology-supported training activity created, implemented, and researched by scholars interested in investigating multimodal learning. Through engaging in EI activities, users build schematic perceptuomotor structures consisting of mental connections between, on the one hand, physical actions they perform as they attempt to solve problems or respond to cues and, on the other hand, automated sensory feedback on these actions. One objective of EI design is for users to develop or enhance targeted schemes that undergird specialized forms of human practice, such as mathematical reasoning. As is true of all simulation-based training, EI is particularly powerful when everyday authentic opportunities to develop the targeted schemes are too infrequent, complex, expensive, or risky. Emblematic of EI activities, and what distinguishes EI from “hands on” educational activities in general, whether involving concrete or virtual objects, is that EI users’ physical actions are intrinsic, and not just logistically instrumental, to obtaining information (cf. Marshall, Cheng, & Luckin, 2010). That is, the learner is to some degree physically immersed in the microworld, so that finger, limb, torso, or even whole-body movements are not only in the service of acting *upon* objects but rather the motions themselves become part of the perceptuomotor structures learned. Thus, all EI gestures are perceived as epistemic actions, even if they are initiated as pragmatic actions (cf. Kirsh, 2006). In EI, the learner’s body—its structure and action—becomes concrete instructional material. EI is “hands *in*.”

EI activities typically emphasize explorative perceptuomotor tasks and draw less on propositional or domain-specific reasoning (e.g., Antle, Corness, & Droumeva, 2009). Notwithstanding, EI activities may include standard symbolic elements, such as alphanumeric notation, diagrams, and graphs (e.g., Cress, Fischer, Moeller, Sauter, & Nuerk, 2010; Nemirovsky, Tierney, & Wright, 1998). Indeed, content-oriented EI activities are often designed explicitly to foster the guided emergence of domain-specific conceptual structures from domain-neutral perceptuomotor schemes.

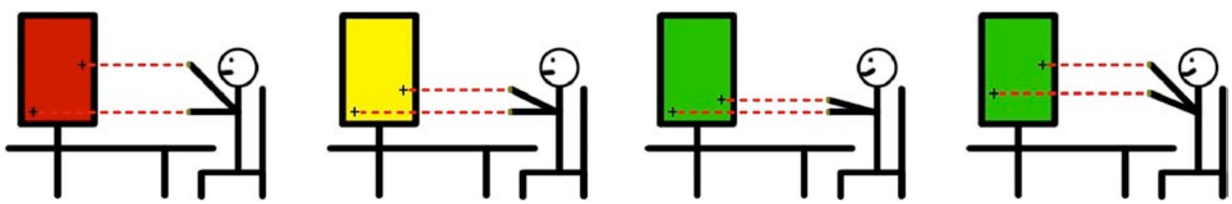
We consider EI activities as creating useful empirical settings for research on guided mathematical ontogenesis. In particular, because EI begins with *a*mathematical hands-in problem solving, data from these activities bring out in relief micro-phases of a learning trajectory that may simulate and generalize to all mathematical development: transitioning from unreflective orientation in a multimodal instrumented space to reflective mastery over the disciplinary re-description of this acquired competence. We thus propose to merge enactive and sociocultural theory to investigate how social interaction steers individuals to leverage perceptuomotor competence in appropriating mathematical forms of reasoning; more broadly, how learners come to embody, inhabit, and signify epistemic practice mediated through guided participation in cognitively demanding social activity (cf. Roth, 2009).

Our paper re-analyzes data from a recent study, in which we investigated an instructional methodology for scaffolding the emergence of proportional reasoning from EI problem-solving activities. Our analyses implicate the vital role of natural discursive modalities, such as verbal and gestural utterance, as well as mathematical semiotic artifacts, such as a virtual Cartesian grid and numerals, as the means by which students re-describe their entrained perceptuomotor enactment in disciplinary form (cf. Edwards, Radford, & Arzarello, 2009). Moreover, we found that these re-descriptions can take surprising, pedagogically useful directions, as students discover *in situ* and *ex tempore* better ways of using the symbolic artifacts so as to enact, explain, or evaluate their task strategy (Abrahamson, Trninic, Gutiérrez, Huth, & Lee, in press). As such, we see our work as expanding on neo-Vygotskian conceptualizations of appropriation (e.g., Bartolini Bussi & Mariotti, 2008; Sfard, 2002). Namely, we implicate learners' creative *re*appropriation of symbolic artifacts in ways that are *not* modeled by the instructor yet students nonetheless discover as semiotic–enactive affordances.

Finally, as reflective designers we also wish to contribute to the theory and practice of EI-based mathematics instruction, which we view as bearing promise. We therefore conclude this report with a summary of our current heuristic design framework for mathematics learning activities in learning environments availing of affordances unique to EI technology.

Design and Implementation of the Mathematical Imagery Trainer

Our design conjecture, which built on the embodied/enactive approach discussed above, was that some mathematical concepts are difficult to learn because mundane life does not occasion opportunities to embody and rehearse particular schemes that constitute the requisite cognitive substrate for meaningfully appropriating these concepts' numerical procedures. Specifically, we conjectured that students' canonically incorrect solutions for rational-number problems—"fixed difference" solutions (e.g., "2/3 = 4/5" - Lamon, 2007)—indicate students' lack of multimodal action images to ground proportion-related concepts (Pirie & Kieren, 1994). Accordingly, we engineered an EI inquiry activity for students to discover, rehearse, and thus embody presymbolic dynamics pertaining to the mathematics of proportional transformation. At the center of our instructional design is the Mathematical Imagery Trainer, which we introduce below (MIT - see Figures 1&2, below, and for detailed descriptions of the device's rationale and technical properties, see Abrahamson et al., in press; and Howison, Trninic, Reinholz, & Abrahamson, 2011, respectively).



a. b. c. d.

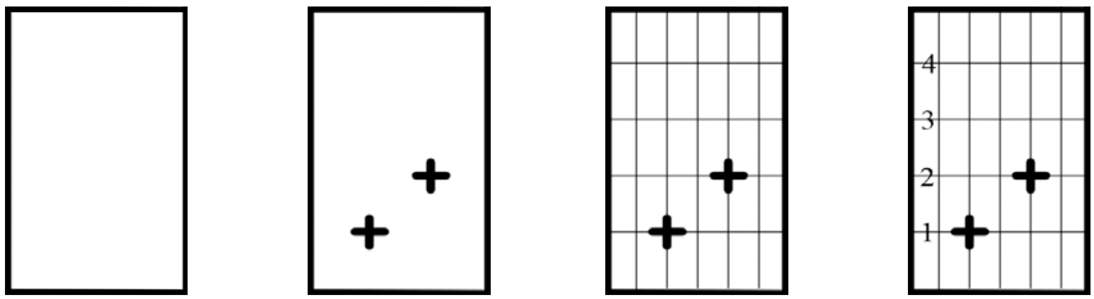
Figure 1. MIT interaction schematics, with the device set at a 1:2 ratio, so that the right hand needs to be twice as high than the left hand: (a) incorrect performance (red feedback on exploratory gestures); (b) almost correct performance (yellow feedback); (c) correct performance (green feedback); and (d) another correct performance.

a. b.

Figure 2. MIT in action: (a) "incorrect" enactment turns the screen red; and (b) "correct" enactment turns the screen green. See www.tinyurl.com/edrl-mit for a 5 minute video clip showing the MIT in action.

The MIT measures the height of the users' hands above the desk. When these heights (e.g., 10'' & 20'') match the unknown ratio set on the interviewer's console (e.g., 1:2), the screen is green. So if the user then raises her hands proportionate distances (e.g., to 15'' & 30''), the screen will remain green. Otherwise, it will turn red (e.g., raising equal distances to 15'' & 25''). As such, this MIT is designed to hone pre-numerical struggle around the additive/multiplicative tension commonly implicated in the literature as underlying student challenges in moving into rational numbers (Lamon, 2007). Study participants were tasked first to find green then to maintain it while moving their hands. The protocol included layering a set of mathematical artifacts onto the display, such as an adaptable Cartesian grid (see Figure 3c, below), to stimulate progressive mathematization of emergent strategies.

Participants included 22 students from a private K–8 suburban school in the greater San Francisco Bay Area (33% on financial aid; 10% minority students). Care was taken to balance for students of both genders from low-, middle-, and high-achieving groups as ranked by their teachers. Students participated either individually or paired in a semi-structured clinical interview (duration of mean 70 min.; SD 20 min.). Interviews consisted primarily of working with the MIT. At first, the condition for green was set at a 1:2 ratio, and no feedback other than background color was given (see Figure 3a; we used this challenging condition only in the last six interviews). Then, crosshairs were introduced (see Figure 3b): these virtual objects mirrored the location of participants' *hands* in space yet, so doing, became the objects users acted *on*, then *through*. Next, a grid was overlain on the display (see Figure 3c) to help students plan, execute, and interpret their manipulations and, so doing, begin to articulate quantitative verbal assertions. In time, numerical labels "1, 2, 3,…" were overlain along the grid's *y*-axis (see Figure 3d): these enabled students to construct further meanings by more readily recruiting arithmetic knowledge and skill so as to distribute the problem-solving task.



a. b. c. d.

Figure 3. Display configuration sketches: (a) continuous-space mode; (b) continuous-space mode with crosshairs, i.e. virtual objects users manipulate; (c) crosshairs with grid overlay; (d) crosshairs with grid overlay and *y*-axis numerals.

For the purposes of this paper, we focus on two brief episodes demonstrating milestones in students' instrumenting their perceptuomotor solution strategies then redescribing them.

Results and Discussion

All students ultimately succeeded in devising and articulating strategies for making the screen green, and these strategies were aligned with the mathematical content of proportionality. We observed minor variation in individual participants' initial interpretation of the task as well as consequent variation in their subsequent trajectory through the protocol. However, by and large the students progressed through similar problem-solving stages, with the more mathematically competent students generating more strategies and coordinating more among quantitative properties, relations, and patterns they noticed.

Each student began either by working with only one hand at a time, waving both hands up and down in opposite directions, or lifting both hands up at the same pace, possibly in abrupt gestures. They soon realized that the actions of both hands are necessary to achieve green and that the vertical distance between their hands was a critical factor. Importantly, all children initially moved their hands at a fixed difference, certainly a legitimate, reasonable strategy.

The following data excerpts will sketch how we used the MIT-based design first to foster student development of a perceptuomotor scheme centered on obtaining "green" feedback and then to leverage their skill in mediating its mathematically instrumented re-descriptions.

We begin with a 6th-grade male student, Penuel, who took longer than others in realizing that the relation between the hands' respective positions is a critical task-relevant quality.

Penuel: So it looks like... they have to be a certain distance away from each other for it to turn green….and if it's not a certain distance, it's not green, it's yellow or red.

Penuel then identified that the positions of the hand should be reinterpreted as magnitudes. That is, he re-saw the location of each hand in space in terms of how high that hand is above the desk, so that empty space below each hand took on the palpability of virtual substance.

Penuel: Well, they obviously can't be at the same distance [above the desk]. But if I start here, and if the right one is moving, like, a little faster, and it's going farther and farther away from the left hand, it will still stay green.

Note references to velocities. Later still, once the grid and numerals were introduced, Penuel quantified his sense of "moving… a little faster" as a proto-ratio by noticing a distinctly mathematical pattern emerging from green locations. Prompted to sum his discovery, he said:

Penuel: You start from the ground [indicates desk], you try to get to the first green… you have to have one… left hand on "1," right hand on "2." Exactly. And you start from there, and you keep doubling it.

Like all students, Penuel was prompted to "make the screen green." As he interacted with the MIT, and through our interview prompts, "green" transformed from an *objective* to *feedback*, as seen by his observations about the "correctness" of types of movements that elicit green. Finally, this feedback enabled him to discern a *mathematical* notion ("doubling") from the set of hand locations eliciting green. This pattern of emergence of mathematical meaning was common to all the students interviewed. Here we can provide only one more illustrative case.

Liat, a 5th-grade female student, exhibited a telltale indication of conceptual transition: mismatch between gestured action and verbal explanation (Church & Goldin-Meadow, 1986). She consistently moved her hands up in a fixed-distance motion, received red feedback, and adjusted the left hand down for green, yet she stated a fixed-distance strategy.

Liat: I think if I keep them apart and keep going up, it stays the same...
Int: If you keep them apart and you keep going up it stays the same?
Liat: It's not becoming red, but...
Int: So... how are you thinking about keeping them apart?
Liat: Oh maybe it's more. If it's farther up, then it has to be…they have to be more apart.

Later, upon the introduction of the grid and numerals, Liat was asked to predict green locations without moving her hands. She noted "one row" in between the crosshairs when the left hand is at 1 and the right hand is at 2, making green. She extended the thought:

Liat: And if you go… 10… if you go up to 10, there's gonna be like 4 or 5 rows. [i.e., if the right hand is at 10, the left should be 4-5 rows lower so as to make green.]

Thus, Liat was able to instrumentalize the grid to enhance her previous qualitative strategy for green, namely that the "farther up" her hands are, the "more apart" they ought to be. However, the 1:2 ratio was yet to become articulated, as her guess indicated she was still thinking in terms of approximate magnitude, "4 or 5," rather than relying upon more powerful mathematics (e.g., half of ten is five). Yet here precisely came the moment of guided transition to the more powerful mode of reasoning, multiplicative relations, as seen from the following exchange, where the interviewer asked her to decide between 4 and 5:

Liat: No… five!
Int: Five? How did you do that so quickly? How did you know it was five?
Liat: Half of ten is five.

Later, during the post-interview debriefing, Liat reflected on the activity of finding green.

Liat: It's not just moving hands… it's… [Liat moves her hands up and down, grasping for words]… it's… you're trying to do something and get the number.

In the ensuing discussion, Liat said that, at first, the activity was "not easy" yet that "actually, now it's easier" because she figured out how it works mathematically. Thus Liat, like Penuel, *comes to re-describe her newly developed skill of "green finding" via mathematics*, concurrently using green as an objective, feedback, and "conservation" for an ontogenesis of proportion. This pattern, common to all our study participants, suggests certain stable affordances of EI design for mathematics learning, as we discuss below in the closing section.

Conclusions and an Outline for a Heuristic Embodied-Interaction Design Framework

Even as learning scientists are increasingly accepting a view of mathematical reasoning as multimodal spatial–temporal activity, technological advances and free-market forces bode an impending ubiquity of personal devices capable of utilizing remote-embodied input. Poised between theory and industry, design-based researchers are only beginning to wrap their minds around the protean marriage of embodied cognition and remote action. Embodied interaction, a form of physically immersive instrumented activity, is geared to augment everyday perceptuomotor learning by fostering cognitive structures that leverage homo sapiens' evolved capacity to orient and navigate in a three-dimensional space, wherein the brain developed *by* and *for* action. We currently have far more questions than answers respecting both the prospects of EI and principles for best design and facilitation of these innovations. Our strategy has been to engage in conjecture-driven cycles of building, testing, and reflecting. In this spirit, the current paper aimed to share our excitement with EI and offer some early observations and caveats. Yet, as often occurs when new media are encountered, we learn as much about *pan*-media practice as about the new media per se. As such, the "ontological innovations" we have stumbled upon through our design-based research appear to bear more generally on how people do and could learn (cf. diSessa & Cobb, 2004).

Our analyses depicted learning as the evolution of users' subjective meaning for the automated feedback and, in particular, the role of perceptuomotor scheme as a vehicle or platform for the mediation of conceptual development. EI automated feedback (such as "green" in our design) evolved in the functional and cognitive roles it played. That is, green: (a) began as the task *objective*; (b) soon became the perceptuomotor *feedback*, as the users attempted to complete the task objective; and (c) came to hold together a set of otherwise unrelated hand-location pairs sharing a common effect and begging a name. Feedback on perceptuomotor performance thus came to demarcate the set of "green" number pairs as all belonging to an emerging *ontology*—a phenomenal class connecting seemingly disparate conceptions, observations, and hunches. To the expert, this emergence is centered around the concept of proportion; the student, however, is merely trying to "make the screen green" and explain exactly what makes it green. It is in this sense that green functioned as more than an objective or feedback—it served as an ontological scaffold or conceptual placeholder. Through appropriate facilitation, the scaffold ultimately collapses, or the placeholder is filled, once users determine the activity's mathematical rule and recognize the rule's power for anticipating, recording, and communicating the MIT's solution procedure. As one child gleefully quipped, upon determining the multiplicative relation of an unknown ratio, "I hacked the system!" Similar, when Penuel referred to "green" as the objective of his strategy (see his last excerpt, above), it is evident in his response that he has populated the notion of green with appropriate mathematical machinery needed to explain and predict "green."

EI thus creates arenas for launching mathematical learning trajectories from body-based qualitative notions. As the students engage in problem-solving our MIT mystery device, their physical actions inscribe a "choreographed" form with increasing deftness—forms that are very difficult or perhaps impossible to mediate outside of EI design. Whereas the student views these forms as physical solution procedures, the educator—who views the forms from the vantage point of an expert's disciplinary perspective—conceptualizes these forms as the multimodal image schema underlying the cognition of the targeted concept. Using representational resources and discursive guidance, the instructor may then steer students to progressively signify these image schema into what become concept images of the emerging mathematical ideas. That is, even as the gestured forms lend meaning to mathematical propositions, they take on the epistemological role of metaphorical simulations (concept-specific "math kata," if you will). In practice, the mathematical concept emerges when students utilize new mathematical symbolic artifacts, which the instructor introduces into the problem-solving space, as means of enacting, explaining, enhancing, and/or evaluating their solution procedure. As such, mathematical knowledge emerges through recognizing a particular cultural form (e.g., the Cartesian grid) as contextually useful tools. Specifically, students utilize these available forms to articulate their physical solution procedures, first multi-modally (verbally and gesturally) and then also symbolically (by utilizing numerical inscriptions). Initially, these articulations are naive and qualitative, but they progressively adhere to mathematical forms via situated ascension from the physical to the mathematical.

In sum, we view EI as bearing the capacity of supporting transformative teaching and learning. Specifically, EI enhances the implementation of visionary design frameworks, by which students should begin inquiry into complex mathematical concepts from presymbolic action-based quantitative reasoning (Forman, 1988; Thompson, 1993). More generally, we submit, EI activities constitute rewarding empirical contexts for research aiming to deepen and expand our field's understanding of how instructors discipline learners' perception of a shared domain of scrutiny (Stevens & Hall, 1998). Whereas our work is in its early stages and our conclusions tentative, we hope to have conveyed some enthusiasm over EI's unique instructional and theoretical affordances. Our future work will compare our results with non-EI interventions and continue to seek improvements in both theory and design, availing of recent hands-free EI development.

SPATIAL MATHEMATICS TEACHING AND LEARNING THROUGH IMPLEMENTATION OF A TECHNOLOGY-RICH, PROJECT-BASED UNIT WITH 21ST CENTURY EDUCATORS

Jennifer Wilhelm
University of Kentucky
jennifer.wilhelm@uky.edu

This study documented means by which STEM educators experienced the mathematics and science associated with understanding lunar phenomena. The paper reports how well STEM Education graduate students interacted with project-based materials as they engaged in transdisciplinary teaching and learning. A mixed-methods approach was used with this semester-long design study to expose how focused project work facilitated spatial understanding. Significant gains were made on lunar-related concepts that had been previously resistant to conceptual change. An implication of this study suggests that technologies, such as Stellarium and Geometer's Sketchpad, facilitated project progress and aided understanding on these particular domains including spatial mathematics.

This paper describes a project-based environment created in a graduate course designed for 21st Century STEM (science, technology, engineering, mathematics) educators. The modeled environment was designed with a project-based framework aimed to allow educators the opportunity to experience the Principles and Standards for School Mathematics (NCTM, 2000), the National Science Education Standards (NRC, 1996), and the National Educational Technology Standards (ISTE, 2008) in a transdisciplinary manner. Through project work, students formulated questions, engineered research methods, collected and analyzed data, and communicated their findings. Project investigations often situated mathematics in an astronomical context and employed the use of various technologies. Use of innovative technologies embedded within a STEM project-based environment provided opportunities for future 21st Century educators to realize and apply "outside of the box thinking to create solutions that will lead to results for students" (U.S. DOE, 2010, p. 13). Four groups of students were compared as they conducted project work that required the mathematization of the Earth, Moon and sky. Students' pre/post spatial mathematical understandings were also analyzed for change.

Theoretical Framework

Project-based instruction allows students to represent, model, and apply their content knowledge in novel ways. Necessary criteria for a project classroom include driving research questions (Krajcik & Blumenfeld, 2006), benchmark lessons and innovative technologies to scaffold understanding (Singer, Marx, & Krajcik, 2000), and milestones (Polman, 2000) to give students feedback and time for revisions. Project-based instruction that embraces these key features can provide opportunities for students to improve their understanding of both mathematical and scientific practices by problematizing various situations, placing a demand for knowledge, discovering new principles, refining preexisting understanding, and applying understanding in the pursuit of research questions (Edelson, Gordin, & Pea, 1999, p. 394).

Previous research (Wilhelm, 2009) on the effectiveness of a project-based lunar unit has shown middle level students and preservice teachers significantly improved their understanding on the mathematics related to *periodic patterns* (e.g. periodicity of lunar phases), *geometric* *spatial visualization* of a moving three-bodied system, and *cardinal direction* (e.g. documenting an object's vector direction from a given position). Significant improvement on understanding these topics is noteworthy since students have had historically difficult times comprehending the spatial mathematics needed to understand physical phenomena such as lunar phases and have often harbored numerous misconceptions (Baxter, 1989; Zeilik & Bisard, 2000). Although research studies on project effectiveness (Wilhelm, 2009) have shown that participating students' mathematical skills were significantly developed in areas of periodicity, cardinal direction, and geometric spatial visualization, some spatial concepts have been more difficult to teach and resistant to change. These concepts include spatially visualizing the Moon's motion; how Moon phase, sky location, and time of day are related; and how the change in Earthly location affects the observed lunar phase. The following research reports significant gains in understanding some of these spatial topics that have been resistant to change. Some implications of this design study suggest that technologies [such as *Stellarium* (2010), free planetarium software, and *Geometer's Sketchpad* (KCP, 2009), dynamic mathematics visualization software] played an important role toward engaging students and facilitating understanding.

Research Questions and Methods

Eleven students (from an eastern south-central university in the United States) participated in the graduate course, *Project-enhanced Environments in STEM Education*, which met for 16 weeks (2.5 hours/week). Of these eleven students (three male, eight female), two were practicing teachers – one kindergarten teacher and one secondary mathematics teacher. The rest were obtaining their Masters of Education Initial Certification degrees in the areas of math or science.

In this course, the Moon was used as a context for students to experience project work since it was inherently interdisciplinary and demanded integration of mathematics and science. Students were to consider the mathematics and science involved with understanding the Moon and its phases. Approximately 20% of class meetings (on average) involved a Moon related activity or discussion. Research questions pursued were: 1) *How will students' spatial mathematics and scientific understandings develop as they engage in a contextualized, technology-rich, project-based environment?* 2) *How will the students' group projects affect their understanding of lunar related concepts?*

	Scaffolding Benchmark Lessons and Project Work
1.	Moon observations (both nature and Stellarium) and journaling.
2.	Earth/Moon/Mars scaling lesson.
3.	Initial practice project investigation: Collecting data to debunk claims of skeptics who believe the lunar landings were a hoax.
4.	Investigation of what affects a crater's size.
5.	Exploration of craters across the Solar System.
6.	Two and Three-Dimensional Modeling of Earth/Moon/Sun geometry required for various lunar phases.
7.	Asynchronous Internet discussion groups with Australian preservice teachers.
8.	Formation of groups and generation of driving questions.
9.	Multiple sharing and feedback sessions of group project data collections and representations.

Table 1. Benchmark lessons and project work task sequence

This design study was a semester-long investigation of classroom interactions provoked by the use of carefully designed project tasks (Confrey, 2006). Throughout the term, the instructor (author) refined the design task sequence (see table 1) based on the students' progress and their need for scaffolding via benchmark lessons. During the enactment of benchmark lessons and project work, students had the opportunity to work cooperatively in small groups, communicate their project status on several occasions to the whole class, and revise their work based on peer and teacher feedback.

A mixed methods approach was used with this design study to expose how project work facilitated understanding. Students' lunar-related mathematical and scientific understandings were documented before, during, and after project implementation. The mixed methods approach was employed with both quantitative and qualitative data sources and data analysis methods. Multiple research methods used in tandem allowed for triangulation and strengthened the study in greater ways than could have been done with either the qualitative or quantitative research alone (Creswell & Clark, 2007). The quantitative data sources used to assess students' pre and post understandings were a Lunar Phases Concept Inventory (LPCI; Lindell & Olsen, 2002) and a Geometric Spatial Assessment (GSA; Wilhelm, Ganesh, Sherrod, & Ji, 2007). The LPCI is a 20-item multiple-choice instrument that assesses eight science domains with four embedded mathematics domains and the GSA is a 16-item multiple-choice survey that assesses the same four mathematics domains not posed in a lunar context (see table 2). Qualitative data sources included students' Moon journals, on-line discussions with Australians, and project artifacts.

LPCI Scientific Domains	GSA Mathematics Domains
A - Period of Moon's orbit around Earth **B** - Period of Moon's cycle of phases	**Periodic Patterns** (*occurring at regular intervals of time and/or space*)
C - Direction of the Moon's orbit around Earth **E** - Phase due to Sun/Earth/Moon positions **G** - Cause of lunar phases	**Geometric Spatial Visualization** (*visualizing the geometric spatial features of a given system as it appears in space above/below/within the system's plane)*
D - Moon Motion from Earthly Perspective **F** - Phase-location in sky-time of observation	**Cardinal Directions** (*documenting an object's vector direction in space as a function of time from a given position*)
H - Effect of lunar phase with change in Earthly location	**Spatial Projection** (*projecting one's self into a different location, confined to the surface of an object, and visualizing from that global perspective)*

Table 2. Concept Domains: LPCI science domains and corresponding GSA math domains

Students began their preliminary project work by exploring the question: *Why does the Moon's appearance always seem to change?* Over a five-week period, students sketched the Moon and sky, recorded the Moon's altitude and azimuth angles, and documented patterns. One of the first design changes occurred due to inclement weather. The instructor employed the use of free planetarium software, Stellarium, in order for students to continue observations without interruption. Another design modification (an addition of a mini-project) was implemented to scaffold struggling students towards understanding how to conduct project work. The mini-project concerned an investigation of "Moon Hoax" claims. After the lunar journaling, students participated in asynchronous Internet discussion groups in a *Blackboard* blog with Australian preservice teachers (five additional weeks). Each week, students discussed an assigned topic and compared and contrasted their observation patterns.

Engaging students in inquiry benchmark investigations, Moon journaling, and on-line discussions with Australians helped to direct their follow-up Moon project work and to assist them in the generation of their own driving questions. Table 3 displays the questions that emerged from the students' preliminary investigations of the Moon and sky. Four groups transpired with topics concerning a) an evaluation of star visibility and location throughout a lunar month; b) an exploration of cratering distribution rates on Earth's surface; c) a comparison of orbital paths of Earth's Moon and other planetary moons; and d) an investigation of seasonal day length from the perspective of observers in northern and southern hemispheres.

Groups	Driving Questions
Stargazers	*Are stars in the same location each night, or do they change position?*
Craters	*What factors determine the distribution of impact craters in Earth's hemispheres?*
Orbiters	*How is our moon's path similar to other moons'?*
Anglers	*In the Northern Hemisphere, why are the days shorter in the winter than in the summer?*

Table 3. Group Driving Research Questions

Data and Analysis

The students' Moon journals contained daily lunar sketches, date and time of observations, the Moon's azimuth/altitude angles, and questions that caused them to wonder as they performed their viewings. Early journal entries served as snapshots of participants' understandings prior to the commencement of their projects. For example, approximately one-third of the journals contained reference to "a shadow" covering the Moon revealing the Earth's shadow misconception as a cause for lunar phases. An example of a shadow reference is shown in figure 1. Although it appeared this student had a shadow misconception, she did correctly note an eastward movement of the Moon throughout the month; namely, she observed the orbital direction of the Moon which denoted a mathematical development of geometric spatial visualization understanding (i.e. visualizing the geometric spatial features of a 3-bodied system as it appears in space above/below/with the system's plane). Another student wrote correctly in her journal that "*I am thinking and learning about the moon. So, since tonight is a full moon, the sun, earth and moon are in that order, in other words, the moon is on opposite side of the earth as the sun.*" This entry is another evidence of a student's geometric spatial visualization ability.

On the LPCI pre-test, eight of the eleven students (73%) chose an "Earth's shadow" cause for the lunar phases while two students selected a "Sun's shadow" explanation. Only one student chose the correct response of the Moon's position relative to the Earth and Sun as the cause. By the time of the post-test, only two students stated a shadow explanation.

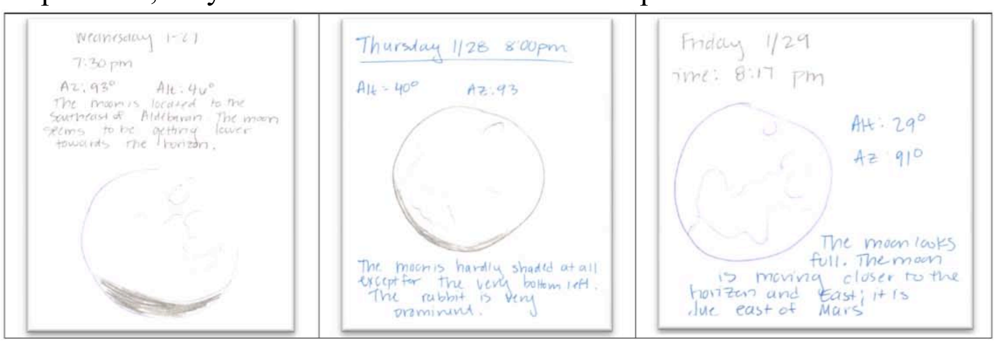

Figure 1. Student's moon observation journal entries with reference to a 'shadow' and a correct reference to the Moon's eastward movement throughout the month

In addition to the students' journals, they also participated in an Australian discussion blog where each group of students (U.S. and Australian) described patterns in their data as well as differences in their observations. For example, one student described how he noticed that when the U.S students witnessed a Moon lit on the left hand side, their Aussie counterparts observed a right hand lit lunar surface. This student attached the Stellarium screenshots (see figure 2) within his blog entry. Later, students made the realization that the reason for this was due to the fact that Australians were looking to the North to see the Moon while U.S. students were looking South.

Such a realization is evidence of a mathematical development in spatial projection understanding (visualizing from multiple global locations).

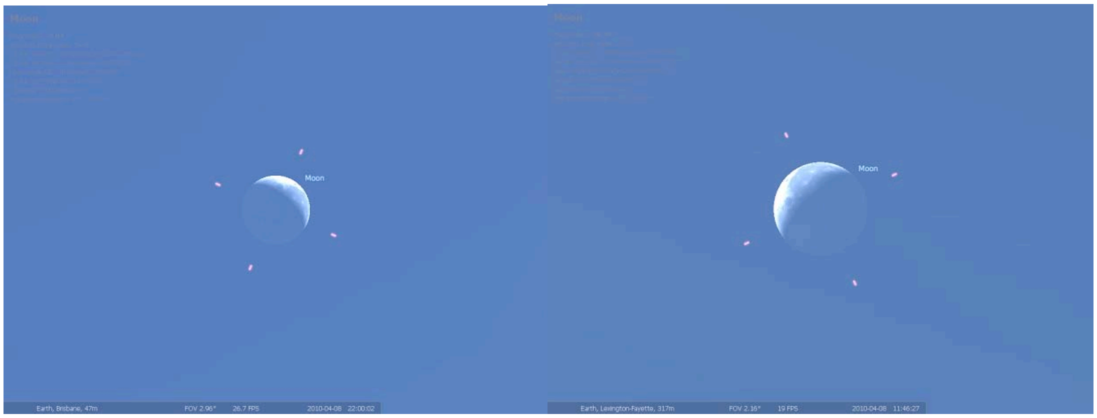

Figure 2. Stellarium screenshots from Brisbane, Australia and Kentucky, respectively.

The LPCI was given to the eleven students both pre and post project implementation. A repeated-measures ANOVA was conducted with overall test scores and by concept domain to test for significant change in mean scores. Overall LPCI results showed a mean pre-test score of 36.8% correct and a mean post-test score of 64.1%. A repeated-measures ANOVA revealed a significant increase in the mean values from pre to post-test, $F(1, 10) = 32.491$, $p<<0.001$, partial $\eta^2 = 0.765$. Final LPCI results (see table 4) showed students making significant gains on topics concerning period of Moon's phase cycle (Domain-B; Periodic Patterns Math Domain), direction of Moon's orbit (Domain-C; Geometric Spatial Visualization Math Domain), and the cause of lunar phases (Domain-G; Geometric Spatial Visualization Math Domain). Gains on these particular domains have been observed in prior studies; however, new significant gains were observed on Domain D – Moon Motion (Cardinal Direction Math Domain) and on Domain H – Effect of lunar phase with change in Earthly location (Spatial Projection Math Domain).

Table 4 also shows the LPCI results separated by gender to compare gender differences in concept domain development. Prior research showed significant gender differences on test performance (Wilhelm, 2009). Realizing that our n number is small, significant gender differences were difficult to observe; however, trends were noted. For example, male students made a 40% significant gain score on the overall LPCI where as the female students made a 22.5% significant gain score. No significant gains by individual science domains were observed for the males due to an n=3; but significant gains on domains D, G, and H were observed for the female students.

Group Project Comparisons

In order to assess whether group project work affected lunar-related conceptual understanding, a repeated-measures ANOVA was conducted with the factor being group and the dependent variables being the pre and post scores. A significant time*group interaction effect was observed, $F(1,3) = 7.528$, $p < 0.05$, partial $\eta^2 = 0.763$. Figure 3 displays the estimated marginal LPCI means by group. The two groups that achieved the greatest significant change from pre to post were the Orbiters and Craters. The gender breakdown of each group was as follows: Orbiters (one male, two females); Craters (two males, one female); Stargazers (two females); and Anglers (three females). It is interesting to note that the Orbiters and Craters groups contained the three males of the class.

Math Domain	Science Domain	All % Correct Pre (SD)	All % Correct Post (SD)	All % Gain	Male % Correct Pre (SD)	Male % Correct Post (SD)	Male % Gain	Female % Correct Pre (SD)	Female % Correct Post (SD)	Female % Gain
Overall	Overall	36.8 (11.5)	64.1 (12.6)	27.3***	36.7 (11.5)	76.7 (5.75)	40*	36.9 (12.3)	59.4 (11.2)	22.5**

Table 4. Percentage correct on pre and post Lunar Phases Concept Inventory by mathematical and scientific domain and gender group (*p < 0.05; **p < 0.01; ***p < 0.001)

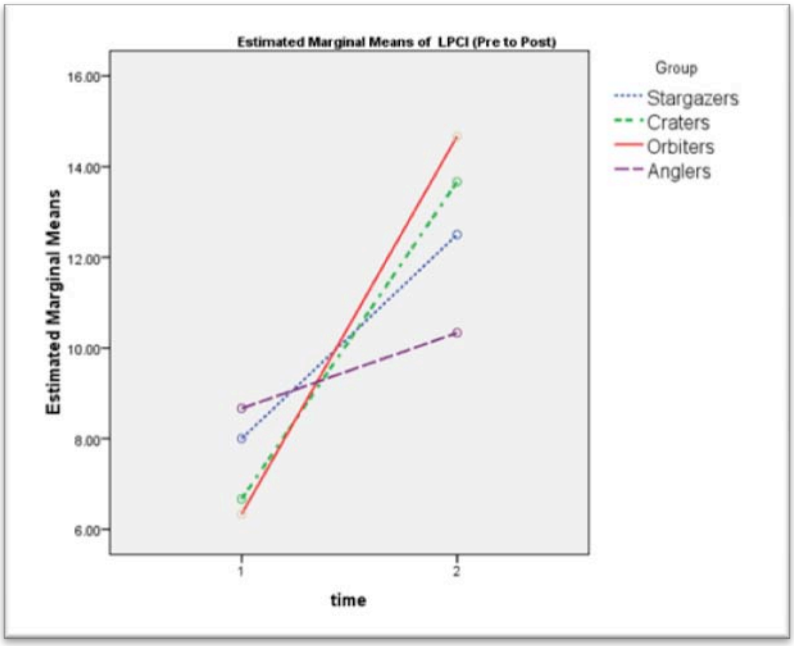

Figure 3. Estimated marginal group means of LPCI (pre to post) with a significant time*group interaction effect observed

Three of the four project groups made significant gains from pre to post on overall LPCI scores; however, due to small n, significant increases by domain were difficult to observe. Only the Orbiters had a significant gain in Domain-G (Cause of lunar phases). Embedded within this domain is geometric spatial visualization. The Orbiters had to pay special attention to the Earth/Moon/Sun geometry in order to model the lunar path for their project. The Orbiters utilized the software program *Geometer's Sketchpad* for their orbital modeling. Similarly, the Anglers achieved the greatest pre to post score increase (66.7%) in Domain H (effect of lunar phase with change in Earthly location; Spatial Projection); however, this increase was not statistically significant. The Anglers' project research involved examination of celestial observations from both the northern and southern hemisphere perspectives creating spatial projection experiences. Both cases are evidences of how students' project work affected their spatial understandings.

Like the LPCI, the GSA was given to the eleven students both pre and post project implementation. A repeated-measures ANOVA was conducted with overall test scores and by domain to test for significant change in mean scores. The only significant gain observed was with the cardinal direction domain. Cardinal direction (CD) results showed a mean pre-test score of 77.3% correct and a mean post-test score of 95.5%. A repeated-measures ANOVA revealed a significant increase in the mean values from pre to post on cardinal direction scores, $F(1, 10) = 26.667$, $p<<0.001$, partial $\eta^2 = 0.727$. Further analysis showed female students with an 18.8% significant gain score on the CD domain, $F(1, 7) = 21.00$, $p = 0.003$, partial $\eta^2 = 0.750$.

Conclusion and Importance

This study documented means by which 21st STEM educators experienced the spatial mathematics associated with understanding lunar phenomenon and how technology became a transdisciplinary partner in this project-rich environment. Stellarium was used to supplement lunar observations when weather issued problems. Lunar blogging with Australians caused students to wonder what others observed across the world—so much so, Anglers made this their project focus. Orbiters used Geometers' Sketchpad to model their lunar paths giving them the largest group LPCI gain score. Significant gains were observed on LPCI domains:

B, C, and G. Even more intriguing, were the significant gains made on LPCI domains D (Moon motion; Cardinal Direction) and H (effect of lunar phase with location change; Spatial Projection) which have been previously resistant to conceptual change. Domain D's corresponding mathematics domain, cardinal direction, also showed a significant gain with GSA results; however, no other GSA gains were observed. An implication of this design study suggests that the use of technology aided spatial understanding.

EMERGING FRAMEWORK FOR MATHEMATICS AND SCIENCE INTEGRATION

Olga M. Kosheleva
The University of Texas at El Paso
olgak@utep.edu

Laura F. Serpa
The University of Texas at El Paso
lfserpa@utep.edu

In this presentation we will explore the emerging framework for classification of types of mathematics and science integration focusing on cognitive level of mathematical task involved. Examples from several longitudinal Professional Development programs for in-service teachers will be used for exploring and investigation of the various integration levels.

The integration of disciplines of mathematics and science helps students develop a better understanding of the concepts and establish more connections between the subject areas. One of the benefits of such integration is that science can provide students with concrete examples of abstract mathematical ideas, and thus can provide relevance to math concepts and a motivation to learn. Mathematics, in turn, gives students a means for quantitative exploration and analysis of scientific processes.

In this presentation we will explore the emerging framework for classification of types of mathematics and science integration focusing on cognitive level of mathematical task involved. For example, the most popular type of integration occurs when a science investigation is conducted, and data is collected through some simple measurements, briefly discussed, and then displayed in tables or graphs. This type of integration is at the first level, since it only involves the simplest mathematical analysis, the procedural.

Integration at level two is when science investigation is conducted, and then mathematical exploration follows with a focus on understanding the mathematical concepts.

Integration at level three is when science investigation occurs, and then mathematical exploration follows with a focus on generalizations and deriving new kinds of mathematical relationships. We strongly believe that this classification of mathematics and science integration is necessary in order for curriculum to include higher order and critical thinking in both content areas.

Examples from a several longitudinal Professional Development programs for in-service teachers will be used for exploring and investigation of the various integration levels.

HUMOR IN MATHEMATICS – IS THERE SUCH A PHENOMENON?

Avikam Gazit
Kibbutzim College of Education/The Open University of Israel
avikam120@walla.com

Mathematics and humor are not perceived as being in line with each other. Mathematics is perceived as an esoteric and alienated body of knowledge without any humanistic elements. Humor constitutes one of the forms of human expression and it has numerous uses in society as well as in daily life. Mathematical contents studied at school mostly lack word messages which are frequently associated with humor as in most other subjects. The mathematician Littlewood wrote that a good mathematical joke is better and better mathematics than a dozen mediocre papers. In a subject like mathematics, considered one of the most difficult to comprehend, it is highly important to integrate humor. Humor serves as relieving tension, removing anxiety, improving self-image and motivating learning. The present paper aims to present the functions of humor in general and the possibility to integrate it in the teaching of mathematics in particular. The following example may serve as the first course. A math teacher is riding his bicycles. On the way he meets one of his students driving a deluxe Volvo. The teacher turns to the young man, who he recalled as the student with the lowest grades in class, and asks him: "How did you become so successful with your attainments in mathematics?" The young man replies: "I owe it all to you, my teacher. I buy pens for $2.00; sell them for $4.00 earning only 10%..." More mathematical jokes examples will be included.

TEACHER KNOWLEDGE OF STUDENTS AND ENACTMENT OF MOTIVATIONAL STRATEGIES IN TEACHING THE CONCEPT OF FUNCTION

Giang-Nguyen Nguyen
University of West Florida
giangnguyen.n@gmail.com

Kathleen M. Clark
Florida State University
kclark@fsu.edu

This research linked educational psychology and mathematics education to investigate how a teacher ("Mr. Algebra") used his knowledge of students in designing and implementing mathematical tasks related to piecewise functions and composition of functions. The study revealed that Mr. Algebra faced many challenges in the implementation of mathematical tasks because students had not mastered early algebra concepts. Additionally, students carried with them incomplete formal learning about domain and range, function evaluation, and constant functions, which made learning piecewise functions and composition of functions more difficult. The study employed various frameworks of mathematical tasks, Self-Determination Theory, and Keller's (2010) ARCS Model.

This research linked educational psychology and mathematics education to investigate how a teacher ("Mr. Algebra") used his knowledge of students to design and implement mathematical tasks related to piecewise function and composition of functions. To guide the study, we applied several theoretical frameworks of teacher knowledge (Ernest, 1989), mathematical tasks (Stein, Grover, & Henningsen, 1996), Self-Determination Theory (Ryan & Deci, 2000), and the ARCS Model (Keller, 2010).

Our study revealed many students in Mr. Algebra's course had lost confidence, but he had the power to restore that confidence with his flexible teaching strategies and making the course materials relevant to their lives. However, he faced many challenges in the task implementation because students had not mastered previous course content. Their understanding of function was limited in terms of their abilities to (1) identify pre-images and images; (2) transfer from one representation to another; or (3) identify functions satisfying some given constraints. Students' limited understanding contributed to their incomplete formal learning when working with function concepts. Hence, recognizing the origins of misunderstanding (incomplete formal learning) is necessary to improve the teaching of algebra (Kieran, 2007).

The study also called for a deeper understanding of students from motivational perspectives. As McLeod (1992) suggested, "research in mathematics education can be strengthened if researchers will integrate affective issues into studies of cognition and instruction" (p. 575). In other words, increased attention to motivational variables can play a vital role in improving mathematics teaching and learning. Therefore, the analysis of students' understanding of function concept discussed in our study contributes to the literature on how to engage students in mathematics learning related to function concepts.

INTERPRETING ZONE OF PROXIMAL DEVELOPMENT THROUGH THE ONTOLOGICAL QUADRIVIUM

Definition: *Zone of Proximal Development* (ZDP) "is the distance between the actual developmental level as determined by the independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers" (Vygotsky, 1978, p. 86). Traditionally, it is interpreted as (a) the difference between what a learner can do without help and what the learner can do with help, or (b) the range of abilities that a person can perform with assistance, but cannot perform independently.

Proposition: ZDP can be interpreted through *metric*. There are many issues on Russian/English translations involving Vygotsky's works (Wertsch, 1985), including those on ZDP (Junior, 2010). If distance is an appropriate word to define ZDP, then it is possible to interpret it through topology and metric spaces (Lewin, 1936). Thus, it is convenient for educational psychologists (or any individual interested in developmental psychology) to investigate mathematical problems as such as "the taxicab problem or taxicab geometry." Let $M \neq \varnothing$. $d: M \times M \rightarrow R_+$ is a metric in M if: (1) $d(x, y) = 0 \leftrightarrow x = y$, (2) $d(x, y) = d(y, x)$, $\forall$ x, y $\in$ M and (3) $d(x, z) \leq d(x, y) + d(y, z)$, $\forall$ x, y, z $\in$ M. What are the representations of circles when $d(x, y) = \sqrt{|x_2 - x_1|^2 + |y_2 - y_1|^2}$ and when $d(x, y) = |x_2 - x_1| + |y_2 - y_1|$?

Theorem: ZDP can be interpreted through the *ontological quadrivium* (Levy, 1998). ZDP is defined under the traditional Aristotle's notion of metaphysics, where the dialectical relation between actual/potential defines reality. However, regarding Deleuzian perspectives (Deleuze, 1994; Deleuze & Guattari, 1994; Deleuze & Parnet, 2002), Levy (1998) highlights four states of being. They are: real-possible and actual-virtual. Levy (1998) uses the expression *ontological quadrivium* to discuss the notion of *becoming virtual* as the nature of collective intelligence. Thus, ZDP can be interpreted as *a path connected by humans-technologies through virtual, actual, real, and possible levels of development*.

Corollary: Mathematical learning can be understood through this alternative notion of ZDP.

BASE-x: BRIDGING THE COGNITIVE GAP BETWEEN ARITHMETIC AND ALGEBRA

Lance Burger
California State University, Fresno
lburger@csufresno.edu

A teaching intervention study demonstrates the effective bridging of arithmetic to algebra through the linear algebra concept of 'basis.' After a unit on base-5 emphasizing the isomorphic structural relationships between number bases, students learn to work in 'base-x,' applying their ordinary notions of arithmetic to compute algebraic arithmetic 'basis-free,' without variables. Students exposed to base-x performed significantly better at computing algebraic arithmetic than a non-treatment control group; and moreover, base-x students demonstrated significant retention of knowledge, as compared to control, upon taking a post-post test one month later.

Several studies on algebra pedagogy indicate that the variable concept presents significant challenges for many beginning algebra students. Herscovics and Linchevski (1994) describe difficulties with the variable concept as a 'cognitive gap' between arithmetic and algebra, defined as an 'inability for students to operate spontaneously with or on the unknown (p.59).' While much of previous research highlights the 'differences' between arithmetic and algebraic thinking, this poster describes a teaching intervention focusing on key structural similarities using the concept of isomorphism to link algebraic formalism to familiar arithmetic. After generalization of the number base concept by exploring base 5 and other bases, the instructor introduces a generalized 'base-x.' Base-x teaches students to perform subtraction, multiplication, and division by first converting polynomials to base-x 'numbers,' perform the familiar typical algorithms, and then convert back from base-x numbers to their algebraic representations, as seen in the following example of polynomial multiplication (see Fig.1).

x^5	x^4	x^3	x^2	x^1	$x^0 = 1$
			1	-11	13
		×	1	0	-1
			-1	11	-13
		0	0	0	
+	1	-11	13		
	1	-11	12	11	-13

Figure 1. $(x^2 - 1) \cdot (x^2 - 11x + 13) = x^4 - 11x^3 + 12x^2 + 11x - 13$ **in base-x.**

The significant results of the study support the hypothesis that isomorphic understanding relating arithmetic and algebra enhances transfer of inert arithmetic ability to polynomial arithmetic. The results appear particularly interesting due to the apparent retention demonstrated by the treatment group, which the author believes to be evidence of the possible anchoring of new isomorphic algebraic thinking to the students' stable well-known knowledge of arithmetic.

EXAMINING STUDENTS' UNDERSTANDINGS OF CHANGE IN AN ALGEBRA CLASS

Anna Fricano
University of Illinois Urbana Champaign
fricano1@illinois.edu

Gloriana González
University of Illinois Urbana Champaign

The Algebra Standard (NCTM 2000) emphasizes that one of the essential elements in the teaching and learning of Algebra is the analysis of change (p. 36). However, many students still struggle with developing an understanding of rates of change (Bell & Janvier 1981; McDermott et al. 1987). This poster contributes to work that has been done to describe how students develop an understanding of rates and speed (e.g. Thompson 1994; Thompson & Thompson 1994, 1996). We present an analysis of students' work on a problem where they made use of the concept of change to study piecewise linear functions. We draw upon Sfard's (1991) work describing two different ways in which mathematical concepts can be conceived of: *structurally*—as objects, or *operationally*—as procedures. We argue that students' work on the problem provides evidence that they were able to move beyond an operational knowledge of change, to a structural knowledge.

We looked for evidence in students' work of a three-phase transition from an operational conception to a structural conception of speed: interiorization, condensation, and reification (Sfard 1991, p. 18). Interiorization is when the learner becomes acquainted with the processes that give rise to the concept of speed; for example the learner can compute the difference between starting and ending points, starting and ending times, and the quotient of the two. Condensation is when the learner is able to think of the process as a whole, without needing to consider separately every step in the procedure. Reification is the point when the idea of speed becomes a static object, for example a property of a graph.

We analyzed 44 students' written work on the problem. We found that 32 students showed evidence of interiorization, 27 students showed evidence of condensation, and 20 students showed evidence of reification. We discuss possible elements in the design of the task that could have supported students' transition through these phases. For example, the lesson provided students with a piecewise linear graph to analyze; and students used this graph as an opportunity to consider how speed is related to a graph. An examination of students' understanding of change is helpful for practitioners because teachers can become aware of the resources that students may deploy when learning this mathematical concept.

HOW TEXTBOOKS INFLUENCE STUDENTS' ALGEBRA LEARNING: A COMPARATIVE STUDY ON THE INITIAL TREATMENT OF THE CONCEPT OF FUNCTION

Qintong Hu
The University of Tennessee
qhu@utk.edu

Ji-Won Son
The University of Tennessee
sonjiwon@utk.edu

To illustrate cross national differences in schooling, this study analyzed content and problems in three curricula: a U.S. conventional text, a U.S. standards-based text, and a Chinese reform oriented text on the topic of the initial treatment of the concept of function. Analysis results revealed that content presentation in the Chinese text is aligned with that in the U.S. conventional text; they are designed for teacher-centered instruction. Problems in the Chinese text are aligned with those in the U.S. standards-based text, aiming at cultivating students' critical abilities.

To give insights into cross national differences in schooling this study analyzed the initial treatment of the concept of function in three curricula: a U.S. standards-based text--*Connected Mathematic 2: Variables and Patterns*, a U.S. conventional text--*Glencoe: Mathematics Applications and Concepts: Course 2*, and a Chinese reformed text--*Shu Xue: Grade 8, first volume*. The concept of function is the fundamental concept of algebra. NCTM (2000) stressed that the concept of function should be placed as one of the cornerstones of middle and high school mathematics curricula. However, the results from the international assessment studies showed that U.S. students fall behind their counterparts from high-achieving countries on this topic. Although various factors influence student learning, many researchers generally agree that textbooks, as potentially implemented curricula, have a large influence on learning and teaching (e.g., Son & Senk, 2010). This study may raise hypotheses about factors affecting achievement of students in the U.S. and China, and reveal insights into improving mathematics education practice in those countries.

This study analyzed the corresponding content and problems in three textbooks. For content analysis, we explored how the concept of function was introduced, defined, and developed. Problems were then analyzed extensively with respect to three criteria: (1) contextual feature, (2) response expectation, and (3) cognitive expectation to investigate the kind and level of learning opportunities provided by different textbooks.

Analysis results showed that *Connected Mathematics* is designed for student-centered instruction while Glencoe and the Chinese text are more teacher-centered. However, in terms of problems, *Glencoe* presented mostly procedure-based examples and problems without illustrative contexts. Chinese reform-oriented textbook and *Connected Mathematics* aimed at cultivating students' critical mathematical abilities, such as mathematical reasoning and problem solving. Different from the U.S. texts, the Chinese text provided enough explanations and illuminations to facilitate students' understanding; rather than just presenting worked-out examples, it also provided explanations of why and how.

AN INTIAL LOOK AT COLLEGE INSTRUCTORS' CONCEPTUALIZATIONS OF SLOPE

Courtney Nagle
Pennsylvania State University, The Behrend College
crt12@psu.edu

Deborah Moore-Russo
University at Buffalo, State University of New York
dam29@buffalo.edu

This study provides an initial investigation into college instructors' conceptualizations of slope. Data were collected from 26 instructors of 11 two- and 3 four-year colleges. Participation was optional, and each participant had 15 minutes to complete five items. Working independently the members of the research team coded each response using the 11 conceptualizations of slope identified by Moore-Russo and colleagues (Moore-Russo, Conner, & Rugg, 2011; Stanton & Moore-Russo, in press) and adapted from the work of Stump (1999, 2001a, 2001b). After discussing findings and reaching a consensus on each response, the researchers reviewed the frequency of use for each conceptualization.

The number of conceptualizations used by a single instructor on the five items varied from three to nine, with a majority of instructors using five, six, or seven conceptualizations. While all 11 conceptualizations were used by the instructors, some conceptualizations occurred more frequently than others. Based on responses across all five items, *functional property* was the most common conceptualization of slope, followed in order by *calculus conception*, *geometric ratio*, and *real world situation*. However, the researchers recognized that some of the assessment items might elicit particular conceptualizations while limiting others. Thus, further analysis was done to determine the number of instructors who used each conceptualization at least one time on the five-item assessment. Based on this analysis, *geometric ratio* was the most common conceptualization, followed by *functional property* and *real world situation* (tied) and *calculus conception*. Stump (1999) similarly reported that *geometric ratio* was the most common conceptualization of slope used by secondary teachers.

While nearly 85% of the instructors used the *geometric ratio* conceptualization at least one time, *functional property* and *calculus conception* were more robust conceptualizations in terms of being used on multiple items. The strong presence of these two conceptualizations among college instructors provides some evidence that teachers' dominant conceptualizations of slope may be linked to the emphasis of the content they teach. Additional research is required to fully understand college instructors' conceptualizations of slope and how their conceptualizations compare with those of college students.

COGNITIVE AMBLYOPIA

Aaron M. Schmidlin
The Ohio State University
Schmidlin.5@OSU.edu

The purpose of this work is to identify the transformative effects that traditional teaching can have on student cognition and learning, and to posit a new theoretical framework to connect research about basic neurological development and function to phenomena associated with mathematics learning.

This framework identifies basic functions of the brain that produce certain natural phenomena that may be observed both at a cellular level and at, what this author will term, the "conscious/subconscious" level. The conscious/subconscious level is the area of conscious functioning under study that is impacted by subconscious mechanisms independent of conscious will. Further, this author proposes a name, cognitive amblyopia, and a justification for the existence of these phenomena.

Amblyopia is a partial or complete loss of eyesight that is not caused by abnormalities in the eye (Hubel, 1988). *Cognitive amblyopia* is the partial or complete loss of the ability to see and understand concepts that is not caused by abnormalities in the brain. One aspect of this phenomenon may be explicated by discussion of the research underlying the development of the theory of cognitive amblyopia.

While attempting to induce visual amblyopia during a neurobiological research project it was found that mechanically inducing discordant visual input between the mammalian subjects' eyes resulted in damage to the subjects' still plastic eye brain connections. Specifically connections between the eyes and the brain that served both eyes developed into connections that were dominated by the connections' dominant eye (Hubel, 1988). In short the non dominant eye brain connection was effectively lost. This loss of vision indicates that the brain rejects confusing input at the most fundamental level.

Research conducted by Dr. Jerome Bruner and Leo Postman provides an extension of this phenomenon into the conscious/subconscious level. In their research, they identified what they termed a "dominance" reaction and an extended denial of incongruous stimuli in adult humans who were asked to identify flash cards (Bruner & Postman, 1949). This subconscious denial of comprehension was the result of a dominant anticipation and represented a mild and easily reversible cognitive amblyopia.

The theoretical framework surrounding the phenomenon of *cognitive amblyopia* proffers that the brain naturally rejects contradictory and confusing information at a conscious/subconscious and cellular level. Additionally, it asserts that extended exposure to confusing or contradictory input will cause structural changes to plastic regions of the brain.

Some student thinking is subject to change and is plastic by nature. Therefore, ineffective methods of teaching mathematics including covering material, inducing potentially irresolvable perturbations and presenting material, without respect for student thinking, in a contradictory or confusing manner may not just fail to foster learning but may also engender a *cognitive amblyopia* and damage students' future ability to see meaning in mathematics.

A great majority of children in Canada and the United States from Grades 2-6 fail to solve equivalence problems (e.g., 2 + 4 + 5 = 3 + __) despite having the requisite addition and subtraction skills. The goal of the present study was to determine the relative influence various instructional variables in improving performance. Instructions emphasizing procedural and conceptual understanding both were very effective in improving problem solving, but conceptual instruction was superior in facilitating performance on other measures to understanding equivalence. Manipulatives had no effect. These findings provide insights into optimizing children's understanding of equivalence.

A great majority of children in Canada and the United States from Grades 2-6 fail to solve equivalence problems (e.g., 2 + 4 + 5 = 3 + __) despite having the requisite addition and subtraction skills (e.g., Falkner, Levi, & Carpenter, 1999; Hattikudur & Alibali, 2010; McNeil and Alibali, 2005b). The goal of the present study was to determine the relative influence of two variables, instructional focus (procedural or conceptual) and use of manipulatives (with or without), in helping children learn to solve equivalence problems and develop an appropriate understanding of the equal sign. Instruction was provided in four conditions consisting of the combination of these two variables.

Students in Grade 2 (n = 122) and Grade 4 (n = 151) participated in four sessions designed to assess the effectiveness of four instructional methods for learning and retention. Session 1 included a pretest of equivalence problem solving and three indicators of understanding of the equal sign. In Sessions 2 and 3 instruction was provided in one of the four instructional conditions or a control condition. Students were tested for their skill at solving equivalence problems immediately following instruction and at the beginning of Session 3 to assess what they had retained from Session 2. In Session 4, one month later, children were re-tested on all of the tasks presented in Session 1 to assess whether instruction had a lasting effect.

All four instructional groups greatly outperformed the control group in solving equivalence problems, but differences among instructional groups were minimal. Performance on indicators of understanding, however, favoured students who received conceptually focused instruction. Preliminary evidence was found that children's understanding of problem structure and attentional skill may be associated with the ability to benefit from instruction on equivalence problems. Children clustered into four groups based on their performance across tasks that are consistent with the view that children's understanding of the equal sign develops gradually, beginning with learning the definition.

These findings suggest that a relatively simple intervention can markedly improve student performance in the area of mathematical equivalence, and that these improvements can be maintained over a period of time and show some limited generality to other indicators that children understand equivalence.

THE ROLE OF QUANTITATIVE REASONING IN DEVELOPING MEANINGFUL FORMULAS

Eric D. Weber
Arizona State University
ericweber@asu.edu

Marilyn P. Carlson
Arizona State University
marilyn.carlson@asu.edu

Overview

In this poster, we describe an investigation of precalculus students' behaviors as they attempted to make sense of novel word problems. For this report we focus on the processes by which students developed meaningful formulas to relate the relevant quantities in applied problems. The study revealed that formulas are only meaningful to students if they have first conceptualized the quantities and how they are related, and see the development of expressions and formulas as a means for representing how the quantities are related and change together.

Research Questions

Our primary research focus was to understand the role of quantitative and covariational reasoning in a student's ability to make sense of novel word problems. We identified two research goals.

1) Describe the ways of thinking about solving novel mathematics problems students have prior to receiving instruction in a redesigned precalculus course.
2) Describe, explain and theorize about the role construction of quantity and covariation of quantity play in students' orienting to novel applied precalculus problems.

Results

A few major aspects of orienting to novel problems emerged in these analyses: (1) constructing an image of the situation by relating the attributes (quantities) of the box and bottle problems and (2) imagining those attributes simultaneously changing (variable quantities) and (3) modeling these dynamic situations with functions defined algebraically and graphically. We propose that students' make sense of complex, novel problems by creating diagrams of the measurable attributes of the situation, and these diagrams become useful to the student as a tool for thinking about how quantities vary and how they are related. We believe that the students' creation of these diagrams depicting relationships between the measurable attributes of a situation provided the students an image with which they could reason about a solution to the problem. We think that students' images of quantities and their relationships, and covariation of those measurable attributes allow a student to predict and explain patterns in the formulas that represent the relationships between those attributes by generating a specific algebraic function.

Learning progressions hold promise as a basis for formative assessment. We describe the first phase of a four year project intended to develop and pilot two forms of formative assessment based upon mathematical learning progressions for equations and expressions, linear functions, and proportional reasoning.

This poster describes the first phase of a four year project focused on improving teaching and learning in the classroom by creating and evaluating a set of formative assessments that are built around developmental models of student learning. The models guide the assessment design and provide support for teachers in understanding the terrain of student learning. The assessments focus on four core algebraic constructs — equality, notion of a variable, proportional reasoning, and linear functions— and build on what the project team has learned in the context of other research projects regarding developmental models (reference removed). The evaluation plan addresses the technical quality of the assessments, with a multi-faceted approach to collecting validity evidence.

The poster will focus our approach in the project to characterizing patterns of learning in middle school students, called learning networks (LNs), Recently, learning progressions (LPs) (Heritage, 2009) have gained popularity among researchers as a way of describing increasingly sophisticated ways that students understand and use concepts. LPs typically take the form of a linear sequence of levels with respect to one concept. Characterizing students with respect to a learning progression then means collecting evidence of their mathematical behavior to make an inference to categorize them as being at a particular level. But the learning of one concept may be connected to the learning of other concepts. Lesh, Lamon, Gong, and Post (1993) explored this notion of connectivity within the idea of Learning Progress Maps (LPMs), which provide a view of the achievement of students with respect to “big ideas” within a curriculum. LPMs provide information about students’ depth of understanding of each idea and the connections between the ideas.

In our work, we use research-based LPs as a starting point to develop a learning network (LN) that describes likely pathways students can take as they learn multiple concepts in mathematics. In assessment, the LN becomes a predictive model of the likely states of understanding and pathways through these states. This approach can then draw upon the relative simplicity of assessing students with respect to individual LPs while reporting on and supporting learning of multiple concepts and the connections among them as in LPMs.

HIGH SCHOOL TEACHERS' DISCOURSE-BASED FORMATIVE ASSESSMENT PRACTICES IN MATH INSTRUCTION

Michele D. Crockett
University of Illinois at Urbana-Champaign
mcrocket@illinois.edu

Takayuki Namikawa
University of Illinois at Urbana-Champaign
tnamika2@illinois.edu

Chang-Hua Chen
University of Illinois at Urbana-Champaign
cchen72@illinois.edu

The effective use of formative assessment methods during instruction improves students' learning, particularly low-performing students' achievement (Black & Wiliam, 1998). Though the achievement gap is a national concern embodied in the US's No Child Left Behind Act, researchers note that many teachers are not engaged in such practice. The current situation prompted three broad questions: First, do teachers believe they are engaged in formative assessment practices as they teach? Second, could we develop a tool to document formative assessment practice? Last, if so, are teachers' beliefs about their assessment practices similar or different from our classroom observations? Thus, the purpose of this illuminative study was (a) to develop an analytic framework that captured teachers' instructionally-embedded formative assessment practices (discourse-based assessment practice or DAP), (b) to identify the nature of teachers' questions and forms of feedback in extended exchanges with their students and (c) to discuss teachers' interpretations of their own practices and to consider them in light of what we observed.

In this study, we take DAP to be teachers' provision of questions and feedback prompted by their students' thinking manifested in classroom discourse as they make moment-by moment instructional decisions. Literatures on questioning, feedback and classroom discourse inform the analysis (Cazden & Beck, 2003). We borrow the construct "extended sequence" from Mehan's (1979) ethnomethodological approach for structuring classroom lessons, which is the primary unit of analysis. The extended sequence conmprises teachers' extended exchanges with students, providing an opportunity to examine the nature of these exchanges in terms of their questions and feedback, which constitute formative assessment practices as teachers deliver instruction.

The preliminary examination of 17 lesson videotapes and teacher interview transcripts suggests that (a) the analytic framework, though parsimonious, can differentiate teachers' formative assessment practices in terms of questions and feedback and (b) that some aspects of teachers' beliefs about their practices were in alignment with what we observed. If formative assessment is critical for productive teaching and learning, then intensive professional development is needed to bring beliefs and practices in line.

JOURNAL WRITING IN COLLEGE MATHEMATICS

Alexis Johnston
Virginia Tech
alexis05@vt.edu

The effect of journal writing on achievement in and attitudes toward mathematics has been generally inconclusive (Jurdak & Zein, 1998). Results differ based on the age of the students and the type of journal writing employed. However, at the college level, results indicate that there are strong relationships between journal writing and conceptual understanding (Grossman, Smith, & Miller, 1993).

By writing in journals, students make use of writing as a learning tool in the context of mathematics; by reading students' journals, teachers gain insight into their students' understanding in unique and valuable ways (Borasi & Rose, 1989). Furthermore, by responding to students' journals, teachers open up lines of communication with students that traditionally are not open. This in-progress study seeks to explore the benefits of journal writing. Particularly, three different types of benefits: benefits for students, benefits for teachers, and benefits for communication between students and teachers.

College students enrolled in beginning calculus classes will write homework journals throughout the semester. Each homework journal will be a two-column homework assignment based on a mathematical problem of each student's choosing from the course textbook (Powell & Ramnauth, 1992). The left-hand column is the mathematical problem worked out in detail. The right-hand column is a written reflection of the problem. The written reflection is guided by a number of different prompts. For example, "What connections do you see between this problem and other topics from this course or other mathematics courses?" The teacher responds to what each student writes by posing additional problems, challenging thinking, and drawing out conclusions. Students then have the opportunity to respond to the teacher's comments, continuing the communication.

At the end of the semester, students will be asked to give an evaluation of homework journals by responding to open-ended questions. Therefore, data will be collected in these two ways: homework journals collected throughout the semester as well as end of the semester evaluations.

Analysis of the data will hopefully provide rich descriptions of the journal writing experience and the benefits of the journal writing experience. The results of this study could be useful to college mathematics instructors. Possible implications of this study are for the teaching and learning of college mathematics, especially when it comes to communication between instructors and students.

USING NEURAL-NETWORKS TO PREDICT AP-CALCULUS TEST SCORES FROM PCA AND ACT MATHEMATICS TEST SCORES

Rusen Meylani
Arizona State University
rusen.meylani@asu.edu

Dawn Teuscher
Brigham Young University
dawn.teuscher@asu.edu

Neural-Networks are a powerful alternative to regression especially for prediction and forecasting but not widely used in educational research. This study explores how AP-Calculus AB and BC scores can be predicted from the Precalculus Concept Assessment (PCA) and American College Testing (ACT) mathematics scores employing two commonly used Neural-Networks models of MLP (Multilayer Perceptron) and RBF (Radial Basis Function). Strong positive correlations between the actual and predicted values of the AP-Calculus exam scores confirm that Neural Networks are an efficient toolset for prediction. This can help identify the students who are at the risk of not passing the AP-Calculus exams and help students, parents and teachers take remedial measures in a timely manner.

Neural-Networks are a powerful alternative to linear and nonlinear regression especially for predicting and forecasting but not widely used in the field of education. A neural-network is an interconnected group of artificial neurons, processing information through a series of connections as a means of computing. The modern neural networks are used for non-linear modeling of statistical data revealing the complex nonlinear relationships between the inputs and outputs better than nonlinear regression methods for discovering the patterns in the data.

On the other hand, the PCA was developed by faculty from the Department of Mathematics at Arizona State University and was designed to reflect core content and common misconceptions students have about functions (Carlson et al., 2010). Carlson et al. (2010) administered the PCA to 902 college precalculus students and found the "Cronbach's alpha of 0.73 indicating a high degree of overall coherence" (p. 137).

Overall, this study demonstrates how AP Calculus AB and BC scores can be predicted from the Precalculus Concept Assessment (PCA) results (Carlson et.al. 2010) and ACT mathematics test scores (ACT, 2011) employing two commonly used Neural-Networks models: the MLP and the RBF Models (Kutner et.al. 2005). The simulation revealed Pearson correlation values, between the actual and predicted values of the AP Calculus AB and BC, in the range of 0.50 to 0.95 and statistically significant at the 0.01 level. This confirms that Neural Networks are an efficient toolset in predicting students' AP Calculus AB or BC scores from the PCA and the ACT mathematics scores which can help identify the students at the risk of not passing the AP Calculus AB or BC exams and help students, parents and teachers take the necessary measures in a timely manner.

TECHNOLOGY TOOLS IN HIGH SCHOOL MATHEMATICS: PROMOTION, PERCEPTIONS AND USE

Allison W. McCulloch
North Carolina State University
allison_mcculloch@ncsu.edu

Karen A. Keene
North Carolina State University
Karen_allen_keene@ncsu.edu

This poster is a preliminary report for a research project that aims to build an understanding of the complexity of teachers' technology tool promotion in classrooms as it relates to students' adoption of such tools in their independent mathematical work. The project focuses not only on the mathematical aspects of technology tool promotion and use, but the affective aspects as well. We examine how these aspects impact the *how* and *why* of students' choices to use technology tools when working independently. Given the expectation that today's students must use technology tools to engage in mathematical problem solving (CCSSI, 2010; NCTM, 2000) both in and outside of the classroom (i.e. on homework, teacher created and standardized assessments, the application of mathematical concepts to other contexts) this is an important sequence of events to understand.

This investigation is a mixed method multi-case study of six high school mathematics classes. We are investigating six classes, two classes each from three high school teachers who work in three types of schools (rural, suburban, and urban). Teachers that regularly use technology tools and who teach at least one section of algebra I and one of algebra II, pre-calculus or calculus were invited to participate. Since the purpose is to gain insight from all members of the classroom community about how technology use is being promoted by the teacher and actually used by the students, data will be collected from both the teacher and the students before, during, and after designated units of study. Data will include video recording of two instructional units for each class, teacher interviews, student surveys, student task-based journal artifacts, post assessment questionnaires and focus students' interviews. The quantitative data will be analyzed using descriptive statistics. Qualitative data will be analyzed using rubrics developed based on an adaptation of Pierce and Stacey's (2004) framework for aspects of effective technology use. Ultimately this study will develop an empirically refined set of conjectures about teacher-related factors that impact students' independent technology use when doing mathematics.

The study will be in its early stages at the time of PME-NA 2011 and we will use the poster session to report preliminary results and to engage in critical conversations about the project design with fellow researchers.

THE COLLABORATIVE NATURE OF GROUP DISCUSSIONS AND THEIR ROLE IN MATHEMATICAL REASONING

Nancy Payne
University of North Carolina at Greensboro
ntpayne@uncg.edu

Sarah B. Berenson
University of North Carolina at Greensboro

The purpose of this study was to investigate the nature of group collaboration as student's reasoned about a pattern task. The fifth grade participants attended a science, mathematics and technology magnet school. The participants were asked to complete a series of three isomorphic pattern finding tasks using pattern block squares, triangles, and hexagons to generalize a rule. During the teaching experiment students were encouraged to collaborate with their partners to find patterns and write either recursive or explicit rules. Once the participants had generalized their rules a whole class discussion was held so that participants could share their ideas and justify their reasoning to the entire group.

Mueller, Maher and Yankelewitz (2009) developed a framework for analyzing the ways that collaboration influences the construction of mathematical arguments and its promotion of mathematical understanding. We used this framework to answer the research questions: What types of collaboration emerged during the teaching experiment and which types influenced the reasoning of the group? This framework, which is composed of three modes of student collaboration, includes: *co-construction, integration and modification.* With the *co-construction* mode of collaboration, students build their argument in a negotiary or back and forth type of dialogue. *Integration* occurs when another student strengthens another student's ideas. Finally, *modification* occurs when one student finds another student's argument faulty or unclear and attempts to help that student make sense of the argument.

This study focused on one pair of students, Jennifer and Felix, as they reasoned about the tasks. It is important to note that the students typically did not work in collaborative pairs. During day one of the teaching experiment, the pair did not collaborate at all. Each worked on the task separately and only Jennifer was able to find both a recursive and explicit rule for the task. On day two, the pair began to collaborate with each other; however, their collaborative effort switched back and forth between modification and integration in an argumentative manner. Felix found a rule for the triangle tables, but Jennifer did not agree. Her participation consisted of trying to understand his argument and pointing out his mistakes. During day two the pairs' collaborative effort did not progress to an explicit rule. On day three, as the pair worked on a rule for hexagon tables, their collaborative effort took the form of co-construction, with each student contributing to the effort. The final results of day three were that the pair found both a recursive and explicit rule for hexagon tables.

Over the three day experiment the collaborative efforts of these students progressed from no-collaboration, collaboration based on defending one's strategy to productive collaboration on the final day. During day one only one student was able to find an explicit rule, during day two neither was able to find any rule and on day three both found an explicit rule.

SUPPORTING ELEMENTARY MATHEMATICS TEACHERS IN FACILITATING CLASSROOM COMMUNICATION THROUGH THE USE OF CURRICULUM MATERIALS

Nancy Tseng
University of Maryland
ntseng@umd.edu

Recent reforms in math education have outlined particular processes students should use to develop meaningful mathematical understandings (NCTM, 2000). Extant literature indicates that teachers' responses to student mathematical thinking shapes the ways in which students communicate about their thinking and can influence levels of mathematical understanding (Franke, Webb, Chan, Ing, Freund & Battey, 2009). The purpose of this study is to examine how curricula provide teachers with pedagogical support as they build and promote students' capacities in communicating mathematically. Although curriculum materials can be considered a "representation of the content for instruction" (Ball & Cohen, 1996, p. 7), a body of research conceptualizes it as a transformative educative tool for teachers (Collopy, 2003; Remillard, 2000). Specifically, curricula may be valuable artifacts that support teachers in introducing students to the practices and language of the mathematical community (Herbel-Eisenmann, 2007). Past studies have examined texts as an *objectively given structure*, in which "the structure and discourse of the written unit – not what happens when an individual (i.e., the teacher or student) interacts with it – is the focus" (Herbel-Eisenmann, 2007, p. 346). I analyzed the written language of the textbook's pedagogical guidance to see how it actively guides teachers to create opportunities for students to make their thinking visible and facilitate communication of mathematical ideas. The theoretical basis for the framework was developed from interpretations of mathematical communication drawn from existing empirical studies (Brendefur & Frykholm, 2000; Cai, Jakabcsin, & Lane, 1996; NCTM, 2000). Five lessons from three NSF funded elementary mathematics texts were analyzed to illuminate how teacher learning opportunities are instantiated. The results suggest the possibility of a divergence between the conceptualized ways in which the texts may intend for teachers to interpret the pedagogical guidance and the ways teachers may be "reading the textbook" (Remillard, 2000). Some pedagogical guidance provided could potentially be read in ways that lead to the implementation of discussions where students rely on the authority of the teacher to validate the "correctness" of an answer.

LEARNING MATHEMATICS THROUGH PLAY: THE EMERGENCE OF MATHEMATICS DURING PLAYTIME IN PRESCHOOL

Diana Chang
University of Georgia
dblom@uga.edu

This poster focuses on the quality of mathematics that emerged during playtime in a prekindergarten classroom. Studies have shown that play contributes to math development in the early ages (e.g., van Oers, 2010); however, there is still relatively little research on the "naturally occurring mathematics activities in which children engage" (Tudge & Doncet, 2004, p.34). To address this need, my study focused on two main questions: (1.) How does mathematics emerge during play? and (2.) Under what conditions does play promote deep thinking in mathematics?

Theoretical Frameworks and Methods

In this study, I drew on socio-cultural theories of learning that see children's mathematical learning as shaped by interactions among children, with teachers, and with materials in the classroom (Vygotsky, 1978). The study was situated in the preschool of Taylor County Public School, a small rural school with a largely African-American student body. I collected fieldnotes from August until mid-November, observing two focal children: Carter and Jamal. I observed the children six times during weekly visits to the school. In total, I collected around 12 hours of data, including written observations, audio records and video clips. Following traditional methods of ethnographic analysis (Erickson, 1986), I coded my data for formal and informal learning settings, mathematical topics, activity type, and materials used.

Results

In this classroom, I found that students engaged with more significant mathematical concepts during their play when they were allowed to work independently than when their play was guided by teachers. For example, when Carter built a tall Dulpo structure of two towers that stood side-by-side, he had an opportunity to experiment with symmetry, composing and decomposing shapes, equivalence and comparison of size. He searched for only 4-by-2 blocks or 8-by-2 blocks to build his tower, rejecting all others, and worked to make sure that his two towers stayed the same size. In contrast to episodes like this one, interactions that involved teachers often were limited to basic mathematics, like counting and shape identification.

Discussion

I am not arguing that all teachers focus on low-level mathematics during play interactions; however, at a time when we are pushing toward more formal mathematics curricula for PK children, it is good to remember that there is still educational value in play. Giving children the ability to explore on their own without adults monitoring, guiding, and interrupting them is important. Playing without adult interruption can give children a comfortable environment where they do not have to worry about right or wrong answers, or think about the expected answer that adults want to hear. At the same time, teachers need professional development on how to push children toward more significant mathematics in their interactions with students during play.

BEYOND THE "PUZZLED PENGUIN": ENGAGEMENT WITH ERRORS IN ELEMENTARY MATHEMATICS TEXTBOOKS

Laura Cline
University of Delaware
lcline@udel.edu

Analysis of mathematical errors can serve as learning opportunities for elementary school students. Whether they function as a "springboard for inquiry" (Borasi, 1996) or a turning point in improving a solution method (Hiebert, Carpenter, Fennema, Fuson, Wearne, Murray, Oliver, Human, 1997), by discussing and analyzing errors, students can learn how to productively work with errors when they encounter them in their work. This study draws on error analysis models in mathematics education research (Lannin et al., 2006, Oser (1999) as cited by Heinze, 2005, Schleppenbach, et al., 2007), to develop a new, three-part framework for analyzing text and tasks that deal with errors in elementary mathematics textbooks. The framework illustrates characteristics of (1) error *analysis* tasks, and also expands our understanding to include text and tasks that can support students in (2) *preventing* and (3) *recognizing* errors in their own work.

In this study, I applied the framework to analyze a fractions chapter in two fourth-grade *Standards*-based textbooks, *Math Expressions* and *Math Trailblazers*. An interesting contrast resulted from applying this framework. Through suggestions of tools or strategies to use in *Math Trailblazers*, and example problems for students to view (prior to completing a set of similar problems) in *Math Expressions*, both units offered suggestions and hints for students that could result in *preventing errors* in their own work. There were also multiple problems in both units where students were asked to explain their thinking, however, only *Math Expressions* required students to show work for every story problem given, which could potentially result in students *recognizing their own errors* on a more regular basis. In regards to the nature of error analysis problems, the *Math Expressions* chapter was nearly evenly split between conceptual and procedural, while the *Math Trailblazers* chapter focused exclusively on concepts, with one exception bringing in non-mathematical content. The content of error analysis tasks in both units was similar, primarily focusing on comparing and ordering fractions, as well as analyzing different sized wholes. Overall, results from the application of this framework illustrate the variety of opportunities available to students to engage with errors through curriculum materials.

CONNECTING PLACE VALUE AND FRACTIONS

Katherine L. Rhee
Drexel University
kle38@drexel.edu

Jason Silverman
Drexel University
silverman@drexel.edu

Ellen L. Clay
Drexel University
elc37@drexel.edu

Place value and fractions are two of the major concepts in the elementary mathematics curriculum. While there is no doubt about the importance of teachers' understandings of these concepts, there is little focus in mathematics education or mathematics teacher education on the mathematical structures that underlie these concepts. As a result, when these concepts are taught in each grade level, it creates the illusion that there are many independent ideas to learn. However, when teachers and students become aware of the invariants across a variety of ideas and connections that exist among these topics, they develop a deeper understanding of mathematics that allows them to see the sameness and the ways in which various mathematical ideas can build upon each other (Ma, 1999; Silverman and Clay, 2009).

In this poster presentation I will highlight the existing research on students' understandings of fractions and place value and describe a framework that includes three key ideas that can be used to highlight the similarities between conceptual understandings of fractions and place value. For example, research has documented that understanding place value involves two interrelated concepts: (1) understanding the rate of change between units and (2) concurrently recognizing a number in terms of different units (Ma, 1999; McClain, 2003; Thanheiser, 2009). Similarly research has identified conceptual structures that underlie an understanding of fractions, including multiplicative relationships and also being able to compose a fraction in terms of different units (Lamon, 2007; Thompson and Saldanha, 2003). Building on these ideas, I will discuss a framework for understanding the similarities between fractions and place value that highlights unitizing, composition, and decomposition. I will also present my ideas for an online course for preservice teachers that seeks to help them develop mathematical understandings that includes underlying similarities between fractions and place value and to understand the mathematical and instructional affordances of developing an understanding of the connections between place value and fractions.

TEACHING MATHEMATICS AS AGAPE: ARTICULATING A RELATIONSHIP BETWEEN STUDENTS AND MATHEMATICS

Joel Amidon
University of Mississippi
jcamidon@olemiss.edu

In this poster, I illustrate a desired relationship between all students and mathematics within a classroom community of practice that challenges the status quo. The premise for how to teach mathematics begins with a guiding principle of agape, or universal love, and organizes the literature according to that principle of "intentionally promoting success in others".

The realm of mathematics education has a few positions that most would not dispute: 1) mathematical practices are necessary for access to academic and economic opportunities and 2) not all students are given an equal chance at learning those practices (Diversity in Mathematics Education, 2007). Given the importance of providing students with access to mathematical practices, and the influential role mathematics educators can have in promoting or denying access (Berry, 2008), this poster illustrates a pedagogical ideal for how to teach mathematics. The guiding principle of agape, or unconditional love, is used to organize equitable approaches to teaching (e.g. culturally relevant pedagogy (Ladson-Billings, 1994), inclusive pedagogy (Udvari-Solner, Villa, & Thousand, 2005)) and teaching mathematics (e.g. teaching mathematics for social justice (Gutstein, 2006)) within a classroom community of practice (Lave & Wenger, 1991), to construct *teaching mathematics as agape*. *Teaching mathematics as agape* is partitioned into four facets that are defined and necessitated through the literature, with the end product being a relationship between students and mathematics that promotes the access to mathematical practices that is necessary for participation in society (Moses & Cobb, 2001).

A LONGITUDINAL STUDY OF THE VIEWS AND COGNITION OF AFRICAN-AMERICAN STUDENTS FROM URBAN COMMUNITIES

Sarah Gilchrist
The Ohio State University
gilchrist.42@osu.edu

Candace Joswick
The Ohio State University
joswick.1@osu.edu

Jenna Tague
The Ohio State University
tague.6@osu.edu

Inequitable access to mathematics instruction and, consequently, low mathematical achievement among students from urban communities have been identified as major contributors to societal inequalities (Moses & Cobb, 2001) and economic deprivation (Gutstein & Peterson, 2005). Nationally, students from poor communities struggle through mathematics courses and become less engaged in the subject as grade level increases. On the one hand, it has been suggested that school experiences typically fail to provide early adolescents with opportunities to learn the subject matter in meaningful ways, thus de-emphasizing the subject's importance and perpetuating adverse attitudes toward enrolling in elective mathematics courses beyond those required for graduation. On the other hand, academic expectations set for children in such settings are often too low, resulting in gaps in achievement. Many teachers' attitudes toward children from poor communities remain negative, as they believe them to be incapable of academic success (Gutierrez, Baquedano-López, & Tejeda, 1999). Indeed, scholars have revealed that even when children in urban schools do succeed, their success is often attributed to factors other than ability (Tiezzi & Cross, 1997). In short, formal schooling not only fails to enhance children's education; often it both implicitly and explicitly hinders their motivation, desire to learn, and their sense of efficacy towards mathematics (Nasir & Cobb, 2007). Despite this, empirical data which documents how school experiences might impact children's mathematical thinking, their views about the nature of mathematics, and sense of efficacy are rare. Indeed, it is not clear what aspects of children's mathematical thinking might be influenced by their school experiences over time. Our research project addresses this gap.

Our longitudinal research project traced the growth of mathematical thinking and practices of a cohort of 20 children from urban communities as they progressed from 7th to 9th grade. Each child was interviewed once a year for three years using a focused clinical interviewing format. Each interview consisted of two parts. The first part of the interview elicited children's views about mathematics and their level of confidence towards mathematics. The second part of the interview aimed to capture their internalized mathematical practices as exhibited on tasks chosen from various mathematical areas. Featuring members of this cohort, our poster offers an analysis of areas in which children have shown greatest growth and decline over time.

TEACHING FRACTION EQUIVALENCY THROUGH RATIO INTERPRETATIONS: PERFORMANCE OF STUDENTS WITH MLD

Jessica H. Hunt
University of Texas at Austin
Jessica.hunt@austin.utexeas.edu

Students with mathematics learning disabilities (MLD) have been shown to have a weak understanding of fraction concepts that underlie success in fraction computation, problem solving, and estimation (Mazzacco & Devlin, 2008). One such concept is fraction equivalency. A multiple baseline across participants design was employed to evaluate the effects of a fraction intervention based in ratio interpretations on performance on a test of fraction equivalence. A functional relationship was demonstrated between the instruction and performance through replication of skill increase across three students. Results as well as possible implications and future research are discussed.

Learning fraction equivalency through ratio interpretations removes the act of partitioning used in traditional part-whole approaches that have been demonstrated as problematic for many students with MLD (Grobecker, 2000; Hecht, et al., 2006; Lewis, 2010). This study evaluated the effects of a fraction intervention rooted in ratio interpretations on performance in fraction equivalency for middle school students with MLD. A multiple baseline across participants design was used. The experimental design demonstrated a functional relationship between the intervention and understanding of fraction equivalence by repeatedly increasing performance of correct responses after the introduction of treatment (Horner et al., 2005; Kazdin, 1982). Two additional tests, a conventional independent t-test and a split-middle technique, were employed to further evaluate the results of the intervention.

Visual analysis suggests relatively flat trends in data points collected during baseline as opposed to positive, steeper slopes in intervention for all three students. The combined baseline mean was 4.47 (SD = 3.17; range = 1-11); during instruction the mean increased to 18.38 (SD = 4.95; range = 7-26); at the end of instruction, the mean number of points earned was 25.00 (SD = 1.00; range = 24-26). Treatment effects were also calculated using percentage of non-overlapping data (PND) (Kazdin, 1982), a non-parametric means of finding effect size. A moderate PND of 70% was revealed for the intervention effects.

Using elements of Lamon’s (1993) ideas on ratio-backed unitization and expansion of concepts of equivalency, the instructional sequence seemed to have built an increased understanding of fraction equivalency through the ratio interpretation. The students’ initial inability to generate equivalent fractions from their part whole based instruction from school was evident before instruction; after instruction, students increased their performance in fraction equivalency.

A LONGITUDINAL STUDY OF THE RELATIONSHIP BETWEEN MATHEMATICAL AND LINGUISTIC GROWTH OF ELL STUDENTS

Candace Joswick
The Ohio State University
joswick.1@osu.edu

Sarah Gilchrist
The Ohio State University
gilchrist.42@osu.edu

Jenna Tague
The Ohio State University
tague.6@osu.edu

The fastest growing student population in the United States is children of immigrant families. In 2000, 5 million school-age children, totaling more than 10 percent of all K–12 students, were English language learners (ELL) (National Clearinghouse for English Language Acquisition, 2006). While 63% of all U.S. schools have students enrolled who are considered limited-English-proficient (National Center for Education Statistics, 2004), that statistic grows to 77% for urban communities. In 2007-2008, according to NCES, total populations of ELL students were below 10% for suburban, 9% for town, and 6% for rural, while urban was nearly 20%. Indeed, the U.S. Latino population is expected to grow to 100 million by 2050, which will result in ELL students in most city, suburb, and rural schools and classrooms (Moschkovich, 2007). As the ELL school population continues to grow, and with the importance of mathematical achievement and literacy at an all-time high, the relationship between mathematics and English language learning is becoming important. Yet little is known about how these children transition in their mathematical development when immersed in prominently English language environments.

Our poster features the profiles of two ELL students, one male and one female, with differing limited-English-proficiency classifications, from our longitudinal research cohort of 20 children from urban communities. Our data, captured through three years of annual clinical interviews, traces the growth of each child's mathematical thinking using Pirie and Kieren's (1994) theoretical model. The interviews elicited the children's view about mathematics and their level of confidence towards mathematics, as well as captured their internalized mathematical practices as exhibited on tasks chosen from various mathematical areas. Gee's (1996) critical discourse theory was used to analyze the interview data. The poster features an analysis of areas in which children showed greatest growth and decline over time. Data indicated that with greater linguistic diversity reliance on multiple representations diminished; students with limited linguistic ability rely more frequently on pictorial representations to communication their understanding. Over time, the ELL students have increased participation, are more resistant to agreeing to different views of mathematical thought. These students also displayed more standard and conventional ways of doing mathematics as their English language fluency increased.

CHALLENGES IN TEACHING IN APPLIED MATHEMATICS CLASSES IN URBAN SCHOOLS

Dorian Stoilescu
University of Toronto
dstoilescu@yahoo.ca

Egodawatte Gunawardana
University of Toronto

Douglas McDougall
University of Toronto

Secondary school mathematics teachers, mathematics department heads, curriculum leaders, and administrators from 11 schools, with support from a local university, participated in the project Collaborative Teacher Inquiry. In this presentation, we will focus on challenges that teachers face when they teach grade 9 applied mathematics.

INTRODUCTION

The transition from Grade 8 to Grade 9 is particularly challenging in many school systems (Galton, 2009). In Ontario, students are promoted to the next grade regardless of their level of performance until Grade 8. In addition, Grade 9 students in Ontario are subject to streaming, being categorized into academic, applied, or essential levels (Ontario Ministry of Education, 2007). As a result, Grade 9 is a critical year for students and teachers. This is especially challenging for urban populations such as the Greater Toronto Area (GTA), where there is a large multicultural population with the highest percentage of foreign-born students in Canada (Statistics Canada, 2005). In fact, 44% of the student population of the GTA has a first language other than English. In this paper, we report the findings to the research question: What challenges do Grade 9 Applied Mathematics teachers face? By identifying the difficulties encountered by mathematics teachers, this research promises to move forward teaching mathematics in applied classrooms, by energizing teams of teachers within schools to activate and guide the teacher improvement process.

FINDINGS AND DISCUSSIONS

We will discuss the various challenges faced by teachers in teaching Grade 9 Applied Mathematics. Due to time limitation, we selected only few categories. There are a number of challenges in urban mathematics education in Greater Toronto schools. There were a number of situations when challenges identified were multifold. Sometimes teachers did not believe in their capability to achieve success under these circumstances. Teachers said that these negative attitudes along with the students' lack of mathematical background were major barriers to foster student success. Teachers mentioned that they can not be successful alone if their students and their parents do not believe themselves in succeeding.

A mix of behavioral issues and lack of attitudes toward learning was another area of concern. Family situations of students differ considerably and these contexts also brought many issues for several schools. Teachers emphasized the complexity of students being in the same time with behavioral issues and having individual education plans. Lack of time for teachers to prepare their lessons, students need to learn the basics first, concerns about student behavior; and the concerns of preparing students for provincial tests were common themes in both studies. At times, teachers' professional development programs had their own limitations. Implementing reforms that the new curriculum required was challenging by many teachers. In addition, some new teachers had problems in class management. By contemplating on teachers' views in our study, some teachers faced considerable pressure when teaching for applied.

A CASE STUDY OF A CHINESE-AMERICAN STUDENT'S MATHEMATICAL ABILITIES

Xianwei Yuan Van Harpen
Illinois State University
xyuan@ilstu.edu

In recent decades, many cross-national studies showed that students in East Asian countries outperformed their counterparts in the United States in mathematics. However, there are also claims that East Asian students and U.S. students have different strengths in their mathematics learning. In this sense, Chinese-American students, who are raised in Chinese families and educated in U.S. schools, become a special group for mathematics education researchers to investigate the possibility of combining the strengths of both U.S. and Chinese ways of mathematics education. This study investigated a Chinese-American student's strengths and weaknesses in his mathematical abilities. The participant of this study was a fifth grade Chinese-American student. The student was interviewed one and a half hours every week for four weeks and was asked to give both written responses to the problems as well as oral explanations of his solutions. All the interviews were videotaped. The tasks used in this study included computational tasks, component problems, open-ended problems, and problem posing tasks. These tasks were adopted from Krutetskii's (1976) study on the structure of mathematical abilities and Cai's (1995) comparative studies on sixth grade Chinese students and American students. The results of the study indicate that, on the one hand, like the Chinese students in Cai's research, this student has proficient computational skills and simple-problem solving skills, and tends to use symbolic or notational representation more frequently than visual or pictorial representation in solving problems. On the other hand, like the American students in Cai's research, he shows a good ability in solving complex problems. These findings suggest that this student has obtained both Chinese students and U.S. students' strengths in mathematical abilities. The results of this study also indicate that the student' mathematical ability type can be categorized as "abstract-harmonic type" (Krutetskii, 1976, p. 327), which means that the student can depict mathematical relationships equally well by verbal-logical and visual-pictorial means but shows an inclination for mental operations without the use of visual-pictorial means. The findings of this study also suggest that the middle zone (Gu, 2003) between the U.S. and the Chinese way of teaching and learning of mathematics may exist.

BEYOND THE "PUZZLED PENGUIN": ENGAGEMENT WITH ERRORS IN ELEMENTARY MATHEMATICS TEXTBOOKS

Laura Cline
University of Delaware
lcline@udel.edu

Analysis of mathematical errors can serve as learning opportunities for elementary school students. Whether they function as a "springboard for inquiry" (Borasi, 1996) or a turning point in improving a solution method (Hiebert, Carpenter, Fennema, Fuson, Wearne, Murray, Oliver, Human, 1997), by discussing and analyzing errors, students can learn how to productively work with errors when they encounter them in their work. This study draws on error analysis models in mathematics education research (Lannin et al., 2006, Oser (1999) as cited by Heinze, 2005, Schleppenbach, et al., 2007), to develop a new, three-part framework for analyzing text and tasks that deal with errors in elementary mathematics textbooks. The framework illustrates characteristics of (1) error *analysis* tasks, and also expands our understanding to include text and tasks that can support students in (2) *preventing* and (3) *recognizing* errors in their own work.

In this study, I applied the framework to analyze a fractions chapter in two fourth-grade *Standards*-based textbooks, *Math Expressions* and *Math Trailblazers*. An interesting contrast resulted from applying this framework. Through suggestions of tools or strategies to use in *Math Trailblazers*, and example problems for students to view (prior to completing a set of similar problems) in *Math Expressions*, both units offered suggestions and hints for students that could result in *preventing errors* in their own work. There were also multiple problems in both units where students were asked to explain their thinking, however, only *Math Expressions* required students to show work for every story problem given, which could potentially result in students *recognizing their own errors* on a more regular basis. In regards to the nature of error analysis problems, the *Math Expressions* chapter was nearly evenly split between conceptual and procedural, while the *Math Trailblazers* chapter focused exclusively on concepts, with one exception bringing in non-mathematical content. The content of error analysis tasks in both units was similar, primarily focusing on comparing and ordering fractions, as well as analyzing different sized wholes. Overall, results from the application of this framework illustrate the variety of opportunities available to students to engage with errors through curriculum materials.

MATHEMATICS TEACHER EDUCATORS' DIFFICULTY IN ASSESSING PRE-SERVICE TEACHERS' MATHEMATICAL KNOWLEDGE

Dana E. Olanoff
Syracuse University
deolanof@syr.edu

This poster reports on the difficulties that three instructors of mathematics content courses for prospective elementary teachers had in designing assessments to test their students' understandings of fraction multiplication and division. It discusses the nature of these difficulties and some possible reasons why they occurred.

Researching and designing assessments to determine mathematical knowledge for teaching (MKT) has been an important part of educational research since the 1960s and before. Being able to determine what teachers know is important for multiple reasons, especially providing "highly qualified teachers" to our nations' students. (Hill, Sleep, Lewis, & Ball, 2007). However, designing assessments to accurately assess teacher knowledge beyond procedures is very difficult (Hill, Schilling, and Ball, 2004). Skemp, (1976) discusses "the difficulty of sound examining in mathematics" (p. 24) because knowing whether a person understands mathematics relationally or instrumentally by looking at what he or she writes on paper is very challenging.

Despite the difficulties of designing appropriate assessments, an integral part of the job of mathematics teacher educators is being able to assess what teachers know and also how these teachers are able to access that information. This poster reports on the difficulties that three instructors of mathematics content courses for prospective elementary teachers had in designing assessments to test their students' understandings of fraction multiplication and division.

This study, which is part of a larger study looking at mathematical knowledge for teacher educators looked at three mathematics teacher educators (MTEs) who were teaching mathematics content courses for prospective elementary teachers. Despite all three of the MTEs expressing that their goals were for their students to develop conceptual understanding of fraction multiplication and division, only one of the teacher educators designed assessments that helped her determine if her students were actually developing these understandings. The other two had questions that were either strictly procedural, or seemed conceptual in nature, but produced procedural responses from their students. The poster will discuss possible reasons for the difficulty the MTEs had in designing effective assessments as well as implications of these difficulties for teacher education.

MATHEMATICS TEACHING, 20-26.INSTITUTIONALIZATION OF KNOWLEDGE IN THE MATHEMATICS CLASSROOM: A STUDY ON CLASSROOM DISCOURSE

Apolo Castañeda Alonso
CICATA- Instituto Politécnico Nacional, Mexico
apcastane@gmail.com

Alejandro Rosas Mendoza
CICATA- Instituto Politécnico Nacional, Mexico

Juan Gabriel Molina Zavaleta
CICATA- Instituto Politécnico Nacional, Mexico

Taking as a basis a collection of video recordings from a mathematics classroom at the secondary level, this article presents an analysis of several forms of discourse used in the process of institutionalization of knowledge. In particular, the functions and effects of the teacher's interventions in formulating generalizations, synthesis and recapitulations of certain activities in the classroom are analyzed. This study allowed us to identify regularities in the verbal forms, which affect the development of the lesson, either by maintaining the continuity of the discourse, or supporting the institutionalization process.

What the teachers and students express during the collective construction of mathematical ideas? To answer this question we use the concept of institutionalization. This concept is associated with the definition and articulation of the mathematical ideas studied in the classroom. We analyze the institutionalization process through the identification and characterization of the verbal structures used during classroom discussions. We believe that the words used, their meaning and emphasis, have an impact on how the mathematical ideas are defined and structured; but also on how arguments are validated and justified. The methodology used in this study is based on the assumption that the discursive devices can be inferred from observable indicators in the classroom. Furthermore, such indicators have an explicit role in teacher's discourse. These indicators become variables in the institutionalization process, because as explained before, institutionalization is associated with the conclusion or synthesis of ideas in the classroom. We consider necessary to place this study in a school setting, so we could observe the everyday teacher's and students' discourse during the process of institutionalization of knowledge. We claim that this institutionalization process is associated with very specific discursive resources having their own semantics. Thus, our aim in this paper is to analyze the video recordings of the classroom discourse in order to identify empirical evidence indicating the existence of a process of institutionalization. This not only involves identifying phrases or words, but also the effects that the teacher's discourse has in the construction of knowledge.

LISTENING MATTERS: UNDERSTANDING THE OTHER SIDE OF LANGUAGE IN MATHEMATICAL LEARNING

Allison Hintz
University of Washington, Bothell
ahintz@uwb.edu

Kersti Tyson
University of New Mexico
kersti@unm.edu

Over the past decade and a half, reform efforts have called for mathematics classrooms to become discussion and inquiry based (National Council of Teachers of Mathematics [NCTM], 2000). As this reform has taken hold teachers and students have been called upon to envision and enact new and different participation patterns while engaging in the study of mathematics. The primary voice in the classroom is no longer the teacher telling students how to solve problems, but rather students sharing their ideas about their understandings and (mis)conceptions of mathematics. Thus, discussions in mathematics classes have become an important part of learning mathematics. It is ambitious work for teachers and students. Ambitious not only in terms of what teachers and students say to one another in mathematical discussions, but ambitious in how teachers and students are called to listen to one another as well.

While much work has been done to learn about and understand what teachers and students need to know and do to engage in this ambitious work (e.g. Lampert, 1992) very little effort has been directed toward understanding the other side of language (Fiumara, 1990), listening. How we listen, and what we listen for informs the ways we hear words and ideas, process and understand (or not) what has been said, and respond to others, and yet, only a handful of researchers and educators have fully considered listening and it's potential to reveal and expand what it means to teach and learn mathematics.

In this poster, we present findings from two different qualitative studies that focused on listening in elementary mathematics classrooms. Study A took place in a first and fourth grade classroom and focused specifically on identifying the mathematical and interactional demands students experience as listeners during mathematical discussion. Study B occurred in a fourth and fifth grade classroom in a school with high numbers of students who are becoming bilingual and who are from households who live in poverty. The purpose of this study was to learn about the roles of listening in learning, by studying how teachers and children listened to one another. Both studies drew from aspects of the same theoretical framework, socio-cultural theory, and both researchers collected and analyzed video data of mathematics lessons, interview data with children, and artifacts of students' work.

Our findings reveal important implications for learning and teaching, the details of which will be highlighted on our poster. First, listening, which includes not only what students hear, but also whether or not they feel heard, is an important form of participation. In addition to broadening their own listening practices, teachers can deepen students' learning by supporting students to grow their repertoires for listening. Second, different kinds of listening produce different types of mathematical learning. What teachers and students listen for has important implications for participation. Third, when students feel heard, it creates a socially supportive environment. Reciprocally, students are more willing to risk sharing their thinking in a safe environment.

INTERSECTIONS OF MATHEMATICAL IDENTITIES

David J. Fischer
Drexel University
djf49@drexel. edu

Queer students face special challenges in their schooling, this schooling includes the mathematics classroom. This group of students has not been studied in regards to mathematics. This poster examines preliminary data pertaining to the lived experience exploring the intersection of a queer identity and mathematical identity. Because of the inclusive nature of Queer Theory there is also discussion of the impact of racial/ethnic identities and gender identity within this study.

Students with a queer identity, non-heteronomative, face special challenges in in the classroom. Harassment and discrimination lead to high rates of skipping school, and this in turn is problematic for students' educational attainment (Kosciw Et.Al, 2008). A positive attitude towards mathematics, a positive mathematical identity, results in greater engagement in mathematics (Nasir, 2002).

This Phenomenological study explored the intersection of the participant's mathematical identity with their queer identity. This poster will present preliminary findings and analysis from multiple participants and reports on the essence of the intersection. It also reports on the variance of experiences that improve resilience as well as those that cause barriers to improving mathematics performance. By using the lens of Queer Theory this study seeks to include the complicating factors of racial/ethnic identity and gender identities (Kumashiro, 2002).

The poster will begin the conversation of how queer students both perceive and respond to mathematics and the mathematics classroom. While it is not possible to separate all of the various factors involved quantitatively, this qualitative examination of the data seeks to make sense of the queer students experience while examining risk factors and factors that lead to resilience in the mathematics classroom. This data may assist teachers and teacher educators in working toward an anti-oppressive pedagogy in the mathematics classroom.

MATHEMATICALLY PRODUCTIVE AND SOCIALLY SUPPORTIVE DISCOURSE: A TEACHER AND HER STUDENTS' PERSPECTIVES

Allison Hintz
University of Washington, Bothell
ahintz@uwb.edu

Megan Kelley-Petersen
University of Washington, Seattle
meg199@u.washington.edu

Recent efforts within practice-based teacher education have spurred the development of innovative pedagogies that support teachers to learn the practice of teaching as they enact practice (Grossman & McDonald, 2008). One such effort employs a set of *Instructional Activities (IA's)* that provide a purposefully-bounded space for teachers to manage complex interactions among students and content (Lampert et al., 2010). Teacher educators are using IA's that travel across contexts as teachers learn how to create interactive environments for mathematics learning that include: eliciting student thinking, pushing for mathematical reasoning, and orienting students to each others' ideas. As teachers facilitate the IA, they enact pedagogical moves that support a range of student participation, manage discursive interactions, and foreground important mathematical ideas that arise from student contributions. All of this occurs within the accessible, bounded space of the activity.

The use of IA's, then, is a way to make the demands of facilitating and participating in mathematical discourse accessible while maintaining mathematical rigor. Just as teachers navigate a host of demands as they orchestrate mathematical discourse, students simultaneously encounter a wide range of mathematical and interactional demands as well. Mathematically, there is subject matter knowledge a student must make use of, and work with, in order to engage in the IA. Interactionally, a child must be able to engage socially because s/he is a student in a classroom with other children engaging in the IA.

This poster highlights two qualitative studies that focused on a particular IA, *choral counting*. *Choral counting* is a 10-15 minute warm-up activity where students engage in chorally counting by a number as the teacher records the count, discussing both strategies and patterns within the count. Across the two research studies, we examined what the IA of *choral counting* affords for mathematics teaching and learning from two distinct angles within the same elementary mathematics classroom. Study A examined the teacher's role within *choral counting*, tracking pedagogical moves and considering the potential for the enactment of "ambitious instruction" (e.g. Lampert, 2001). Study B examined the affordances of the IA from the students' point of view, documenting the mathematical and interactional demands that students must manage while engaged in chorally counting with classmates. Uniquely drawing from the dual perspectives of a classroom teacher and her elementary students, our research makes connections to current research on teaching and learning while offering implications for practicing teachers and teacher educators who strive to create discourse that is both mathematically productive and socially supportive for students.

TECHNOLOGY TOOLS IN HIGH SCHOOL MATHEMATICS: PROMOTION, PERCEPTIONS AND USE

Allison W. McCulloch
North Carolina State University
allison_mcculloch@ncsu.edu

Karen A. Keene
North Carolina State University
Karen_allen_keene@ncsu.edu

This poster is a preliminary report for a research project that aims to build an understanding of the complexity of teachers' technology tool promotion in classrooms as it relates to students' adoption of such tools in their independent mathematical work. The project focuses not only on the mathematical aspects of technology tool promotion and use, but the affective aspects as well. We examine how these aspects impact the *how* and *why* of students' choices to use technology tools when working independently. Given the expectation that today's students must use technology tools to engage in mathematical problem solving (CCSSI, 2010; NCTM, 2000) both in and outside of the classroom (i.e. on homework, teacher created and standardized assessments, the application of mathematical concepts to other contexts) this is an important sequence of events to understand.

This investigation is a mixed method multi-case study of six high school mathematics classes. We are investigating six classes, two classes each from three high school teachers who work in three types of schools (rural, suburban, and urban). Teachers that regularly use technology tools and who teach at least one section of algebra I and one of algebra II, pre-calculus or calculus were invited to participate. Since the purpose is to gain insight from all members of the classroom community about how technology use is being promoted by the teacher and actually used by the students, data will be collected from both the teacher and the students before, during, and after designated units of study. Data will include video recording of two instructional units for each class, teacher interviews, student surveys, student task-based journal artifacts, post assessment questionnaires and focus students' interviews. The quantitative data will be analyzed using descriptive statistics. Qualitative data will be analyzed using rubrics developed based on an adaptation of Pierce and Stacey's (2004) framework for aspects of effective technology use. Ultimately this study will develop an empirically refined set of conjectures about teacher-related factors that impact students' independent technology use when doing mathematics.

The study will be in its early stages at the time of PME-NA 2011 and we will use the poster session to report preliminary results and to engage in critical conversations about the project design with fellow researchers.

THE COLLABORATIVE NATURE OF GROUP DISCUSSIONS AND THEIR ROLE IN MATHEMATICAL REASONING

Nancy Payne
University of North Carolina at Greensboro
ntpayne@uncg.edu

Sarah B. Berenson
University of North Carolina at Greensboro

The purpose of this study was to investigate the nature of group collaboration as student's reasoned about a pattern task. The fifth grade participants attended a science, mathematics and technology magnet school. The participants were asked to complete a series of three isomorphic pattern finding tasks using pattern block squares, triangles, and hexagons to generalize a rule. During the teaching experiment students were encouraged to collaborate with their partners to find patterns and write either recursive or explicit rules. Once the participants had generalized their rules a whole class discussion was held so that participants could share their ideas and justify their reasoning to the entire group.

Mueller, Maher and Yankelewitz (2009) developed a framework for analyzing the ways that collaboration influences the construction of mathematical arguments and its promotion of mathematical understanding. We used this framework to answer the research questions: What types of collaboration emerged during the teaching experiment and which types influenced the reasoning of the group? This framework, which is composed of three modes of student collaboration, includes: *co-construction, integration and modification.* With the *co-construction* mode of collaboration, students build their argument in a negotiary or back and forth type of dialogue. *Integration* occurs when another student strengthens another student's ideas. Finally, *modification* occurs when one student finds another student's argument faulty or unclear and attempts to help that student make sense of the argument.

This study focused on one pair of students, Jennifer and Felix, as they reasoned about the tasks. It is important to note that the students typically did not work in collaborative pairs. During day one of the teaching experiment, the pair did not collaborate at all. Each worked on the task separately and only Jennifer was able to find both a recursive and explicit rule for the task. On day two, the pair began to collaborate with each other; however, their collaborative effort switched back and forth between modification and integration in an argumentative manner. Felix found a rule for the triangle tables, but Jennifer did not agree. Her participation consisted of trying to understand his argument and pointing out his mistakes. During day two the pairs' collaborative effort did not progress to an explicit rule. On day three, as the pair worked on a rule for hexagon tables, their collaborative effort took the form of co-construction, with each student contributing to the effort. The final results of day three were that the pair found both a recursive and explicit rule for hexagon tables.

Over the three day experiment the collaborative efforts of these students progressed from no-collaboration, collaboration based on defending one's strategy to productive collaboration on the final day. During day one only one student was able to find an explicit rule, during day two neither was able to find any rule and on day three both found an explicit rule.

SUPPORTING ELEMENTARY MATHEMATICS TEACHERS IN FACILITATING CLASSROOM COMMUNICATION THROUGH THE USE OF CURRICULUM MATERIALS

Nancy Tseng
University of Maryland
ntseng@umd.edu

Recent reforms in math education have outlined particular processes students should use to develop meaningful mathematical understandings (NCTM, 2000). Extant literature indicates that teachers' responses to student mathematical thinking shapes the ways in which students communicate about their thinking and can influence levels of mathematical understanding (Franke, Webb, Chan, Ing, Freund & Battey, 2009). The purpose of this study is to examine how curricula provide teachers with pedagogical support as they build and promote students' capacities in communicating mathematically. Although curriculum materials can be considered a "representation of the content for instruction" (Ball & Cohen, 1996, p. 7), a body of research conceptualizes it as a transformative educative tool for teachers (Collopy, 2003; Remillard, 2000). Specifically, curricula may be valuable artifacts that support teachers in introducing students to the practices and language of the mathematical community (Herbel-Eisenmann, 2007). Past studies have examined texts as an *objectively given structure*, in which "the structure and discourse of the written unit – not what happens when an individual (i.e., the teacher or student) interacts with it – is the focus" (Herbel-Eisenmann, 2007, p. 346). I analyzed the written language of the textbook's pedagogical guidance to see how it actively guides teachers to create opportunities for students to make their thinking visible and facilitate communication of mathematical ideas. The theoretical basis for the framework was developed from interpretations of mathematical communication drawn from existing empirical studies (Brendefur & Frykholm, 2000; Cai, Jakabcsin, & Lane, 1996; NCTM, 2000). Five lessons from three NSF funded elementary mathematics texts were analyzed to illuminate how teacher learning opportunities are instantiated. The results suggest the possibility of a divergence between the conceptualized ways in which the texts may intend for teachers to interpret the pedagogical guidance and the ways teachers may be "reading the textbook" (Remillard, 2000). Some pedagogical guidance provided could potentially be read in ways that lead to the implementation of discussions where students rely on the authority of the teacher to validate the "correctness" of an answer.

LEARNING MATHEMATICS THROUGH PLAY: THE EMERGENCE OF MATHEMATICS DURING PLAYTIME IN PRESCHOOL

Diana Chang
University of Georgia
dblom@uga.edu

This poster focuses on the quality of mathematics that emerged during playtime in a prekindergarten classroom. Studies have shown that play contributes to math development in the early ages (e.g., van Oers, 2010); however, there is still relatively little research on the "naturally occurring mathematics activities in which children engage" (Tudge & Doncet, 2004, p.34). To address this need, my study focused on two main questions: (1.) How does mathematics emerge during play? and (2.) Under what conditions does play promote deep thinking in mathematics?

Theoretical Frameworks and Methods

In this study, I drew on socio-cultural theories of learning that see children's mathematical learning as shaped by interactions among children, with teachers, and with materials in the classroom (Vygotsky, 1978). The study was situated in the preschool of Taylor County Public School, a small rural school with a largely African-American student body. I collected fieldnotes from August until mid-November, observing two focal children: Carter and Jamal. I observed the children six times during weekly visits to the school. In total, I collected around 12 hours of data, including written observations, audio records and video clips. Following traditional methods of ethnographic analysis (Erickson, 1986), I coded my data for formal and informal learning settings, mathematical topics, activity type, and materials used.

Results

In this classroom, I found that students engaged with more significant mathematical concepts during their play when they were allowed to work independently than when their play was guided by teachers. For example, when Carter built a tall Dulpo structure of two towers that stood side-by-side, he had an opportunity to experiment with symmetry, composing and decomposing shapes, equivalence and comparison of size. He searched for only 4-by-2 blocks or 8-by-2 blocks to build his tower, rejecting all others, and worked to make sure that his two towers stayed the same size. In contrast to episodes like this one, interactions that involved teachers often were limited to basic mathematics, like counting and shape identification.

Discussion

I am not arguing that all teachers focus on low-level mathematics during play interactions; however, at a time when we are pushing toward more formal mathematics curricula for PK children, it is good to remember that there is still educational value in play. Giving children the ability to explore on their own without adults monitoring, guiding, and interrupting them is important. Playing without adult interruption can give children a comfortable environment where they do not have to worry about right or wrong answers, or think about the expected answer that adults want to hear. At the same time, teachers need professional development on how to push children toward more significant mathematics in their interactions with students during play.

BEYOND THE "PUZZLED PENGUIN": ENGAGEMENT WITH ERRORS IN ELEMENTARY MATHEMATICS TEXTBOOKS

Laura Cline
University of Delaware
lcline@udel.edu

Analysis of mathematical errors can serve as learning opportunities for elementary school students. Whether they function as a "springboard for inquiry" (Borasi, 1996) or a turning point in improving a solution method (Hiebert, Carpenter, Fennema, Fuson, Wearne, Murray, Oliver, Human, 1997), by discussing and analyzing errors, students can learn how to productively work with errors when they encounter them in their work. This study draws on error analysis models in mathematics education research (Lannin et al., 2006, Oser (1999) as cited by Heinze, 2005, Schleppenbach, et al., 2007), to develop a new, three-part framework for analyzing text and tasks that deal with errors in elementary mathematics textbooks. The framework illustrates characteristics of (1) error *analysis* tasks, and also expands our understanding to include text and tasks that can support students in (2) *preventing* and (3) *recognizing* errors in their own work.

In this study, I applied the framework to analyze a fractions chapter in two fourth-grade *Standards*-based textbooks, *Math Expressions* and *Math Trailblazers*. An interesting contrast resulted from applying this framework. Through suggestions of tools or strategies to use in *Math Trailblazers*, and example problems for students to view (prior to completing a set of similar problems) in *Math Expressions*, both units offered suggestions and hints for students that could result in *preventing errors* in their own work. There were also multiple problems in both units where students were asked to explain their thinking, however, only *Math Expressions* required students to show work for every story problem given, which could potentially result in students *recognizing their own errors* on a more regular basis. In regards to the nature of error analysis problems, the *Math Expressions* chapter was nearly evenly split between conceptual and procedural, while the *Math Trailblazers* chapter focused exclusively on concepts, with one exception bringing in non-mathematical content. The content of error analysis tasks in both units was similar, primarily focusing on comparing and ordering fractions, as well as analyzing different sized wholes. Overall, results from the application of this framework illustrate the variety of opportunities available to students to engage with errors through curriculum materials.

CONNECTING PLACE VALUE AND FRACTIONS

Katherine L. Rhee
Drexel University
kle38@drexel.edu

Jason Silverman
Drexel University
silverman@drexel.edu

Ellen L. Clay
Drexel University
elc37@drexel.edu

Place value and fractions are two of the major concepts in the elementary mathematics curriculum. While there is no doubt about the importance of teachers' understandings of these concepts, there is little focus in mathematics education or mathematics teacher education on the mathematical structures that underlie these concepts. As a result, when these concepts are taught in each grade level, it creates the illusion that there are many independent ideas to learn. However, when teachers and students become aware of the invariants across a variety of ideas and connections that exist among these topics, they develop a deeper understanding of mathematics that allows them to see the sameness and the ways in which various mathematical ideas can build upon each other (Ma, 1999; Silverman and Clay, 2009).

In this poster presentation I will highlight the existing research on students' understandings of fractions and place value and describe a framework that includes three key ideas that can be used to highlight the similarities between conceptual understandings of fractions and place value. For example, research has documented that understanding place value involves two interrelated concepts: (1) understanding the rate of change between units and (2) concurrently recognizing a number in terms of different units (Ma, 1999; McClain, 2003; Thanheiser, 2009). Similarly research has identified conceptual structures that underlie an understanding of fractions, including multiplicative relationships and also being able to compose a fraction in terms of different units (Lamon, 2007; Thompson and Saldanha, 2003). Building on these ideas, I will discuss a framework for understanding the similarities between fractions and place value that highlights unitizing, composition, and decomposition. I will also present my ideas for an online course for preservice teachers that seeks to help them develop mathematical understandings that includes underlying similarities between fractions and place value and to understand the mathematical and instructional affordances of developing an understanding of the connections between place value and fractions.

A CASE STUDY OF A CHINESE-AMERICAN STUDENT'S MATHEMATICAL ABILITIES

Xianwei Yuan Van Harpen
Illinois State University
xyuan@ilstu.edu

In recent decades, many cross-national studies showed that students in East Asian countries outperformed their counterparts in the United States in mathematics. However, there are also claims that East Asian students and U.S. students have different strengths in their mathematics learning. In this sense, Chinese-American students, who are raised in Chinese families and educated in U.S. schools, become a special group for mathematics education researchers to investigate the possibility of combining the strengths of both U.S. and Chinese ways of mathematics education. This study investigated a Chinese-American student's strengths and weaknesses in his mathematical abilities. The participant of this study was a fifth grade Chinese-American student. The student was interviewed one and a half hours every week for four weeks and was asked to give both written responses to the problems as well as oral explanations of his solutions. All the interviews were videotaped. The tasks used in this study included computational tasks, component problems, open-ended problems, and problem posing tasks. These tasks were adopted from Krutetskii's (1976) study on the structure of mathematical abilities and Cai's (1995) comparative studies on sixth grade Chinese students and American students. The results of the study indicate that, on the one hand, like the Chinese students in Cai's research, this student has proficient computational skills and simple-problem solving skills, and tends to use symbolic or notational representation more frequently than visual or pictorial representation in solving problems. On the other hand, like the American students in Cai's research, he shows a good ability in solving complex problems. These findings suggest that this student has obtained both Chinese students and U.S. students' strengths in mathematical abilities. The results of this study also indicate that the student' mathematical ability type can be categorized as "abstract-harmonic type" (Krutetskii, 1976, p. 327), which means that the student can depict mathematical relationships equally well by verbal-logical and visual-pictorial means but shows an inclination for mental operations without the use of visual-pictorial means. The findings of this study also suggest that the middle zone (Gu, 2003) between the U.S. and the Chinese way of teaching and learning of mathematics may exist.

In this poster, I illustrate a desired relationship between all students and mathematics within a classroom community of practice that challenges the status quo. The premise for how to teach mathematics begins with a guiding principle of agape, or universal love, and organizes the literature according to that principle of "intentionally promoting success in others".

The realm of mathematics education has a few positions that most would not dispute: 1) mathematical practices are necessary for access to academic and economic opportunities and 2) not all students are given an equal chance at learning those practices (Diversity in Mathematics Education, 2007). Given the importance of providing students with access to mathematical practices, and the influential role mathematics educators can have in promoting or denying access (Berry, 2008), this poster illustrates a pedagogical ideal for how to teach mathematics. The guiding principle of agape, or unconditional love, is used to organize equitable approaches to teaching (e.g. culturally relevant pedagogy (Ladson-Billings, 1994), inclusive pedagogy (Udvari-Solner, Villa, & Thousand, 2005)) and teaching mathematics (e.g. teaching mathematics for social justice (Gutstein, 2006)) within a classroom community of practice (Lave & Wenger, 1991), to construct *teaching mathematics as agape*. *Teaching mathematics as agape* is partitioned into four facets that are defined and necessitated through the literature, with the end product being a relationship between students and mathematics that promotes the access to mathematical practices that is necessary for participation in society (Moses & Cobb, 2001).

A LONGITUDINAL STUDY OF THE VIEWS AND COGNITION OF AFRICAN-AMERICAN STUDENTS FROM URBAN COMMUNITIES

Sarah Gilchrist	Candace Joswick	Jenna Tague
The Ohio State University	The Ohio State University	The Ohio State University
gilchrist.42@osu.edu	joswick.1@osu.edu	tague.6@osu.edu

Inequitable access to mathematics instruction and, consequently, low mathematical achievement among students from urban communities have been identified as major contributors to societal inequalities (Moses & Cobb, 2001) and economic deprivation (Gutstein & Peterson, 2005). Nationally, students from poor communities struggle through mathematics courses and become less engaged in the subject as grade level increases. On the one hand, it has been suggested that school experiences typically fail to provide early adolescents with opportunities to learn the subject matter in meaningful ways, thus de-emphasizing the subject's importance and perpetuating adverse attitudes toward enrolling in elective mathematics courses beyond those required for graduation. On the other hand, academic expectations set for children in such settings are often too low, resulting in gaps in achievement. Many teachers' attitudes toward children from poor communities remain negative, as they believe them to be incapable of academic success (Gutierrez, Baquedano-López, & Tejeda, 1999). Indeed, scholars have revealed that even when children in urban schools do succeed, their success is often attributed to factors other than ability (Tiezzi & Cross, 1997). In short, formal schooling not only fails to enhance children's education; often it both implicitly and explicitly hinders their motivation, desire to learn, and their sense of efficacy towards mathematics (Nasir & Cobb, 2007). Despite this, empirical data which documents how school experiences might impact children's mathematical thinking, their views about the nature of mathematics, and sense of efficacy are rare. Indeed, it is not clear what aspects of children's mathematical thinking might be influenced by their school experiences over time. Our research project addresses this gap.

Our longitudinal research project traced the growth of mathematical thinking and practices of a cohort of 20 children from urban communities as they progressed from 7th to 9th grade. Each child was interviewed once a year for three years using a focused clinical interviewing format. Each interview consisted of two parts. The first part of the interview elicited children's views about mathematics and their level of confidence towards mathematics. The second part of the interview aimed to capture their internalized mathematical practices as exhibited on tasks chosen from various mathematical areas. Featuring members of this cohort, our poster offers an analysis of areas in which children have shown greatest growth and decline over time.

TEACHING FRACTION EQUIVALENCY THROUGH RATIO INTERPRETATIONS: PERFORMANCE OF STUDENTS WITH MLD

Jessica H. Hunt
University of Texas at Austin
Jessica.hunt@austin.utexeas.edu

Students with mathematics learning disabilities (MLD) have been shown to have a weak understanding of fraction concepts that underlie success in fraction computation, problem solving, and estimation (Mazzacco & Devlin, 2008). One such concept is fraction equivalency. A multiple baseline across participants design was employed to evaluate the effects of a fraction intervention based in ratio interpretations on performance on a test of fraction equivalence. A functional relationship was demonstrated between the instruction and performance through replication of skill increase across three students. Results as well as possible implications and future research are discussed.

Learning fraction equivalency through ratio interpretations removes the act of partitioning used in traditional part-whole approaches that have been demonstrated as problematic for many students with MLD (Grobecker, 2000; Hecht, et al., 2006; Lewis, 2010). This study evaluated the effects of a fraction intervention rooted in ratio interpretations on performance in fraction equivalency for middle school students with MLD. A multiple baseline across participants design was used. The experimental design demonstrated a functional relationship between the intervention and understanding of fraction equivalence by repeatedly increasing performance of correct responses after the introduction of treatment (Horner et al., 2005; Kazdin, 1982). Two additional tests, a conventional independent t-test and a split-middle technique, were employed to further evaluate the results of the intervention.

Visual analysis suggests relatively flat trends in data points collected during baseline as opposed to positive, steeper slopes in intervention for all three students. The combined baseline mean was 4.47 (SD = 3.17; range = 1-11); during instruction the mean increased to 18.38 (SD = 4.95; range = 7-26); at the end of instruction, the mean number of points earned was 25.00 (SD = 1.00; range = 24-26). Treatment effects were also calculated using percentage of non-overlapping data (PND) (Kazdin, 1982), a non-parametric means of finding effect size. A moderate PND of 70% was revealed for the intervention effects.

Using elements of Lamon's (1993) ideas on ratio-backed unitization and expansion of concepts of equivalency, the instructional sequence seemed to have built an increased understanding of fraction equivalency through the ratio interpretation. The students' initial inability to generate equivalent fractions from their part whole based instruction from school was evident before instruction; after instruction, students increased their performance in fraction equivalency.

A LONGITUDINAL STUDY OF THE RELATIONSHIP BETWEEN MATHEMATICAL AND LINGUISTIC GROWTH OF ELL STUDENTS

Candace Joswick
The Ohio State University
joswick.1@osu.edu

Sarah Gilchrist
The Ohio State University
gilchrist.42@osu.edu

Jenna Tague
The Ohio State University
tague.6@osu.edu

The fastest growing student population in the United States is children of immigrant families. In 2000, 5 million school-age children, totaling more than 10 percent of all K–12 students, were English language learners (ELL) (National Clearinghouse for English Language Acquisition, 2006). While 63% of all U.S. schools have students enrolled who are considered limited-English-proficient (National Center for Education Statistics, 2004), that statistic grows to 77% for urban communities. In 2007-2008, according to NCES, total populations of ELL students were below 10% for suburban, 9% for town, and 6% for rural, while urban was nearly 20%. Indeed, the U.S. Latino population is expected to grow to 100 million by 2050, which will result in ELL students in most city, suburb, and rural schools and classrooms (Moschkovich, 2007). As the ELL school population continues to grow, and with the importance of mathematical achievement and literacy at an all-time high, the relationship between mathematics and English language learning is becoming important. Yet little is known about how these children transition in their mathematical development when immersed in prominently English language environments.

Our poster features the profiles of two ELL students, one male and one female, with differing limited-English-proficiency classifications, from our longitudinal research cohort of 20 children from urban communities. Our data, captured through three years of annual clinical interviews, traces the growth of each child's mathematical thinking using Pirie and Kieren's (1994) theoretical model. The interviews elicited the children's view about mathematics and their level of confidence towards mathematics, as well as captured their internalized mathematical practices as exhibited on tasks chosen from various mathematical areas. Gee's (1996) critical discourse theory was used to analyze the interview data. The poster features an analysis of areas in which children showed greatest growth and decline over time. Data indicated that with greater linguistic diversity reliance on multiple representations diminished; students with limited linguistic ability rely more frequently on pictorial representations to communication their understanding. Over time, the ELL students have increased participation, are more resistant to agreeing to different views of mathematical thought. These students also displayed more standard and conventional ways of doing mathematics as their English language fluency increased.

Challenges in Teaching in Applied Mathematics Classes in Urban Schools

Dorian Stoilescu
University of Toronto
dstoilescu@yahoo.ca

Egodawatte Gunawardana
University of Toronto

Douglas McDougall
University of Toronto

Secondary school mathematics teachers, mathematics department heads, curriculum leaders, and administrators from 11 schools, with support from a local university, participated in the project Collaborative Teacher Inquiry. In this presentation, we will focus on challenges that teachers face when they teach grade 9 applied mathematics.

INTRODUCTION

The transition from Grade 8 to Grade 9 is particularly challenging in many school systems (Galton, 2009). In Ontario, students are promoted to the next grade regardless of their level of performance until Grade 8. In addition, Grade 9 students in Ontario are subject to streaming, being categorized into academic, applied, or essential levels (Ontario Ministry of Education, 2007). As a result, Grade 9 is a critical year for students and teachers. This is especially challenging for urban populations such as the Greater Toronto Area (GTA), where there is a large multicultural population with the highest percentage of foreign-born students in Canada (Statistics Canada, 2005). In fact, 44% of the student population of the GTA has a first language other than English. In this paper, we report the findings to the research question: What challenges do Grade 9 Applied Mathematics teachers face? By identifying the difficulties encountered by mathematics teachers, this research promises to move forward teaching mathematics in applied classrooms, by energizing teams of teachers within schools to activate and guide the teacher improvement process.

FINDINGS AND DISCUSSIONS

We will discuss the various challenges faced by teachers in teaching Grade 9 Applied Mathematics. Due to time limitation, we selected only few categories. There are a number of challenges in urban mathematics education in Greater Toronto schools. There were a number of situations when challenges identified were multifold. Sometimes teachers did not believe in their capability to achieve success under these circumstances. Teachers said that these negative attitudes along with the students' lack of mathematical background were major barriers to foster student success. Teachers mentioned that they can not be successful alone if their students and their parents do not believe themselves in succeeding.

A mix of behavioral issues and lack of attitudes toward learning was another area of concern. Family situations of students differ considerably and these contexts also brought many issues for several schools. Teachers emphasized the complexity of students being in the same time with behavioral issues and having individual education plans. Lack of time for teachers to prepare their lessons, students need to learn the basics first, concerns about student behavior; and the concerns of preparing students for provincial tests were common themes in both studies. At times, teachers' professional development programs had their own limitations. Implementing reforms that the new curriculum required was challenging by many teachers. In addition, some new teachers had problems in class management. By contemplating on teachers' views in our study, some teachers faced considerable pressure when teaching for applied.

PATTERNS OF MATHEMATICAL PROBLEM SOLVING AMONG FEMALES: A LONGITUDINAL STUDY

Over two decades ago, Leder (1990) reported that fewer women enroll in advanced courses in mathematics, suggesting that this trend leads to unequal participation of females in STEM related careers (cited in Geist & King, 2008). More recent reports suggest this trend has been reversed, as currently there is no enrollment bias in advanced high school math courses. According to Science Daily (2008) women earn 48 percent of mathematics bachelor's degrees in the US. Despite gender equality in number of courses taken, there is sufficient evidence that while boys and girls achieve at the same level in elementary school mathematics (4th and 6th grades), gaps in achievement widen as high school approaches (Amelink, 2009). This performance gap is most apparent on open-ended problem solving tasks. Several scholars have attributed this gender gap to affective factors such as a loss of confidence in mathematics ability and a lower valuation of the usefulness of mathematics (Zhu, 2007). These scholars offer that with less confidence, girls tend to feel less autonomous when experiencing mathematics, particularly during problem solving when they must make decisions about how to proceed and what strategies to use. Other studies posit that differences in performance might be due to the use of differing strategies and problem solving patterns (Zhu, 2007). Zhu (2007), in synthesizing a substantial body of research, advocated the need to study patterns of performance and problem solving strategies of females on authentic tasks to create a platform for discourse on gender differences. The goal to meet this need motivated the current study.

Our longitudinal research traced attitudes and growth of mathematical thinking and practices of 5 female adolescents from urban communities as they progressed from 7th to 9th grade. Each child was interviewed once a year (for three years) using a focused clinical interviewing format. Each interview consisted of two parts. The first part elicited views about mathematics, level of confidence towards mathematics, and usefulness of a concept being learned about in school. The second part aimed to capture their performance on problem solving tasks from different areas of mathematics including discrete mathematics, geometry, and probability. The contexts chosen for data collection elicited the use of differing heuristics and modes of reasoning. While subjects' attitudes towards mathematics remained positive, their performance on mathematical tasks that resembled contexts seen in school became more mechanical. In their inclination to rely on procedures learned in school, they became reluctant to aggressively tackle problems that appeared more open ended.

ELEMENTARY STUDENTS' VIEWS OF MATHEMATICS AND MATHEMATICIANS: BOYS' AND GIRLS' PERSPECTIVES

Jennifer Hall
University of Ottawa
jennifer.e.hall@uottawa.ca

In North America, many people fear or dislike mathematics and fail to see its relevance to their lives (Boaler, 2008). Mathematicians are often negatively stereotyped as white, middle-aged males who are socially inept and unattractive (Mendick, Moreau, & Hollingworth, 2008). These views are perpetuated by popular media, which portray mathematics as a difficult subject only understood by a select few, who are depicted negatively (Applebaum, 1995).

This study investigates elementary students' views of and experiences with mathematics and mathematicians. It also examines how those views may be impacted by popular media, parents' views, and teachers' views. This ongoing, multi-faceted study, conducted in Ontario, Canada, involves Grade 4 and 8 students, teachers, and parents. To date, students have completed online questionnaires and drawn pictures of mathematicians, and parents and teachers have participated in interviews. Children's media will later be analyzed for representations of mathematics, and these examples will be used in focus group interviews with students.

This poster session reports on initial findings from an analysis of student questionnaire data, specifically 30 Likert-scale questions regarding views of and experiences with mathematics and mathematicians. These questions were divided into four topics – views of mathematics, views of mathematicians, parents and mathematics, and gender and mathematics – and the results were separated by the gender of the 156 participants (86 girls, 70 boys).

As with similar studies (e.g., Picker & Berry, 2001), boys and girls in my study had very comparable, generally positive views about mathematics, but expressed little interest in becoming mathematicians. My participants generally felt there were no gender differences in mathematics ability or enjoyment. These sentiments accord with contemporary views of mathematics as an increasingly gender-equitable field at the school level (Forgasz, Leder, & Kloosterman, 2004). Participants' parents were perceived as holding positive views of mathematics, which may have impacted the participants' views (Toliver, 1998).

The similarities in boys' and girls' views of mathematics, particularly in terms of confidence, enjoyment, and gender issues, are encouraging. However, students continue to adhere to some stereotypes regarding mathematics and mathematicians, and the lack of occupational interest in the field they enjoy is troubling. These and other issues will be discussed in the poster session.

EXAMINING COGNITIVE DEMAND, FUNCTIONAL REPRESENTATIONS, AND TEACHER QUESTIONS IN CONNECTED MATHEMATICS PROJECT 2

Erin Meikle
University of Delaware
emeikle@udel.edu

This study aims to analyze how two *Connected Mathematics Project 2(CMP2)* units, *Variables and Patterns* and *Moving Straight Ahead*, adhere to the reform goals of the 2000 NCTM *Standards* with respect to functional representations and high-level student thinking. In order to determine the extent to which CMP2 utilizes high-level tasks, the Investigations were analyzed using the Task Analysis Guide levels of cognitive demand (Boston and Smith, 2009). Ronda (2009) claims that teachers are not provided with the appropriate tools in a textbook to know how to facilitate student learning to a more advanced level. Therefore, questions that were specifically written in the teachers' materials as suggestions to pose to students were analyzed to see what support teachers were given for implementing high-level tasks. A framework was developed in which Boaler and Brodie's (2005) question types were ranked based on their importance in students' cognitive development of mathematical understandings. The two units claim to focus on getting students to understand and use different functional representations. Results from the analysis indicated that most tasks in the CMP2 chapters provided opportunities for students to use multiple functional representations and had higher-level demands, most frequently Procedures with Connections. Questions provided for teachers in the teachers' materials were most frequently higher-level questions that could lead to the development of deeper understandings. The most cognitively demanding tasks, Doing Mathematics tasks, usually had fewer functional representations and fewer suggested questions for teachers to pose than Procedures with Connections tasks, potentially due to the range of multiple solution strategies or their ambiguous nature. These findings suggest implications for teachers, professional developers, and curriculum writers.

CONCEPT ANALYSIS AND THE PRESEVICE MIDDLE SCHOOL MATHEMATICS TEACHER

Jean M. Mistele
Virginia Tech
jeanm@vt.edu

Cong Ze Xu
Virginia Tech
jmf@vt.edu

Over the last several decades mathematics teachers and their knowledge about mathematics have been under close scrutiny. This new era with standardized testing has placed the spotlight on the mathematics teacher and demands teachers ensure their students master mathematical skills and develop a conceptual understanding of the mathematics. This requires that teachers gain skill and knowledge about the mathematics and skill and knowledge about teaching. The joining of mathematics knowledge and the related pedagogy that is required to teach mathematic, pedagogical content knowledge (PCK) that Shulman (1986) defines as the "understanding of what is to be learned and how it is to be taught" (p.7). We believe that a conceptual understanding of mathematics and the integration of the appropriate pedagogical knowledge as promoted by PCK can be achieved by examining mathematics teaching as an applied mathematics, as suggested by Usiskin (2001) for preservice middle school mathematics teachers.

Researchers have demonstrated the interplay between teachers' content knowledge and pedagogical content knowledge during teaching practice that influences the quality of their teaching (Ball, & Wilson, 1990; Usiskin, 2001; Hill, Rowan, & Ball, 2005). Walshaw and Anthony (2008) found that teachers, who engage their students in mathematical argumentation, critique, interpretation, generalization, and the defending of their own ideas, enhance the development of their student's mathematical thinking on key concepts. We believe the notion of mathematics teaching as an applied mathematics, like engineering, offers a new perspective for mathematics teacher educators when unpacking PCK for the middle school mathematics teacher. Considering mathematics teaching as an applied mathematics places the focus on three categories of mathematics: mathematical generalizations and extensions, problem analysis, and concept analysis (Usiskin, 2001). We believe concept analysis is the foundational component for PCK when applied to mathematics education. Concept analysis includes "alternative definitions or conceptions of mathematical ideas and their consequences, why the concepts arose and how they have changed over time and the range of applications of the concept" (Usiskin, 2001, p. 90). Usiskin (2001) draws on a four dimensional model of understanding that is found in the UCSMP texts, "Skills, Properties, Uses, and Representation" (p. 90), SPUR[1]. We applied concept analysis to geometric concepts to explore the potential benefit of addressing mathematics teaching as an applied mathematics.

ADIDACTIC ACTIVITY FOR THE INVERSE TRIGONOMETRIC RATIO

Juan Gabriel Molina Zavaleta

apcastane@gmail.com

In this report we deal with the design of software that has been programmed in the Program of Mathematics Education (PROME) hold at the National Polytechnic Institute (named IPN for the Spanish Instituto Politécnico Nacional) of Mexico. In PROME we do research on the mathematics teaching-learning processes; PROME also offers a Master Degree and a PhD Degree in Mathematics Education, both are on line. The programmed software is one of the first results of a project co-sponsored by National Council of Science and Technology and the Government of the State of Veracruz. The project is titled “Design, development and generation of on line didactic materials for teaching mathematics in the school system of Veracruz” (Register number CONACYT108952). We used Java® language for the programming of the adidactic activity (AUTHORS, 2010).

As Java applets already are used in education our question is ¿which are the new aspects our programmed activities offer? Under constructivism approach we know that people learn with the interactions with objects (Chevallard, Bosch & Gascón, 1998), we agree with this idea and this is why the basement of the project is the interactions student-computer that applets provide. It is also necessary to determine many variables: what information should the applet show on computers’ screen, how and why information is presented, and how the applet collects information from the student. This artificial place where interactions happen is called “environment” (Chevallard, Bosch & Gascón, 1998).

Many applets available in the web and designed by other researchers give to students some means to interact with the computer. Our proposal’s novelty is the implementation of an adidactic situation in the environment; in other words, a school mathematics problem given by the teacher to the student to be solved (Brousseau, 1997). This solving procedure leads the student to build new mathematical knowledge. We call adidactic activity to the couple of a computer program and an adidactic situation.

This poster includes one adidactic situation to study inverse trigonometric ratio.

WHAT DO PROSPECTIVE MIDDLE LEVEL MATHEMATICS TEACHERS LOOK FOR IN CLASS?

Nermin Tosmur-Bayazit
Georgia State University
nbayazit@gsu.edu

Stephanie Behm-Cross
Georgia State University
scross@gsu.edu

Prospective teachers' (PTs) struggle to make connections between what they learn in their teacher education programs and "real" classroom practices has been a focus of much research (Worthy, 2005). Student teaching is generally viewed as the most valuable part of teacher preparation as it offers an avenue for prospective teachers to employ theory in real classroom settings (Feiman-Nemser, 1983). However, there is considerable research showing that student teachers tend to "survive" instead of taking the benefit of the experience to practice the theories (Korthagen & Kessels, 1999). With the intent of promoting the integration of theory with practice, we developed an assignment called "observation protocol". The purpose of this presentation is to share the PTs experiences as they developed their observation protocols and to also highlight their thoughts on the role of teachers and the structure of effective classroom tasks.

Participants in this study were 20 middle grade PTs in an undergraduate mathematics methods course. The course met once weekly for three hours, and took place during Fall 2010 at a large urban state university in the South-Eastern region of the United States. The course focused primarily on theoretical readings, field-based observations guided by those readings (as described below), and lesson plan development. All students enrolled in the course were also required to be in a field experience course, which required 2 full days per week attendance in a middle school mathematics classroom.

For this assignment, each PT was required to keep an observation and interview journal for the following two course topics: nature of classroom tasks and role of the teacher. PTs were instructed to list things they thought were critical to observe and come up with questions to ask their mentor teachers in the field. Students were also required to take observation notes for each item that they listed.

Data for this presentation consists of the 20 prospective teachers' written observation protocol assignments. To analyse the assignments we read and re-read all narratives separately in order to identify general themes. After we developed these themes individually, we worked together to re-examine each of the 20 papers more carefully to confirm themes and generate a list of quotes to support each idea.

The results of the study revealed that majority of the PTs see the major role of the teacher as facilitator who should promote scaffolding, reasoning, and student participation. However, they also see the pressure of the high stake testing, curriculum load and the classroom management issues as the three major barriers for them to carry out this role. In a similar vein, the PTs looked for classroom tasks that are "problematic", intriguing, engaging and developing mathematical insight. They argued that the classroom tasks should foster classroom discourse, reasoning and "true" understanding.

STATISTICAL REASONING IN STANDARDS-BASED MIDDLE SCHOOL MATHEMATICS CURRICULA

Heather Gallivan
University of Delaware
heatherg@udel.edu

Being able to analyze data, graphs, charts, and tables is essential for students to be able to effectively engage as a citizen in a democratic society. After the NCTM *Standards* introduced statistics as a major content area, there has been a trend in recent research studies that stress the importance of shifting instruction from introducing procedural skills to developing students' abilities to reason statistically (Garfield & Ben-Zvi, 2007). The purpose of this study is to analyze two standards-based eighth grade curriculum units on data analysis from the *Connected Mathematics Project 2* (CMP2) (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006) and *Mathematics in Context* (MiC) (Encyclopaedia Britannica, 2006) to determine what opportunities are available for students to learn to exhibit statistical reasoning.

The analytic framework developed to analyze the questions presented in each unit integrated a number of different conceptualizations of statistical reasoning found in the mathematics education research literature. Mooney (2002) identified four data-handling processes that are essential for middle school students to exhibit statistical reasoning: describing data, organizing and reducing data, representing data, and analyzing and interpreting data. Curcio's (1987) graph comprehension levels served as a means to rank the data-handling processes into three levels, which were labeled as suggested by Friel et al. (2001): elementary, intermediate, and overall. The questions from each unit were coded according to sub-processes defined for each data-handling process.

Application of the analytic framework revealed that both units appear to provide students ample opportunities to engage in all of the data-handling processes that are required for students to learn to exhibit statistical reasoning, despite a majority focus on the elementary level processes. There were some notable differences between the two units, including the fact that MiC lacked questions that addressed measures of center and spread and that CMP2 had significantly fewer questions addressing the analyzing and interpreting data data-handling process. Despite these issues, both units provide ample opportunities for students to engage in questions which encourage students to learn to exhibit statistical reasoning.

ENHANCING K-8 MATHEMATICS COACHES' KNOWLEDGE FOR TEACHING PROBABILITY

Yating Liu
The Ohio State University
liu.891@buckeyemail.osu.edu

Ryan Harrison
The Ohio State University
harrison.407@osu.edu

Scott Zollinger
The Ohio State University
zollinger.4@buckeyemail.osu.edu

This study is embedded in the Mathematics Coaching Program (Brosnan & Erchick, 2010), a statewide professional development program designed to enhance K-8 teachers' Mathematical Knowledge for Teaching (MKT) using children's cognition as a vehicle to situate the learning. In the current study, we examined the impact of sessions designed for improving participants' knowledge of probability. 19 mathematics coaches participated in the intervention sessions. Two types of activities were designed and used. First, samples of students' work with corresponding quantitative data on certain probability items of the state achievement tests were shared. The coaches were asked to: 1) make conjectures about students' sources of misconception, 2) judge the quality of given problems, 3) offer suggestions about improving either students' learning or the quality of the problems. Second, the coaches engaged in solving probability problems which were designed to help them realize the necessity of developing an understanding of the concept of "randomness" in probability thinking (Shaughnessy, 1992). Key concepts for discussions included: experimental probability, theoretical probability and probability assumption due to their centrality in the conceptual map of the probability knowledge as identified by NCTM.

To evaluate the effect of the intervention sessions, we administered an identical pre- and post-questionnaire to the coaches. The questionnaire asked coaches to identify: 1) the concept of probability, 2) the reason why probability should be taught to children, and 3) the appropriate probability knowledge that school children would need to learn. Participants' responses to each of the questions were studied first to determine categorical themes that emerged from them. These categories were used to trace changes in coaches' knowledge. Analysis of data indicated that on the pre-questionnaire, a majority of the coaches used general descriptions of probability and referenced reasoning, decision making, and real life application as chief rationale for teaching probability in schools. Among the post-questionnaire responses, we observed that over half of the coaches were more explicit in identifying probability concepts and referenced "importance of understanding and interpreting probability" using precise and correct language of probability; we also observed that statements that logically connected two or more probability topics (as opposed to listing concepts separately) significantly increased. To further investigate coaches' learning of these concepts, a follow-up plan using a more focused evaluation program is under development. Our poster presentation will offer a detailed account of categories of coaches' responses that reveal misconceptions about their own understanding of probability.

USING DYNAMIC GEOMETRY SOFTWARE FOR PROBABILITY TEACHING AND LEARNING WITH AREA PROPORTIONAL VENN DIAGRAMS

Nenad Radakovic
University of Toronto
nenadradakovic@yahoo.com

In this poster presentation, I will explore the use of dynamic geometry software as a visual dynamic tool for supporting high school students' understanding of probability, more specifically, understanding of conditional probability and Bayes' theorem. Kahneman, Slovic & Tversky (1982) claimed that intuitive errors proceed from using certain heuristic principles that often lead to erroneous probability judgments. For instance, people tend to neglect the base rates which are, according to Bayes' theorem, relevant to the calculation of probabilities. On the other hand, in the last couple of years there has been a focus on dynamic learning environments which allow us to create mathematical objects and explore them visually and dynamically. Moreno-Armella (1999) and Kaput and Hegedus (2008) describe learning environment in which students can visualize, construct and manipulate mathematical concepts. The dynamic learning environments can enable students to act mathematically, to seek relationship between object that would not be as intuitive with a static paper and pen representations.

The goal of my research is to substantiate the claim that dynamic learning environment enables student to grasp abstract mathematical concept by manipulating mathematical objects constructed within these systems. More specifically, I investigate the role of dynamic visualization using area proportional Venn diagrams in students' understanding of Bayes'theorem. Moreover, I am interested whether the introduction of visualization has an effect on student's committing the base rate and the inverse fallacy. Using a quasi-experimental design, I presented a well known breast cancer problem (Eddy,1982) in which Bayes' theorem needs to be applied to students who are introduced to Bayes' theorem via the Bayes' formula as well as to the group of students who were presented with the visualization of the Bayes' theorem created by the author.

The results show that the students who were introduced to the dynamic visualization of the Bayes' theorem were significantly more successful in solving the breast cancer problem. In this case, using the dynamic visualization provided by the animation feature of dynamic geometry software, students could easily grasp the idea that the conditional probability depends on the base rate and were also less likely to commit the inverse fallacy. This serves as the evidence that dynamic visualization do create means for the deeper analysis of mathematical concepts. In addition, my research contributes to the research on application of area-proportional Venn diagrams which have not received much attention in the mathematics education community.

EXPLORING THE EFFECTS OF CURRICULA ON FIFTH-GRADE STUDENTS' PROBLEM SOLVING

Jonathan D. Bostic
Bowling Green State University
bosticj@bgsu.edu

This study explores the impact of different curricula on students' problem solving. Effective problem solvers (1) read and understand the problem, (2) create a situation model, (3) develop a mathematical model, (4) implement a strategy and arrive at a result, (5) interpret the result, and (6) communicate the solution (Verschaffel, Greer, & De Corte, 2000). Students' using reform-oriented materials tend to use more representationally diverse strategies than peers using traditional materials (Senk & Thompson, 2006), which may impact how they solve problems.

Two fifth-grade students were selected from a larger sample based on curricula use and self-reported prior achievement. All names are pseudonyms. Kristy has been using *Everyday Mathematics* (Bell et al., 2004) materials since Kindergarten whereas Gavin has only used traditional mathematics textbooks. Word problems were selected from prior research with fifth-grade students (Bostic & Jacobbe, 2010; Verschaffel et al., 1999). Students practiced thinking aloud and then solved five tasks during an audio-recorded interview. After solving each problem, participants were asked whether they could show another strategy. The interviews were transcribed and analyzed using thematic analysis (Hatch, 2000).

Both participants employed symbolic strategies initially, used the problem's context to assist with interpreting their result, and were fairly successful. Gavin read each problem one time, carried out the problem-solving process, and reported his answer as a number. Kristy read the problem, reflected on it, and reread the problem, specifically attending to areas of text. Next, she offered a conjecture of the solution followed by creating a situation model. She continued to execute the problem-solving process and reported her solution as a number with corresponding units. Gavin was usually unable to provide another strategy; however, Kristy successfully used symbolic and pictorial strategies. Kristy also often located errors in her prior strategies. Kristy's utterances and behaviors suggest she self-evaluated her progress while problem solving whereas Gavin did not reread the problem, reexamine his situation model, or employ a pictorial strategy. Results offer directions for future research.

THE STRANGE CASE OF THE FOURTH-AND-A-HALF FLOOR: THE WAY 3rd-6th-GRADERS COPE WITH THE SOLUTION OF A REAL-WORLD PROBLEM

Avikam Gazit
The Open University of Israel/Kibbutzim College of Education
avikam120@walla.com

Does mathematics aim to develop abstract- logical thinking and find original and interesting relations in its various structures, or to serve as an auxiliary aid for solving problems in areas of science, society and daily life? One could say that the debate is senseless since mathematics is designed for both goals. However, teaching it in elementary school does not take the authentic daily component very seriously, in spite- of the curriculum statement of intents. The aim of this study was to investigate how 3rd to 6th grade students solve a real-world problem: What is the middle floor in a 9-floor building? The highest success percentage was at the 4th-grade and the lowest at the 6th-grade. Nevertheless, the most interesting finding of the study was the students' reference to the illogical and unrealistic answer: the fourth-and-a half floor, being the result of 9:2. About half of the 6th-graders and about one third of the 5th-graders gave such answer without any word of criticism about the obtained number. Only about 13%-15% of the 3rd-4th grade students gave such an answer. An inevitable conclusion is that the higher the elementary school age group is, the more the learnt mathematics detaches students from reality. The students do not use logical considerations, solving problems mechanically, without critical reflection. It is recommended dedicating a considerable part of mathematics lessons at elementary school to the solution of real-world day-by-day problems and to pay more attention to the processes of reflection about the received answers.

DEVELOPING STUDENTS' INFORMAL UNDERSTANDING OF THE COMMUTATIVE PROPERY OF ADDITION

Tracey H. Howell
University of North Carolina at Greensboro
thhowell@uncg.edu

Sarah B. Berenson
University of North Carolina at Greensboro
sbberens@uncg.edu

The aim of this poster is to share insights gathered on students' informal understanding of the commutative property of addition. Three lessons from the ON TRACK Learn Math pilot study were selected that provide substantial insight into the students' developing reasoning. By scaffolding progressively more challenging problem-solving activities, our enrichment program provided the students with the opportunity to make important connections.

The aim of this poster is to share insights gathered on students' informal understanding of the commutative property of addition during the pilot phase of the ON TRACK Learn Math study conducted during the fall semester of 2010. ON TRACK Learn Math is an after-school program for students in grades 3-5 that focuses on problem-solving enrichment activities. For the pilot, nine sessions were held over five weeks at a local elementary school.

Of the nine sessions, three lessons were selected that provide substantial insight into the students' developing understanding of the commutative property of addition. In the Towers Task (Maher & Martino, 1996), students used blocks of only two colors and determined the number of different towers that could be built of varying heights. The video recordings show that several students recognized that they could build both a red-blue-blue tower and a blue-blue-red tower, yet none of the students were able to notate this on their papers or generalize a rule. During the third week in a similar activity, students used Cuisenaire Rods to determine how many pairs of smaller rods would sum to a specific larger rod. As with the Towers Task, the video recordings show that several of the students recognized the distinction between a purple-yellow pair and a yellow-purple pair, for example, yet they still did not notate this in writing. In the following session, students attempted to list all of the different pairs of numbers that sum to a given value. It was noteworthy that many of the students not only wrote expressions such as 2+3 and 3+2 as distinct pairs, but also made references to the Towers and Rods Tasks. We considered this to be a significant development in the students' understanding. Though they were unable to clearly notate their thinking at the times of the first two tasks, they were now connecting all three of the activities. By scaffolding progressively more challenging problem-solving activities, our enrichment program provided the students with the opportunity to make these important connections.

Peer-reviewed articles on the development of students' understanding of commutativity are scarce and this portion of the ON TRACK study is an attempt to address that gap. As the study moves into full implementation in five local elementary schools, we plan to continue gathering more written data on the development of students' understanding of commutativity.

A PILOT STUDY ON THE IMPACT OF A MATHEMATICAL MODELING APPROACH ON TEACHERS AND THEIR STUDENTS

Zhonghong Jiang
Texas State University San Marcos
zj10@txstate.edu

George O'Brien
Florida International University
obrieng@fiu.edu

With the support from an NSF grant, twenty mathematics teachers participated in a 2-week summer Mathematical Modeling Workshop. In the fall semester after the workshop, these teachers used what they learned at the workshop (mathematical modeling ideas/skills and related pedagogy) to teach students in their own classrooms. This study was conducted to investigate the impact of the mathematical modeling approach on the teachers who participated in the summer modeling workshop and on their students (including at-risk students).

The general hypothesis of this study was that the reformed teaching featured by mathematical modeling can effectively enhance the content and pedagogical knowledge of the teachers and the performance of their students in mathematics learning. Specifically, the study sought to answer the following research questions: 1) What is the impact of the summer modeling workshop on the participating teachers? 2) Do the students taught by the teachers who participated in the summer modeling workshop perform better than the students taught by the teachers who did not?

Experimental designs were the main research method used for the study. A pre-test and a post-test were administered for all participating students. The instrument for the pre- and post-tests of the students was the test created by the California Mathematics Diagnostic Testing Program (MDTP). The pre-test was administered during the beginning weeks of the school year for students in the Algebra II, Geometry, Algebra I and Pre-Calculus classes. The post-test was administered one week before Christmas break for the same classes of students. Analyses of variance (ANOVA) and t-tests were implemented to analyze the quantitative data.

Classrooms observations were conducted, and different surveys were administered respectively for the participating teachers in the experimental group and those in the control group. The classrooms observations and the surveys were designed to collect information about what was going on in the classrooms, the teachers' teaching styles, their students, any issues and concerns, possible obstacles, what support the teachers expected from the researchers, etc. The pilot study also used in-depth interviews of six teachers (three experimental teachers and three control teachers) to collect more qualitative data, and the case study method (Yin, 2003) was used to analyze the data.

The main findings of the study included: 1) The teachers who participated in the above-mentioned modeling workshop ("experimental" teachers) developed teaching styles that were significantly more Standards-based, reform-oriented, and student-centered than those who did not have such experience ("control" teachers); and 2) The "experimental" teachers were more effective in helping students understand concepts and develop problem-solving skills than the "control" teachers, at least in most of the cases. In summary, this study has, at least initially, provided evidence to support its general hypothesis about the role of the reformed teaching featured by mathematical modeling.

PROMOTING TEACHERS' DIVERGENT THINKING WHILE PROBLEM SOLVING IN A HYBRID GEOMETRY COURSE

Nikita Patterson
Kennesaw State University
npatte10@kennesaw.edu

Darryl L. Corey,
Kennesaw State University
dcorey1@kennesaw.edu

The purpose of this ongoing study is to examine practicing middle and secondary teachers' different strategies and method of solutions towards given geometry problems in a hybrid (online & face-to-face) geometry course. The course is designed to encourage divergent thinking during problem solving while reflecting on and discussing solution processes. While the larger study includes 25 middle and secondary mathematics teachers, this poster is a case study that reflects the thinking of one female teacher middle school teacher. Data collected includes online and in-class discussions, solutions to problems and the teacher's reflections problems. Guilford and Merrifield's five features of *divergent thinking are used to frame this case study. Results indicate evolving levels of divergent thinking by the teacher during the semester while using technologies such as MS Excel and Geometer's Sketchpad.*

Method

Guilford and Merrifield (1960) define five kinds of thinking abilities that involve creativity and divergent thinking:

- Sensitivity to problems: seeing defects, needs, deficiencies, seeing the odds, the unusual; seeing what must be done.
- Flexibility: ability to shift from one approach to another, one line of thinking to another, to free oneself from a previous set.
- Fluency: ability to produce large number of ideas.
- Originality: ability to produce remote, unusual, or new ideas or solutions to "embroider" or elaborate.
- Redefinition: ability to define or perceive in a way different from the usual, established, or intended way, use, etc.

The teacher explored problems to seek multiple solutions while using technologies.

Results

An analysis of this teacher's solution procedures, reflections, and discussions shows an evolution of divergent thinking and seeking creative ways to solve geometry problems throughout the course. The use of technologies, more specially internet research, MS Excel, and Geometer's Sketchpad served as key elements in sparking her divergent thinking and mathematical creativity. Examples of her solutions and evolving reflections that demonstrated increases in divergent thinking and creativity will be on display.

PROOF AND ARGUMENTATION IN THE SOLUTION OF TRIANGLE CONGRUENCE PROBLEMS: A STUDY WITH HIGH SCHOOL STUDENTS

José-Luis López
Cinvestav-IPN
jllopez@cinvestav.mx

José Guzmán
Cinvestav-IPN
jguzman@cinvestav.mx

In this article we report the proofs and argumentations provided by 15 high school students (16-17 years of age) when solving triangle congruence problems, in a paper and pencil environment. The proofs provided by the students, from the nine problems which were assigned, coincide with those reported in the research literature related to this subject matter. Our results suggest that students, many a time, in their proofs and argumentations, lean over empirical evidences, institutions and even on personal experiences brought about by the geometric figures which were provided in the problems.

Introduction

The appropriateness of whether or not including the topic of proof in the mathematics syllabus at basic levels (secondary school and high school) has been discussed for about 40 years. It is true that not all the mathematical contents at these educational levels need formal proofs; however, when the study of Euclidean geometry topics begins, students are required to provide arguments of why certain propositions are true or false, or how to argue that a geometry problem is adequately solved. The majority of students at these educational levels are not interested in either comprehending, or learning how to prove Euclidean geometry theorems, since, for them, the geometric properties and some propositions are often evident, due to the fact that they are supported by figures.

The research literature related to proof in mathematics, and to the academic field is vast. Due to space restrictions, in this paper we only include some bibliographic references; whose emphasis is the proof and argumentation given by the students at the different academic levels. For instance, Van Dormolen (1977, quoted by Ibañes & Ortega, 2005, p.25) refers to three levels of proof, provided by students; such levels are: a) zero level, characterized thus because the student focuses only on concrete objects, b) level one, thus characterized because the student thinks of objects as representative of one kind, c) level two; in this level the student is capable of generalizing. Bell (1976) proposed three objectives for proof; they are: verification, illumination and systematization; de Villiers (1993, quoted by Ibañes & Ortega, 2005, p.29) propose two functions of proof: discovery and communication; whereas, Balacheff (1987) mentions two kinds of proof by students, supported by examples: the pragmatics, based upon the *ostention*; in this kind of proof, students resort to the action and concrete examples, and the intellectual ones; based upon the formulation of the mathematical properties brought into play and the relationships that exist between them. In turn, pragmatic proofs are subdivided into different kinds: the naïve empiricism, the crucial experience, the generic example and the mental experience. Siñeriz and Ferraris (2005), Van Ash (1993, quoted by Ibañes & Ortega, 2005, p.26) and Hanna (1990), among others, have contributed as well to the study and development of proof, in accordance with the kind of language and the level of formality used.

Paying attention to the problems outlined above, we pose the following objective for this research: To explore the function of the task in a paper and pencil environment in the proof. That is to say, how the task suggested by the teacher, motivates and makes evident the necessity to prove propositions. In this paper, we pretend to provide an answer to the question: What kinds of proofs emerge during the solutions given by students to geometric problems of triangle congruence?

Theoretical Perspective

This research was theoretically supported by diverse kinds of argumentation and proof provided by some of the authors mentioned aforesaid. For instance, the different kinds of pragmatic proofs which are referred to by Balacheff (1987, pp. 156-157):

a) *Naïve empiricism:* is based upon a few examples; generally, selected in a random way, in order to verify the statement to prove;

b) *Crucial experience*: based upon the careful selection of an example, convinced that if the conjecture is true for that case, then it will be for all the others;

c) *Generic example*: based upon the selection of an example that acts as representative of its kind; in such a way that even though the proof refers to that particular case, it could be generalized to all that kind;

d) *Mental experience*: based upon the actions previously carried out by the student who, afterwards, internalizes (generally they are observations of examples) and then separates the particular actions to turn them into deductive abstract arguments.

Montoro (2009, pp. 5-6) identifies the following categories:

a) *Formal deductive argumentation*: when the subject makes inferences based on the hypotheses, properties or definitions and presents a logic sequence of symbolic expressions;

b) *Colloquial deductive argumentation*: when the subject makes inferences based upon the hypotheses, properties or definitions, above all, in a colloquial way;

c) *Colloquial explanation*: when the subject clarifies (or it is clarified) the situation. Generally, the subject presents an aspect of deductive argument without being real inferences;

d) *Explanation by evidence*: when the subject tries to evidence the proposition by the use of affirmation of that some property or some definition is fulfilled without arguing; only making affirmations;

e) *Explanation by means of a draw*: when the subject shows, using a draw; his affirmations lack arguments.

Hanna (1990, pp. 6-12) identifies the following kinds of proof:

a) *Formal proof*: a finite sequence of affirmations where the first one is an axiom and each one of the following ones is an axiom as well, or else it derives from the previous affirmations, by means of the correct application of inference rules. The last affirmation is the one which should be proven;

b) *Proof that proves:* it is used to see that a fact is true, but it is not necessary to explain because it is. This kind of proof can be based upon mathematical induction or even only upon syntactic considerations;

c) *Proof that explains*: it provides a series of reasons which derive from the phenomenon itself. It should provide a justification based on the mathematical ideas involved, and on mathematical properties.

Beyond the different processes of argumentation and proof used by students in order to justify their results in geometry, there exist the problems related to the diverse types of interpretation of a geometric representation, in which reasoning and visualization are aspects of paramount importance, as they are discussed by Camargo, Pery and Samper (2005) and by Palais (1999).

Methodology

Participants

This study was carried out with 15 students (16-17 years old) in the second year of a high school located in Mexico City. The students did not have experience on how to carry out demonstrations in geometry. During three working sessions (the first one of one hour and the remaining two of two hours, each one was conducted by one of the authors of these paper), students solved problems of Euclidean geometry; which included tasks as: recognition of figures, geometric constructions, use of theorems and criteria of triangle congruence, as well as the validation of their results. Due to the fact of space restrictions, in this paper we will only document the work of seven students; whose demonstrations exemplify the diverse types of demonstrations reported in the research literature.

Selection and Modification of the Problems

From the book Plane and Solid Geometry (Wentworth & Smith, 1979), nine problems of triangle congruence were chosen; these problems were modified in their original writing. The a priori solution of the problems posed to students was carried out; such solutions are aimed at foreseeing the possible proofs and argumentations by students. Due to space restrictions, such a priori solutions of the problems are not included in this paper.

Data Gathering

Between 10 and 15 minutes were allocated for the solution of each problem (individually), and some minutes were devoted to group discussion; conducted by the researcher. We have the register of the nine problems of the activity, with their respective answers provided by each one of the students, using paper and pencil, as well as the video recordings from the individual work and group discussion.

Data Analysis and Discussion of Results

Next are shown four problems (the numbering of them does not correspond to the order in which they were proposed) and the argumentations provided by the students.

Problem 1

In $\square ABCD$ (Figure 1), P is the midpoint of $\overline{AB}$. Prove that $\overline{PC} = \overline{PD}$.

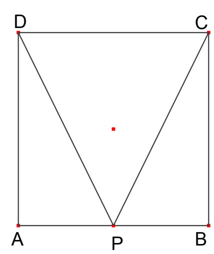

Figure 1. Problem Representation

Some solutions

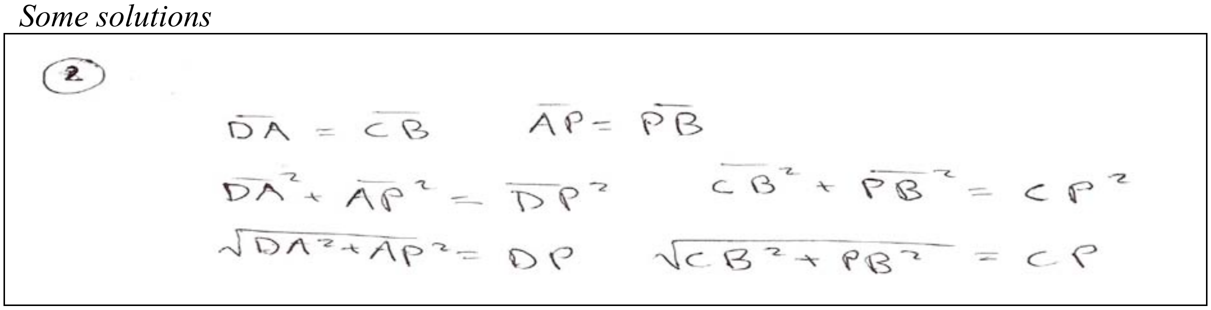

Figure 2. Student A2: Formal Deductive Argumentation; Use of the Pythagoras Theorem

Figure 2 shows the use of the problem's hypotheses: given that $\overline{DA} = \overline{CB}$ and $\overline{AP} = \overline{PB}$, then, using *The Pythagoras Theorem*, conclude that $\overline{CP} = \overline{DP}$.

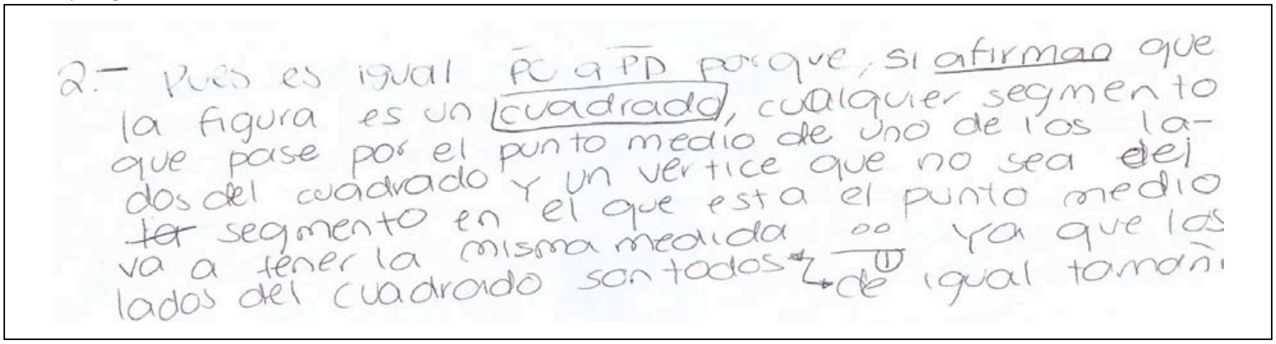

Figure 3. Student A4: Argumentation Based upon Evidences

As it is shown in Figure 3, the student asserts that the segments $\overline{PC}$ and $\overline{PD}$ measure the same, only by the fact that the figure, whose vertexes are *A*, *B*, *C* and *D*, is a square, but no argumentation is given.

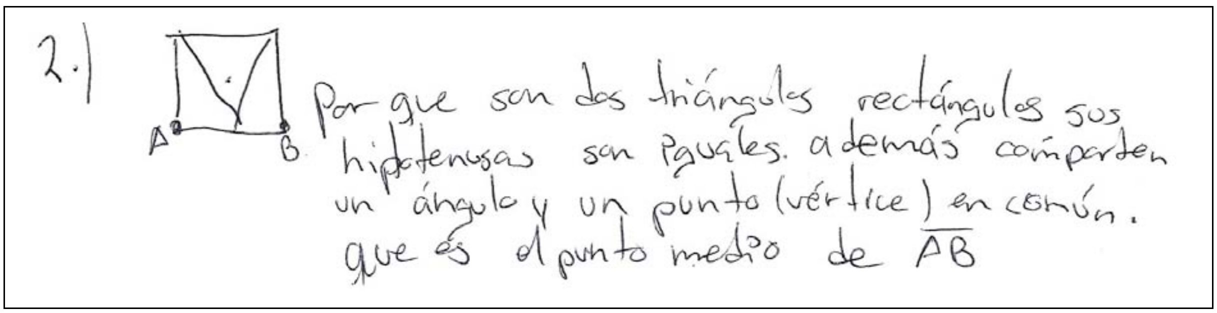

Figure 4. Student A5: Affirmations Based upon the Initial Figure

As shown in Figure 4, the student asserts that $\overline{PC} = \overline{PD}$, because he observes that *P* is the midpoint of one of the sides of the square and that right-angled triangles are formed, whose sides are the sides of the square. He only asserts without arguing.

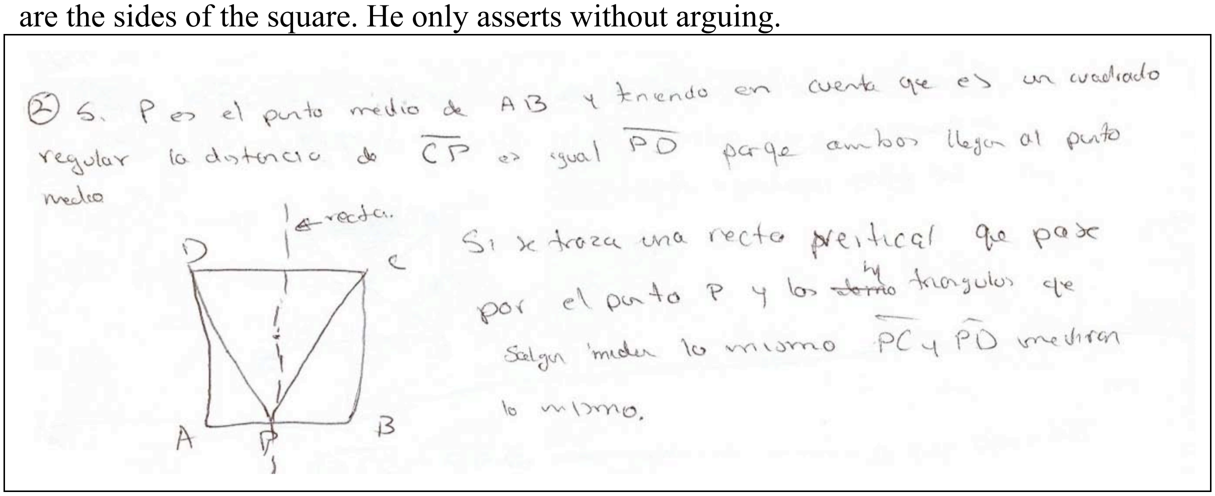

Figure 5. Student A11: Proof by Visualization

Figure 5 allows to observe that the students focuses on the elements or graphic representation, and builds the auxiliary straight line that passes *P*, in order to obtain four congruent triangles, which helps him conclude that $\overline{PC} = \overline{PD}$.

Problem 2

In Figure 6, $\overline{AC} = \overline{BC}$ and $\overline{AD} = \overline{BD}$. Prove that $\angle CBD = \angle DAC$.

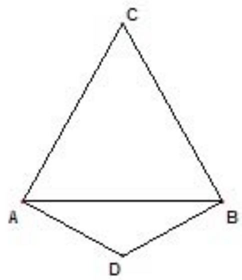

Figure 6. Representation of the Problem

Some solutions

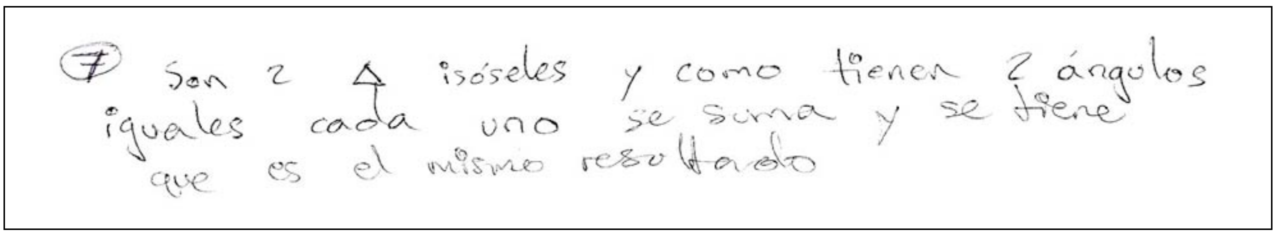

Figure 7. Student A2: Colloquial Deductive Argumentation Based on the Figure; Use of Unclear Language

In accordance with Figure 7, the student uses colloquial language in order to argue the validity of the proposition based upon the properties of isosceles triangles. Similarly, he seems to deduce that the triangles of interest are equal since he sees him as the same addition of two angles; however the way of writing his ideas is not clear.

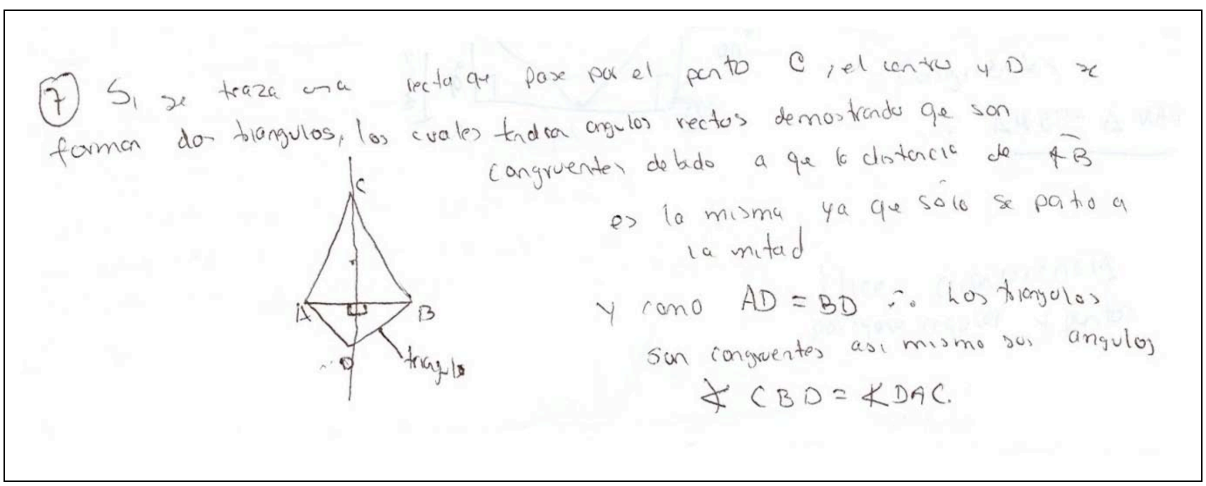

Figure 8. Student A11: Colloquial Argumentation Based upon Evident Actions

According to Figure 8, the student uses colloquial language to prove the affirmation. He traces the auxiliary straight line $\overline{CD}$ which cuts $\overline{AB}$ at its midpoint in a perpendicular way, and since $\overline{AD} = \overline{BD}$, he concludes (by the SSS criterion) that ΔADC is congruent to ΔBDC.

Problem 3

In ΔABC equilateral (Figure 9), *P* and *Q* are midpoints of $\overline{BC}$ and $\overline{AC}$, respectively. Prove that $\overline{AP} = \overline{BQ}$.

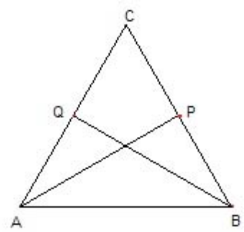

Figure 9. Problem Representation

Some Solutions

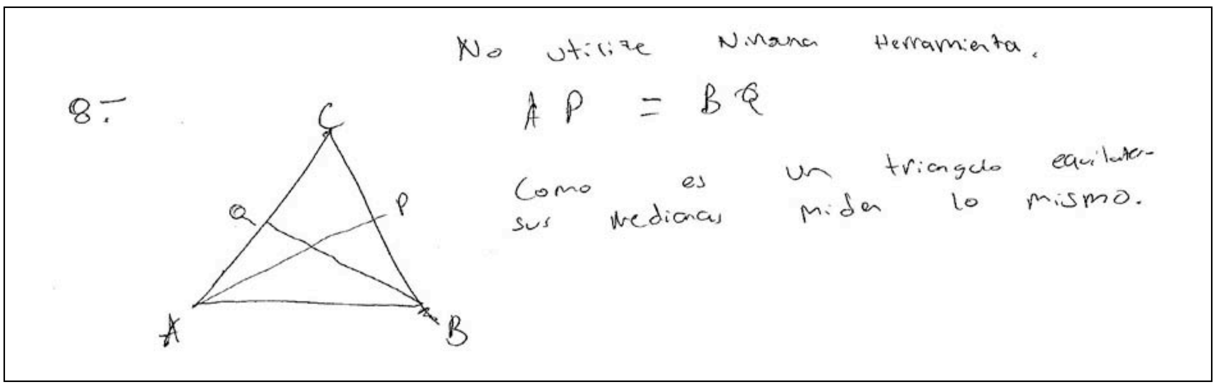

Figure 10. Student A10: Argumentation Based upon Evidences

In accordance with Figure 10, the student asserts that the measurements have the same length by the mere fact that the triangle is not equilateral. He does not provide any argumentation.

Problem 4

In W$ABCD$ (Figure 11), the midpoint of $\overline{AB}$ is *M*. With center in *M* an arc is described that cuts $\overline{AD}$ in *Q* and $\overline{BC}$ in *P*. Prove that $\Delta MBP \cong \Delta MAQ$

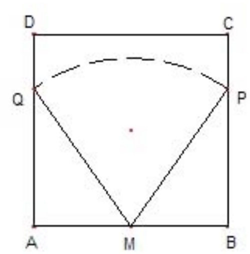

Figure 11. Problem Representation

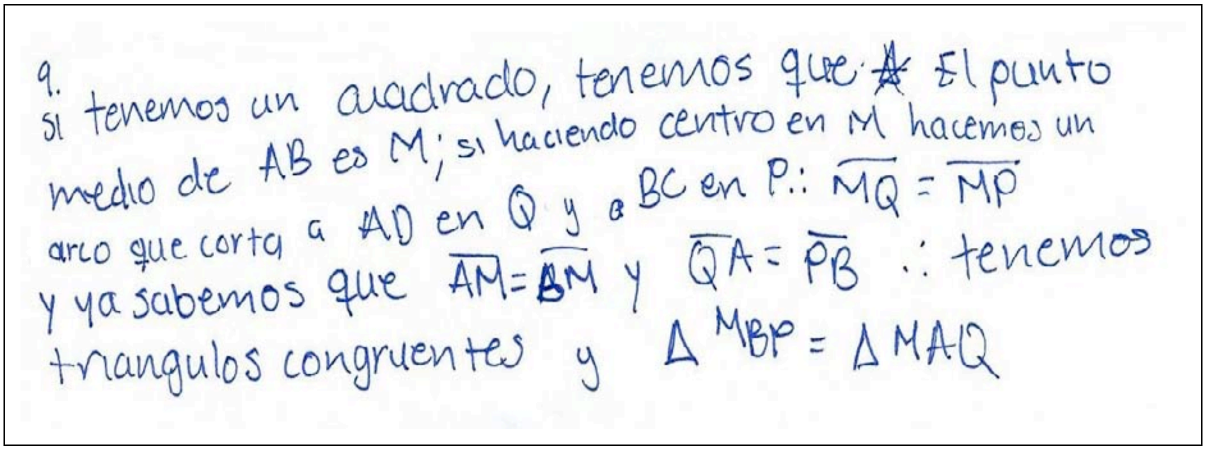
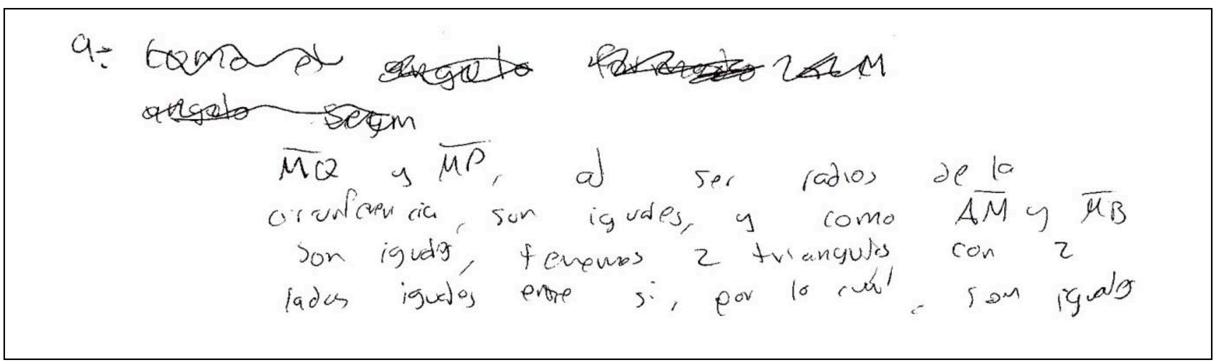
Some solutions



9.
si tenemos un cuadrado, tenemos que ~~A~~ El punto
medio de AB es M; si haciendo centro en M hacemos un
arco que corta a AD en Q y a BC en P.: $\overline{MQ} = \overline{MP}$
y ya sabemos que $\overline{AM} = \overline{BM}$ y $\overline{QA} = \overline{PB}$ ∴ tenemos
triangulos congruentes y $\Delta MBP = \Delta MAQ$

Figure 12. Student A12: Argumentation Supported by the Use of non Evident Colloquial Language

It is observed in figure 12 that for the student, two triangles are congruent is two of the sides of one are equal to two of the sides of the other, and then he concludes that the right-angled triangles are equal, even though he does not refer to the right angle.



9: ~~toma el~~ ~~angulo~~ ~~[illegible]~~ 2AM
~~angulo~~ ~~SQM~~
$\overline{MQ}$ y $\overline{MP}$, al ser radios de la
circunferencia, son iguales, y como $\overline{AM}$ y $\overline{MB}$
son iguales, tenemos 2 triangulos con 2
lados iguales entre si, por lo cual, son iguales

Figure 13. Student A7: A Proof he explains by the Use of geometric concepts

As it is observed in Figure 13, the student provides a justification based on triangle congruence (SAS criterion). Two equal corresponding sides (and the right angle which he does not mention) are enough for him to affirm that the two right-angled triangles involved are equal.

Conclusions

Generally, from the second and third working session it was observed that the majority of students justified the results using a colloquial language, and, sometimes, the processes of argumentation were imprecise or incomplete; however, in some cases, they did use a formal symbolic language with clarity. In general, students elaborated, in an acceptable way, the demonstration in which they resort to triangle congruence, or at least, this element allowed them to infer and elaborate a discourse with which they tried to justify the results.

To the light of students' answers, in this research, the kinds of proof which emerge during the solution the geometric problems of triangle congruence are the ones already mentioned in the research literature related to proof in mathematics. In our research, we could verify that there exists a great difficulty, on behalf of the students, to identify auxiliary elements which could be useful in order to ensure the veracity of the result. Students need to develop intuitive reasoning of the geometric objects in order to access both a better understanding of Euclidean geometry and a formal deductive reasoning for its study; in order to reach the lather, it is required to take into account the kind of tasks to be solved and the way in which they are guided.

USING TRANSFORMATIVE TASKS AND TOOLS TO CONCEPTUALIZE PROSPECTIVE MATHEMATICS TEACHERS' ARGUMENTATION PRACTICES

Sandra Richardson
Lamar University
sandra.richardson@lamar.edu

Introduction

Recent reforms in mathematics education have led to an increased emphasis on argumentation practices in mathematics curricula (National Council of Teachers of Mathematics, 2000). The relevance of argumentation in mathematics curricula has been demonstrated at various levels of K-16 mathematics. All findings consent that argumentation should be a central aspect of mathematics teaching and learning at all levels of schooling.

Argumentation, in this work, is defined as an act of communication intended to lend support to a claim. This definition presupposes a relationship between argumentation and proof, where proof is defined, in this work, as a logically correct argument constructed from given conditions, definitions, and theorems within an axiom system.

This exploratory work provides a description of argumentation practices among pre-service secondary mathematics teachers during an undergraduate mathematics capstone course. The work presents a possible relationship between the use of transformative mathematical tools, specifically technological tools, and pre-service teachers' argumentation practices. Additionally, this exploratory work investigates: (1) the role of pedagogically sound mathematical tools in the advancement of teaching acceptable argumentation practices, which lead to sound reasoning and proof processes; and (2) mathematical tasks useful to prospective teachers in the teaching of argumentation practices.

Results

This work revealed that the pre-service teachers' conception of argumentation directly influenced their instructional approaches in teaching. Involving them in reasoning through argumentation under different instructional practices enhanced their abilities to evaluate, integrate, bridge, and explain their mathematical knowledge. Significant developments in students' argumentation practices occurred as students used technological tools as a medium to support and define their reasoning. The integration of these transformative tools (i.e. Geometer's Sketchpad, Mathlab, etc.) with the students' content knowledge led to the production of strong mathematical products in the form of argumentation, reasoning, and proof.

With the use of similar tasks and tools, students' argumentation practices were conceptualized and categorized in four different categories: Argumentation as Confirmation, Argumentation as Validation, Argumentation as Discovery, and Argumentation as Explanation. Many aspects of the pre-service teachers' conception of argumentation are represented in work samples from each argumentation category. Models of student work from each category will be visually displayed in the full presentation.

THE STUDY OF MOTION PHENOMENA THROUGH MULTIPLE REPRESENTATIONS

Martha L. García Rodríguez
ESIME IPN
martha.garcia@gmail.com

Alma A. Benítez Pérez
CECyT 11 W.M. IPN
benitezperezalmaalicia4@gmail.com

This paper reports the results of research with the objective of analyzing the ways students related two or more representations to make sense of motion situations. In the study of movement phenomena some researchers have identified and documented the students' difficulties to read and interpret distance-time graphs. In line with this observation Bowers and Doerr (2001) point the tendency for students to interpret the distance time graph as a picture of the path of the motion phenomena. In the same sense Monk (1992) documents that when the students work with distance time graph, they can determine correctly the distance traveled by a car at different time intervals, although they can´t identify if the car speed increased or decreased. Goldin and Kaput (1996) said that when students are in problem solving activities they use different representations to work with the information provided, each representation bring forward different aspects related to the same concept. Previous researches make clear how important it is the underlying information in each representation.

The conceptual framework is based on complementary external representations to support the construction of deeper understanding. Ainsworth and Van Labeke (2004), pointed out that when learners interact with appropriate representations, their performance is enhanced.

We report three students' work which was selected after us identifying that they showed a representative work of the group, also they wrote their reports in more detail than their peers.

The activity reported was undertaken during two sessions of one hour and one half each. In this task we analyzed the relationship that students established between verbal and graph representations to make sense of motion situations; particularly we were interested in two points: a)Identify if they relate, in a distance-time graph, the slope whit the speed value; b) Identify how they represent in a distance-time graph the velocity changes at different time intervals

The findings obtained make it possible to assert that when students work on tasks that include complementary external representations they improve their understanding of motion situations.

THE CLOTHESLINE METHOD FOR MEASURING MATHEMATICS SELF-EFFICACY

Mark Causapin
Teachers College Columbia University
mgc2119@tc.columbia.edu

Many researchers have used Albert Bandura's work on self-efficacy as a theoretical framework in analyzing how beliefs affect educational performance. He defines it as "beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments (Bandura 1997)." Investigators have found evidence that support his theory when applied to school mathematics. Studies among college students (Hackett and Betz 1989), 7th grade (Chen 2002), and high school students (Randhawa, Beamer et al. 1993) provide data that show positive correlations between self-efficacy measurements and mathematics performance. Likewise, a qualitative research documenting the beliefs and performance of middle school children present congruent information (Usher 2009).

This research was conducted as part of a study that investigated the relationship of self-efficacy beliefs to mathematics achievement among Filipino high school students selected from a homogenous, rural, and low-SES community. Utilizing observations, interviews, and focus group discussions, self-efficacy was related to academic behavior, peer group activities, and parental support, and to mathematics performance.

Despite the emphasis on qualitative techniques, there was still a need to quickly assess self-efficacy for the whole student population of the school. The Clothesline Method is one instrument that allowed the respondents to rank and rate beliefs at the same time. Based on test-retest statistics, it was shown that the data produced were more reliable compared to a typical belief rating scale. Nonetheless, there were disadvantages in using this method. It can produce confusion among students and may result to many invalid data. The effectiveness of the instrument was highly dependent on how well the administrator explained the instructions. Finally, it was more time consuming. If perfected however, this may serve as an alternative to Likert or Bandura's scales especially for populations who are not familiar to conventional survey techniques.

Teaching Science and Mathematics to the E-Generation Introduction

Sherrie Bonderson
University of Nevada, Reno
sbonderson@washoe.k12.nv.us

Mike Robinson
University of Nevada, Reno
robinson@unr.edu

Students of tomorrow not only need basic ideas of science but also need to have an understanding of why science is so important to societies financial, social, political and cultural being (COSEPUP, 2007). Consequently, educators and researchers have begun to carefully evaluate how today's students learn and it is generally accepted that students learn best by "doing" especially in science classrooms (Dalton et al., 1997). However, besides hands-on instruction, current researchers and educators have also recognized the impact of technology on today's learners. In the new millennium, literacy takes on a new meaning. For example, the current generation of teenagers often referred to as the E-Generation have grown up in the era of Internet, cell phones, I-pods, and Nintendo which some believe has not only changed the way students think but also the way that they learn. (Jones-Kavalier, 2006). Therefore, some argue that that the use of multimedia technologies such as virtual laboratories, simulations and computer models are better suited for today's science students (Roschelle et al., 2000).

Purpose of the Study

The study will compare the effectiveness of student learning in a virtual computer laboratory experience to that of a traditional hands-on laboratory experience. Student attitudes and opinions of virtual labs will also be considered. Students will be asked to partake in a survey where they share individual feelings of the overall effectiveness and future usefulness of computer models.

Significance of Study

The significance of this study is to gain a better perspective on today's technological learners. In planning lessons, teachers can give more consideration to computer models and virtual lab simulations if this study and future studies show that such applications are more effective and motivating to present learners.

Methods Research Design

This study randomly divided four high school chemistry classes into two control groups and two experimental groups. The control groups conducted an in-class experiment under the supervision of the teacher and the experimental groups conducted an experiment using a computer module. The objective for all groups was the same; students were to determine the limiting reactant in a chemical reaction.

The experimental groups were assigned a virtual computer simulation. Students met at the school's computer lab and were assigned a lab on limiting reactants. The computer module asked students to make a comparison between building a cheese sandwich and chemical reactions. For example, students determined the limiting reactant in making a cheese sandwich when they were given eleven pieces of bread but only four pieces of cheese.

The control groups participated in a very similar experiment which took place in the classroom with the science instructor. Again, the key concept was asking students to deduce the limiting factor in a chemical reaction. Similar to the virtual lab in which students were making a relationship between recipes and chemical reactions, students were given the ingredients and the recipe for rice crispy treats or otherwise referred to in the experiment as carbohydrate chewies. Students were instructed to make chewies following the recipe they were given and then determine which ingredient limited the product.

Prior to both experiments, all students were given identical pretests concerning their attitudes and opinions towards virtual labs and hands-on experiences. Both experimental and control groups were given identical quizzes on limiting reactants and scores were compared.

Finally, approximately three months after carrying out the study, all students who participated in the study will be given a follow up or post quiz so as to gain a better understanding of student retention. The follow up quiz scores will then be compared to the original quiz scores of all students.

Results

T-Test will be used to compare means of treatment and control group subjects. Attitudes of the experimental and control groups toward virtual and hands-on experiments will also be compared. Results and conclusions with a discussion of results will be presented at the October PME conference.

AP COHORT MODEL: A STRUCTURE FOR TRANSFORMING HIGH SCHOOL MATHEMATICS PEER CULTURE

Melva R. Grant
Old Dominion University
mgrant@odu.edu

The Algebra Project's Cohort Model (APCM) offers a structure for high school mathematics classrooms that supports the development of an effective peer culture for developing mathematical understanding and mathematics learning efficacy. The APCM is built on 15 years of experience. The purpose of this study was to observe the peer culture transformation in one APCM classroom.

Poster Summary

The Algebra Project's Cohort Model (APCM) offers a structure that supports the development of an effective peer culture for developing mathematical understanding and mathematics learning efficacy. The APCM is an innovative approach for high school mathematics for students who have been consistently low performing on state or national achievement tests to "catch up" by graduating in four years and qualify for college mathematics courses, if they choose to attend (West, 2011). The APCM is built on 15 years of experience in middle schools and high school pilot programs that included instructional materials development funded by the National Science Foundation.

The purpose of this study is to observe within one Algebra Project Cohort Model classroom's peer culture transformation from "'I dare you to teach me' to 'I need and want you to teach me'" (Bob Moses, Summer 2010). The idea of harnessing the peer culture for mathematics learning is anticipated to occur during the traditional four years of high school in response to an APCM implementation. However, after a little over one year evidence of the transformation has manifested in the site that I have been studying.

The target Algebra Project Cohort classroom is located in a small urban community and is comprised of 19 students. My poster will present preliminary evidence of the peer culture transition using a multimedia and print display and include an overview of the Algebra Project's Cohort Model including an introduction of the cohort class and teacher, an APCM structural description, and community outreach through the Young People's Project.

TEACHER AND PROFESSOR PERSPECTIVES ON CONTRIBUTING FACTORS FOR COLLEGE MATHEMATICS SUCCESS

Elizabeth Kocher
The Ohio State University
kocher.3@osu.edu

Throughout the United States, high school students who take a college preparatory curriculum are often surprised when they are placed into a remedial mathematics course in college as they assume their high school courses have adequately prepared them to enroll in courses such as calculus. Although a college preparatory curriculum is necessary for college readiness, it alone is not sufficient to assure success. Indeed, in 2004 Achieve conducted a study which confirmed a gap between what students knew leaving high school and the actual knowledge that they needed to know coming into college (2010). Differences in the skills gained in high school and the expectations of knowledge needed in college may be a key component in this issue (Kirst & Venezia, 2001). Research has also suggested that the lack of coordination between high school and post secondary institutions could be part of the problem (Kirst & Venezia, 2001). Most scholars agree that this "expectations gap" exists, yet how to address this gap and provide an easy transition from high school to college has yet to be found.

Research done by the US Department of Education shows that the single best predictor of college success is not test scores, class rank or GPA, but the intensity and quality of a student's secondary school curriculum (Adelman, 1999). Too often the college preparatory curriculum in high school does not get a student through the mathematics placement test in college. The skills and knowledge actually necessary for success in post secondary mathematics courses needs to be clarified (Haycock, 2003). High school and college courses may not use the same criteria to determine what constitutes "success" (Berry, 2003).

What should readiness standards include? What knowledge or skills are needed and expected at the college level for success? Do both high school teachers and college professors agree on these factors? Exploring these questions this study looked at the perspectives of high school teachers and college professors surrounding factors which contribute to college mathematics success. Interview data from both groups was analyzed to determine if perspectives on contributing factors were uniquely or collaboratively viewed as important for success in college mathematics courses. Initial findings indicate both overlapping and disjoint views on what contributes to student success.

FOUR STAGE MODEL FOR DESCRIBING TEACHER IDENTITY FORMATION IN POST-SECONDARY MATHEMATICS

Mary Beisiegel
Harvard Graduate School of Education
marybeisiegel@yahoo.com

In an effort to understand the development of teaching practices of future post-secondary teachers of mathematics, individual and group interviews with mathematics graduate students were undertaken to explore their experiences and perspectives of mathematics teaching. These conversations probed their personal histories in studying mathematics, current experiences as mathematics graduate students, views of mathematics, and their possible futures in academia. In observing their lives during the academic year, it was noted that as they learned of the relative importance (or unimportance) of different aspects of a life in mathematics, the research participants observed that post-secondary mathematics teaching took on a certain form and that mathematicians adopted particular identities. Framed by the idea of legitimate peripheral participation (Lave and Wenger, 1991), in their transitions from graduate students to professors, the participants in this study seemed to move from a marginal position to a central place in the community as their identities, actions, and teaching more closely resembled those of the mathematicians in their department.

Four stages through which the participants passed and by which this transition process can be described are: replication, resignation, despondence, and repetition. First, in their process of becoming mathematicians, the participants first felt a need to replicate – not only mathematical content, but also who they could be as post-secondary teachers of mathematics. They were limited in what they could do as future teachers by the structures of the department and by the advice, or lack of it, from their faculty advisors. The participants were thus left to creating meaning amongst themselves, relying solely on the replication of the teaching they observed. Beyond the sense of replication came feelings of resignation, where the participants felt as though they must resign their aspirations and expectations for their teaching practices in order to be considered legitimate within the department. However, in attending to what was legitimate in the department, there seemed to be a considerable cost, bringing about a sense of despondence, where the participants began to feel hopeless about what they could do and how they could be as post-secondary teachers of mathematics. Finally, Caputo's (1987) notion of repetition, where an individual "forges his personality out of the chaos of events" despite the "incessant 'dispersal' of the self" (p. 21), helps to understand the elements of their identities and practices the participants held onto as they transitioned to becoming professors. These themes – replication, resignation, despondence, repetition – will be illustrated on this poster presentation, along with the transitions and connections between them. Also, the details and structure of the research project, as well the data that relates to each theme, will be presented.

TRANSFORMING PRACTICES BY UNDERSTANDING CONNECTIONS BETWEEN NEW MATHEMATICS TEACHER EDUCATORS AND NEW K-12 MATHEMATICS TEACHERS

Mary Beisiegel
Harvard Graduate School of Education
marybeisiegel@yahoo.com

Jennifer Eli
The University of Arizona

Andrea McCloskey
Penn State University

Rachael Welder
Hunter College, The City University of New York

Jan Yow
University of South Carolina

New K-12 mathematics teachers enter classrooms with “high expectations for themselves and for their students,” where the “early years of teaching are often characterized by a ‘sink-or-swim’ or ‘survival’ mentality because we have often failed to provide for careful support and thoughtful development of teaching expertise over time” (Bartell, 2005, p. 3). Similarly, new mathematics teacher educators must learn to navigate the often rocky terrain of their institutions, wherein they seek support for finding ways to strike a balance between teaching, research, and service. As Reys, Cox, Dingman, and Newton (2009) point out “important aspects to be monitored are the challenges that lie ahead for these new Ph.D.s as they begin their careers in higher education” (p. 9). While others (e.g., Golde & Walker, 2006) have looked to these challenges to help understand how doctoral education could provide better preparation for careers in academe, this research project sought to look at the similar challenges faced by two groups of novice teachers (with less than three years of experience): those teaching mathematics education courses at universities and those teaching mathematics in K-12 classrooms. In particular, this research study focused its attention on addressing the research questions: How are the experiences of new mathematics teacher educators similar to those of new K-12 mathematics teachers? In what ways could the knowledge of these similarities help to inform and possibly transform new mathematics teacher educators’ practices in working with pre- and in-service teachers?

To explore these questions, we asked a cohort of new mathematics teacher educators to answer questions related to their new academic positions. This poster will present: 1) the preliminary results of a survey of new mathematics teacher educators, 2) results of a meta-analysis of recent research that explores the experiences and challenges of new K-12 mathematics teachers; 3) a comparison of the two groups’ experiences and challenges; and 4) how this research has the potential to inform and transform our approaches to mathematics teacher education at all levels.

NEW "TIP" FOR ENHANCING MATHEMATICS INSTRUCTION

Pier A. Junor Clarke
Georgia State University
pjunor@gsu.edu

Candace Williams
Georgia State University
cwilliams136@student.gsu.edu

Grounded in constructionism, socio-cultural theories, and a cognitive apprenticeship model of learning, this study investigated the dynamics of the teacher-intern-professor model as a support to effective mathematics instruction and how they used the teacher work sample as a tool for instruction and performance assessment to enhance the teaching and learning process conducted by pre-service intern teachers as they implement standards-based lessons.

Although teacher preparation programs offer the strategies needed for pre-service intern teachers to be successful in their first years of teaching, the retention rates for new teachers, especially those in urban schools and high needs areas, are declining. As a result, student success is compromised with the transiency of qualified individuals (Wright & Nassar, 1991). In spring 2011, at a research I university in the southeastern region of the United States, the *TIP Anchor Action Research Project* was implemented to address the needs of teachers through their preparation phase and examine the effect on student achievement. The Teacher-Intern-Professor (TIP) model consists of a mentor or supervising classroom teacher, a pre-service intern teacher, and a university professor.

Through the use of the teacher work sample (TWS) as a tool for instruction and performance assessment, each of ten TIP groups and its comparison class examined a unit of instruction administering similar pre- and post-tests. Reflective of the knowledge gained from the pre-test, each intern use the results to hone the instructional design and to build more meaningful lessons aligned with the desired learning goals. During the study, the university professor ensured that: (1) each group received needed supplies, (2) school visits were made to support and conduct discussions with the TIP group, and (3) the research activities were in progress. Earlier research suggested that interns' teaching experiences benefit by having support that bridges both university and school experiences (Zeichner, 2010).

The TIP group participates in discussions, interviews, and records data in journals. This serves as the qualitative technique to support the quasi-quantitative data being collected from the pre- and post-tests. This study, which is grounded in constructionism, socio-cultural theories, and a cognitive apprenticeship model of learning seeks to answer the following research questions: (1) In what ways did the TWS enhance the teaching and learning process conducted by pre-service intern teachers as they implement standards-based lessons in the TIP model and (2) what are the dynamics of the TIP model as a support to effective mathematics instruction?

Preliminary results suggest that: (1) the intern teachers felt comfortable and more open to the groups' decisions on pedagogical and classroom management concerns, (2) the collaborative approach in meetings, observations, and research was useful and effective, and (3) the use of the TWS was recognized as a constructive and meaningful way in be-coming an effective mathematics teacher who consistently reflects on his/her practice.

PRE-SERVICE TEACHERS OF COLOR INCORPORATING A CHILD'S HOME AND COMMUNITY MATH KNOWLEDGE

Crystal Kalinec Craig
University of Arizona
CKalinecCraig@email.arizona.edu

The purpose of this study was to analyze the experiences of four Pre-Service Teachers (PSTs) of Color as they crafted math lessons that utilized a child's home and community knowledge. Diverse, underrepresented students benefit from such lessons because learning is more meaningful and relevant. Some PSTs have personal experiences as diverse learners that help them to effectively teach students from similar backgrounds. Data collected included lesson plans, individual interviews, and written reflections. Findings showed that while PSTs of Color eagerly incorporated a diverse child's home and community knowledge into their lessons, they did not feel confident in sustaining this practice.

As part of a larger dissertation study aimed at describing four pre-service elementary teachers' beliefs and experiences related to teaching mathematics for conceptual understanding (Fennema & Romberg, 1999) and with cultural relevance (Ladson-Billings, 1995), this poster will focus specifically on how the Pre-Service Teachers (PSTs) of Color come to teach elementary mathematics to diverse learners by connecting to the child's home and community knowledge. Children possess a home and community knowledge that may be rooted in their culture (Ladson-Billings, 1997), in their Funds of Knowledge (González, N., Moll, L. C., & Amanti, C. 2005), and/or is based on their experiences within the local community (Turner, E., Gutierrez, M. V., Simic-Muller, K., & Diez-Palomar, J., 2009). It is widely understood that PSTs come to the teacher preparation program with prior beliefs and experiences in education and mathematics (Featherstone 1992; Lidstone and Hollingsworth, 1992) and what it means to teach diverse learners (Meaney et al., 2008). Throughout the mathematics methods coursework and elementary field experiences, research has suggested that PSTs should be challenged and/or supported in their prior beliefs and experiences on teaching diverse learners (Cabello & Burnstein; 1995; Aguirre, 2009). Work in this area is particularly important for PSTs who are diverse learners and/or are from underrepresented backgrounds (Montecinos, 2004). The prior experiences of PSTs of Color may shed some insight into how all teachers (not just those from the demographic majority) might better educate diverse students in the field of mathematics—a content area that has historically marginalized students based on culture, language, ability, and class.

The three female and one male PSTs in the study (all self-identified as Latina/o) were a part of a larger elementary methods cohort in the Fall 2010 and were placed in field experience classrooms at three local elementary and middle school, made up largely of Latina/o and low socioeconomic populations. My poster will analyze how PSTs' of Color acquired and integrated the knowledge of the local community and of their students in order to write more meaningful, relevant math lessons. The experiences were recorded in a variety of ways: three interviews individual reflections on the School and Community Math Project, reflections about relevant course readings, and reflections on a case study with a young child.

The findings showed that all of the PSTs of Color considered a child's home and community knowledge as being important in how he/she learns mathematics, yet they still wanted more experiences in making meaningful and sustainable connections to their daily practice.

Additionally, nearly all of the PSTs of Color framed a child's home and community knowledge around consumption (e.g. buying a toy or consuming food). The adage of "getting the most bang for your buck" ran predominantly throughout their lessons. Bilingual PSTs of Color saw a student's native language as another way to connect to a child's home and community knowledge. Other themes and implications for teacher education will be included in the analysis.

"I AM NOT SEEING WHAT I READ ABOUT": A MATHEMATICS STUDENT TEACHER'S STRUGGLE WITH DISCONNECTED TEACHING EXPERIENCES

Stephanie Behm Cross
Georgia State University
scross@gsu.edu

Nermin Bayazit
Georgia State University
nbayazit@gsu.edu

In the U.S. and most parts of the world, the student-teaching internship is the culminating experience of initial teacher education programs (Guyton & McIntyre, 1990). Most teachers view this internship as the most valuable part of their preparation, claiming that most of what they know comes from first-hand teaching experience (Feiman-Nemser & Buchmann, 1985). The purpose of this presentation is to share the story of Julie as she navigates this experience.

Julie is a middle level prospective mathematics teacher enrolled in an undergraduate teacher education program at a large urban state university in the South-Eastern region of the United States. In Fall 2010, she participated in a 2-day per week field-based practicum experience and a university-based mathematics methods course. The course and field experiences in the fall focused primarily on theoretical readings, field-based observations guided by those readings, and lesson plan development. In Spring 2011, Julie completed her full-time student teaching in the same 6th grade mathematics classroom where she completed her practicum hours in the fall.

Data for this paper consist of Julie's written assignments from the Fall 2010 mathematics methods course, observation field notes from student teaching, and transcribed interviews from both fall and spring semester. To analyse the assignments and interviews, the researchers read and re-read all narratives separately and collectively to identify general themes. Common themes from Julie's case include the following: philosophical differences between mentor and student teacher, the disconnect between theory and practice, and the question of whether this is the correct career choice. These themes are highlighted below.

From the beginning of the fall practicum experience, Julie struggled with the disconnect between her newly developing teaching philosophy as shaped by her university coursework, and the quite different mathematics teaching actions of her mentor teacher. She states,

> I wanted so badly to be with the picture perfect teacher, but I am not. I think what is frustrating for me is how she teaches math. The goal is not to understand the concept and the why but be able to do the steps and get the answers. I also know she was frustrated with me because I was spending so much time on things. We're just very different. (Interview 1)

In addition to the struggle between coursework and field experiences, Julie also appeared to be struggling with her decision to become a teacher. She states,

> I've been down and questioning whether or not I'm really going to teach and go forward. It has been difficult. It is a lot of work, which I don't think I was prepared for. (Interview 2)

These, and other quotes from Julie's written work and interviews, will be shared during the presentation to explore issues of disconnect. In particular, we focus on the lack of autonomy and flexibility experienced in this setting and possible implications for teacher education.

INVESTIGATING PRE-SERVICE CANDIDATES' IMAGES OF MATHEMATICAL REASONING

C.E. Davis
North Carolina Central University
cedavis@nccu.edu

Subject Matter Knowledge (SMK) and Pedagogical Content knowledge (PCK) are seen as diverse, multidimensional, and vital to a teachers' knowledge base for teaching. Understanding pre-service candidates' (PSC) organizational knowledge, connections among ideas, proof and inquiry, and knowledge growth within mathematics are important factors to explore when examining their images of mathematical reasoning. This research was conducted during a methods course.

Research Focus

Borko and Putnam (1996) suggested that learning opportunities for teachers be grounded in the teaching of subject matter and "provide opportunities for teachers to enhance their own subject matter knowledge and beliefs" (p. 702). In response to this assertion and Schoenfeld's (1999) call for theoretical research that is focused on practical and relevant applications throughout education, the focus of this research is to explore PSCs' images of mathematical reasoning.

Conceptual Framework

The conceptual framework for the research helps explain PSCs' images of mathematical reasoning when examining responses to several related questions about reasoning and proof. The conceptual framework uses components of Shulman's (1986) knowledge base in teaching and incorporates Pirie-Kieren's (1994) notions of primitive knowledge and images from their model for growth in mathematical understanding.

Methods of Inquiry

The investigation of PSC' knowledge of mathematical reasoning was part of a study investigating prospective teachers' knowledge of *what* and *how* to teach concepts in an elementary mathematics methods course. The study was done over a 15-week semester, involving several PSCs.

Results

In examining the PSCs' responses to the questions there is a need to help them define terminology when explaining their images. As the PSCs draw upon their images of mathematical reasoning, the data has strong implications for their propositional knowledge while examples of case knowledge and strategic knowledge are combined throughout to exemplify either observations or the personal experiences they have had as a student in a mathematics classroom. In addition, the data reveals that it becomes evident that the PSCs have strong images with regards to propositional knowledge.

Discussion

With current reform efforts such as the Core Common Standards guiding curriculum decisions, it is imperative that teacher education programs look forward to the Standards for Mathematical Practice, so that instruction is aligned with these efforts. These practices are built on established processes and proficiencies for mathematics education that rely heavily on PSCs' knowledge and beliefs of mathematical reasoning. Therefore, investigations into PSCs' beliefs on mathematical practices need to be continually explored and best practices further defined for all mathematics teachers.

NOVICE TEACHERS' PERSPECTIVES OF TEACHER PREPARATION

Brian W. Gleason
University of New Hampshire
brian.w.gleason@gmail.com

I report here on research that examined novice secondary mathematics teachers' perceptions of their preparation and their perceptions of ideal teacher preparation. The teachers expressed more positive views of teacher preparation than those typically found in the literature. Furthermore, the teachers provided insights into how teacher preparation could be made more meaningful and effective. These suggestions were grounded in their teaching experience, their beliefs about teaching, and their experiences as prospective teachers.

Most interested groups have a less than favorable view of teacher preparation (Labaree, 2006). To examine how teachers perceive their preparation, I interviewed relatively recent graduates of a large, well-respected secondary mathematics teacher preparation program. Contrary to what might be expected, the teachers were generally satisfied with their preparation. The suggestions they made for future teacher preparation were phrased as improvements, rather than reinventions, of the existing program. Moreover, their views of their preparation were heavily rooted in their beliefs about what teaching is and should be, so that as this latter belief shifted or stabilized during their preparation and initial years of teaching, so too did their view of their preparation experience. This phenomenon aligns with Green's (1971) notions of primary and derivative beliefs.

In particular, the teachers held a view of teaching that was more social and less cognitive than many teacher educators, which sometimes led to teacher educators and prospective teachers having conflicting goals during the teacher preparation program. This in turn led to missed opportunities that directly affected the teachers' level of preparedness. For example, the teachers acknowledged a tendency to disengage from coursework they perceived as irrelevant or inefficient. From their current point of view as experienced teachers, this disengagement deprived them of possible learning experiences that would have benefited them in their later teaching. Consequently, the teachers suggested direct actions teacher educators and teacher preparation programs could take that would prevent these episodes of disengagement, thereby improving teacher education by encouraging more continuous and authentic participation from prospective teachers.

The teachers' views of ideal teacher preparation are also revealing, and surprisingly similar. One alteration every participant proposed was to either increase or foreground (or both) the field experience component of their preparation wherein they observed and taught in middle or secondary schools. This recommendation is connected to the prior point about disengagement. Field experiences, the teachers felt, had a significant impact on their beliefs about what teaching is. Experiencing classrooms from the point of view of teachers rather than students, often for the first time, affected their thinking about the nature of teaching. The experiences also provided concrete knowledge for them to draw upon in later mathematics and methods courses. Thus, foregrounding and expanding the field experience component would prompt prospective teachers to seriously attend to later instruction in mathematics and pedagogy and also allow them to better make sense of that instruction because they would have personal experiences to connect it to.

WHAT DOES "REAL-LIFE" REALLY MEAN TO ELEMENTARY PRESERVICE MATHEMATICS TEACHERS?

Ping-Chi Hsieh
University of Arizona
hsiehp@email.arizona.edu

Marcy Wood
University of Arizona
mbwood@email.arizona.edu

Many mathematics teacher educators and teachers emphasize the importance of connecting mathematics to real-life in order to engage students in learning mathematics. Several researchers have also explored the benefits of involving students in real life contexts (e.g. Civil, 2007 and Gutstein, 2003). For example, Luis Moll and his colleagues (Moll, Amanti, Neff, & Gonzalez, 1992) suggest that connections to household funds of knowledge can motivate students to learn mathematics in the classroom. While researchers have extensively explored the outcomes of engaging students in real-life contexts, what remains unexplored is how teachers understand and use ideas about real-life in their classrooms (Author 2 and others, 2011). This poster begins the exploration of teacher understandings by examining how one preservice teacher (Francis) made sense of real-life in her school experiences.

Francis participated in an elementary teacher preparation program at a large university in the southwest. She was also part of a research project examining the relationship between the math methods classroom and her field placement. The research project collected a variety of data from Francis including transcripts from 2 interviews and copies of all written work for the course. In total, the written data on Francis comprises over 53 pages of text. The findings below arise from examination of each of these documents.

Francis' work shows three different ways in which she connected real-life to mathematics teaching and learning: (a) *Using students' "real-lives"* – their already lived experiences (i.e. their home, language, and cultural experiences) – to engage them in mathematics. For example, Francis tried to make mathematics more accessible for one of her students from Mexico by discussing the mathematics problem in Spanish with her. (b) *Creating "real-life"* experiences for students to help them understand mathematics problems. Francis helped a student understand "round-trip" (which was an important component of a mathematics word problem) by asking the student to walk across the classroom back and forth. (c) *Using mathematics to make sense of real world* situations. Francis stated that she would use mathematical explorations of her students' community to help her students become more aware of the social issues around them. Making sense of teachers' use of "real-life" provides insights into teachers' mathematics pedagogical thinking including their constructions of students' lives and how to connect students to content. This poster is an initial exploration into this sense-making.

GATHERING EVIDENCE AS A SUPPORT FOR NOTICING

Wenjuan Li
University of Illinois at Chicago
wli26@uic.edu

Alison Castro Superfine
University of Illinois at Chicago
amcastro@uic.edu

The purpose of the poster is to present preliminary findings from an exploration of gathering evidence as a support to develop preservice elementary teacher's (PST's) ability to notice to children's mathematical thinking. This research focuses on two primary questions: (1) How do PSTs report evidence of children's mathematical thinking? (2) How do the processes of gathering evidence and reporting evidence support PST to notice the specifics in children's mathematics thinking? Recent research provides evidence that, in-service teachers, if given opportunities to discuss children's mathematical thinking in the form of video clips, can learn to notice more specific aspects of children's mathematical thinking as opposed to noticing aspects about teaching (e.g., Sherin & Van Es, 2006). However, the trajectory of PSTs developing their ability of noticing children's mathematical thinking is different from that of in-service teachers in that they have had fewer opportunities to work with children as compared to in-service teachers, and thus have fewer resources from which to draw from. Little attention has been paid to the design of activities that can help PSTs notice children's thinking. Building on this work, we use gathering evidence as a scaffold to develop PSTs' noticing of children's mathematical thinking and examined how the activity of gathering evidence supported PSTs' ability to notice children's mathematical thinking in terms of the evidence PSTs provided for their noticing.

Data from this study is taken from the Videocases for Preservice Elementary Mathematics (VPEM) Project, which involved the implementation of 8 videocases in a mathematics content course for PSTs. Videocases were implemented at regular intervals across one semester. During the implementation of the videocases in the content course, PSTs first worked on the mathematics problems discussed in the video, and then viewed the videos through the lens of the focus questions. PSTs were encouraged to gather evidence, as part of their responses to the focus questions, to support their noticing. We analyzed PSTs' collective discussions of what they noticed and the types of evidence they provided employing a grounded theory approach (Strauss & Corbin, 2008). We first identified the discussion of notice (DON), after which we examined the ways PSTs reported their evidence to support their noticing. We then examined the patterns of evidence reported and its relation to the quality of noticing, i.e. general noticing or specific noticing.

Four types of reported evidence emerged from the data: (a) citing line numbers from the transcript, (b) quoting what children said in the transcripts or videos, (c) describing or summarizing the events that happens in the video, and (d) making interpretations. More than one third of the DONs share the following pattern: starting with a noticing by providing evidence using inferences, then being prompted by the facilitator, more specific noticing with line numbers or quotes or general descriptions are shared. As the way of reporting notice increase, the more the specific details that are provided.

PRESERVICE TEACHERS' KNOWLEDGE OF KEY GEOMETRY TERMS

Barba Patton
University of Houston – Victoria
PATTONB@uhv.edu

Yolanda Parker
University of Texas-Arlington
YolandaParker@uta.edu

Data from assessments such as TIMSS and NAEP indicate that students are weak in the area of measurement (Thompson & Preston, 2004). Bearing this in mind, it is important to make sure that preservice teachers are prepared to teach measurement topics to their future students. As such, in the fall of 2010, fifty-two preservice teachers were given a measurement application test as part of their mathematics methods course. About 94 % of the group were female, ranging in age from 20-59. The largest ethnic group was Anglo followed by Hispanics and then African American.

The measurement application test consisted of 12 multiple-choice questions that were modeled after the released 5th grade state tests. The scores on this section were approximately 33% mastery (scoring 90-100%), 33% passed (scoring between 75-90%) and 33% failed (scoring below 75%). The results of this test were used to develop skills modules to help the students master these concepts. In addition, a majority of the missed questions appeared to be due to a misapplication of key measurement and geometry terms and concepts. Some researchers believe curriculum should not focus solely on terminology (e.g., National Council of Teachers of Mathematics, 2000). However, there is a place for vocabulary instruction in the content areas (Gunning, 2003). Since our students will become teachers some day, our purpose was not to assess their knowledge of vocabulary, but to determine if the students, perhaps, were not able to apply this knowledge properly. As a follow-up, in the Spring 2011 semester, the students were given a vocabulary test which included 24 words that were listed by several textbook sources as geometry words expected to be mastered by 6th graders. It was given in a matching format. There were three groups of eight words where each group had one or two distracters (i.e. a triangle has three sides). While the distracter was true it could have fit several of the choices but there was only one correct answer for the other questions in the set. The distracter had to be used after the one and only correct answers were selected for the other questions. Approximately 60 % of the participants scored mastery (90-100%) on the vocabulary section. Less than 5% had a failing score (below 75%) and the remaining 35% scored passing but not mastery.

The tests or inventory of skills were given within the first month of the semester. The inventories were given in order that skill modules can be developed to meet the student specific needs. These will be developed and given to the students during the Spring 2011 semester. A large majority of these students will be in the classroom either for student teaching or as teacher of record within a year. Therefore it is imperative that the teacher candidates are prepared to teach these geometry skills effectively.

The challenges of simultaneously developing deep content knowledge and pedagogical content knowledge (e.g., Shulman, 1986; Ball & Bass, 2000) for both in-service teachers and pre-service teacher candidates have been expressed for some time. Utilizing the power of the hidden mathematics framework as suggested by Abramovich and Brouwer (2006) requires finding, creating and working with mathematical problems that connect across the mathematics curriculum. We have met these challenges, and achieved new levels of success through a set of unique inquiry experiences, which develop visualization and deep, analytical content knowledge as well as pedagogical knowledge within an urban pre-teacher mathematics methods course. Of particular interest in this approach are the unique objects that are used - Giant Triangles. These triangles are equilateral, 1-meter in edge length, made of highly resilient, lightweight and brightly colored plastic (similar to that used in many popular kites), and can be quickly assembled and reassembled to create a wide range of polyhedra. The giant triangles, as constructed, have powerful inbuilt mathematics that naturally emerge as learners interact with them using very carefully designed activities. Furthermore, the triangles relate physically to learners through their kinesthetic character and aesthetic appeal. The learners' use of the materials changes as their knowledge develops observably shifting from concrete to abstract through interaction, in groups, with the materials.

The university where this work was done is one of the most ethnically diverse liberal arts institutions in the mid-south-western United States and is a federally designated Minority Serving Institution. It provides 4-year degree programs and has an open enrolment policy. A large percentage of its undergraduate students are the first college attendees in their families, and work full-time while attending college. We share a learning trajectory that was successfully enacted in ten mathematics methods classes for elementary and for middle-grades pre-service teachers in single 160-minute class sessions during two successive semesters.

The learning trajectory consists of constructing and comparing the pyramids formed from equilateral triangles; constructing the triangle-faced Platonic solids and reasoning about the limited number of Platonic solids through newly developed visualizations; enumeration of patterns relating the numbers of vertices, edges and faces of a variety of polyhedra; doubling the edge lengths of the tetrahedron to determine the scaling effect on surface area and volume, and associated tessellation of space using tetrahedra; and, duality among the Platonic solids. Reflective comments from learners attest to the power of this learning trajectory in changing attitudes among pre-service teacher candidates about doing and teaching mathematics.

HELPING PROSPECTIVE TEACHERS PAY ATTENTION TO STUDENT THINKING: THE EFFECTS OF AN ONLINE DISCUSSION BOARD

Sandy M. Spitzer
Towson University
sspitzer@towson.edu

Christine Phelps
Central Michigan University
phelp1cm@cmich.edu

Some educators have recently suggested taking a new orientation toward teacher education, in which prospective teachers (PTs) are taught the skills and dispositions needed to improve their teaching over time through a systematic study of their own practice. One method for this improvement of teaching, in which teachers use a framework of setting learning goals, teaching a lesson and collecting evidence of student achievement of those goals, creating hypotheses about how instruction helped that achievement, and revising the lesson accordingly, was outlined by Hiebert, Morris, Berk and Jansen (2007). This method ("lesson experiments") is similar to the practices of lesson study, but does not require a collaborative group of educators and may thus be easier to implement for individual teachers.

Emerging research (e.g. Spitzer et al., 2010) suggests that classroom interventions can help PTs improve their lesson experiment skills. However, the time needed for interventions may be difficult to integrate into already-full teacher education programs. Thus, online formats, in which PTs can interact with each other and collaboratively improve their skills outside the classroom, have an obvious advantage. This study aims to investigate the effectiveness of an online discussion board in helping PTs improve their analysis of a lesson.

To investigate this question, we used an online discussion board to help PTs (N = 15) learn to evaluate evidence of students' learning and form hypotheses about the success of a lesson. PTs were given a learning goal and asked to watch a videotaped lesson online. Then, PTs posted initial reactions analyzing the effectiveness of the lesson. Next, PTs read classmate's posts and responded with a reflective comment. Finally, PTs read all posts and then wrote a short paper about their final judgment of student learning and the success of the lesson. Data were analyzed in terms of how well PTs we able to look past surface features of the lesson and instead attend to students' mathematical thinking related to the learning goal.

Initial results suggest that participation in the discussion board activity helped PTs improve their lesson experiment skills; specifically, PTs moved toward evaluating the lesson in terms of student achievement of the learning goal. Specifically, by the end of the intervention (i.e. after the discussion board participation), a higher percentage of PTs' claims were mathematical and relevant to the learning goal (47% compared to 38% in their initial responses). PTs' focus on irrelevant mathematics declined (22% of claims compared to 30%), indicating that they made the learning goal more of a focus in their analysis. However, PTs continued to reference non-mathematical ideas in their evaluation of the lesson (23% of claims in initial responses and 24% at conclusion), suggesting that the PTs' beliefs about teaching, rather than a focus on student mathematical thinking, continued to play a major role in their analysis of lessons. These results suggest that an online discussion board can be used to help improve PTs' lesson experiment skills, though room for improvement remains.

FACE-TO-FACE AND SYNCHRONOUS ONLINE DISCOURSE AND TEACHERS' KNOWLEDGE ABOUT TEACHING VARIABILITY WITH TECHNOLOGY

Tina T. Starling
NC State University
ttstarli@ncsu.edu

There is a growing emphasis on the development of prospective mathematics teachers' technological, pedagogical, content knowledge, but little is known currently about how discourse in mathematics education courses may affect the construction of this specialized knowledge. Knowing more about how prospective teachers may engage and interact with one another and the knowledge they construct in face-to-face and online settings may reveal important similarities and differences for teacher educators to consider. With variability being the content focus of this study, the TPSK framework (Lee and Hollebrands, 2008) is used to identify knowledge disclosed through discourse in face-to-face and synchronous, online settings.

Research Question and Methodology

- What is the relationship between discourse and the development of knowledge for teaching variability with technology in face-to-face and online mathematics education courses?

Because discourse and constructed knowledge cannot be completely identified and analyzed quantitatively, a qualitative research methodology was selected (Patton, 2002). The author taught a five-week unit on teaching data analysis and probability with technology to middle and secondary prospective teachers as part of a *Teaching Mathematics with Technology* methods course. The face-to-face group (n=25) and an online group (n=17) which met live, using the web-conferencing tool *Elluminate Live* used the same curriculum (Lee, Hollebrands, & Wilson, 2010). Each class session was video-taped or recorded. In addition, a small focus group was selected to watch closely during small group discussions during class and each member of the focus groups was interviewed twice during the study. A pre/posttest was given to obtain information about prospective teachers' statistical and probabilistic knowledge, particularly as it related to variability.

Discussion

Data for this study is under analysis. However, data from a pilot study with face-to-face (n=14) and online (n=8) groups revealed discourse patterns between prospective teachers and misconceptions regarding box plots, residuals, and the law of large numbers. This poster will present: (1) three tasks, given to prospective teachers in the current study, aligned to address those misconceptions, and (2) a comparative analysis of discourse from both environments and prospective teachers' knowledge about how to teach variability with technology.

IMAGES, ANXIETIES AND ATTITUDES TOWARD MATHEMATICS

Shashidhar Belbase
University of Wyoming
sbelbase@uwyo.edu

Images of mathematics as fallible or infallible can have potential negative and positive impacts on pedagogy of mathematics with the subsequent change of attitude towards mathematics as positive or negative (Belbase, 2010; Goolsby, 1988; Lakoff and Nunez, 2000; & Ma and Kishor, 1997). An image of mathematics due to a lack of comfort that someone might encounter when required to perform mathematically may result into a mathematics anxiety (Wood, 1988), or the feeling of tension, helplessness, and cognitive disorganization one may face when required to manipulate numbers, symbols and shapes (Richardson and Suinn, 1972; Tobias, 1978). In a long run, mathematics anxiety can harvest different feelings such as like/dislike, happiness/worrisome, and motivation/fear (Hart, 1989; Wigfield and Meece, 1988).

A theoretical-analytical model with combinations of images (fallible, infallible), anxieties (high, low self-esteem), and attitudes (positive, negative) toward mathematics resulted eight possible outcomes representing philosophical-psychological-perceptions about mathematics. These combinations are- (1) infallible, high self-esteem, and positive attitude; (2) infallible, high self-esteem, and negative attitude; (3) infallible, low self-esteem, and positive attitude; (4) infallible, low self-esteem, and negative attitude; (5) fallible, high self-esteem, and positive attitude; (6) fallible, high self-esteem, and negative attitude; (7) fallible, low self-esteem, and positive attitude; and (8) fallible, low self-esteem, and negative attitude (Belbase, 2010). Some of these combinations (1, 4, 5, & 8) seem to be theoretically and practically viable, but others (2, 3, 6, & 7) can be non-practical because high self-esteem and negative attitude and low self-esteem and positive attitude toward mathematics seem contradicting. Such analyses may be helpful to understand possible consequences of these relationships with viable research and pedagogical implications.

TEACHERS' BELIEFS ABOUT THE MEANINGS OF THE DERIVATIVE

Corina Georgescu
University of Toronto
corinaeg@hotmail.com

Dorian Stoilescu
University of Toronto

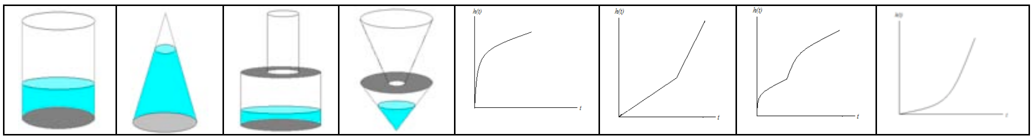
In this report we researched about the beliefs calculus teachers in Mexico have about meanings associated to the derivative function. We designed a questionnaire containing problems: one of them qualitative related to the filling of containers and the other one conceptual related to the analysis functions. Their written and spoken arguments allowed us to categorise their beliefs, determine their strength, coherence and the relations that they establish individually which internally form individual systems that are called Internally Coherent Systems of Beliefs.

Introduction

One of the most serious problems that Mathematics teaching faces in Mexico is a heavy operative load (De la Peña, 2002). This contributes very little to construction, to the comprehension of the meaning of concepts and it deteriorates the conceptual part (Amit y Vinner, 1990; Schoenfeld, 1985; Hiebert y Lefevre, 1986). Particularly the derivative function, we have a concept with many meanings associated to it, his comprehension is more complex because it is not the same learning derivative techniques, understanding its meanings. This doesn't mean that calculus teaching at High School level must be aimed at a strict presentation that takes the place of meanings, not by any means. But the direction depends on the teacher because he is the one who in the end chooses teaching topics and decides on their organisation moved of course by his or her beliefs, ideas and attitudes (Philipp, 2007; Sivunen & Pehkonen, 2009). But, ¿Do teachers understand and distinguish between qualitative and conceptual parts and the management of ideas? ¿What are their beliefs about those ideas? There is very little research about such questions in the field of calculus (Törner, 1999; Badillo, 2003; Speer *et al.* 2005; García, *et.al.* 2006 Hähkiöniemi, 2006;). Exploring the beliefs of teachers is important since recognising such beliefs has a great potential to inform about educational research and practice. According to MaaB & Schlöglmann (2009), identifying them is an essential prerequisite, mostly in relation to central concepts contained in the curricula of school mathematics in order to change and improve teaching in schools. This is our research's rationale whose objective is to describe and interpret the beliefs calculus teachers at a High School level have and the relationships such teachers establish among them, about the meanings of the derivative function. The questions that guide it are: ¿Do calculus teachers notice that the derivative function allows the study of instant change rate? ¿Is the adequate nature of the derivative function clear for calculus teachers?

Methodology, Questionnaire and Participants

The research we did is a qualitative one and is a study of multiple cases. We chose the survey. The instrument we used was a questionnaire whose design responds to the warning made by Tirosh (2009) in the sense that the design of reliable research instruments or tools is one of the challenges that research in mathematical education generally faces. Besides this, we brought about conversations between pairs considering that it demands proof and refutation about their arguments. Those conversations allowed us to prove the effectiveness of the intervention in the creation, modification and elimination of one of the teachers' beliefs. The questionnaire contains two problems that are no routine: the first of them involves an activity of matching seventeen containers that can be either cylindrical, conical or both in which water is poured at a constant rate. It contains graphs showing water height variation in function of time



The second problem involves obtaining the derivative of a function:

$$f(x)=\begin{cases}\sqrt[3]{x} & 0\le x\le 1\\ -\left(x-\dfrac{7}{6}\right)^2+3 & 1<x\le \dfrac{13}{6}\\ 2x-\dfrac{7}{3} & \dfrac{13}{6}<x\le 4\end{cases}$$

This type of functions simulate the filling of combined water containers with different radius and have been utilized in other research studies (Hirst, 1972; Hohensee, 2006). Participants are made up of twelve teachers that belong to three different teaching communities: four engineers who studied at a Polytechnic Institute , four engineers who studied at public Universities and four engineers who studied at normal schools. In Mexico there is no institution devoted to the formation of mathematics teachers for high school levels. Regarding experience in calculus class, teachers Roldán, Buendía, González, López and Camacho are fairly experienced, whereas Zedillo, Rosas, Matías and Zavala show an intermediate level of experience. On the other hand, Gutiérrez, Montoya and Elizarrás show very little or no experience.

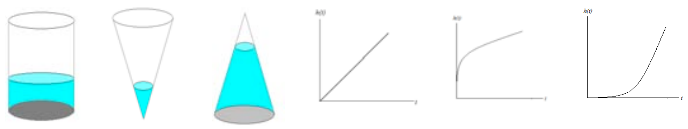
Theoretical Framework

In this theoretical framework it is assumed, to begin with, that beliefs exist in the subject related in a system which is logical to its bearer (internal coherence) and probably 'illogical to the researcher' (inconsistency); the reason for this lies in the explanation that beliefs being highly psychologically loaded take the place of logic. In this sense, the dimensions of Green's (1971) metaphor about beliefs are used: *strength* (central or not peripheral central), *quasi logical relations* (basic or not basic) *and cluster grouping,* along with Thagard's (2000) coherence theory as theoretical references.

Results

When the fact that teachers have different mathematical qualifications comes to mind, one could pose a hypothesis stating that differences between beliefs would be significant; however, reality shows the opposite.

one variable (shape)

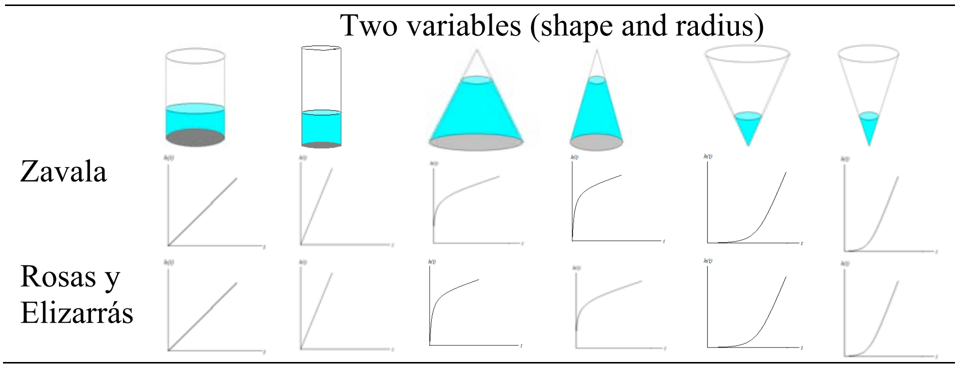


Everybody makes associations correctly like this: cylindrical container-straight line and conical container-curve and in the latter not everyone does it. Most of them use visual and geometric arguments for instance, Rosas

$V = \frac{\pi}{3} r^2 h$ 1) La altura se mantiene constante 2) La variación cambiara con respecto al radio 3) Se mantiene constante al inicio 4) Cambiara su variación y despues crecera de manera casi constante
Trad: 1).The height remains constant 2). Variation changes in relation to the radius 3) It remains constant at the beginning 4) It changes its variation and after that it will grow in an almost constant way

Or physical arguments like López who talks about celerity and speed:

López: First of all the graphs were considered to have two axes *t and h(t)*. That is *t=time; h(t)=speed or filling celerity*. In the first exercise it is possible to appreciate that since the shape is a cylinder, the speed is constant and so is time, for which reason a function of a straight line appears and that is answer C. In exercise two it is a cone where the base is at the top, wherefore, the celerity is pretty high at the beginning; as time passes the filling speed becomes slow and the graph that sticks to this is option A. In exercise three it is a cone where the part of the base (wide) starts filling, so the filling is slow and as time passes the filling is faster because the container is narrower at the top, the answers is B.



When the radius of the containers is changed, teachers' answers show an advance in the cognitive route because they notice the direct relationship that exists between straight line inclination and radius variation. They establish the functional relationship: straight line slope-base radius, a function like $f(t)=f'(t)t$. When it comes to conical tanks the situation changes a little Zavala, Rosas and Elizarrás identify the curve as the graph that simulates but fail to associate the corresponding concavity. Particularly when analysing cones standing on their vertex, Zavala is also unable to notice the celerity with which the height changes in the containers when $t \to 0$. For the third activity involving mixed containers, in the case of cylindrical assembled containers all of the teachers establish the correct and coherent association: container-broken line, even when such containers are made up of a conical section, container-smooth curve. The following dialogue between Roldán and Gaby shows the change of beliefs regarding a smooth curve resulting from the solution of this task

Gaby: But now in these ones, I mean for instance here we obtain a smooth curve because this base is the same as the other, and also here and also here (pointing at some graphs that correspond to containers that join with the same radius).

<table>
<tr><td></td><td></td></tr>
<tr><td>Trad:
Smooth curve</td><td>Trad:
Different radius, not smooth curves</td></tr>
</table>

Gaby: Then where the shape changes where they join. Lets say this thin cylinder and this big part, the curve is not smooth any more.

Roldán: And this one no, it is the curve that is not smooth…

Gaby: That means, C, D and H, mmmm

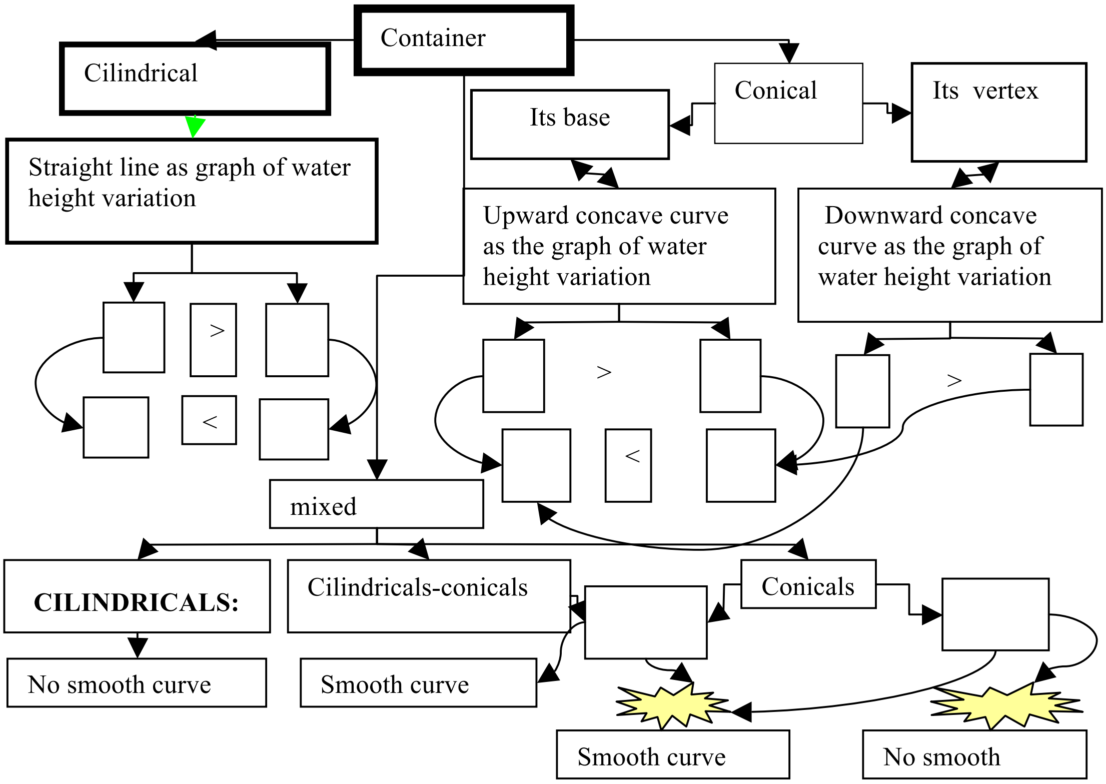
<table>
<tr><td></td><td></td><td></td></tr>
<tr><td>Trad:
No smooth</td><td>Trad:
No smooth</td><td></td></tr>
</table>

Roldán: Well, they are not physically smooth where they join they are from different areas.

For some teachers like Lopez, it only meant the combination of the two previous activities

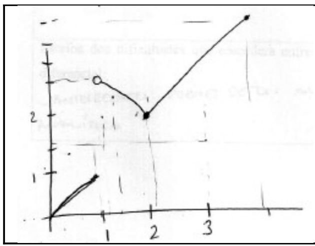
el ejercicio 1 son 2 cilindros i gráfica del cilindro delgado y la del grande juntas (H)		el 3 juntas (B) **Trad:**		
Trad: Exercise 1 consists of two cylinders, thin cylinder graph and big cylinder graph together		The three together		 la 4 juntas (E) **Trad:** Four…Together

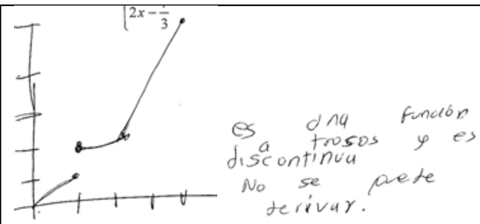
The following chart shows a net of concepts established by them

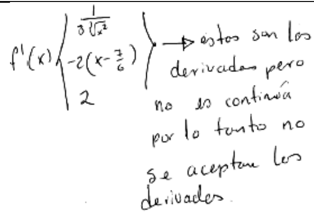


Net of beliefs in the problem of container-graph association

In the task of calculating the derivative of the function defined by pieces, most teachers notice singular characteristics of the function regarding continuity of the function and its relation with its capability of differentiation. They obtain formulae parting from the formulae with which it is defined by using derivation techniques disdaining what the graph visually offers to them. Buendía and López provide two sample cases where definition intervals simply disappear.

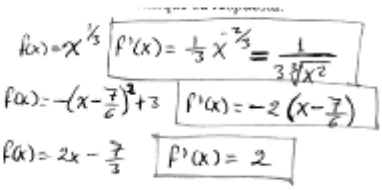




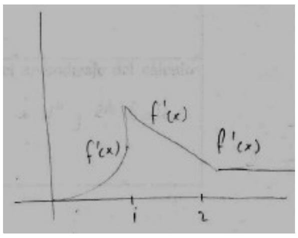
Trad: These are the derivatives but it is not continuous, therefore the derivatives are not accepted.	**Trad:** it is a function by pieces and is not continuous. It can't be derived

Cedillo comes a little close to a good reasoning but ends up doing the same:

	**Trad**: all the function is not continuous, that's why it can't be derived. Only its intervals can be derived separately



others like Montoya apply derivation rules and even sketch out the “derivative of the function”



$$f'(x)=\begin{cases}\frac{1}{3\sqrt[3]{x^2}}\\ -2\left(x-\frac{7}{6}\right)\\ 2\end{cases}$$

So the task of obtaining the derivative of these functions defined by pieces is reduced to obtaining formulae from the formulae that define the function. This is a very strong belief. Roldán's dialogue shows this strong belief as well but trough the dialogue, from which an extract is presented, he is able to relate continuity-smoothness of the curve-differentiability.

Roldán: But the criteria to say that a function can be derived is that…it is continuous ¿isn't it? It is the first criterion ¿isn't it? Er…¿Because of the limit or? …(silence) since in my classes I never get to these… from mi classes at university I don't remember it divides in intervals… er, by pieces. I don't remember functions by pieces because the teachers I think they were cheating, I don't remember them teaching me a function by pieces; then um… it must be continuous…

Guide: I don't know.

Roldán: They must be united smoothly and to do this we have to get the same slope in the value that I am considering, which in this case is one and in this, for these two, it is thirteen sixths. Then I'm going to replace the derivative... of all of them in the number… well of the two first ones in number one,…in number one the result of the first exercise is one.

Conclusions

Teachers have a qualitative "understanding" of the rate of change which is independent from any meaning of the derivative function. What can be perceived is that the concept of differentiability of the function is an encapsulated concept without any relations with real situations as long as they don't make clear the need for using it. Coherent association in all the cases is due to good perception more than to the posing of an analytic strategy since the arguments offered respond more to what is believed and felt. This is confirmed in the second problem where teachers are coherent with their ideas about derivation. They simply apply techniques without paying attention to the intervals that define the function. Any function defined by formulae believes that it must have a derivative defined by other formula. This research allows us to obtain a general conclusion: beliefs are an independent variable in teacher formation and their experience. It has two separate beliefs clusters, the one of the concepts and another one, the one of perceptions both of which are incompatible. However, this doesn't stop teachers from being sure about the coherence between elements that they cause to intervene. In this sense the teacher and the general subject have an Internally Coherent Beliefs System (ICBS). A secondary conclusion emerging from this research has to do with the design of didactic situations which show the beliefs of the subjects and provide precise information which allows to pronounce, just as a good doctor would do, a precise diagnose in order to design the appropriate treatment. The intervention project to eliminate, modify or create certain beliefs, in this sense the dialogue, is the technique that allows this. Roldán illustrates this situation because he shared many of the beliefs at first, he agreed on their strength, on the quasi logical relations and even on the clusters. Intervention by means of "dialogue" shows that it is possible to modify those beliefs.

Discussion

This research leads to consider deeply teachers beliefs. Perhaps attention should not be paid in looking for didactic situations but first address the need of changing teachers' beliefs about concepts into real knowledge.

MATHEMATICS TEACHERS' BELIEFS AND THEIR TEACHING PRACTICES

Hee-jeong Kim
University of California, Berkeley
hj_kim@berkeley.edu

This study focuses on exploring in detail the relationship between teachers' professed beliefs and their classroom practices. The goals of the paper are to examine the kinds of beliefs a mathematics teacher states and to compare those professed beliefs with two teacher's enacted beliefs as seen through their teaching practices. Professed beliefs were elicited through interviews with the teachers. To compare professed beliefs with enacted beliefs, I then analyzed episodes of their classroom teaching. Analyses suggest that a teacher's professed beliefs may differ from his or her enacted beliefs and the relationship between professed and enacted beliefs is complex, and mediating factors need to be further explored.

Teachers' beliefs about teaching, learning, and the nature of mathematics play a major role in the ways that teachers shape their classroom practices. Yet, as David Cohen's study of "Mrs. Oublier" demonstrates, there is not necessarily a clear relationship between teachers' professed beliefs and their beliefs as they appear to be enacted in classroom practices (Cohen, 2009). Accordingly, this study set out to explore in depth the relationship between professed beliefs and classroom practices.

Although there is no universally agreed upon definition of beliefs in education research, there are many common threads between different definitions. For the purposes of this study, I adopted the following definition, which is largely consistent with general conceptions of beliefs in the literature:

> [Mathematical beliefs are] interpreted as an individual's understandings and feelings that shape the ways that the individual conceptualizes and engages in mathematical behavior (Schoenfeld, 1992, p. 358).

Most studies of teachers' beliefs use questionnaires and surveys. However, data from survey methods can be limited in how far it allows a researcher to examine beliefs in detail. Also, data from questionnaires are often superficial. Therefore, in order to create an accurate representation of teachers' professed beliefs, I conducted in-depth recorded interviews with two teachers. In order to compare these professed beliefs to teachers' enacted beliefs, I analyzed recorded episodes of the teachers' classroom teaching as well. The video data is drawn from a lager study, the mathematics component of the Strategic Education Research Partnership. Analyses began with a transcription of all interviews and teaching videos. I then developed a coding scheme for each teacher separately. From this coding, I generated a summary of all teacher beliefs that appeared from what they stated in their interviews. Upon generating categories of teachers' professed beliefs identified in the interview, I then applied these two teacher-specific coding schemes to analyze their enacted beliefs in the classroom.

Analyses suggest that a teacher's professed beliefs may differ from his or her enacted beliefs. Some of their professed beliefs were strongly consistent with their enacted beliefs. Others were weakly consistent with their enacted beliefs. Furthermore, some professed beliefs were not enacted at all in their teaching practices. Findings may have some implications for mathematics teachers' professional development, pre-service teacher education, and research about teachers' beliefs. The examples of these results and findings will be discussed in the poster.

There are some limitations in this study. Interviews may not sufficiently capture teachers' beliefs and I may need to examine their beliefs more deeply with other methods. Furthermore, the teaching videos that I analyzed are limited cases for examining their beliefs. Therefore, expanded cases and mediating factors of the relationship between professed beliefs and enacted beliefs need to be further explored.

CONSTRUCTING EQUITABLE TEACHING PRACTICES: AN ANALYSIS OF MATHEMATICS TEACHERS' CONVERSATIONS

Nicole A. Bannister
Clemson University
nbannis@clemson.edu

This poster traces teachers' evolving narratives of student performance that arise in their conversations. Analysis of the conversations showed teachers' frames became more nuanced in their representation of mathematical competence, disentangling issues of ability from school-savvy. Overall, teachers' frames shifted from less agentic to more agentic ways of understanding problems of practice as co-occurring with development of more equitable teaching practices.

Poster Summary

How does teacher community matter to teachers' development of equitable teaching practices? Teachers' collegial conversations about student ability not only provide important frameworks for collective understandings but shape consequential decisions about teaching (Horn, 2007). Teachers' colleagues thus play an influential role in constructing notions of and potential solutions to problems of practice. The same situation can be narrated differently—a student "flunked out" or "was not yet ready to learn"—and each interpretation positions teachers differently in relationship to less agentic and more agentic ways of understanding such problems.

This poster represents an analysis of conversations among 5 mathematics teachers at urban Clark High School who sought to raise the achievement of students in first year college preparatory mathematics classes. The project aimed to help teachers reconceptualize student competence while they made major changes to their teaching practices to combat the struggling student problem, shifting away from direct instruction toward a particular equity-centered groupwork method. The focal department had 50% failure rate in these classes before the project began. After one year of deliberate work, the failure rate fell to 29%. State exam scores demonstrated increased student learning, especially among underperforming student populations.

To understand teachers' learning throughout this process, we traced the evolving narratives of student performance that arise in their conversations over the year using a case study design and ethnographic methods. Out of a dataset of 32 audiotaped meetings, we focused on 4 meetings that took place in October, January, March, and May of the school year. Using discourse analytic concepts, particularly Goffman's (1974) idea of frames, we analyzed the shifting understandings evidenced in teachers' talk.

Analysis of the meetings showed that many initial framings did not provide teachers with an obvious actionable response. For example, the teachers diagnose students' academic troubles in the October meeting as stemming from students "choosing to fail" or "being flaky." In contrast, during the May meeting, frames emerge that allow for clearer action, such as students "having low academic status" and "not knowing how to do school." While the former frames place the onus for achievement primarily on the students, the latter provides teachers a means for action. As such, the teachers' frames became more nuanced in their representation of mathematical competence, disentangling issues of ability from school-savvy. Overall, teachers' frames shifted from less agentic to more agentic ways of understanding problems of practice as co-occurring with development of more equitable teaching practices.

PROMOTING MATHEMATICS TEACHERS' DISCOURSE-BASED ASSESSMENT PRACTICE IN LOW SOCIO-ECONOMIC STATUS SCHOOLS IN TAIWAN

Chang-Hua Chen
University of Illinois at Urbana Champaign
cchen72@illinois.edu

Michele Denise Crockett
University of Illinois at Urbana Champaign

Ching-Yuan Chang
Tzu Chi University

A large achievement gap of mathematics learning between high and low socioeconomic status (SES) students has been observed in Taiwan, possibly coming from the difference of SES-different teachers' instruction (Chen, Crockett, Namikawa, Zilimu, & Lee, accepted). Research (Crockett, Chen, Namikawa, & Zilimu, 2009) has suggested that improving teachers' discourse-based assessment practice (DAP) helps enhance the weak link between teacher professional learning and their students' learning. This article aims to bridge this gap by reporting a research project that tries to improve mathematics teachers' DAP in low-SES schools in Taiwan. The teacher professional development program for DAP was conducted from the end of August 2010 to mid-April 2011. In the study, the first author facilitated participating teachers to view videotapes and transcripts of their own lessons, to analyze the quality of teacher-student discourse with a focus on questioning and feedback, and then to discuss their own findings with one another. Mehan's (1979) ethnomethodological approach, a parsimony framework for analyzing DAP (Chen et al., accepted), was applied to identify IRE and extended sequences.

Research findings indicate that after professional development, the participating teachers: (a) allowed more wait time for their students' responses; (b) were more aware of the quality of questioning; (c) used more high-level questions to cultivate their students' mathematics understanding; and (d) invited greater student participation in teacher-student discourse. In addition, students' learning benefits from their teachers' professional learning. They actively participated in classroom discussions more than before and began to pose questions and debate on mathematics ideas with one another.

TRANSFORMATION OF MATHEMATICS COACHES: EXAMINING CHANGES IN MATHEMATICAL KNOWLEDGE FOR TEACHING

Scott Coniam
The Ohio State University
coniam.1@osu.edu

Ryan Harrison
harrison.407@osu.edu

Patti Brosnan
brosnan.1@osu.edu

Diana Erchick
erchick.1@osu.edu

This presentation examines changes in mathematical knowledge for teaching of mathematics coaches participating in an ongoing, embedded professional development program. This in-progress study aims to determine whether the coaching program is making statistically significant change as it relates to coaches' mathematical knowledge for teaching.

The Mathematics Coaching Program (MCP) is an ongoing professional development program aimed at improving student understanding of mathematics using mathematics coaches embedded in low-performing schools throughout the state of Ohio (Brosnan & Erchick, 2010). heir intensive model provides sustained professional development of teachers within their own classrooms. Additionally, MCP provides two days of professional development every month for their mathematics coaches. Regionally located facilitators provide two additional days of coach professional development each month.

Over the course of roughly six weeks, MCP coaches provide daily support to participating teachers; helping them to examine and understand their students' mathematical thinking and how to use this knowledge to guide classroom instruction. Dialogues between coach and teacher improve practice through collegial interactions and personalized support (Becker, 2001). Throughout the course of both the coaches' and teachers' involvement in MCP, growth in mathematical knowledge for teaching (Ball, Hill, & Bass, 2005; Hill, Schilling, & Ball, 2004) as well as transformation of pedagogical methods may occur.

Data will be drawn from the past six years of MCP participants, using the University of Michigan Learning Mathematics for Teaching (LMT) Project's instrument. All participating coaches are analyzed for development of mathematical knowledge for teaching over time. Coaches are tested at the beginning of their first year of participation, and again at the end of their first, second, and third years of participation. Average pre-post change for each group of coaches (first year, second year, third year), as well as p-values and effect sizes will be displayed. Interpretation of said analysis will occur and be presented on the poster. Preliminary results from the first three years of data indicate growth in all three LMT content areas, most notably in algebra.

METAPHOR TO METONYMY OF SLOPE

Hamidy Dogan
University of Texas
hdogan@utep.edu

In this paper, the nature of an intermediate algebra student's use of a metaphor and a metonymy is discussed. A metaphor of slope is used in the description of the concept and the same metaphor became a metonymy in responding to mathematical questions.

Introduction

The concept of slope is essential to college mathematics learning, especially for those covered in courses calculus and up. Because of the importance of slope in higher mathematical understanding, it is necessary to make sure that students gain an accurate understanding of the basics of the concept before taking advanced courses. Many students in entry-level courses do not have a background of mathematical knowledge from which to attempt to make sense of newly introduced mathematical information (Sfard, 1997).Thus they turn to their existing knowledge, which mainly originates from everyday experiences. This paper reports on a metaphor originating from everyday experiences and a metonymy formed as a result of classroom instructions, which are used to construct an understanding of the slope ideas.

Metaphor

A metaphor can be defined as an implicit analogy (Presmeg, 1997). Presmeg adds that a metaphor has both ground and tension. According to her, similarities between concepts constitute the ground and differences constitute the tension. For instance, for the mathematical statement, "A is an open set," the tension of a metaphor may be the physical idea of openness (an open space view) without a boundary and the mathematical idea of an open set with a boundary. Consider a set of all points that satisfy the inequality, x2+y2<1. Here, the open set is bounded by the unit circle (XXXX, 2007). Considering that similarities between concepts (source and target) are mainly determined by students based on past experiences, rather than being given to them (Sfard, 1997), students, in this case, may apply the no boundary characteristic of the source concept, and come to a conclusion that the particular set is not open since it has a boundary (XXXX, 2007). Moreover, the students' misconception may further be strengthened if initially introduced examples of mathematical open sets are those without boundaries.

Metaphors play an important role in reasoning in mathematics (Lakoff and Nunez, 2000; Presmeg, 1997). Presmeg illustrates how one may reason with metaphors in her example of a high school student who used "Dome" metaphor to reason in solving the question of finding the sum of the first 30 terms of a sequence (5, 8,11,…). This high school student's personal metaphor seemed to play a significant role in solving the problem. The student whose interview excerpts are reported here also appeared to reason with his metaphor in describing slope.

Metonymy

Work on metonymies mainly focuses on them as literary devices, rather than cognitive constructs that are used to encode information. Presmeg (1998; 1997) and Lakoff &Johnson (2000) on the other hand view metaphor and metonymy as cognitive structures. The act of using one object to stand for another is considered as functioning with metaphors or/and metonymies. Presmeg (1998; 1997) considers two types of metonymies. One of which, namely metonymy proper, is defined as "*a figure by which one word is put for another on the account of some actual relation between the things signified*" (Webster). An example of this kind is "*We studied Gauss*." Here, the word "*Gauss*" is used to indicate Gauss' work (*Gauss Gauss' work*). Moreover, mathematical symbols can be put for various mathematical entities such as number families. The symbol "x" for example can represent real numbers (*x real number*) even though the symbol x and the numbers are two unrelated objects.

Second type of metonymy is considered as figure of speech. In this type, a part is used to represent the whole or vice versa (Presmeg, 1998). An example of this kind may come from the sentence, "*I've got a roof over my head.*" Here, the part "*roof*" stands for the whole "*house*" (*roof house*). An illustration of a circle taken to represent the class of all circles can also be considered as the metonymy of this kind. Presmeg (1997) however argues that this example may go beyond the figure of speech type to metonymy proper for the signifier may not be an element of the class represented. In other words, because the elements of classes are mental constructs, and an act of interpretation by an individual is involved in setting up the metonymy, individual may use the illustration to consider a class of circles that are not closely related to the figure. Hence, the illustration may become an example of a metonymy proper.

Methodology

Data comes from an intermediate algebra student's interview conducted as part of a study that gathered concept maps (Novak and Gowin, 1984) and interpretive essays along with interviews to investigate students' conceptualizations as they were introduced to the various aspects of the mathematical slope and function concepts throughout the fall 2003 semester from two intermediate algebra sections offered at a four year midsize Southwest University in the United States. The intermediate algebra course at the University provides basic mathematical concepts and skills that are prerequisite for college mathematics courses such as pre-calculus and calculus. Both sections of the course were traditional in the sense that its material was covered through a lecture by instructor mode. We refer to the student, whose interview responses reported in this paper, with a pseudo name "SAL" (Hispanic-American Male).

Each interview was videotaped and lasted about an hour and a half. Interviews began with more personal questions, and proceeded to questions on the slope or function concepts and concept maps. Students' inaccurate responses were not corrected throughout the interviews in order to further understand the sources of their mistakes, and to eliminate the possible influence of the interviewer's opinion on students' thought processes. Two mathematics graduate students transcribed the interviews, which were then analyzed by the same graduate students and the investigator in order to identify emerging patterns applying a qualitative approach, namely the constant comparison method (Glaser, 1992).

Table 1. SAL's metaphor of slope.

Source	Attributes	Target
Arcs of houses Edges of buildings Sides of roofs	Meaning of "slope" in English Inclination of physical structures Inclination of common examples of graphs of linear functions (lines)	Mathematical slope concept

RESULTS

Metaphor of Slope and Student Description

During the interview, student SAL provided descriptions in both everyday and mathematical settings. Descriptions came about when SAL was asked to introduce and teach the ideas of slope to the interviewer, and to talk about what he thinks of when he hears the word "slope" as well as to address the question, "what a slope is."

Table 1 outlines SAL's metaphor of slope. As seen in the table SAL compares similarities between houses/buildings and graphs of non-horizontal linear functions to form a mathematical understanding of slope. The setting for the metaphoric comparison appeared to have emerged from his instructors both from high school and early college courses giving examples from daily life.

When student SAL was asked to tell the first time he was introduced to slope, he talked about his high school and early college teachers introducing "slope" as the tilt of a line or physical entity that is used in construction (see excerpts below). These examples appeared to have encouraged SAL to consider houses as an example of having "slopes" in the sense of the edges of roof tops, a physical attribute. Even though SAL also considered slope as something used to determine how tilt lines are, the physical feature of slope was more dominant in his knowledge and reasoning.

Physical objects like houses/construction buildings seemed to encourage a formation of a physical entity of slope in the case of SAL. That is, examples provided by his instructors appeared to have acted as analogies for SAL in forming an understanding of the mathematical concept slope. The similarity between the inclined edges of a building described by the English word "slope" may have further enhanced SAL's consideration of the physical attribute of "inclined lines" as being "slopes."

In the following responses, SAL is clearly comparing the aspects of buildings/houses with lines. His phrases "depend how **tilt** it is" and "it's like **a way** to know how **tilt** the line is" provide the clues for his comparison. He is focusing on the tilt/inclination of edges of buildings, beams and houses in describing the mathematical aspects of the slope. Specifically, it is clear in his third response below that he is in fact focusing especially on one attribute of the examples given in the source domain, which is the inclination of structures.

> *SAL: OK, slope? During my second year in high school? Yeah, It was basically said some about, you know, lines, depend how **tilt** it is. That's **the slope**. So like, you didn't get into it really that much. That's about the first time I heard.*

> *SAL: Yeah, he* [his college instructor] *said slope was something that it could be used on almost anything, even like constructions, even buildings, things like that. So it's like **a way** to know how **tilt** the line is used in the field of engineers.*

*SAL: Oh, yeah. I guess when the teacher said it could be used as an engineering tool and as a way of beam stuff, yeah, it makes sense, you know, everything has, I mean, **an inclination**, also you can see the inclination, so, I started looking at the stuff. so…house has **inclination**…*

Metonymy *(Slope ⟶ Tilted Line)* and Student Reasoning

Later in the interview when asked why he included "house" in his concept map, SAL described more of a metonymic aspect of the concept than a metaphoric one. It is evident with two phrases "You know "**house looks like two slopes"** and **"**have a **house slope"** that, for SAL**,** the term **"slope"** solely stands for **"an inclined line."**

*SAL: because I don't, when I … I don't perceive slope, but house is just an example like you know. You know **house looks like two slopes**.*
*SAL: I guess architecture, houses, even anything a house they can have a **house slope**…*

In answering mathematical questions, SAL's preference appeared to be the particular metonymy (slope ⟶ tilted line) over his metaphor. SAL used this metonymy consistently throughout the interview. For instance, when he was asked to give an example for the slope of a linear function, he drew an inclined line and said:

SAL: OK. This could be a slope [draws an x-y coordinate with a line on].

He further stated that a horizontal line is not a slope. This response leaves no doubt that during the interview SAL used the term "slope" as a metonymy to stand for inclined lines.SAL provided further explanation to why he did not consider a horizontal line as a slope. In fact, his explanation below reveals that he is associating slope with a characteristic of lines, that is their "*tiltedness*," and through this association tilted lines are becoming slopes for him**.**

*SAL: Because the line is **tilt**…*
*SAL: So I know it's sloppy. I know. I think I know that any **tilt line is a slope**. That line* [pointing to a horizontal line drawn on a paper] *doesn't, it isn't tilt at all… and **doesn't just slope**.*

Later in the interview he was asked about the role of a numerical value that the interviewer called "a slope" of a linear function. His response (given below) to this question is further verifying his metonymic use of slope as tilted line. He in fact declares that the value can be graphed, clearly meaning a line.

> *I: I guess I was wondering and just curious why it's that we need to get that number* [referring the slope value written on a paper].
> *SAL: Which?*
> *I: This number.*
> *SAL: Oh, you know because so you can* ***graph it.***
> *I: Oh, I see. Graph what?*
> *SAL: You can graph* ***this slope****.*

During the interview, SAL was aware of the slope formula and was able to calculate the slopes of lines provided that two points on the graphs of lines are given. He however did not appear to hold the meaning of slope as "a measure of rate of change."

> *I: What is that formula for?*
> *SAL: ... This formula is, when they give you two points, so you* ***can get a slope on those two points****. And this one, the one with "m," like y equals to m and and b. This is to get a, just to get a slope.*

Lack of the knowledge of slope as a measure of rate of change can further be seen clearly in his response below. When SAL was asked whether he could obtain a function value for a given x-value provided that another point and the slope value of the function are given, he stated that, with the given information, he could get the intersection points of the graph of the function. He also added that, with slope and a point, he only taught of a line and a point, and nothing more. It is evident in his phrase "this point will intersect with the slope" and the excerpts below that he is clearly not considering slope as a measure of rate of change, but using the term "slope" to mean a line.

> *SAL: Ok, the slope is 2 and the point is… we can get the intersection of the, the line….*
> *SAL: This point…yes, it is just this point. I don't know****, what all that I see is a line and a point****, that's all I see…*
> *I: Which line do you see? Which line?*
> *SAL: Oh, the* ***slope****, anyway, it's supposed to go…*
> *SAL: I'm thinking maybe this point will intersect with* ***the slope****, but, it's just some, maybe, I don't know.*

Discussion and Conclusion

Student SAL used one kind of metaphor in his description of the mathematical slope concept. SAL furthermore, later in the interview, turned this metaphor into a metonymy of “slope” for “tilted lines.” Mathematical concept formation appeared to be embedded in one’s social, cultural and pedagogical activities. SAL’s understanding of slope in fact does not solely come from classroom activities but from the cognitive processing of his social and cultural experiences integrated with classroom experiences.

SAL formed an understanding of slope as tilted lines or “*tiltedness*” of lines by adopting the similarities between two domains; source domain of inclined edges (that are called slopes in English) of buildings/houses and the target domain of the inclination of the graph of linear functions (tilted lines). The fact that “slope” term is used to describe both the inclined edges of physical objects and to describe the mathematical concept seemed to have encouraged SAL to form only a visual (physical) understanding of the mathematical slope ideas.

It was apparent in the interview responses that SAL’s metonymy of slope standing for tilted lines began with his metaphor of slope. After the initial metaphoric understanding of slope, SAL turned this metaphoric understanding to metonymic reasoning. In fact, when it came to answering mathematical questions, he consistently preferred the metonymic aspect of slope. Recalling that student SAL had instructors using “construction/houses” as analogies to introduce the mathematical slope concept one implication of the findings for the teaching and learning of mathematics may be that the teachers of mathematics need to be cautious with the use of analogies such as “beams/bridges” and “ski slopes” in introducing the concept. As Max Black indicates, “*Similarity is created in the mind of conceivers of the metaphor rather than being given to them*” (reported in Sfard (1997, page 342)). What is tension in the eye of a teacher may become the ground for students. It is an unavoidable fact that students bring their everyday experiences into mathematics classroom, and consider them during the process of conceptualizing a newly acquired mathematical concept. Teachers may need to explicitly cover the relevant similarities between source and target objects especially when there is a potential of applying irrelevant or incomplete aspects by students. In the case of slope, the rate of change aspect needs to be emphasized. Furthermore, the similarities and differences between the examples from the source domain and the mathematical slope concept from the target domain need to be covered explicitly to make sure students do not consider irrelevant aspects and/or only one relevant feature such as the physical attributes to form an understanding of the subject. This paper reported findings of a single student’s metaphoric understanding and metonymic reasoning. They by no means can be taken as generalization to all mathematics learners. The findings reported in this article though may become the springboard for future investigations with larger sample groups.

DEVELOPING TEACHER UNDERSTANDINGS OF EARLY ALGEBRAIC CONCEPTS USING LESSON STUDY

Jodie Hunter
University of Plymouth
Jodie.hunter@plymouth.ac.uk

Roberta Hunter
Massey University
r.hunter@massey.ac.nz

This poster illustrates the use of lesson study as a professional development tool. In particular the poster focuses on the way in which the teachers increased their understanding of how tasks, classroom activity and teacher actions scaffolded student learning of early algebraic reasoning of equivalence and the commutative principle. Teacher voice is used to illustrate how lesson study cycles caused the teachers to reflect and review their own understandings of early algebraic concepts and how their students considered them.

This poster reports on the use of lesson study as a professional development tool to facilitate a group of teachers enhanced development of their algebraic 'eyes and ears' (Blanton & Kaput, 2003). Lesson study is a form of professional development which aims to increase teachers' knowledge about mathematics, knowledge about ways of teaching mathematics, and knowledge about the ways to engage learners in, and make sense of, mathematics (Fernandez & Yoshida, 2004). A specific focus of the poster is on how teachers increased their understanding of how tasks, classroom activity and teacher actions scaffolded student learning of early algebraic reasoning of equivalence and the commutative principle through the lesson study process.

Research studies investigating children's development of early algebraic reasoning covers a wide field including those which focus on classroom practices which scaffold student justification and generalizations. However, in this poster, focus is placed on how lesson study supported teachers to understand how their students constructed early algebraic reasoning in two areas of early algebra; equivalence (equality) and the commutative principle. Participants included two groups of elementary teachers who worked as a professional learning community within their own schools. 'Study lessons' were planned and taught in one classroom and observed by the research group. In-depth analysis and discussion followed observations of the study lesson and subsequent iterations as it was re-planned, re-taught and re-observed in different classrooms as part of the lesson study cycle.

In the poster, teacher voice is used to illustrate how lesson study cycles caused the teachers to reflect on and review their own understandings of early algebraic concepts. The opportunities to closely observe student responses provided a foundation for them to build understandings of how their students approached tasks which challenged their understandings of the commutative principle, and the equal sign. The teachers recognised the pivotal role they held in making links between the early arithmetical and algebraic reasoning and pressing the students towards situations of generality.

EXAMINING SHIFTS IN TEACHERS' CLASSROOM PRACTICE

jamador@indiana.edu

An analysis of how a teacher's instructional practice changed over time as a result of participating in professional development is presented. The specific questions addressed in this analysis include an analysis of the shifts that took place over a three year period. A framework for analyzing teacher's practices as a useful tool for professional development is presented.

Supporting teachers to make shifts in their instructional practice towards reformed approaches that support conceptual understanding is not an easy task. Even though, teachers attend professional development sessions, understanding how it impacts their practice is critical for designing effective professional development. Teachers have to make pedagogical decisions that are adaptive to the learning situation. Recent research on teacher professional noticing (Gamaron, Sherin, Jacobs & Phillips, 2010) point out that teachers' ability to make professional decisions is influenced by their ability to notice and interpret what is going on in the classroom.

Method

Three classroom episodes of a teachers instruction over three years is analyzed using Strauss and Corbin (2001) Constant Comparative method. This teacher participated in a larger Math Science Professional development project in a western state.

Results

The results revealed that shifts in teacher questioning changed along with her beliefs of teaching math. The initial class discussion data revealed that the teacher asked direct questions aimed at getting the "correct" answer such as "So ' ¾ is equivalent to how many 28th?" Students directly answered teacher comments. The teacher questioning shifted along with student participating. She asked more questions aimed at understanding student reasoning and understanding. In addition, students started to respond to each other's comments.

Discussion

We argue that professional developer's ability to notice shifts in teachers' instructional practices and break practice into core components is an important part of designing professional development tasks for teachers. We agree with Gamaron, Sherin, Jacobs & Phillips (2001), that teachers' ability to professionally notice their practice is an important part of improving teaching.

TEACHER QUESTIONING: TRYING NOT TO REINVENT THE WHEEL

Elif Safak, Illinois State University, esafak@ilstu.edu
Josh Hertel, Illinois State University
Cynthia Langrall, Illinois State University
Marilyn Morey, Illinois State University

In this poster presentation we discuss the theoretical and practical issues that we have encountered in trying to conceptualize and document teacher change by examining teacher questioning. Our work is situated within the context of a mathematics-science partnership project, conducted as a 3-year Master's degree program, that engages teachers in intensive coursework and practical experiences designed to enhance their content and pedagogical content knowledge in mathematics and science. The 22 teacher participants are from a public school district in a mid-sized city in the Midwest.

This poster traces our efforts to utilize questioning frameworks that are prominent in the mathematics and science education literature to characterize changes in teachers' questioning practices. Our focus on questioning, per se, was motivated by the IICC teachers' interest in this aspect of their instructional practice. Accordingly, we sought a framework that could be useful from both theoretical and practical perspectives. We examined the literature for models that could inform our analysis of teachers' video-recorded lessons, hoping that an existing framework might be applied to our data, directly or with only slight modification. At the same time, we sought a framework that would be accessible and meaningful to teachers in improving their questioning practices. Drawing on the extant literature to meet the dual requirements of theoretical and practical utility posed certain challenges.

A recurring concern was that of grain size–whether frameworks were detailed enough to detect subtle changes in questioning, yet expansive enough to offer teachers insights into the nature of their questioning. For example, Oliveira (2010) used a broad echoic/epistemic – teacher-centered/student-centered framework. In our analysis we found that the categories were not easily distinguishable and did not provide enough detail to identify subtle changes in the teachers' questioning. Chin's (2007) four overarching categories of questions that promote productive thinking addressed many of our concerns, yet we encountered issues in distinguishing between nonproductive and productive questions. Boaler and Brodie's (2005) framework enabled us to detect differences in the types and frequency of questions teachers posed and could assist teachers in making micro-level changes in specific *questions*, however it might not necessarily support them in making macro-level changes in *questioning*. We conjecture that teachers require a different kind of framework to further promote their development, one that acknowledges the flow of discourse rather than focusing on specific questions only. That is, teachers need to consider what is asked, how it is asked, when it is asked, and how it is followed up; essentially the context within which a specific question occurs.

A FRAMEWORK FOR ANALYZING TEACHERS' USE OF DATA DURING COLLABORATIVE INQUIRY

David Slavit
Washington State University
dslavit@wsu.edu

Tamara Holmlund Nelson
Washington State University

Angie Deuel
Washington State University

Michele R. Mason
Washington State University

Objectives

We present a theoretical framework for understanding teachers' uses of student learning data in collaborative inquiry processes. The framework is useful to researchers interested in describing and analyzing the ways teachers conceptualize, collect, and analyze student learning data, as well as how teachers discuss results of their analyses

The framework is grounded in five years of analyses of multiple teacher groups at multiple sites. We address the term inquiry stance in the context of a teacher *group* to more fully capture the dialogic aspects of collaborative inquiry. We have found that a group of individuals, even with various stances, do construct a describable group stance toward collaborative work, and our analysis considers the nature of the *interactions* amongst group members rather than any individual teacher's orientation. We further narrowed our own perspective to that which seemed most pressing to the work of the teacher group – their conceptualization and use of student mathematics learning data. We detail the two core dimensions of our framework below.

Framework

For the purposes of this paper, we describe an **epistemological stance** as a way of thinking and being in relation to a particular phenomenon. In our specific case, we are analyzing mathematics teacher interactions in the context of collaborative inquiry processes that incorporate student learning data. Our framework for considering and discussing teachers' epistemological stance toward data lies on a continuum from proving to improving. Teachers with an improving stance toward student data seek to surface limitations in classroom practice through an examination of the data. Teachers with a proving stance toward student data attempt to verify strengths in their practice by uncovering changes in student achievement. The second dimension of our theoretical framework involves the ways in which teachers **position and interact with each other** in the context of collaborative uses of student data. When differing perspectives are surfaced and made explicit, these may be questioned, tested against evidence, compared and contrasted to others' ideas and experiences, and potentially transformed. We characterize these types of interactions as *negotiation*, during which cognitive conflicts are surfaced and explored by group members. At the other extreme, *not negotiation* is evidenced by conversational turns that may be superficially connected through sharing related stories about teaching or students, or teachers taking a task-oriented approach to data. Conversational turns may be related to each other in short sequences, but remain at the descriptive level.

Findings

This study is part of a larger NSF-funded research project involving 8 secondary mathematics and science teacher groups. The above framework was continually refined and described in a matrix used to code transcripts of collaborative inquiry meetings across three years. These data reveal descriptive statistics on the nature of talk and uses of student learning data inside a wide range of teacher groups. Our analysis also focused on the kinds of data teachers accessed during interactions related to student learning. Findings were also related to broader contexts, such as extrenal mandates and school or teacher leadership.

Challenges in Teaching in Applied Mathematics Classes in Urban Schools

Dorian Stoilescu
University of Toronto
dstoilescu@yahoo.ca

Egodawatte Gunawardana
University of Toronto

Douglas McDougall
University of Toronto

Secondary school mathematics teachers, mathematics department heads, curriculum leaders, and administrators from 11 schools, with support from a local university, participated in the project Collaborative Teacher Inquiry. In this presentation, we will focus on challenges that teachers face when they teach grade 9 applied mathematics.

INTRODUCTION

The transition from Grade 8 to Grade 9 is particularly challenging in many school systems (Galton, 2009). In Ontario, students are promoted to the next grade regardless of their level of performance until Grade 8. In addition, Grade 9 students in Ontario are subject to streaming, being categorized into academic, applied, or essential levels (Ontario Ministry of Education, 2007). As a result, Grade 9 is a critical year for students and teachers. This is especially challenging for urban populations such as the Greater Toronto Area (GTA), where there is a large multicultural population with the highest percentage of foreign-born students in Canada (Statistics Canada, 2005). In fact, 44% of the student population of the GTA has a first language other than English. In this paper, we report the findings to the research question: What challenges do Grade 9 Applied Mathematics teachers face? By identifying the difficulties encountered by mathematics teachers, this research promises to move forward teaching mathematics in applied classrooms, by energizing teams of teachers within schools to activate and guide the teacher improvement process.

FINDINGS AND DISCUSSIONS

We will discuss the various challenges faced by teachers in teaching grade 9 applied mathematics. Due to time limitation, we selected only few categories. There are a number of challenges in urban mathematics education in greater toronto schools. There were a number of situations when challenges identified were multifold. Sometimes teachers did not believe in their capability to achieve success under these circumstances. Teachers said that these negative attitudes along with the students' lack of mathematical background were major barriers to foster student success. Teachers mentioned that they can not be successful alone if their students and their parents do not believe themselves in succeeding.

A mix of behavioral issues and lack of attitudes toward learning was another area of concern. Family situations of students differ considerably and these contexts also brought many issues for several schools. Teachers emphasized the complexity of students being in the same time with behavioral issues and having individual education plans. Lack of time for teachers to prepare their lessons, students need to learn the basics first, concerns about student behavior; and the concerns of preparing students for provincial tests were common themes in both studies. At times, teachers' professional development programs had their own limitations. Implementing reforms that the new curriculum required was challenging by many teachers. In addition, some new teachers had problems in class management. By contemplating on teachers' views in our study, some teachers faced considerable pressure when teaching for applied.

This poster shows one piece of a larger Research and Development effort to design a professional development focused on math discourse in elementary classrooms. This professional development evolved from the idea that merely exposing teachers toimportant instructional moves was not enough to support high quality implementation in mathematics classrooms. Rather, we claim that it is necessary to instruct teachers on howto implement instructional moves that support math discourse.

Through collaboration with experts in literacy, the professional developmentincorporates literacy instructional models that support classroom discourse into mathematics teaching and learning. The project has a focus on fully engaging all studentsin mathematics discourse, including English Language Learners (ELL). We contend thatthese models are beneficial to all students (Saunders & Goldenberg, 1999).

Here we focus on the results of presenting one graphic organizer, the Frayer model, to a group of elementary math coaches. One important feature of a classroom rich in mathematical discourse is appropriate use of mathematical vocabulary. Thus, weproposed to the coaches the use of the Frayer model as one tool to launch a discourse-rich mathematics lesson. Using the model can support the assessment of prior knowledge ofvocabulary, allow the class to discuss multiple representations of concepts, and develop acommon understanding of the meaning of a word. We engaged the coaches in completing a Frayer model, with an emphasis on how the model could be used to launch a lesson rich in Math Talk. We then asked them to plan how to take the tool back to their respectiveschools. Coaches were given the option to implement the tool with teachers or students.

In examining the work implemented by the coaches, we addressed the following research questions: What did coaches consider appropriate adaptation of the Frayer Model? What issues emerged for the coaches as pros and cons of using the Frayer Modelin a math lesson? For this study coaches' written reflections and audio-recorded group debriefings were analyzed. Among the fifteen coaches' implementations, a majorityimplemented the model directly with students. Those who implemented with teacherschose to do so as they had experienced the model. The implementations of the modelvaried, with common themes including: student engagement, teacher adoption and adaptation, and the tool as an assessment. The analysis of this data has implications for how graphic organizers are presented in the professional development.

MATHEMATICS TEACHERS' INVESTIGATIONS OF REASONING THROUGH COLLABORATIVE ACTION RESEARCH

Lindsey M. Umbeck
Purdue University
lumbeck@purdue.edu

The National Council of Teachers of Mathematics published *Focus in High School Mathematics: Reasoning and Sense Making* (NCTM, 2009) to address the need for high school mathematics programs to align with the K-12 curriculum goals that were set forth by *Principles and Standards for School Mathematics* (NCTM, 2000). This focus document places emphasis on developing students' reasoning and sense making abilities in order to develop mathematically literate citizens who are prepared for an array of postsecondary work or study options. This study investigates the experiences of seven mathematics teachers responding to these curricular recommendations through individual action research.

Teacher action research is a democratic form of professional development in which teachers can critically examine curricular recommendations generated by outsiders (Stenhouse, 1975). In addition to professional development, action research values the 'insider' stance that teachers hold in their own classroom, and positions teachers as knowledge generators rather than simply recipients and consumers of the knowledge of others (Cochran-Smith & Lytle, 2009). Through collaborative action research, teachers can investigate their individual inquiries while collaborating around a common theme.

A group of mathematics teachers was formed by recruiting teachers interested in investigating their practice through action research. We initially agreed upon the theme of *Reasoning and Sense Making* (NCTM, 2009) as the focus of our work together. We met regularly throughout the school year, a total of nine times, as teachers read *Reasoning and Sense Making* and related practitioner literature that aligned with their chosen foci for their action research. As teachers learned about action research, they individually selected specific actions to take in their practice to incorporate reasoning and sense making. Meetings served as a time for them to share their goals, dilemmas, and successes.

This study used a narrative inquiry approach to investigate the ways teachers incorporated the recommendations for *Reasoning and Sense Making* into their practice, how they interpreted the impact of their actions, and the challenges and opportunities that they encountered throughout the process. Data collected include teachers' conversations, journal reflections, interviews, and classroom observations. This poster presentation will present the preliminary analysis of this study, sharing the variety of ways that teachers focused their action research inquiries, and how their choices were a reflection of those aspects of the recommendations that held meaning for them within the context of their teaching and their visions for their practices. Dilemmas that teachers identified and the lessons they learned will also be shared.

SECONDARY SCHOOL MATHEMATICS TEACHERS' UNDERSTANDING OF PROOF BY CONTRADICTION

Hyungmi Cho
Seoul National University
earthan1@snu.ac.kr

Oh Nam Kwon
Seoul National University
onkwon@snu.ac.kr

The goal of this study is to inquire into secondary school mathematics teachers' understanding about logical structure and validity of proof by contradiction. Three proof tasks were given to 23 teachers and they were asked to evaluate the tasks and to provide reasons. Sixteen teachers were unable to find the premises and conclusions of the statement which were really proved in proof by contradiction, and only a few teachers could explain the validity of the method of proof.

Researches on proof by contradiction which has a specific logic structure of proof, that focus on students' difficulties seem to be greater than those related to direct proof. A proof by contradiction is different from a direct proof which infers a straightforward conclusion from the premise of a given statement. Thus a proof by contradiction shifts from the given statement to another one in which the hypothesis is the negation of the given statement and the conclusion is a contradiction. This research examined teachers' understanding of proof by contradiction, a topic that has not received adequate attention (Antonini & Mariotti, 2008).

This research focused on the following questions: How do teachers understand the logical structure of proof by contradiction and how do teachers understand its validity? Three proof tasks that were purportedly written by students were given to 23 teachers, and they were asked to evaluate tasks and to provide reasons.

After investigating participants' understanding about the hypotheses and conclusions of the new statements which were proved in the format of direct proof, their hypotheses were identified as p q, p ~q and ~q. Their conclusions were identified as a contradiction of the premise, a contradiction of the conclusion for the given statement, and a false proposition. Seventy percent of the teachers were unable to find the correct hypotheses and conclusions of all tasks. On the other hand, six of the participants recognized the valid logical structure of proof by contradiction. To validate the proof method, four of them used truth-table, contraposition and partial contraposition which make a contrapositive statement with one premises and conclusion in case a given statement contains two premises and one conclusion. Only a few teachers could explain the validity, but their responses were inconsistent with the contradiction which occurred in the premise or false proposition. Furthermore, their understanding of the validity of the method of proof was an unconscious one for the majority of the teachers.

PRESERVICE ELEMENTARY TEACHERS' SUSPENSION OF SENSE-MAKING WHEN SOLVING PROBLEMATIC WORD PROBLEMS

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

Armando M. Martínez-Cruz
California State University, Fullerton
amartinez-cruz@exchange.fullerton.edu

In this paper we investigate the phenomenon of "suspension of sense-making" (Schoenfeld, 1991) with preservice elementary teachers (PETs) when solving word problems whose solution is not obtained by the straightforward application of the arithmetic operation suggested by the numbers given in the problem. A paper-and-pencil test was administered to 68 PETs enrolled in two sections of a content mathematical course. The test consisted of 8 experimental items and 4 buffer items. The experimental items were adapted from Verschaffel and De Corte's (1997) study. Prospective teachers performed poorly on the experimental items. The number of realistic responses varied from 5 to 58. One of the two lowest numbers of realistic responses was for the problem "Sven's best time to swim the 50 m breaststroke is 54 seconds. How long will it take him to swim the 200 m breaststroke? One of the two highest numbers of realistic responses was for the problem "228 tourists want to enjoy a panoramic view from the top of a high building that can be accessed by elevator only. The building has only one elevator with a maximum capacity of 16 persons. How many times must the elevator ascend to get all the tourists on the top of the building?" In summary, 178 (33%) out of 544 responses were correct or involved a realistic comment. Prospective teachers' difficulties with modeling problematic word problems is also examined in Contreras and Martínez-Cruz (2007). Possible explanations about mature adults' suspension of sense-making when solving problematic word problems will be provided in the poster presentation.

PROSPECTIVE ELEMENTARY AND MIDDLE SCHOOL TEACHERS' INITIAL ABILITIES TO POSE MATHEMATICAL PROBLEMS WITHIN GEOMETRIC CONTEXTS

José N. Contreras
Ball State University
jncontrerasf@bsu.edu

Armando M. Martínez-Cruz
California State University, Fullerton
amartinez-cruz@exchange.fullerton.edu

The continuous search to find solutions to mathematical problems has extended the frontiers of mathematical knowledge since antiquity. Creating mathematical problems is conceived by both mathematicians (e.g., Halmos, 1980) and mathematical educators (e.g., Silver, 1994) as a fundamental mathematical activity. Professional organizations (e.g., NCTM, 2000) and the National Research Council (Kilpatrick, Swafford, and Findell, 2001) include problem posing as a core element of mathematical proficiency. NCTM (2000) for example, calls for teachers to regularly ask students to pose and solve interesting problems based on a wide variety of situations. However, we know very little about both prospective and practicing teachers' abilities to pose mathematical problems and their dispositions to engage their students in problem-posing activities.

One of the goals of our research project is to document prospective teachers' initial abilities to pose mathematical problems. To this end, and as a starting point, we asked a group of 25 prospective elementary and middle school teachers to complete four problem-posing tasks within geometric contexts. The students were enrolled in a geometry course for elementary and middle school teachers in spring 2011. The students were told verbally that they will have about 45 minutes to complete each problem-posing task, but they spent about 20 minutes on each problem-posing activity. The written responses are the data sources for examining their initial problem-posing abilities.

In the first problem-posing task, the diagonals task, students were asked to observe a quadrilateral, a pentagon, and a hexagon with all of their diagonals. The diagrams were accompanied with the statement "We notice that a quadrilateral has 2 diagonals, a pentagon has 5 diagonals, and a hexagon has 9 diagonals". The directions asked students to examine the examples and think about other analogous diagrams and to write down as many different mathematical problems or questions as they could.

For the diagonal task, the students generated 63 responses out of which 56 were problems. The students generated 13 extended problems, 14 general problems, 1 proof problem, 2 converse problems, 13 further extended problems involving formulas or patterns, and 13 additional further extended problems of other kind. A more complete description of the data coding, analysis, and discussion of the results for each of the four problem-posing tasks will be reported in a longer version of this paper.

INSERVICE TEACHERS: CONCEPTUAL UNDERSTANDING OF DIVIDING FRACTIONS

Heather Glynn Crawford
University of Nevada, Reno
hcrawford@unr.edu

Diana L. Moss
University of Nevada, Reno
dmoss@unr.edu

Teruni Lamberg
University of Nevada, Reno
terunil@unr.edu

This study is part of a larger study on designing and implementing professional development. Research indicates that teachers' understanding of fractions is limited (Squire & Bryant, 2002) with few teachers being able to explain reasons and meanings for division of fractions (Ball, 1990). "Greer (1992) argued that though people were usually able to solve division sums involving fractions written mathematically, they were not able to use the concept to represent real life situations" (Rizvi & Lawson, 2007). Similarly, Toluk-Ucar (2009) found pre-service teachers to be unable to provide appropriate representations and explanations in given fraction situations.

The central focus of our study is to investigate elementary in-service teachers' abilities to make connections between algorithmic representations and word problem representations with division of fractions. This study examines the teachers' ability to pose problems based on a given algorithm and generate and solve an algorithm from a given word problem. The problems are listed below:

1. Write a story problem for the following division problem: 5 1/4□ 1/2.
2. Nancy has 6 2/3 meters of material. It takes 5/6 of a meter to make her fabulous fancy hair ribbons. How many fabulous fancy hair ribbons can she make?

Of the 35 participants in the sample, 8 successfully wrote a word problem from a given algorithm. 31 participants translated a word problem into an algorithm and successfully solved it. All 8 participants successful in generating a word problem were also successful at solving a given word problem. A sign test was calculated on this data and yielded significant results (□). The analysis of a sign test revealed that participants are more likely to successfully solve a given word problem than generate a word problem from a given algorithm.

These results emphasize the importance of problem posing in teaching division of fractions for professional development. Teachers must have a conceptual understanding of fractions in order to accurately pose problems within a context. Therefore, problem posing cannot only serve as valuable and necessary teaching tool, but also as an assessment tool.

INVESTIGATING MIDDLE LEVEL TEACHERS' MATHEMATICAL CONTENT KNOWLEDGE FOR TEACHING

Heidi L. Fleharty
University of Nebraska – Lincoln
heidifleharty@hotmail.com

Traci Kutaka
University of Nebraska - Lincoln

Transformative mathematics teaching and learning is predicated upon high-quality instruction which requires sophisticated, professional knowledge that goes beyond pedagogical skill. Hill, Rowan, and Ball (2005) demonstrated that first- and third- grade teachers' specialized content knowledge significantly predicted the size of student gain scores. Clotfelter et al. (2008) found evidence that teacher credentials, particularly licensure and certification, positively impacted high-school student achievement on statewide end-of-course exams in comparison to their lateral entry peers. However, less is understood about the mathematical content knowledge necessary or background characteristics of teachers that might influence instructional quality in the middle-school grades. The current study uses data from a five year NSF-funded project whose goal was to improve teachers' specialized mathematical content knowledge for teaching.

The sample included urban and rural middle-level mathematics teachers ($N = 66$; 89% female) in a Midwestern state with elementary ($n = 11$), middle ($n = 19$), and secondary ($n = 27$) certification. Two longitudinal linear mixed models were estimated in SAS PROC MIXED to examine the relationship between teachers' certification level as well as knowledge of Number & Operations (N&O) and Patterns, Functions, & Algebra (PF&A) across three testing occasions. Mathematical Content Knowledge for Teaching (MCK-T; Hill, Ball, & Schilling, 2004) is a pre-post measure that contains both of these subscales. We hypothesize algebra requires sophisticated knowledge of numbers and operations and will predict content knowledge in that area. We tested this by comparing two models. In Model 1, N&O was treated as the outcome and PF&A a time-varying predictor. Model 2 reversed this treatment. Both models included teacher certification level as a time-invariant predictor. We constructed piecewise slopes to observe the effect of time.

In Model 1, the intra-class correlation indicates 34% of the variance is cross-sectional. The unconditional baseline model suggests there are individual differences in the linear rate of change in initial N&O subscale scores. We found two main effects: for every 1-unit higher than the mean PF&A subscale score, N&O increased significantly by .55, $p < .0001$; and for every 1-unit change from baseline score, N&O increased significantly by .32 at that testing occasion, $p < .001$.

In Model 2, the intra-class correlation indicates 58% of the variance is cross-sectional. Through an examination of linear mixed models we determined the model that best represented the data was a compound symmetry model that examined the between person effects of N&O on the intercept and slopes, with main effects of initial N&O, change from initial N&O, and certification level. We found greater initial N&O scores lead to greater initial PF&A subscale scores ($p<.001$). We found for N&O scores between the first two exams, PF&A scores were statistically unchanged, $p > .05$. For N&O scores between the second and third exams, PF&A scores increased by .19, $p = .05$.

There is still a significant amount of variance to account for within both of the final models. Future directions include analysis of the Geometry subscale of the MCK-T, for a more holistic portrait of how knowledge in one area of mathematics might be related to different branches. Other teacher background characteristics will be included as predictors.

INFLUENCE OF CONTENT KNOWLEDGE ON TEACHERS' INTERACTIONS WITH STUDENTS

Ryan Fox
Pennsylvania State University-Abington
rdf16@psu.edu

This study examined how two teachers handled unanticipated student questions during typical classroom interactions. I grounded this study in the literature of the specialized knowledge for teaching mathematics and the activities of teaching mathematics. To answer the research questions, I observed and interviewed two experienced teachers of accelerated secondary school mathematics. Each teacher was observed for one unit of instruction and interviewed four times. From the observations and interviews, I found that these teachers responded to unanticipated student questions in four ways. When responding to the student questions, these teachers followed one of three approaches.

How does a teacher use his or her own mathematical knowledge? In particular, when an unexpected moment occurs during the normal course of teaching, how does he or she apply what he or she knows? This study investigated how teachers of students in an accelerated secondary mathematics course applied their mathematical knowledge in unexpected moments during classroom discussions. The research questions that guided this study are as follows:

- What mathematical knowledge does a teacher call upon when presented with an unanticipated/unplanned student question?
- What are the approaches a teacher uses when responding to a student who has posed an unanticipated question?

There are two parts to this study, observations and interviews. I observed teachers in their typical classroom environment in order "to illuminate an understanding of the culture, not to predict future behavior" (Pirie, 1997, p. 82). I used two recording devices for the classroom observations: one device focused on the teacher, and the captured additional student discussions in another part of the classroom. I observed the participants for one unit of instruction. In addition to the observations, I interviewed both teachers four times as part of this study: once before the observation, twice during the observation, and once after the observation. I interviewed each teacher for a total of three hours.

I identified four ways these teachers handled unanticipated student questions or comments. I used three of Fernandez's (1997) categorizations: posing simpler or related questions, providing counterexamples, and following through with a student's thought. The fourth category, acknowledging challenging questions, reflected gifted students' ability to ask teachers complex questions quickly (Park & Oliver, 2009). The teachers' content knowledge built from prior experience explained the infrequent occurrences of these episodes. Future studies would examine teachers' responses to unanticipated student questions in longer observations in a variety of mathematics courses.

A RESEARCH SYNTHESIS OF PRESERVICE TEACHERS' KNOWLEDGE OF MULTIPLYING AND DIVIDING FRACTIONS

Jennifer M. Tobias	Dana E. Olanoff	Jane-Jane Lo	Cyndi Edgington
Illinois State University	Syracuse University	Western Michigan University	North Carolina State University
jtobias@ilstu.edu	deolanof@syr.edu	jane-jane.lo@wmich.edu	cpedging@ncsu.edu

This poster describes a synthesis conducted to determine what research says regarding preservice teachers' understanding of fractions and to identify the gaps in their existing fraction knowledge. Specifically, this poster will address a smaller portion of the synthesis and report the findings from fraction multiplication and division topics. Results indicated that preservice teachers' understanding of fraction multiplication and division is limited and largely based on rote procedures. Implications for teacher education programs and future research studies are provided.

Teachers need a "solid understanding of mathematics so that they can teach it as a coherent, reasoned activity and communicate its elegance and power" (Conference Board of the Mathematical Sciences (CBMS), 2001, p. xi). In particular, the National Mathematics Panel affirmed the "proficiency with fractions" as a major goal for K-8 mathematics education because "such proficiency is foundational for algebra and, at the present time, seems to be severely underdeveloped" (p. xvii). Therefore, developing such proficiency in preservice elementary teachers is a critical task for mathematics educators. In this poster, we discuss the main findings from a research synthesis of existing studies on preservice elementary teachers' fraction knowledge to identify critical directions for future research specifically in the area of fraction multiplication and division.

Research regarding preservice teachers' mathematical content knowledge illustrates that preservice teachers have a rule-based conception of fraction multiplication and division. Within the topics of fraction multiplication and division, misconceptions result from overgeneralized rules from other number systems, such as multiplication always makes bigger, or result from not understanding algorithms for multiplying and dividing fractions. Other difficulties preservice teachers have with fraction multiplication and division stem from not having a conceptual understanding of the mathematics. Thus, when asked to provide contextualized situations for multiplication and division problems, preservice teachers tend to create situations not related to the original problem or are unable to generate a situation at all.

By understanding preservice teachers' knowledge of fraction multiplication and division, future studies and improvements in teacher education programs can start to investigate the ways in which preservice teachers overcome their misconceptions to develop the mathematical understandings needed to be an effective teacher. Virtually every study suggests that strong teacher education programs and improvements to teacher education courses are needed, however little has been done to document the types of experiences preservice teachers need. There is still not enough for teacher educators to have an adequate understanding of how preservice teachers think.

EXPLORING THE EFFECTS OF USING GRAPHIC CALCULATORS IN TRIGONOMETRY

Corina Georgescu
University of Toronto
corinaeg@hotmail.com

Dorian Stoilescu
University of Toronto

The aim of this study is to investigate the effects of students learning of trigonometric functions through the use of TI-Nspire technology. The effects of students learning are assessed in terms of (a) students ability to explore trigonometric functions, to develop mathematical modeling skills and to solve problems involving trigonometric functions concepts with the use of TI-Nspire CAS technology; (b)students ability to use the TI-Inspire CAS technology to engage in mathematical discussions and reflections and to communicate their understanding of the key concepts of trigonometric functions; and (c) students attitudes towards the use of TI-Inspire CAS technology in exploring and learning about trigonometric functions in the grade 12 Advanced Functions course.

The theoretical framework of this study is The Ten dimensions of Mathematics Education Framework which breaks down the essential components of a successful mathematics education program (Ross, McDougall, Hogaboam_Gray, & LeSage, 2003).

The mixed methods triangulation design procedure, specifically the convergence model is used to collect and analyze different but complementary data on the effects of using TI Nspire technology in the process of learning trigonometric functions.

The findings of this paper might disclose significant factors that contribute to improve the teaching and learning or Trigonometric Functions with the use of TI Nspire technology. For example, it might reinforce some educational research conclusions that simulations of different real life situations with the use of technology help students extend their mathematical understanding and enhance their critical thinking either through helping them visualize mathematics or by applying the mathematics to everyday settings.

This study guides and informs educators about the potential benefits and limitations of using TI Nspire CAS technology in mathematical explorations, investigations and problem solving. It also helps reveal strategies and techniques to be incorporated or avoided in the teaching of Trigonometry in grade 12 Advanced Functions course.

ONE CLASSROOM IN TWO LOCATIONS: USING DISTANCE LEARNING TECHNOLOGY TO PROVIDE EQUITY

Benjamin Hedrick
Stanford University
ben.hedrick@stanford.edu

Access to advanced mathematics courses is often denied to students in low SES schools, which negatively impacts their ability to attend more selective universities and obtain technical jobs in STEM fields. This poster details an innovative program that used technology to link a high and low SES school to provide access to AP Calculus BC. The students at both schools attained statistically significant AP examination scores and cited rigor, motivation, and collaboration as main aspects of the program that led to success in a challenging mathematics class. This poster candidly describes this program and discusses both the benefits and concerns in the hope of increased research into and application of technology to address equity issues.

When discussing equity in education, there is often a focus on providing students with equal access so that the average student in one community has the same resources and affordances as the average student in another community. Rarely does the discussion extend to the needs of the high achieving student. The National Council for Teachers of Mathematics writes that equity, "demands that reasonable and appropriate accommodations be made and appropriately challenging content be included to promote access and attainment for *all* students" (NCTM, 2000). The emphasis on all students, italicized in the original document, highlights the belief that equity is not simply an issue for students who are performing below standards, but rather an issue for all students at all levels of performance. As such, an important part of achieving equity concerns students who have the potential to succeed in higher level mathematics classes (whom we will term "high achieving students") but lack physical access to these classes or to a highly qualified teacher.

This poster presentation documents a two year project designed to address the equity disparity faced by a group of high achieving, underrepresented high school students in the southern United States through the use of distance learning technology. By adapting teaching practices to include such elements as teacher focused cameras and microphones, two high school teachers at two different schools were able to collaborate and bring Advanced Placement (AP) Calculus BC to high achieving students who previously had no access to such a course. This case study presents to the mathematics education community an example of how practitioners in the field are utilizing advances in technology in order to achieve equity in advanced mathematics courses.

TECHNOLOGY INNOVATION IN SECONDARY MATHEMATICS: TEACHERS' STAGES OF CONCERN

Keri Johnson
University of Washington
kerij@uw.edu

Robin L. Angotti
University of Washington, Bothell

Technology has the potential to transform the teaching and learning of mathematics (NCTM, 2000). For many teachers however, technology brings fears and feelings of uneasiness. Thus teachers and administrators seek out professional development opportunities to learn about technological innovations before trying them in a classroom. But with little consistency in professional development or time to implement new technology, "the average individual is doomed to a cycle of continual technology implementation" (Straub, 2009, p. 643) without thought of its impact on student learning. Thus, teachers "must be able to locate and take advantage of appropriate professional development" (Heid, 2005, pp. 364-365) in order to create a paradigm shift for technology readiness.

The research presented in this poster is part of a three year professional development initiative involving 34 teachers from rural districts in the Northwest. This geographic area is agrarian, has a high population of ELL students, and is economically disadvantaged. Teachers were immersed in 96 hours of professional development involving a week long summer institute and three two-day follow up seminars throughout the school year and ongoing regular classroom observations. The professional development introduced teachers to dynamic software and a variety of Web 2.0 applications and asked them to consider how they might be able to implement this technology in their mathematics classrooms to improve student learning.

The Concerns Based Adoption Model (CBAM) (Hall, 2010; Hall& Hord, 2001) is an innovation adoption model that examines teachers' concerns and describes their innovation levels of use, innovation configurations, and facilitator leadership styles. Teachers in this study were measured on the first construct, the Stages of Concern, which examines their feelings and perceptions as they relate to a particular innovation they are facing. Teachers were given a 35 item questionnaire which indicated a score of relative intensity for each of the seven stages of concern. Teachers will have some level of concern for each of the seven stages at any given time and stages are not intended to be hierarchical (Straub, 2009). This poster will present an analysis of the teachers' stages of concern regarding the implementation of new technology in their mathematics pedagogy. Results indicate that as teachers adopted and used the technology, their concerns shifted from self-based at the beginning toward more task- or impact-based as they progressed. These results help fill the gap regarding the process teachers go through as they are presented with new tools and face pedagogical change as a result of new technological tools. By understanding teachers' feelings and perceptions, teacher educators can work to provide successful professional development that impacts student learning and provide support that seeks to meet the teachers' needs and concerns.

EXPLORING MIDDLE SCHOOL PRESERVICE TEACHERS' MATHEMATICAL PROBLEM POSING

A. Fabiola Rangel-Chavez
Texas A&M University
fabiolarangel@neo.tamu.edu

The National Council of Teachers of Mathematics [NCTM] *Principles and Standards for School Mathematics* (2000) suggested that teachers integrate problem solving into the context of mathematical situations by choosing specific problems because they are likely to prompt particular strategies and allow for the development of certain mathematical ideas. Skinner (1991) defined a problem as a question that engages someone in searching for a solution and a problem cannot exist separately from the person who poses and solves it. Problem posing allows students to generate or to reformulate new problems based on a given situation or problem (Gonzales, 1994). In addition, NCTM encouraged teachers to incorporate problem posing as a means of instruction to engage students with problems involving higher order mathematical thinking. Therefore, the objective of this study was to identify the types of problems the preservice teachers (PT) reformulated based on a framework by Stickles (2006). In addition, the study examined the PT' reflections on posing a new problem.

In this research an open-ended mathematical problem was presented to 40 middle school PT at a southwestern public university. Using the Polya's approach (1973), PT were required to solve the problem. Later, based on the given problem, PT were asked to pose a new problem with the same or higher level of difficulty. After some sessions of problem posing interventions, PT were asked to reformulate the original problem based on Brown and Walter's (2005) approach called "What-If-Not". Moreover, using a reflexive journal, the PT' perceptions of posing new problems were investigated. The data were analyzed using both quantitative and qualitative approaches. The classification scheme (Stickles, 2006) was used to categorize the problem posing statements in terms of problem types. Qualitatively, the journal entries were organized by categories of statements and ideas.

Results revealed some significantly different types of problems before and after the intervention. Also, the findings from the reflective journals enabled the researchers to study the differences in PT' perceptions in creating their own problems. In the poster, we will present the details of the problem posing study. Examples from the data analysis of preservice teachers' strategies when posing the problem before and after the "What-if-not" approach will be presented.

DEVELOPING A HAPTIC ENVIRONMENT FOR MATHEMATICAL ACTIVITY

Ryan Robidoux
University of Massachusetts Dartmouth
ryan.robidoux@umassd.edu

Stephen Hegedus
University of Massachusetts Dartmouth

James Burke
University of Massachusetts Dartmouth

Beste Güçler
University of Massachusetts Dartmouth

We are investigating the impact of integrating haptic devices into mathematics classrooms. During the first year of our three-year project we developed a set of activities for 32 elementary and undergraduate students that involved the use of a haptic device. Haptic devices are physical machines that provide force-feedback to users in order for them to interact with computer-simulated objects.

In our investigations we employed the use of the SenseAble PHANTOM Omni® haptic device. We define a *haptic environment* as consisting of the haptic device, *hapticons*, and users and their discourse during interactions within the environment. Hapticons (i.e. "haptic icons") are dynamic visual representations (e.g. a sphere or flat surface) that become tangible through their ability to provide force-feedback to a user via a haptic device. We have defined two classes of hapticons, *objective* and *relative*. Objective hapticons link force-feedback to interactions with a specific visual representation within the haptic environment, e.g. putting a sandpaper-like surface on a box. Relative hapticons, however, link force-feedback to a phenomenon in the haptic environment, such as a force that is a function of the distance between two spheres. The visual representation for a hapticon, in either class, may be hidden.

Informal interviews were conducted with elementary and undergraduate students while they interacted within our haptic activities. Hapticons within the activities included perpetually moving spheres that "bumped" into students, and impenetrable walls impeding students' movements. Through analysis of the students' discourse during these interviews, we identified four hapticons that elicited rich use of metaphors stemming from student reactions to the hapticons: *break point*, *lock-on*, *viscosity* and *pulse*. Break point is an objective hapticon, in that it provides resistance to a student's movement while they are in contact with an object, until the student exerts enough force and the resistance disappears. Lock-on is also an objective hapticon, consisting of a magnetic force attracting the user to an object in the haptic environment (e.g. line, sphere). It is also considered a *composite hapticon*, because a break point acts as the object's magnetic field, keeping users in contact with an object until they provide sufficient force to escape the field. The final two hapticons, *viscosity* and *pulse*, are relative, and affect a user's movement through the haptic environment. While a user moves through the environment, the viscosity hapticon provides a motion-opposing force, such that the user feels as though they are moving through a viscous material, while the pulse provides a vibrotactile force.

These hapticons provide the basic haptic elements that will be incorporated into our mathematical haptic activities. The first mathematical activity created using these hapticons focused on the concept of reflective symmetry. The activity takes place within a 2D haptic environment, in which students are shown a point and must find its reflection across a given line of symmetry. Aiding in this goal is a viscosity hapticon, where the opposing force is a function of the student's perpendicular distance from the line of reflection. While the student's goal in the activity is to correctly identify the placement of a reflected point, the pedagogical goal is for students to abstract a relationship about the opposing forces and the distance from the line of reflection. This activity will be implemented during our main intervention with elementary students in the spring of 2011, as part of a suite of mathematical haptic activities on symmetry.

ONLINE MATHEMATICS FOR BASIC SCHOOL AND HIGH SCHOOL STUDENTS IN MEXICO

Alejandro Miguel Rosas
National Polytechnic Institute of México
alerosas@ipn.mx

Apolo Castaneda
National Polytechnic Institute of México

Juan Gabriel Molina
National Polytechnic Institute of México

Veracruz is a Mexican state placed along the Gulf of Mexico, its natural geography includes many changes in topography: from narrow coastal plains to mountains of over 5,000m height. Veracruz has small arid zones, valleys, jungles, small lagoons and many rivers (more than 40 and tributaries) so that its climate varies from hot and humid to snow. Temperatures range from 0ºC to 40ºC. All these differences make it very difficult to cover the whole state with schools in order to give education to every child in the state. To solve this problem Veracruz's government called for projects to develop an on line education network and cover every city and town of the state (Consejo Nacional de Ciencia y Tecnología, 2009).

In 2009 we started a project co-financed by National Council of Science and Technology (named CONACYT for Consejo Nacional de Ciencia y Tecnología) and the Government of the State of Veracruz in Mexico (Authors, 2009). The project named "Design, development and generation of on line didactic materials for teaching mathematics in the school system of Veracruz" has two main goals. The first is to encourage the design and production of on line didactic materials to teach mathematics and sciences in basic schools and in high schools in the State of Veracruz in Mexico. The second is to create videos and demonstration material for teacher's training in the use of on line didactic activities.

The project is divided in four stages. After the first stage we have designed 20 activities applying the Theory of Didactic Situations (Brousseau, 1997) to teach trigonometry to basic school students (Authors, 2010). Those activities were designed to be used online only because they are programmed in Java®. In this poster we describe and show some of those activities and a few remarks we have received from teachers and students.

MATH + SCIENCE PERFORMANCE FESTIVAL

Ricardo Scucuglia
U. of Western Ontario, CAPES, GPIMEM
rscucugl@uwo.ca

George Gadanidis
U. of Western Ontario, Faculty of Education
ggadanid@uwo.ca

Traditionally, "mathematical performance" is conceptualized as pertaining to the domain of assessment and evaluation. However, we assume a view of *mathematical performance* as the process of communicating mathematics using the performance arts (Gadanidis & Borba, 2008). Exploring mathematical ideas through performance can offer a way to challenge stereotypes around mathematics learning. Learning mathematics can be viewed as an aesthetic and human experience (Higginson, 2006) rather than an impersonal and unpleasant activity. By creating music or skits, math performers can provide surprises to their audiences and communicate deep mathematical ideas in a creative way. Digital technologies play a significant role in mathematical performance. *Digital mathematical performances* are digital media (e.g., video and audio files, flash animations, and virtual objects) used to communicate mathematics through music, cinema, theater, poetry, storytelling, and so forth. Gadanidis, Hughes, and Borba (2008) suggest thinking about mathematics as performance may lead to new ways for (a) students' learning with technologies and (b) sharing mathematics beyond classrooms. Since 2008, students and teachers have been submitting digital mathematical performances to the *Math + Science Performance Festival* (see www.mathfest.ca). This Festival is based on a virtual environment (a website) where digital performances are published and shared. Every year, Canadian celebrities (e.g., musicians, song writers, poets, TV presenters) and mathematicians select their favorite performances in terms of: (a) depth of the mathematical ideas; (b) creativity and imagination; and (c) quality of the performances. Gadanidis and Geiger (2010) have referred to this Festival as "one example that helps bring the mathematical ideas of students into public forums where it can be shared and critiqued and which then provides opportunity for the continued development of knowledge and understanding within a supportive community of learners" (p. 102). In this poster presentation, we highlight a case study to illustrate how Brazilian students created digital mathematical performances for the Festival. Based on the video recordings of students' skit performances, activities in learning sessions, and interviews, we suggest mathematical performance can offer ways to: (a) disrupt students' negative images and stereotypes of learning mathematics; (b) produce mathematical meanings and knowledge with creativity and imagination; and (c) share mathematics beyond classrooms.

AN INVESTIGATION OF A TEACHER'S USE OF TI-NAVIGATOR TO FACILITATE STUDENTS' UNDERSTANDING OF QUADRATIC EQUATIONS

Yasemin Sert
University of Florida
ysert@ufl.edu

Stephen J. Pape
University of Florida
sjpape@coe.ufl.edu

Students can move between representations with the help of technology such as graphing calculators (NCTM, 2000). Using instructional strategies with handheld calculators provides dynamically linked representations and observation of immediate changes, which leads to deeper conceptual understanding. The relationship between the coefficients of a quadratic equation and its graph is a good illustration. Representational fluency is the ability to translate between representations as well as make meaningful interaction and generalizations between different representations (Zbiek, Heid, & Blume, 2007). In the present study, we used representational fluency as the analytical framework to examine one teachers' instructional practice. Through this analysis, we demonstrate how a teacher used the TI-Navigator™ to help students' developing representational fluency skills that facilitate the development of in-depth understanding of quadratic equations.

We used four principles of effective mathematics instruction incorporating Classroom Connectivity Technology (CCT) (Pape et al., 2011) to analyze three videotaped teaching episodes. Additionally, we examined the teachers' post-observation interviews and student focus group interviews using an inductive approach to explore the teacher's instructional strategies. Findings revealed that the teacher used different instructional strategies and processes to provide a context in which students were supported to develop representational fluency including students working in groups to model a parabola in a real-world context by translating and transforming among verbal, symbolic, and graphical representations. In one lesson, students submitted group equations to match the curve of a necklace projected on a screen. A whole-class discussion led to an examination of their responses and suggestions for changes to more closely match the curve. Representational fluency was developed as students made conjectures based on their prior knowledge, checked their conjectures by making changes to the equations, and were able to see the results of these changes immediately. We will focus on the classroom discourse that provided the students the opportunity to analyze the graphs and make generalizations about the impact of changing each of the coefficients in the quadratic equations on the parabola. We argue that this discourse resulted in active student engagement.

THE INFLUENCE OF TECHNOLOGICAL TOOLS ON STUDENTS' MATHEMATICAL THINKING IN SECONDARY CLASSROOMS

Milan Sherman
Portland State University
milansherman@gmail.com

Research has found that the mathematical thinking that students do while engaging with instructional tasks has important consequences for student learning (Stein and Lane, 1996), but few studies have examined how technology influences students' mathematical thinking in general. This study investigates the role of digital cognitive technologies in supporting students' mathematical thinking while engaging with classroom instructional tasks. Data was collected in three secondary and one middle school mathematics classrooms via classroom observations, collection of student work, and post-lesson teacher interviews. The *Mathematical Tasks Framework* (Stein, Smith, Henningsen, & Silver, 2009) is employed to evaluate the opportunities for mathematical thinking present in the mathematical tasks chosen by these teachers, and how those opportunities were realized or not during implementation. The use of technology was coded with respect to whether it served to *amplify* students' thinking by making students' work more efficient or accurate without changing the nature of the task, or whether it was used to *reorganize* students' thinking by shifting their cognitive focus (Pea, 1987). Results suggest a general association of the level of cognitive demand of a task with the way in which technology is used. When technology is used as an amplifier, it generally has no influence on or relationship with the cognitive demand of the task. On the other hand, teachers generally used technology as a reorganizer to set up high level tasks, but three of the four teachers failed to maintain the high level demand during implementation on a consistent basis. The role of technology in the decline or maintenance of high level thinking during implementation is discussed. In particular, the Vygotskian notion of *tool use*, and the process of *instrumental genesis* (Drijvers & Trouche, 2008) by which students construct meaning for and with tools, is used to explain the results. I hypothesize that students' ability to use technology as a reorganizer while engaging in high level mathematical tasks is related to a trajectory of instrumental genesis.

Representatives from five quasi-experimental projects using professional development approaches for K-6 teachers modeled after those of the Cognitively Guided Instruction project and the Early Algebra project will compare the features of their professional development designs. Teacher assessment and student achievement data will promote a discussion of the challenges of documenting the impact of professional development.

When Wayne, Yoon, Zhu, Cronen & Garet (2008) advocated experiments and quasi-experiments as fruitful designs to explore which specific features of professional development matter and what happens to a PD program when implemented across a range of settings by a variety of trainers. Our discussion group will include representatives from five quasi-experimental PD projects focusing on helping elementary school teachers reform their mathematics teaching practices. Our discussion of our PD and our data should provide some of the specificity that Wayne et al. proposed was necessary to guide PD design. All of the projects include a focus on children's mathematical thinking approaches similar to that of the Cognitively Guided Instruction (CGI) project (Carpenter, Fennema, Peterson, Chiang & Loef, 1989) and its sequel, the Early Algebra Project (Jacobs, Franke, Carpenter, Levi & Battey, 2007). All five projects, funded by the Improving Teacher Quality program under the auspices of the California Post Secondary Education Commission, span three years of intensive work with teachers and reflect the best practices identified by Darling-Hammond and Richardson (2009). Foundational to each project is the idea that children have the capacity to develop their own strategies. While this idea comes from extensive research, teachers tend to question whether the students in their classrooms are capable of this. In our discussion group, we will explore similarities and differences among the five projects to determine how each facilitates teachers' learning about students' mathematical thinking and how each project helps teachers' come to believe that these ideas pertain to their students.

While descriptive accounts in the literature attest to the success of CGI oriented professional development (PD) in a variety of settings (see for example, Franke & Kazemi, 2001), these have been limited to what Wayne and his colleagues (2008) called *efficacy trials,* in which the developers of the PD are directly involved with its implementation with teachers. In existing mathematics education literature we were not able to find *effectiveness trials* that document the success of CGI approaches "when delivered in typical settings by those not involved in the development of the program (Wayne et al, p. 470)." Three of our projects claim to implement

CGI with K-2 teachers, and vary in the degree to which PD providers are affiliated with the CGI project designers. In one case, the project director worked as a graduate student researcher on the CGI project, in the second case the project director was an advisee of a former graduate student researcher on the CGI project and in the third case project leaders do not have direct connections to CGI developers. While each of these three settings was in some ways "typical" of California, they were distinct from one another and quite distinct from those of the original CGI project. An examination of teacher and student data from each of these three projects will allow us to explore the *effectiveness* of a CGI approach in CA at this point in time.

We also plan to discuss the professional development design of each project to explore the ways in which each project addressed the recommendations prevalent in the research on PD. Ball and Cohen (1999) in making their case for practice based PD advocated the use of "records of practice" including student work, videotapes of student activity and curriculum activity. They alluded to the challenge of choosing which records to focus and pointed out that "the pull of the personal and the immediate in the case of one's own classroom can mitigate against reflection, analysis, and investigation of alternative perspectives and courses of action. Moreover, the current norms of teacher interaction and discourse do not readily support the kinds of joint consideration of one another's practice that would be useful. (p. 24)." They suggested that analyzing artifacts generated in a stranger's classroom allows teachers to critique and generate questions that would be too awkward to raise about a peer's classroom. On the other hand, analyzing artifacts generated from teachers' own and their colleagues' classrooms has an authenticity that contributes to the meaning and utility of the analysis. Kazemi and Hubbard (2008) noted that records of practice can be considered boundary objects that serve as a conduit between teachers' classrooms and the PD. Each of our projects differed in the types of records of practice utilized and the origins of the record enabling us to explore Kazemi and Hubbard's question "Whose practice is represented in the PD context and with what kinds of records? (p. 431)"

Wayne, et al. (2008) noted research is needed to examine the assumption that PD is best when school-based. School or district-based PD might contribute to the creation of strong working relationships between teachers which breaks the isolation teachers often experience which tends to inhibit their growth (Darling-Hammond, Wei, Andree, Richardson & Orphanos, 2009). Our PD projects had three distinct contexts; two were school-based, one was based in a small district and the other two included many districts. This diversity of settings will allow us to examine the benefits and constraints of each of these contexts.

All of the PD projects served teachers working in "under-performing" schools who faced pressures to use the state adopted textbook and to prepare their students for the state standardized tests. Some teachers had to adhere to administrative mandates including district benchmark assessments and pacing guides that they perceived limited their freedom to experiment with new instructional practices in their classrooms. Our differing contexts led each project to address these pressures differently and we will share our approaches and reflections on the success of our efforts.

Each discussion session will include some brief presentations of data and artifacts from each project. We hope to spend the bulk of our time in discussion of the above issues. We hope that others who have conducted similar PD will join us to discuss ways in which we can establish the efficacy of our work through research and improve our practices.

HOW CAN MODELS OF MATHEMATICAL DEVELOPMENT BE STRUCTURED, REPRESENTED, COMMUNICATED AND USED IN FORMATIVE ASSESSMENT?

Malcolm Bauer Educational Testing Service mbauer@ets.org	E. Caroline Wylie Educational Testing Service ecwylie@ets.org	Karen Harris Australian Council of Educational Research harris@acer.edu.au

The purpose of this working group is to identify ways in which teachers and students can use models of mathematical development productively as part of a formative assessment process. In the sessions, and starting from some existing "seed" examples, participants will identify different ways of representing, communicating, and using these models in formative assessment in the classroom, generate new examples, and draft a research agenda investigating the efficacy of these approaches. Follow-on activities include expanding, piloting, and evaluating the different approaches through collaborations among researchers and practitioners, and convening again to share and learn from our collective experiences.

Background

Formative Assessment

Formative assessment is "a process used by teachers and students during instruction that provides feedback to adjust ongoing teaching and learning to improve students' achievement of intended instructional outcomes." (CCSSO, 2008). There is a large body of research linking the consistent and systematic use of formative assessment to improvements in student learning (Black & Wiliam, 1998, Brookhart, 2005, Nyquist, 2003). Wiliam (2004) stated that "in order for assessment to function formatively, it needs to identify where learners are in their learning, where they are going, and how to get there" (p.5). Most current work on formative assessment draws attention to both the teacher role and the student roles, emphasizing the importance of bringing students into the formative assessment process (Heritage, 2010). There is a small but developing body of research that suggests that within the process of formative assessment, teachers struggle particularly when it comes to determining "how the get there" i.e. the next instructional steps they should take with their students based on the assessment evidence (Heritage, Kim, Vendlinski & Herman, 2008).

Learning Progressions

Heritage (2010) citing Black and Wiliam (1998) reminds us that one requirement of formative assessment "is a sound model of students' progression in the learning of the subject matter, so that the criteria that guide the formative strategy can be matched to students' trajectories of learning" (Black & Wiliam, 1998, p. 37). The notion is that in order for teachers and students to identify what the next learning goal should be, they need to be able to assess where a student currently is on a path of learning. The next step on the path is then a natural learning goal for that student. Progressions define a series of points or states of understanding as an ordered sequence. By knowing a students' current state and the ordered sequence, teachers and students can target the next significant state of understanding that the student should move towards. While progressions can be used to determine the next state of understanding, they do not necessarily define what a student, with teacher support, needs to do to move into this next state of understanding, i.e. they define where to go, but not how to get there.

Within mathematics, Daro, Mosher, and Corcoran (2011) state that the term *learning trajectory* is more commonly used in mathematics, and allows for the possibility that the a trajectory includes the learning and teaching strategies that are needed for shifting students' understanding to the next level.

In our work on learning in mathematics, we have used the term *model of mathematical development* to make clear that the characterization of different levels of understanding is essentially a descriptive theory of the different states of understanding, and is predictive to the extent that the sequence of states captures common sequences of changes in understanding. We define a model of mathematical development as describing the major shifts in understanding that generally occur over medium to large time periods (typically months to years) as students grapple with mathematical knowledge. These shifts describe how a variety of types of knowledge (e.g. conceptual, procedural, contextual and metacognitive knowledge) change over time with respect to central ideas of the domain as students' competency improves due to learning within the domain and related domains, as well as more general cognitive development. Developmental stages can include shifts in view and belief, as in the shift from an understanding of the equal sign as a "calculate something" sign to an understanding of the equal sign as a truth-value statement of equality or balance between two mathematical quantities or objects. Developmental stages also can include increases in generality, integration, and robustness of existing knowledge, as in increases in procedural or representational fluency (Harris & Bauer, 2009).

Two progressions are included in table 1 and table 2. In an in-progress literature review, the authors identified 18 mathematics concepts that have associated candidate models of mathematical development (Bauer, Graf, Harris, Haberstroh, Attali, Wylie, and Leusner, in preparation). The first example, a model characterizing different understandings of central tendency is drawn from Watson and Moritz (1999), and Callingham and Watson (2003). Their proposed a theory of development for the concept of average and measures of central tendency (median and mode) is based upon the SOLO taxonomy Biggs and Collis, 1991) which is a neo-Piagetian framework for characterizing learning and development. The Watson and Moritz (1999) model focuses on how students develop an understanding of average as a measure of representativeness and draw conclusions about a variety of types of data. Table 2 provides a description of each of the levels (excerpted from Watson and Moritz, 1999) and examples drawn from Callingham and Watson, 2003, and Watson and Moritz, 1999).

Table 1
Central tendency developmental levels

Level	Description	Example
Preaverage (P)	Students have no term for average, even in a colloquial sense. When asked to solve problems involving concepts of central tendency, they typically provide tautological responses or idiosyncratic stories about the context.	To a question about the relation between average wage and median home price in Australia, an example response from a 9th grader at this level is “average means it is small and good for little families” (Watson & Moritz, 1999, p. 27)
Single Colloquial Usage for Average (U)	Students use colloquial terms for average, such as *normal* or *okay* and sometimes refer to "add up" colloquially but not in a calculation sense. They do not have an understanding of how to calculate an average.	Student use terms such as “same as others,” “okay,” “normal.” (Callingham & Watson, 2003, p. 31 Avg 2.2) and refer to median of set of measures as “the most accurate value.” (Watson & Callingham, 2003, p. 40 ME 13.1).
Multiple Structures for Average (M)	Students use at least one, often two or three ideas for the concept of central tendency including “most”, “middle”, and the add and divide algorithm for the mean to describe average in straightforward situations. However, they fail to consolidate multiple concepts meaningfully. They rarely use more than one of these ideas in complex questions. Students sometimes acknowledge conflict between incorrect calculations of mean and idea of mode.	“mean is a lot of numbers added up and dived by how many numbers there were to start.” (Watson & Moritz, 1999, p 28).
Representation With Average (R)	Students refer to add-and-divide algorithm for the mean to describe average in straightforward situations. They can distinguish between the concepts of mean and median. They are aware of the association of the decimal form with the algorithm for mean. Students express some ideas related to the representative nature of average (e.g., prediction, estimation, or representing whole data set) and refer to “most” to describe data distributions compatible with mean or offer mode as alternative average concept. They know the algorithm for the mean but do not successfully apply it in complex contexts without prompting;	“not an average which would include all the extremes…out of 100 it would include 49.5 above it and 49.5 below it.” (Watson & Moritz, 1999, p. 28).

A second example is provided in Table 2 which is a model of students’ understanding proposed by the authors of equations and expressions with respect to two underlying concepts: equality and variable. The table begins with a description, that we call level 1, that represents the most basic level of understanding of both of these concepts addressed by the table, and then proceeds through four more levels of understanding. At each level there is a description of how a student thinks about equality and also the notion of a variable, and by combining two understandings, a description of what that student would be able to do and not do at that level of understanding Before looking at the table, which combines both idea, it is worth describing major conceptual changes in student understanding of equality and variable separately.

For equality, the primary distinction that is made is between thinking *operationally* about equality and thinking *relationally* about equality (Kieran, 1981; Knuth, Stephens, McNeil, & Alibali, 2006). The *operational* thinker treats the equal sign as a signal to do something – add or subtract or whatever action was called for on the left hand side of the equation. This way of thinking likely arises from students seeing many more arithmetic problems in math written as 5+3=__ compared to __=3+5 and often teachers will say “five plus three gives you what?” When a student begins to think *relationally,* he or she understands that the expression on the left hand side of the equation has the same value as the expression on the right hand side i.e. they are in balance. And furthermore, when a student understands *relational equivalence*, he or she will understand that equality in an equation is maintained provided you perform the same operation on both sides of an equation and will be able to judge equivalence in many cases without having to calculate values for each side of an equation by using techniques such an compensation and cancellation (Rittle-Johnson. Taylor, Matthews., & McEldoon, in press).

For variable, an important distinction is between students thinking of a variable as representing a *specific unknown*, i.e. as a placeholder for one and only one number, and as a *generalized number* i.e. that a variable can take on many values and be part of more complex mathematical relations as in a linear function (Booth, 1984; Weinberg, Stephens, McNeil, Krill, Knuth, and Alibali, 2004). Prior to these two understandings, students may have one or more contextually dependent beliefs about variables such as an algebraic letter must be the same as the first letter of what it stands for (e.g. ‘b’ for brownies) (Küchemann, 1978; Booth, 1984).. The table below combines these understandings of equality and variable into five levels of understanding overall.

Table 2
Equality and Variable: Equations and Expressions

At **level 1**, students have a superficial understanding of the concept of variable that does not include the idea of variable representing an "unknown." Instead, students may hold one or more beliefs about variable including, for example, that variables represent objects (e.g. that the variable "b" stands for "brownies" in a word problem because it starts with a b). Alternatively students may treat variables like individual digits of a number (if $2x=24$, x must equal 4), they may ignore variables in an equation only operating on the numbers, or separate variables from numbers in an equation or expression. At this level students also have an *operational* sense of equal sign. Students with this type of understanding believe that the equal sign is a signal that indicates that there is s problem to be solved or computation expressed on the left of the equal sign and that the answer should be placed to the right of the equal sign. Given these understandings of equality and variable, students should have trouble solving word problems, even with informal methods, algebra solving follows misconceptions as described in model of equality.
At **level 2** students still have an operational understanding of equality as in level 1 above. Their understanding of variable is different. Students have an understanding of variable as a "specific unknown" in which letters stand for one and only one number. For example, at this level if asked "in the expression 2n+3, can the variable n stand for the number 4?" the, student will say yes and but, then if asked if the variable n can stand for 37 they will say "no. Students can apply informal methods to solve simple algebraic word problems, but will continue to display misconceptions when attempting to solve symbolic equations. Students can attempt to solve equations using guess and check strategy and other approaches that do not involve substantial symbolic manipulation
At **level 3**, students have "specific unknown" level concept of variable as in level 2. What's different is their understanding of equality. They have a more sophisticated understanding of the equal sign as expressing that the quantity to the left of the equal sign has the same value or is in balance with the quantity expressed on the right of the equal sign (described sometimes as a relational understanding of equality). They also know some simple procedures for algebraic manipulation. Students can solve problems with one variable represented in text symbolically using algebraic manipulation. Because students have few ways of understanding algebraic expressions and equations, they may apply less efficient methods to solve equations. Expressions are only understood correctly if they can take on a single numerical value (i.e., consistent with students' understanding of variable as specific unknown).
At **level 4**, students' understanding of equality is richer than in level 3. They understand relational equivalence in most contexts (meaning that they not only understand that both sides of an equation are equivalent, but they also understand that performing the same operation to both sides of the equation maintains the equivalence) and can readily use transformations to balance equations to solve for an unknown. Students still have the same understanding of variable as in level 3 i.e. the "specific unknown" level concept of variable. Students do not yet have a "generalized number" concept but because of relational equivalence they can solve many equations with one unknown algebraically
At **level 5,** students have "generalized number" level concept of variable, in which a variable can function as a pattern generalizer for arithmetic, as in the statement a + b = b + a, or can express relations among sets of numbers as parameters and arguments as in the linear equation x = mx + b. Students have the same understanding of equality as in level 4, i.e. they understand relational equivalence and can readily use transformations to balance equations to solve for an unknown. Students can solve symbolic equations, parsing expressions to flexibly apply operations on to solve equations efficiently.

There is substantial research and development still needed to understand the characteristics of effective and practical formative assessment. Additional research is needed also in identifying, describing, and evaluating models of mathematical development. In this working group, in order to help advance both fields, we will explore the mutual constraints that these two areas provide. We believe answers to a variety of useful questions can be developed by making explicit constraints that models of mathematical development provide to the field of formative assessment, and the constraints that formative assessment can provide to the creation of models of mathematical development. To make this idea clearer, the aims and plans of the working group are described next.

Aims of the Working Group

Models of mathematical development are central to formative assessment. They provide testable theories of how student understanding changes in light of instruction and time. They are needed to define gaps between students' current understanding and learning goals in a way that makes closing the gap feasible. If the gap between two states of understanding has been empirically validated, is present within the population of learners, and many students have moved from one state to the other in the past, teachers and students should be confident that this unit of learning is feasible. There has been research on the feasibility of developing interim and summative assessments to collect evidence and make statistically valid inferences about student levels within models (Watson and Callingham, 2005; Weaver and Junker, 2004; Wilson, 2008). There has been less work on how best to represent models for use by teachers and students, (but see Lesh, Lamon, Gong, & Post, 1993; Wilson, 2005; Watson and Callingham, 2005). Still less is known about how to use models of mathematical development in the service of deciding on next instructional steps to be taken by teachers and students (Heritage, Kim, Vendlinski & Herman, 2008).

Wiggins (1998) provides an example of formative assessment within a welding classroom. In the example, students are learning to weld a ninety degree corner joint. When students think they have completed the weld to industry standards, they compare their welded corner joint to a set of joints to determine to which joint theirs matches best. The joints are ordered in terms of quality and each has specific characteristics relevant to beginning welders In doing this comparison, students are a) assessing at what level they are performing b) determining their next learning goals, and most importantly c) understanding what specific next things they need to do to improve. In other words, a student can consider his or her next instructional steps by, for example, realizing that on the next joint he or she works on, the two pieces to be joined must be more precisely positioned, or that gaps need to be filled, or bubbles removed. In this example, the connections from student performances to level of competency and next instructional step are transparent. Teachers and students can compare student performance to benchmark performances and determine what they need to do next.

Unfortunately, this sequence of inferences is not so transparent in mathematics learning. How does the Wiggins welding example translate to a mathematics context, when it is not skill in a directly observable work product that is evolving and improving, but rather knowledge and understanding around abstract concepts such as the meaning of "average" or "variable"? While there has been some work in this area (e.g. Forster and Masters' work on the Developmental Assessment Resource for Teachers (DART) (2004), much still needs to be learned. How can models of mathematical development be structured to best support formative assessment? Is a linear sequence of levels an adequate model to characterize student understanding to inform formative assessment? Are there circumstances in which model in the form of a network of states of understanding could provide greater value? Is a model in the form of a set of understandings better in some circumstances? What other structures are possible and advisable? How can models of mathematical development be represented and presented to make learning goals and instructional approaches as transparent as possible to teachers and students? What additional information will be helpful to provide? The aim of this working group is to begin to develop answers to these questions.

Plan for the Sessions

The sessions will focus on three work products 1) a list of different ways of representing models of mathematical development with examples that might be especially useful to teachers and students 2) descriptions of the use of these representations in making next instructional choices or adjustments transparent along with descriptions any additional materials and 3) a research agenda for expanding, piloting, and evaluating the use of different representations of models of mathematical development in formative assessment along with specific work individuals or groups will be doing in the coming year with respect to this agenda.

In session 1, the organizers will present the aims of the group and the session, provide some examples of models of mathematical development, a common definition and explanation of formative assessment, example tasks, and a video of the use of one model to support formative assessment as part of a classroom discussion. The bulk of the session will be a facilitated brainstorming session on different structures and representations of models for use in formative assessment. One area of interest to the organizers is how to include students (following from the welding example) in the use of the models of development. Much of the writing around formative assessment has emphasized not just the teacher role in the process, but the centrality of students to the process. Given that models of development may span several years of student development, there are questions about when it is appropriate to be explicit about the developmental model, and how a model can be of most value to students.

In session 2, the working group will select a set of the representations and break into small groups to flesh out examples of their use with respect to specific models of mathematical development. In the later portion of this session, the working group will reconvene to discuss and contrast the examples and potential value of the different representations.

In session 3, the working group will identify research questions and associated approaches and activities for addressing them based upon the work in sessions 1 and 2. Participants will discuss their interest and willingness in engaging in continued research collaborations to address these questions and sketch out next steps for the working group.

Follow-On Activities

Throughout the year, participants may explore the use of the representations of models and ideas for use in formative assessment in their research or in their practice. It is the hope of the organizers that early pre-proposal explorations are carried out. And one or more research proposals may be generated. The work will also inform an aspect of an existing grant on which the organizers are working. The organizers are currently working with a group of approximately 15 middle school teachers, and will have opportunities to pilot some of the emerging ideas from this working group session and will provide feedback to the working group participants on their ideas. The intent is to reconvene at the next PME-NA to share experiences on specific collaborations that developed, to discuss progress on aspects of the work, and to plan and focus continued efforts in this area.

WHY DO UNIVERSITY TEACHERS NOT WANT TO LEARN?

Nadia Azrou
University of Médéa, Algeria
nadiazrou@gmail.com

Training has never been a priority for teachers as it is for other activities for which society demands that someone must be trained to be able to practice. We can't accept buying bread from a baker who never learned how to make bread, neither to be operated on by a surgeon who never knew how to operate, nor to accept a haircut from hairdresser who never learned to use scissors. Teaching has always been considered as natural, easy and possible without necessarily knowing what it is about. Some years ago, this idea changed, mainly because of the multiple results of education and psychological sciences that revalued teaching as an activity that can build the individual and showed further the deep consequences on the individual practice, thinking, working, and all facets of his life. As a result, training teachers of schools (all primary schools and some high schools) became a necessity in many countries. However, training university teachers remains an exception so far in many parts of the world if not all over the world. Aren't we committing, again, the same mistake by considering that university teaching is easy and automatic?

1. The teacher-student relationship

Beyond the socioprofessional obstacles which cause students to fail in mathematics, there exist the psychological impacts related to the failure in mathematics which can create a negative behaviour against this science. You can find many individuals who have graduated in other fields, who could succeed easily in mathematics, but who have kept the fear and the uncomfortable feeling about mathematics from their early school years. Many of these negative beliefs are closely related to the teacher behaviour.

If we do define exactly the teacher's role in the teaching process, it's clear that this latter is very important and even decisive. In addition to being the knowledge transmitter, the teacher is a very important element in the whole system besides curricula, students, knowledge, books, teaching methods ... The teacher's impact on the learner is very strong. Everyone remembers at least one of his teachers and carries certainly with him many memories related to the science and the learning process and many other good or bad details. In fact we learn from a teacher a lot of other things than science.

Many studies show that students identify the science to the teacher, which is very dangerous. Most of teachers aren't aware enough of this question; they don't realize how every move, every side of their personality, and every thought shapes the science for the student. Many students chose to study mathematics because they had teachers who could make them like it, however many decided to never study it after having teachers who were not able to show them what mathematics is besides many complicated and weird formulas. As a result, we receive many students at the universities believing strongly that mathematics is a senseless science full of abstract notions that have no existence in reality. They need time and especially teachers who have to focus on those wrong ideas to change and correct them; otherwise those students will never learn how to write proofs and how to understand mathematics. But it can happen, if these students are unlucky, that they never get such teachers and continue to learn mathematics blindly as a set of nonsense notions.

As the university is the last school, if the wrong beliefs are not corrected there, they can be kept a long time later or forever.

The Relation Evolution

The teacher-student relationship began with a traditional model presenting the teacher as the

1 The elements of teaching: James M. Banner, Jr. and Harrold C. Cannon.

knowledge source who transmits it to the students and assesses them at the end. This relation was qualified as unidimensional, vertical or descending. Later, this traditional model changed because many elements came out, such as:

- The importance of environment made us aware that all is related. Individuals understood that knowledge is not only some written information in some books but it's more focused in the real world and in our daily real life with our health, relationships, thoughts, eating habits, childrising, economic issues, and many other fields.
- The group phenomena focused on leaning and working in groups, in order to serve many students better than learning only with the teacher. Group learning became a part of the learning process.
- The different interactions with others sciences, with the society and with the media make learning became a continuous process and information can be found elsewhere than with the teacher.
- The knowledge conception changed from being a special activity among special people to a normal and a daily activity to anybody. Everyone can learn anything at any time of his life.
- C competency took more and more space beside the knowledge; we value more someone competent than someone highly educated with no competency. Knowledge became more realistic and applicable than before.
- Evaluation changed as competency was taken more into consideration. So, we evaluate more the individual's competency than their ability to get or memorize information.
- The learner 's role changed from being the center of the teaching-learning process to be the principal actor in it.

So, a new model has been created. It's a modern one, by which the student-teacher relationship is different. A data bank exists somewhere outside of the teacher. Both teachers and students have access to it. They collaborate together so that the student transforms the information to knowledge. The student becomes more independent and handles his learning and training himself.

As a result, the relationship is multidimensional:

- Ascending and interactive: from the student to the teacher.
- Transversal and interactive: between the students.
- Multiform and interactive: the student with the whole environment.

This brought the teaching-learning process to be a dual, and a face-to-face meeting for both teachers and students who share continuously the role of teaching and learning at the same time. The teaching process focuses more in integration into the reality, professional actions of comprehension and the understanding of oneself. The result of the pedagogic action is no more in the objects (knowledge) but in building a person made by a complex set of competencies (cognitive, psychological, social, ...).

Difficulties of the Relationship

This teacher-student relationship, even with strong action, has many problems to manage in order to reach the goals.

- Sharing the power or not.
- Managing the great individual diversity.
- Dealing with delicate individuals.
- Managing the age difference between the teacher and the students.
- The teacher personality.
- Managing time.
- Labeling teachers.
- The big humain investment.

Beginning with new students especially in the first year at the university is not easy; the teacher should create above all a confident climate in which he will work on their complex against mathematics, correct and better interpret their wrong beliefs. He should also show that he's not the student's enemy; this complex, long lasting with the students, must disappear to revalue the teacher as a guider and a saver.

A big part of the learning-teaching process rests on the mistake. How to present it, how to use it and how to deal with it has been the subject of much research. It has also been an obstacle for many teachers and many students. The fear and the uncomfortable feeling about the mistake can lead both students and teachers to bad results. It's more present with teachers than with students, so many questions come up. Is it possible to learn without making mistakes? Do we have to avoid mistakes or correct them? Many students have long thought that writing a problem solution comes directly without review by correcting or adjusting some points and some steps; this comes from observation of teachers who have been writing the solution directly. Many teachers also thought that making mistakes at the blackboard when making some calculations would ruin their image and their career in front of their students and so become hostile to a student who notices spontaneously a small mistake of a sign or whatever hidden somewhere.

Another point, not of less importance, is the dialogue between the students and the teacher. A teacher talking to his students and listening to them would understand better their difficulties and the origin of their weaknesses. Most of the time, we think that we found the method that works, but the same teaching method can give different results with different kind of students. The teacher should ask and talk to his students to see how it works with them. Many students hate a teacher that always points out their failures. They need encouragement very often even for the least they do. It's important to a teacher to know that learning is one of the most difficult processes that an individual can undertake. Particularly learning mathematics is often far from simple and delightful. Encouragement will prove to the students again and again how wrong are their prejudices about learning mathematics such as: mathematics is just possible for geniuses, or solutions must be accepted and not understood, or students will never be able to find solutions unless they become teachers.

Believing in students' abilities has always been a strong stimulation to their desire to learn and we need to keep in mind that a student who believes that he or she is bad, will be bad even if it's not true. Even adults need someone to encourage them and appreciate their efforts.

A Study about the Student-Teacher Relationship

The following quiz has been given to almost 250 students in different Algerian universities. It contains three questions about the teacher-student relationship and how students define good and bad teachers according to them. These questions were given to check if the good-bad teacher definition of students is the same, nearly the same or completely different from the definition held by the teachers. We were motivated by noticing that many experienced teachers with high degrees getting less appreciation from the students than some others with fewer degrees and much less experience. We also want to set a training teacher program in our university. With this study, we could know more about which fields should be focused on. We also wanted, throughout this questionnaire, to know what the new generation of students wants in their teachers. With time, everything has changed as the whole world changed, but how has the teacher role or status towards the students evolved? We wanted it mainly as an update for teachers.

1. Who is a good teacher for you?
2. Who is a bad teacher for you?
3. What are your expectations of the student-teacher relationship?

I need to remark before giving the results; first, they were beyond our expectations. Second, we got nearly the same results with the same percentages in different universities. One of them welcomes students from all over the country, so we got the opinion of students from nearly all parts of Algeria. Third, the students gave some requests about point they felt necessary to be given even with no questions.

The answers to the questions are given by decreasing percentage. The answers have been gathered by me under the same idea which is given as a title. The students' exact words are given without any change.

1. The answers to the first question about a good teacher.

- Explains very well: goes slowly, repeats as many times as we ask, teaches without being boring, sure about his information, writes less and talks more, methodical, has simple ideas, spontaneous.
- Answers to the students' questions: even the silliest ones.
- Close to the student: shows that he cares for him, listens to him, talks to him, guides him, corrects his mistakes, considers him as his son, puts himself in his place, pushes him to work even if he has a weak level and tries to understand why, encourages him especially when he has bad grades, trains him, prepares him for the future.
- Modest and nice : smiling, cool, kind, calm, doesn't scare, doesn't give complexes, doesn't show that he is superior because he just has got more information than us, doesn't yell, doesn't became nervous.
- Honest and sincere: doesn't cheat and keeps his promises.
- ∑ Deals with the students in the same way: treats the students equally even if they are at different levels, girls equally with boys, punishes those who do not work and rewards those who work hard.
- Does his best so that the students succeed.
- Masters the class and imposes silence.
- Deals positively with students' mistakes: without yelling, no hard feelings, no intimidation.
- Has clear handwriting.
- Likes his course and his work.
- With a respectable physique.
- Fights social problems: drugs, smoking, disrespectful clothing, and any undisciplined form.
- Is an example for the students.

These two answers came many times:

- When we like the teacher, we inevitably like the course.
- The teacher gives 50% of courage and wills to the student to succeed.

2. The answers to the second question about a bad teacher.

- Haughty: who gets the truth, considers himself as perfect, genius, crack.
- Intimidates and disparages students: treats them as ignorants, of no value, silly, stupid, laughs at them, breaks them down, disheartens them, diminishes their dignity.
- Becomes nervous: yells, sulks, angry, wicked, monster, bad, mocking, never laughs, blames for anything and nothing.
- Doesn't answer the students' questions.
- Imposes himself: doesn't listen, stops students to talk, and imposes his idea even when it's not the best one, not sure about himself, memorizes everything.
- Fast: uses difficult words, skips the work, makes a lot of mistakes, just recites memorized information.
- Doesn't keep his promises.
- Works only with some students: those who are good or those who are sit in the front rows.
- Has no work method: works in a non ordered way, with confused ideas, muddle-headed, complicates even the simple things, wastes time, doesn't prepare his courses, goes

frequently off topic.

- Shows no interest to the students: considers them as objects, talks alone at the blackboard, comes just to write down without even looking at the students.
- Doesn't accept the criticism and doesn't admit his faults and mistakes.
- Refuses to adapt his course and method to the students' level.
- Considers the student as a genius, as a teacher like him.
- Doesn't stop writing: especially when he copies from a sheet that he never leaves.
- Doesn't stop talking about finishing the program and the course: doesn't care about the students' comprehension.
- He's not realistic: doesn't understand the real students' situation, pays attention to nothing.
- Works for money: doesn't like his work, fills the emptiness, makes the students work at his place.
- Gives points to some students and not to others.
- Doesn't give zero to the student that has cheated on the exam.
- Gives very difficult exams.
- Smokes in the classroom.

3. The answers to the third question about the student-teacher relationship.

- Kinship, teachers as parents.
- Fraternal relationship, as brothers and sisters.
- Friendly relationship, as friends but without private life details.
- Respect, exchange, communication, sincerity, reciprocity, familiar ambiance, love.

Conclusion

It's very amazing to notice that nearly all the answers are not related to the scientific side. This is completely opposite to what we teachers do and think. Most of our efforts and thoughts are about preparing the course scientifically. We never pay attention to other sides; if it happens that we do, we always think that it's not so important for the students. We might have some behaviour for years that students hate all that time. We also learned that the teacher behaviour comes first for the students and then the information and then knowledge side; however, teachers think that the opposite is true.

Students consider that the pedagogic relationship is very important and can have a big influence on their learning, on their ability to make the necessary efforts and on their results. They expect their teachers to be competent not only in the scientific side, but also and particularly in the pedagogical side. They consider that the teacher is a guide, a parent, an idol. If we have to train teachers, we need to take this into consideration.

The qualified university teacher has a price to pay, the consideration and the respect of the student-teacher relationship beyond any caprice in full discipline and dignity. In such perspective, it's the one who gets power who should show maturity and make the first steps not to seduce more but to better understand and to reach evolution and improvement.

2. Multiple reforms

Algeria, like many other countries, has made many systemic reforms in many levels especially these last ten years. Many changes have been made in the high schools programs, in primary schools programs, and in the past five years, in the university programs. Difficulties of how to adapt the teaching styles to the new programs came up even for the most experienced teachers. All teachers became beginners after each reform.

For instance, for this last university reform, changes were focused on reducing the scheduled time for each chapter and course; that is, if you are used to teaching some course in four sessions, then with the new program, you have to do the same but in only two sessions. How and in which way?

The teacher has to decide which are the more important and the less important topics, about

the priorities, as when you deal for example with sequences, group theory or integrals. What are the sacrifices to make and at which level; what about the students learning?
Administrators and politicians who supported this new reform have always directed teachers to teach the most important and in a light way and it's up to the teachers to change their teaching method so that they can teach the same materials in less time than before. I asked almost fifty teachers two years after this reform about how they manage their time. Here are the questions and the teachers' answers.
The teachers were divided, according to their answers, into three sets when they were asked about how they manage their time with their courses:

- Those who think that it's easy and fast and even done with less effort than before. However, they guarantee nothing about the students' learning as they don't feel concerned about that now that the administrators do not stop controlling the program progress during the academic year.
- Those who think that it's impossible to realize and even ridiculous as it's in opposition to the didactic contract about learning and teaching.
- Those who are in between and seek so far the best way to deal with it.

I need to define some notions at this point as our reform concerns mainly time. Didactic time, according to Chevallard and Mercier, is the cutting of a knowledge through a duration of time. For instance, if I teach differentiation, I need three courses, and I need to decide what to do in the first, the second and the third. However, if I have been given only two courses, I'll decide again about the cutting and decide again what to put in the first and the second course. I may put the first and the second courses of the first time in the first course of the second time and teach the third course for the entirety at the second course. I may also decide to teach the two first courses in one and let only the last one for the second course. So, many options are offered, but it's not easy to decide. What exactly do we base the decision on? That's why this didactic time management is one of the difficulties in a teacher's work both for beginner teachers and the most experienced ones every time that they are faced with new data. The problem is that this time is closely related to watch time and we have to manage both. It can happen that the watch time advances and didactic time doesn't advance, for instance when some material takes more time than expected. So, the cutting through that period of time didn't work or was not suitable.
Many other questions came up after this reform, such as:

- With a short time, what is can be the most important part in a mathematics course?
- Is it definitions, or theorems and results?
- What should we cut down? What about the proofs?
- Is it possible to make a mathematics course without any proofs?
- If not, which proofs can we cut down?

I asked the same teachers as before how they make their courses with shorter time. I got two sets of answers.

- Those who work in a horizontal way; they were the majority: they do:
  - almost all definitions,
  - some theorems and some results,
  - no proofs.
- Those who work in a vertical way, they do:
  - some definitions,
  - the theorems and the results that correspond to the past definitions,
  - selected proofs.

Other questions arise about the exercises that correspond to both methods and assessment for each one. But still we need necessarily time to be familiar with some notions and notations, let some ideas mature, assimilate the material, learn how to write in mathematics, develop ideas (try to make connections between them), ask and answer questions, take some distance backwards to see things clearly, and just to talk.

Conclusion

Time management and how to adapt any change to teaching style taking into consideration results of both student learning and mathematics teaching is not so easy, neither natural or automatic. Taking all the time where it's necessary and going faster where it is necessary; that's the dilemma in order to be efficient and to reach quality.

3. Evaluation systems

When talking about evaluation, we can't consider any assessment method unless it's faithful. That is, it gives as closely as possible the truth about the students' level, the students' efforts and the teachers's teaching methods. Thirty years ago, the evaluation results in Algeria, in all levels, were not doubted by anyone. Society trusted completely that the results were translating true and real results. Nowadays, the least I can say about evaluation is that the situation is upset and all of society questions it. The worst is that we trust nobody and nothing. If your son gets a very high grade, you know that you can't be so happy, just because you would not to be surprised that this same son will get a worse mark in the next exam or in other course. In the university, the most frequent situation is that almost all new university students (in the first year) come to the university with good and even very good results, but two to three months later, the first exam results show that almost all of them are bad. This situation also exists with every first exam in each year with newcomer students (in a higher level). Another frequent situation that is to be questioned is when many good students who worked hard for a long period get bad results in their exams.

One of the evaluation definitions is (Stufflebeam, 1975) 'assessing a student is measuring the distance which separates his acquisitions from the objectives set and followed by the teacher or the institution'. How is this definition realized with our students and our teaching method?

It's clear that evaluation is managed by many factors. The main question is how to choose and set priorities to realize a faithful evaluation. It's important to know how to make an exam subject, how to set teaching objectives, how to adapt the programs to the given data, what is to be evaluated, how and which way, and who to manage time during an exam. In all exams in any field, (sport competitions, cooking tests, medicinal exams, driving exams,...) the candidates know the evaluation rules, the mistakes to be avoided and know mainly what is required to succeed. So, what about the students in mathematics exams, is it the same? According to what we read in our students' exams, the answer is clearly no!

According to a study made with the first year university students in Algeria, many principal factors were revealed to be directly related to the students exams results, I just give them without any comment to not make the paper longer than it should be.

- The students' comprehension is most of the time wrong before the exams; they correct most of their notions after the exams, but late after paying that by bad grades. The preparation for the exams reveals this important point, or how do we prepare the students for the exams?
- Writing style in mathematics can be a cause of failure even with a student who masters his results or at least thinks he is doing so. We all know that in a mathematical formal sentence, switching the existential quantificator with the universal one gives two different meanings. So, how do we teach our students to write and to read formal sentences, in which level, and do we pay attention to the writing details?
- The grading scale or method. Students generally do not know about the teacher's grading scale. It becomes worse when teachers have all different methods. For instance, a teacher may consider an exercise half correct if the method is correct with a calculation mistake,

but another one may consider it entirely false. For an integral with two parts, a teacher may give half of the credit if one of the parts is correct whereas another one may give nothing considering it all false.

- The mistake is the main element during the evaluation. But how is this element dealt with in the teaching and learning process; do we teach the students mistakes or do we avoid them making mistakes and then give them bad grades when they make them in their exams? It is a full dilemma for the students.
- Time management takes a large part during the examination. A slow student can correctly solve two exercises out of four and get the same score as another one who gets only the simple questions in all the exercises. A frequent situation is to have students who didn't get enough exercises and so not enough practice before the exam. On the exam day, they are still slow and can not solve all the questions.
- The psychological side of the students is also not less important in this matter. We get different results with the same exam given to encouraged students and discouraged ones. And with students treated with hostility and stress versus other students treated with confidence.

Conclusion

Assessment is itself a science. Many factors need to be managed and to be taken into consideration. But the most difficult question remains how to adopt an evaluation which can give true results. Without that, we can never progress, at least not in any good way. How can we strengthen the link so that we teach to evaluate and evaluate to teach?

4. Mathematics education research

We can not teach mathematics without being in touch with what's happening in mathematics education. Research is dealing with almost all sides and all fields of teaching and learning mathematics. The multiple studies and the multiple experiences can serve any teacher. When dealing with, for instance, a course about limits, or a course on rings, you can find many possibilities with good and bad sides for each: you can work on the right examples and avoid the bad ones and choose the right exercises and avoid the wrong ones to reach some objectives and so on. This can make the teaching and the learning process progress. When you find the same mistakes with the same level in many studies, you gain confidence and learn to question and so you progress. Mathematics education research can reveal many secrets, solve many problem situations and explain many difficult enigmas. Nowadays, simply, a training in mathematics education for any teacher is a necessity.

5. What about the principles of the teaching mission?

If you ask many teachers about the definition of teaching, you will get as many definitions as people you ask. Isn't that weird? I wondered one day, when I noticed that we teachers all teach in different ways. You'll say that's a good and not a bad thing; it may be a richness. I would agree if our all different ways were not opposite. The students learn different and opposite principles with their teachers at different levels.

A student can be asked for a long time to accept all the results and one day, he will be asked to prove all the results. He can be told all the time to not ask questions and with some teacher, he'll be asked to ask all the questions, if he doesn't, he'll find some of those questions in the exam. He can never know, for a long time, what mathematical comprehension is and one day he will be asked all the time 'did you understand' without knowing how to answer this question; if it is yes, almost or no as he didn't learn how and what to understand. How is it that we are all different teachers? Shouldn't we have common points that students know for sure that they must exist with every teacher? In a bestseller that I read [1], the writers who consider that teaching is not only a science but rather an art, redefined teaching by the most important elements that should exist with any teacher dealing with any science, giving ~~fruit to a long experienc~~e and a deep study. I'm glad to cite them here to revalue the teacher and to destroy the bad image that has been formed these last years especially about the university teacher as ‘someone who is able to write and to read what’s written at the blackboard’.

Nine principles have been associated to a teacher to accomplish his noble mission:

1. learning before teaching,
2. authority,
3. ethics,
4. order,
5. imagination,
6. compassion,
7. patience,
8. character,
9. pleasure.

Conclusion

I’ll conclude with some quotes from the cited book.

‘It’s much easier to talk or write about teaching than it is actually to teach. The aspects of teaching that we examined in this book are ideals –ends always to be sought if only rarely gained, their pursuit one of life’s most difficult tasks. Those who have never taught probably cannot fully imagine the demands on energy, patience, and will imposed by classroom work It’s exacting labor, often lacking clear and tangible results and requiring teachers to begin all over again what they have already tried to do; and it has been made more demanding today by trying social conditions that all too frequently challenge teachers and their students.’

‘Teaching is also the gift of one person to another. It is a compassionate extension of self in acknowledgment of the needs and aspirations of someone else, usually but not always younger than we are and always, for a time at least, depending on us for some kind of knowledge. In that gift of self consists teaching’s greatest satisfaction –the giving not so much of knowledge, which each person must acquire, as of habits of mind and heart and powers of thought.’

Universities need not only trained teachers, but teachers who challenge the continuous change of the world. We need to prepare and to offer to any society professional citizens, balanced, mastering perfectly their work and knowledge, and ready to give more and better, especially citizens who can handle again and again the permanent challenge of life.

HOW CAN MODELS OF MATHEMATICAL DEVELOPMENT BE STRUCTURED, REPRESENTED, COMMUNICATED AND USED IN FORMATIVE ASSESSMENT?

Malcolm Bauer
Educational Testing Service
mbauer@ets.org

E. Caroline Wylie
Educational Testing Service
ecwylie@ets.org

Karen Harris
Australian Council of Educational Research
harris@acer.edu.au

The purpose of this working group is to identify ways in which teachers and students can use models of mathematical development productively as part of a formative assessment process. In the sessions, and starting from some existing "seed" examples, participants will identify different ways of representing, communicating, and using these models in formative assessment in the classroom, generate new examples, and draft a research agenda investigating the efficacy of these approaches. Follow-on activities include expanding, piloting, and evaluating the different approaches through collaborations among researchers and practitioners, and convening again to share and learn from our collective experiences.

Background

Formative Assessment

Formative assessment is "a process used by teachers and students during instruction that provides feedback to adjust ongoing teaching and learning to improve students' achievement of intended instructional outcomes." (CCSSO, 2008). There is a large body of research linking the consistent and systematic use of formative assessment to improvements in student learning (Black & Wiliam, 1998, Brookhart, 2005, Nyquist, 2003). Wiliam (2004) stated that "in order for assessment to function formatively, it needs to identify where learners are in their learning, where they are going, and how to get there" (p.5). Most current work on formative assessment draws attention to both the teacher role and the student roles, emphasizing the importance of bringing students into the formative assessment process (Heritage, 2010). There is a small but developing body of research that suggests that within the process of formative assessment, teachers struggle particularly when it comes to determining "how the get there" i.e. the next instructional steps they should take with their students based on the assessment evidence (Heritage, Kim, Vendlinski & Herman, 2008).

Learning Progressions

Heritage (2010) citing Black and Wiliam (1998) reminds us that one requirement of formative assessment "is a sound model of students' progression in the learning of the subject matter, so that the criteria that guide the formative strategy can be matched to students' trajectories of learning" (Black & Wiliam, 1998, p. 37). The notion is that in order for teachers and students to identify what the next learning goal should be, they need to be able to assess where a student currently is on a path of learning. The next step on the path is then a natural learning goal for that student. Progressions define a series of points or states of understanding as an ordered sequence. By knowing a students' current state and the ordered sequence, teachers and students can target the next significant state of understanding that the student should move towards. While progressions can be used to determine the next state of understanding, they do not necessarily define what a student, with teacher support, needs to do to move into this next state of understanding, i.e. they define where to go, but not how to get there.

Within mathematics, Daro, Mosher, and Corcoran (2011) state that the term *learning trajectory* is more commonly used in mathematics, and allows for the possibility that the a trajectory includes the learning and teaching strategies that are needed for shifting students' understanding to the next level.

In our work on learning in mathematics, we have used the term *model of mathematical development* to make clear that the characterization of different levels of understanding is essentially a descriptive theory of the different states of understanding, and is predictive to the extent that the sequence of states captures common sequences of changes in understanding. We define a model of mathematical development as describing the major shifts in understanding that generally occur over medium to large time periods (typically months to years) as students grapple with mathematical knowledge. These shifts describe how a variety of types of knowledge (e.g. conceptual, procedural, contextual and metacognitive knowledge) change over time with respect to central ideas of the domain as students' competency improves due to learning within the domain and related domains, as well as more general cognitive development. Developmental stages can include shifts in view and belief, as in the shift from an understanding of the equal sign as a "calculate something" sign to an understanding of the equal sign as a truth-value statement of equality or balance between two mathematical quantities or objects. Developmental stages also can include increases in generality, integration, and robustness of existing knowledge, as in increases in procedural or representational fluency (Harris & Bauer, 2009).

Two progressions are included in table 1 and table 2. In an in-progress literature review, the authors identified 18 mathematics concepts that have associated candidate models of mathematical development (Bauer, Graf, Harris, Haberstroh, Attali, Wylie, and Leusner, in preparation). The first example, a model characterizing different understandings of central tendency is drawn from Watson and Moritz (1999), and Callingham and Watson (2003). Their proposed a theory of development for the concept of average and measures of central tendency (median and mode) is based upon the SOLO taxonomy Biggs and Collis, 1991) which is a neo-Piagetian framework for characterizing learning and development. The Watson and Moritz (1999) model focuses on how students develop an understanding of average as a measure of representativeness and draw conclusions about a variety of types of data. Table 2 provides a description of each of the levels (excerpted from Watson and Moritz, 1999) and examples drawn from Callingham and Watson, 2003, and Watson and Moritz, 1999).

Table 1
Central tendency developmental levels

Level	Description	Example
Preaverage (P)	Students have no term for average, even in a colloquial sense. When asked to solve problems involving concepts of central tendency, they typically provide tautological responses or idiosyncratic stories about the context.	To a question about the relation between average wage and median home price in Australia, an example response from a 9th grader at this level is "average means it is small and good for little families" (Watson & Moritz, 1999, p. 27)
Single Colloquial Usage for Average (U)	Students use colloquial terms for average, such as *normal* or *okay* and sometimes refer to "add up" colloquially but not in a calculation sense. They do not have an understanding of how to calculate an average.	Student use terms such as "same as others," "okay," "normal." (Callingham & Watson, 2003, p. 31 Avg 2.2) and refer to median of set of measures as "the most accurate value." (Watson & Callingham, 2003, p. 40 ME 13.1).
Multiple Structures for Average (M)	Students use at least one, often two or three ideas for the concept of central tendency including "most", "middle", and the add and divide algorithm for the mean to describe average in straightforward situations. However, they fail to consolidate multiple concepts meaningfully. They rarely use more than one of these ideas in complex questions. Students sometimes acknowledge conflict between incorrect calculations of mean and idea of mode.	"mean is a lot of numbers added up and dived by how many numbers there were to start." (Watson & Moritz, 1999, p 28).
Representation With Average (R)	Students refer to add-and-divide algorithm for the mean to describe average in straightforward situations. They can distinguish between the concepts of mean and median. They are aware of the association of the decimal form with the algorithm for mean. Students express some ideas related to the representative nature of average (e.g., prediction, estimation, or representing whole data set) and refer to "most" to describe data distributions compatible with mean or offer mode as alternative average concept. They know the algorithm for the mean but do not successfully apply it in complex contexts without prompting;	"not an average which would include all the extremes…out of 100 it would include 49.5 above it and 49.5 below it." (Watson & Moritz, 1999, p. 28).

A second example is provided in Table 2 which is a model of students' understanding proposed by the authors of equations and expressions with respect to two underlying concepts: equality and variable. The table begins with a description, that we call level 1, that represents the most basic level of understanding of both of these concepts addressed by the table, and then proceeds through four more levels of understanding. At each level there is a description of how a student thinks about equality and also the notion of a variable, and by combining two understandings, a description of what that student would be able to do and not do at that level of understanding Before looking at the table, which combines both idea, it is worth describing major conceptual changes in student understanding of equality and variable separately.

For equality, the primary distinction that is made is between thinking *operationally* about equality and thinking *relationally* about equality (Kieran, 1981; Knuth, Stephens, McNeil, & Alibali, 2006). The *operational* thinker treats the equal sign as a signal to do something – add or subtract or whatever action was called for on the left hand side of the equation. This way of thinking likely arises from students seeing many more arithmetic problems in math written as 5+3=__ compared to __=3+5 and often teachers will say "five plus three gives you what?" When a student begins to think *relationally,* he or she understands that the expression on the left hand side of the equation has the same value as the expression on the right hand side i.e. they are in balance. And furthermore, when a student understands *relational equivalence*, he or she will understand that equality in an equation is maintained provided you perform the same operation on both sides of an equation and will be able to judge equivalence in many cases without having to calculate values for each side of an equation by using techniques such an compensation and cancellation (Rittle-Johnson. Taylor, Matthews., & McEldoon, in press).

For variable, an important distinction is between students thinking of a variable as representing a *specific unknown*, i.e. as a placeholder for one and only one number, and as a *generalized number* i.e. that a variable can take on many values and be part of more complex mathematical relations as in a linear function (Booth, 1984; Weinberg, Stephens, McNeil, Krill, Knuth, and Alibali, 2004). Prior to these two understandings, students may have one or more contextually dependent beliefs about variables such as an algebraic letter must be the same as the first letter of what it stands for (e.g. 'b' for brownies) (Küchemann, 1978; Booth, 1984).. The table below combines these understandings of equality and variable into five levels of understanding overall.

Table 2
Equality and Variable: Equations and Expressions

At **level 1**, students have a superficial understanding of the concept of variable that does not include the idea of variable representing an "unknown." Instead, students may hold one or more beliefs about variable including, for example, that variables represent objects (e.g. that the variable "b" stands for "brownies" in a word problem because it starts with a b). Alternatively students may treat variables like individual digits of a number (if $2x=24$, x must equal 4), they may ignore variables in an equation only operating on the numbers, or separate variables from numbers in an equation or expression.

At this level students also have an *operational* sense of equal sign. Students with this type of understanding believe that the equal sign is a signal that indicates that there is s problem to be solved or computation expressed on the left of the equal sign and that the answer should be placed to the right of the equal sign.

Given these understandings of equality and variable, students should have trouble solving word problems, even with informal methods, algebra solving follows misconceptions as described in model of equality.

At **level 2** students still have an operational understanding of equality as in level 1 above. Their understanding of variable is different. Students have an understanding of variable as a "specific unknown" in which letters stand for one and only one number. For example, at this level if asked "in the expression 2n+3, can the variable n stand for the number 4?" the, student will say yes and but, then if asked if the variable n can stand for 37 they will say "no.

Students can apply informal methods to solve simple algebraic word problems, but will continue to display misconceptions when attempting to solve symbolic equations. Students can attempt to solve equations using guess and check strategy and other approaches that do not involve substantial symbolic manipulation

---

At **level 3**, students have "specific unknown" level concept of variable as in level 2. What's different is their understanding of equality. They have a more sophisticated understanding of the equal sign as expressing that the quantity to the left of the equal sign has the same value or is in balance with the quantity expressed on the right of the equal sign (described sometimes as a relational understanding of equality). They also know some simple procedures for algebraic manipulation.

Students can solve problems with one variable represented in text symbolically using algebraic manipulation. Because students have few ways of understanding algebraic expressions and equations, they may apply less efficient methods to solve equations. Expressions are only understood correctly if they can take on a single numerical value (i.e., consistent with students' understanding of variable as specific unknown).

At **level 4**, students' understanding of equality is richer than in level 3. They understand relational equivalence in most contexts (meaning that they not only understand that both sides of an equation are equivalent, but they also understand that performing the same operation to both sides of the equation maintains the equivalence) and can readily use transformations to balance equations to solve for an unknown. Students still have the same understanding of variable as in level 3 i.e. the "specific unknown" level concept of variable.

Students do not yet have a "generalized number" concept but because of relational equivalence they can solve many equations with one unknown algebraically

---

At **level 5,** students have "generalized number" level concept of variable, in which a variable can function as a pattern generalizer for arithmetic, as in the statement a + b = b + a, or can express relations among sets of numbers as parameters and arguments as in the linear equation x = mx + b. Students have the same understanding of equality as in level 4, i.e. they understand relational equivalence and can readily use transformations to balance equations to solve for an unknown.

Students can solve symbolic equations, parsing expressions to flexibly apply operations on to solve equations efficiently.

There is substantial research and development still needed to understand the characteristics of effective and practical formative assessment. Additional research is needed also in identifying, describing, and evaluating models of mathematical development. In this working group, in order to help advance both fields, we will explore the mutual constraints that these two areas provide. We believe answers to a variety of useful questions can be developed by making explicit constraints that models of mathematical development provide to the field of formative assessment, and the constraints that formative assessment can provide to the creation of models of mathematical development. To make this idea clearer, the aims and plans of the working group are described next.

Aims of the Working Group

Models of mathematical development are central to formative assessment. They provide testable theories of how student understanding changes in light of instruction and time. They are needed to define gaps between students' current understanding and learning goals in a way that makes closing the gap feasible. If the gap between two states of understanding has been empirically validated, is present within the population of learners, and many students have moved from one state to the other in the past, teachers and students should be confident that this unit of learning is feasible. There has been research on the feasibility of developing interim and summative assessments to collect evidence and make statistically valid inferences about student levels within models (Watson and Callingham, 2005; Weaver and Junker, 2004; Wilson, 2008). There has been less work on how best to represent models for use by teachers and students, (but see Lesh, Lamon, Gong, & Post, 1993; Wilson, 2005; Watson and Callingham, 2005). Still less is known about how to use models of mathematical development in the service of deciding on next instructional steps to be taken by teachers and students (Heritage, Kim, Vendlinski & Herman, 2008).

Wiggins (1998) provides an example of formative assessment within a welding classroom. In the example, students are learning to weld a ninety degree corner joint. When students think they have completed the weld to industry standards, they compare their welded corner joint to a set of joints to determine to which joint theirs matches best. The joints are ordered in terms of quality and each has specific characteristics relevant to beginning welders In doing this comparison, students are a) assessing at what level they are performing b) determining their next learning goals, and most importantly c) understanding what specific next things they need to do to improve. In other words, a student can consider his or her next instructional steps by, for example, realizing that on the next joint he or she works on, the two pieces to be joined must be more precisely positioned, or that gaps need to be filled, or bubbles removed. In this example, the connections from student performances to level of competency and next instructional step are transparent. Teachers and students can compare student performance to benchmark performances and determine what they need to do next.

Unfortunately, this sequence of inferences is not so transparent in mathematics learning. How does the Wiggins welding example translate to a mathematics context, when it is not skill in a directly observable work product that is evolving and improving, but rather knowledge and understanding around abstract concepts such as the meaning of "average" or "variable"? While there has been some work in this area (e.g. Forster and Masters' work on the Developmental Assessment Resource for Teachers (DART) (2004), much still needs to be learned. How can models of mathematical development be structured to best support formative assessment? Is a linear sequence of levels an adequate model to characterize student understanding to inform formative assessment? Are there circumstances in which model in the form of a network of states of understanding could provide greater value? Is a model in the form of a set of understandings better in some circumstances? What other structures are possible and advisable? How can models of mathematical development be represented and presented to make learning goals and instructional approaches as transparent as possible to teachers and students? What additional information will be helpful to provide? The aim of this working group is to begin to develop answers to these questions.

Plan for the Sessions

The sessions will focus on three work products 1) a list of different ways of representing models of mathematical development with examples that might be especially useful to teachers and students 2) descriptions of the use of these representations in making next instructional choices or adjustments transparent along with descriptions any additional materials and 3) a research agenda for expanding, piloting, and evaluating the use of different representations of models of mathematical development in formative assessment along with specific work individuals or groups will be doing in the coming year with respect to this agenda.

In session 1, the organizers will present the aims of the group and the session, provide some examples of models of mathematical development, a common definition and explanation of formative assessment, example tasks, and a video of the use of one model to support formative assessment as part of a classroom discussion. The bulk of the session will be a facilitated brainstorming session on different structures and representations of models for use in formative assessment. One area of interest to the organizers is how to include students (following from the welding example) in the use of the models of development. Much of the writing around formative assessment has emphasized not just the teacher role in the process, but the centrality of students to the process. Given that models of development may span several years of student development, there are questions about when it is appropriate to be explicit about the developmental model, and how a model can be of most value to students.

In session 2, the working group will select a set of the representations and break into small groups to flesh out examples of their use with respect to specific models of mathematical development. In the later portion of this session, the working group will reconvene to discuss and contrast the examples and potential value of the different representations.

In session 3, the working group will identify research questions and associated approaches and activities for addressing them based upon the work in sessions 1 and 2. Participants will discuss their interest and willingness in engaging in continued research collaborations to address these questions and sketch out next steps for the working group.

Follow-On Activities

Throughout the year, participants may explore the use of the representations of models and ideas for use in formative assessment in their research or in their practice. It is the hope of the organizers that early pre-proposal explorations are carried out. And one or more research proposals may be generated. The work will also inform an aspect of an existing grant on which the organizers are working. The organizers are currently working with a group of approximately 15 middle school teachers, and will have opportunities to pilot some of the emerging ideas from this working group session and will provide feedback to the working group participants on their ideas. The intent is to reconvene at the next PME-NA to share experiences on specific collaborations that developed, to discuss progress on aspects of the work, and to plan and focus continued efforts in this area.

The Gender and Mathematics Working Group (GMWG) reconvenes this year at PME-NA to: discuss current work on gender at the national and international levels; examine feminist and gender study theories that inform our work; and connect gender and mathematics research findings to practice in schools and communities. Members share seven short summaries within topical subgroups to discuss theoretical frameworks, research questions, and results; and to make recommendations for further work. After sharing out results from the topical subgroups, the GMWG discusses future directions and makes plans for collaborations during the coming year. Collaborations include support in developing research agendas, collaborative writing, and pursuit of funding opportunities. The GMWG is open to any PME-NA members interested in issues of gender and mathematics; one does not have to have been a past participant.

Introduction

The Gender and Mathematics Working Group (GMWG) of PME-NA suspended its activity so that members and leadership could take the time to pursue agendas defined by the group. The GMWG members reconvened at PME-NA XXXIII to discuss current work done by GMWG participants and in the field at large and to organize additional work. In the paragraphs that follow we share a brief history of the working group, explain the emphases of this year's meetings and how they relate to PME-NA goals, and outline our group's agenda.

Brief History of the Working Group

The GMWG met annually at PME-NA from 1998 until 2007, except for the year of the joint meeting with the International Group for the Psychology of Mathematics Education in 2003. The work of the group began with reviews of gender and mathematics scholarship and an effort to identify absences in the research strands reviewed. Committing to an integration of our collective scholarship on gender and mathematics, we defined future directions for research and for the working group. An early result was a visual representation, a graphic, of our conception of the field of gender and mathematics, and the complexity of the elements with(in) which we work (Damarin & Erchick, 1999; Erchick, Condron & Appelbaum, 2000).

After the first meeting of the GMWG, we continued to gather annually at each PME-NA meeting, sharing our scholarship on gender and mathematics, collectively and individually redefining our directions and purposes. We supported each other and sought feedback from the GMWG participants and the PME-NA membership at large. Forming peer groups of individuals with common interests and related research efforts, we reviewed, critiqued, and discussed our body of scholarship. It was the support of the individuals' work that defined our group, as we mentored, critiqued, and collaborated with each other across the varied directions members pursued. This approach to our work exemplifies a way in which the group practiced a particular element of the scholarship connected to gender – agency. As agency became an emphasis of our group, it determined the most appropriate approach for us in our work together.

At the 2004 PME-NA sessions in Toronto, the GMWG members began moving our work into new spaces. In these sessions we explored ways in which we can more deeply examine the relationship between gender and mathematics, with reflection upon international perspectives and critical theory, connected work in gender and technology, and critical perspectives on pervasive, recurring questions about the place for gender work in mathematics education (Erchick, Applebaum, Becker, & Damarin, 2004). At the 2005 PME-NA sessions in Roanoke, we discussed topics across the range of the scholarship of our members, and found a unifying framework emerging in our work. That framework was the role and development of social agency in women and girls' experience as students, teachers, and researchers in mathematics education and led our way until we temporarily suspended our work together after 2007.

Connection to PME-NA Goals

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education.
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians and mathematics teachers.
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

The first of these goals, involving international contacts and exchanges, was one of the areas for which our group had just begun to make gains. We intend through the 2011 meetings to reignite our international initiative with presentations in the sessions and efforts to extend and develop the international aspect of the work of this PME-NA group. The second and third goals are in part addressed by our GMWG goals to utilize the theory of feminist and gender studies in our research, to focus more of that research on teaching practice, and then to apply more of those findings to the classroom setting, at all levels. Both the second and third goals are also addressed in part by our third area of interest, the advancement of theory around concepts related to the study of gender and mathematics (e.g. voice, agency, epistemology), both for its broad theoretical advancement and for its application to teaching and learning. Finally, we encourage emergent agendas that arise within this work, especially those that support the goals of PME-NA.

Plan for Active Engagement of Participants

As has always been the case with the GMWG, the sessions we conduct this year are intended to be active with discussion, decision-making, and work activities. We remain committed to an initiative that depends upon participant voices for direction and support. In this year's sessions, we began with introductions and a very brief presentation of a multi-faceted framework to help inform directions in this year's GMWG meetings. As participants discuss theory, research, and application to practice in the topical subgroups, we asked they consider the framework elements to help guide their work. The framework elements are:

- Recent calls to incorporate additional perspectives such as queer theory, and to clarify the definition of *gender* (see more at *Sexual Identity and Mathematics Education Research and Practice* and *The Importance of Defining "gender"* below);

- Recent findings on international studies on gender and mathematics (see more at *An International Survey of the General Public's Views on Gender-related Issues and Mathematics Learning* and *International Perspectives on Gender and Mathematics Education* below); and
- Attention to the focus of research funding possibilities: Discussion of Gender in Science and Engineering program (GSE), Joanne Rossi Becker.

The GSE programs seeks to develop the nation's knowledge, social, and human capital aimed at broadening the participation of girls and young women in STEM education. The GSE program covers grades K-undergraduate education with particular attention to transition points in women's educational experiences. The program also is broad enough to include research and diffusion activities that focus on men and boys underrepresented in STEM fields. The GSE program funds three types of projects:

1) Research projects to investigate:
   i) Gender-based factors that affect the learning in STEM education and choices students make to choose STEM education and careers
   ii) Societal, formal and informal systems and how they interact with individuals to encourage or discourage interest and persistence in study or careers in STEM fields.
2) Diffusion of research-based innovation projects to:
   i) Provide a mechanism to engage a wider audience of practitioners with research findings and strategies for changing educational practice relative to gender issues
   ii) Pilot, scale up or disseminate
3) Extension services to create a cadre of agents who can inform and assist practitioners in adopting proven gender-inclusive policies and practices in pedagogy (train the trainer model).

We encouraged interested members of the GMWG to consider collaboration and possible grant applications. Discussion supported generating questions for research, questions for diffusion, and models of extension services.

These three themes (gender theory, international perspectives, and funding possibilities) cut across the discussion in the topical subgroups listed below. After the brief framework discussion, the group spent the rest of its time in day one and half of its time in day two working in the topical subgroups, sharing and discussing each others' current work (in various stages of development), feedback on research questions, and recommendations to further the work. Sharing out across subgroups, and making decisions on directions for the year complete day two. Day three was dedicated to participants actively planning research for the upcoming year.

Topical subgroups will be organized around the PME-NA and GMWG goals as follows:

- International Contributions to the Study of Gender and Mathematics
- Utilizing Multiple Theoretical Perspectives in the Study of Gender and Mathematics (Feminism, Postmodernism, and Gender Studies)
- Taking Gender and Mathematics Research Findings into Teaching (School, Teacher Education, and Out-of-School Experiences)

The sharing of work in the subgroups is brief, interactive, and introduces questions to the whole group for further discussion. In the following paragraphs we describe work contributors will share work as a part of the subgroups' discussions.

Introduction to Shared Work

The following sections summarize the work contributors shared in groups and discussion questions to help facilitate the topical groups. Additional participants joining the group at the

PME-NA meeting, also shared their work in discussions receiving feedback and support as well.

Helen Forgasz, Monash University
An International Survey of the General Public's Views on Gender-related Issues and Mathematics Learning

Among many factors found to contribute to gender differences favoring males in mathematics learning outcomes is the perception that mathematics is considered a male domain. Gender-stereotyped beliefs associated with mathematics learning include, for example, beliefs that boys are "naturally" better than girls at mathematics and that males are more suited to careers in mathematics-related fields (e.g., science, computing). While the views of students, teachers, parents, and other stake-holders have been gathered fairly regularly and in a range of countries, less often are the opinions of the general public determined. Using an innovative approach, participants in a survey aimed at gauging the general public's views on gender stereotyping and mathematics learning were recruited using the social networking site, Facebook. The target audience for the advertisement about the survey was limited to those over 18 years of age (an ethical consideration), and the penetration was global. Responses were received from over 300 from 54 different countries. The general findings were that the majority of respondents did not hold gender-stereotyped views. However, among those that did, the traditional male-stereotype persisted.

Discussion questions

- Considering the progress that has been made in many aspects of women's lives in many parts of the world, why is the male stereotype so pervasive with respect to mathematics learning?
- What can or should be done to address the persisting view that mathematics is a male domain? To whom should action be targeted?
- What additional research is needed in this field?

Olof Steinthorsdottir, North Carolina State
International Perspectives on Gender and Mathematics Education

This short report focuses on the recently published book *International Perspectives on Gender and Mathematics Education* edited by Helen J. Forgasz, Joanne Rossi Becker, Kyeong-Hwa Lee, and Olof Bjorg Steinthorsdottir (Forgasz, Becker, Lee & Steinthorsdottir, 2010). This book emerged from five years of working groups at the international conferences of PME. Separated into four sections, the book provides papers on: history, policy and non-school factors affecting gender and mathematics; foci on the status of gender research in various countries; discussions of high achievers and mathematics education; and reports on tertiary students.

The first section begins with a reprint of a 1979 paper by Teri Perl on the Ladies Diary and the mathematics therein published in the US from 1704-1941. Remaining chapters focus on how parents do math with their children, review out-of-school programs, discuss a longitudinal study of youth in New Zealand, and examine how attention paid to gender equality in Australia has changed over time. The second section has a focus on the state of gender research in a variety of international venues, with two chapters from Mexico, a synthesis of several large-scale international studies, and work from Iceland and Germany. The third section of the volume focuses on research on high achievers in mathematics, with work from Korea, Australia, and the US. The final section of the book includes three chapters that focus on gender and mathematics beyond high school, with particular work from Canada, the US, and a variety of other countries.

Discussion questions:

- ∑ Are gender differences in mathematics actually diminishing? Is the situation the same in all countries or just in developed countries?
- ∑ What are some critical areas of research to benefit from cross-cultural investigation?
- ∑ What theoretical frameworks make sense in various cultural contexts?

Lynda R. Wiest, University of Nevada, Reno

Sexual Identity and Mathematics Education Research and Practice

According to Alexander (2008), “Queer theory is a collective of intellectual speculations and challenges to the social and political constructions of sexualized and gender identity” (p. 108). The sciences are charged with being heterosexist in nature with narrow, essentialist perspectives grounded in biological determinism and systems for classifying living things into “neat” categories, and other assumptions (Toynton, 2007). Interestingly, research shows a relationship between sexual orientation and spatial abilities (specifically, mentally rotation of objects), with heterosexual men performing better than bisexual or homosexual men and the reverse being true for women (University of Warwick, 2007). It is thus curious that the field of gender and mathematics education has paid so little attention to sexual identity in research and practice.

Rands (2009) notes that subject areas other than mathematics have incorporated attention to sexual identity and asserts, “The time has come to queer elementary mathematics education” (p. 182). Suggestions for “queering” mathematics education include “adding gays and stirring,” where one has gay people and topics in otherwise heterosexist activities, such as using a story problem about children with two moms, constructing a timeline of gay history, and doing mathematical explorations with gay symbols such as the pink triangle. “Queering” also includes analyzing social statistics on topics such as census figures, same-sex marriage, and the school and everyday experiences of sexual-minority individuals (e.g., school attendance, hate crimes); and challenging fundamental assumptions and perspectives, such as binary male/female and masculine/feminine distinctions in which mathematics is mainly associated with male/masculine and presumptions about opposite-sex attractions and distractions in single-sex schooling (Copping, 2011; Mendick, 2006; Rands, 2009).

Discussion Questions

1. What relationships may exist between sexual identity and mathematics?
2. What research objectives and methods do you suggest for investigating the nature of the relationship between sexual identity and mathematics?
3. What obstacles are researchers and practitioners likely to face when incorporating sexual-identity topics/content into mathematics instruction? How might they address these challenges?
4. Should tests that disaggregate data by other social identities, such as gender, race/ethnicity, socioeconomic status, and language proficiency, also disaggregate data according to students’ sexual identity? Why or why not?

Diana B. Erchick, Ohio State University at Newark

The Importance of Defining “gender”

What do we mean by “gender”? Damarin and Erchick (2010) raise the issue of defining what we mean by gender in their JRME article “Toward clarifying the meanings of *gender* in mathematics education.” They note Glasser and Smith’s (2008) call to the education research community at large, and reviewed all JRME issues between 2000?? and 2007 in their analysis of the meanings of gender therein. What they found is one of the areas we need to keep in our view as we proceed with our work around gender and mathematics. From Fennema and Hart's 1994 JRME article in which those scholars identified the need for bringing cognitive and feminist perspectives to bear on the study of gender and mathematics, to biological perspectives, to postmodern and socio cultural approaches, it is clear that we are not clear about what we mean by gender. Damarin and Erchick argue "it is time to take a new turn by acknowledging that the relationships of gender to mathematics education are much more complex than once thought and bringing theories of gender to bear on research. In this rich context, clarity must supplant vagueness in the meaning of gender in mathematics education research" (p. 321).

Recommendations from Damarin and Erchick (2010) include deconstructing the binary; attending to power, agency and voice; considering what it is about mathematics that might contribute to our struggles to define gender; and considering what it is about sex/gender that makes it different from or similar to other biological/social constructs such as race. One might consider Burton's 1995 seminal work "Moving towards a feminist epistemology of mathematics" to inform our thinking about the nature of mathematics. And consider the collection of works in *International Perspectives on Gender and Mathematics* (Forgasz, Becker, & Lee, 2010) in exploring sociocultural connections. Overall, the sex/gender system, introduced to the first GMWG by Suzanne Damarin in 1998 (Erchick & Damarin, 1999), has a complexity that both challenges us and incites us to define, each in our own work, what we mean by gender.

Discussion questions:

- How can consideration of feminist epistemology help inform our work?
- How can gender identity help us broaden our understanding of gender?
- Do multiple definitions of constructs in the sex/gender system clarify or compound the definitions of gender?

Judith Olson and Melfried Olson, University of Hawaii at Manoa

Nonverbal Communication When Parents and Children Work on Mathematics Tasks

In the project, *The Role Of Gender In Language Used By Parents And Children Working On Mathematical Tasks,* the authors investigated gender-related differences in verbal language used by parents and children working on mathematical tasks. We analyzed three ten-minute videos for each of 114 dyads, mother-son, mother-daughter, father-son, and father-daughter. Additionally, 66 ten-minute videos for 22 dyads (five boys, with both mother and father, and 6 girls, with both mother and father) were analyzed for gender-related differences in nonverbal communication.

Nonverbal communication is sending and receiving wordless messages, both intentional and unintentional. In everyday situations we often use verbal and nonverbal channels simultaneously to convey intent. Nonverbal messages constitute an integral part of speech and provide visual referents, punctuate key points, add structure to words, and synchronize body and thought. Nonverbal communication can be used in a variety of ways, such as to repeat and strengthen a verbal message; complement a verbal message; send opposing or conflicting message; regulate conversation; substitute for a verbal message; or alter interpretation of a verbal message.

While much nonverbal communication is based on arbitrary symbols that differ from culture to culture, a large proportion is to some extent iconic and may be universally understood. Our investigation examined eight different nonverbal actions, each with two subareas: 1. body positioning (proximity or action toward another; proximity or action away from another), 2. gesturing (finger or hand pointing; moving of objects in workspace), 3. head movements (nodding or shaking head or shrugging shoulders; tilting while focused on work area), 4. attempted eye contact (seeking approval and expecting a response; monitoring actions with no response expected), 5. making eye contact (to give or seek approval or a response; face to face discussion); 6. facial expressions (demonstrating emotion; disengaged); 7. smiling (happy; discomfort), and 8. laughing (happy; discomfort). All but the facial expression actions were coded by dyad according to whether a mother, father, daughter or son initiated the action. Hence, when we recorded DF, we recorded actions for the daughter-father dyad, but for which the daughter initiated the action. Facial expression was coded only by dyad, not by who initiated. Preliminary results and initial analysis were shared in the GMWG.

Discussion Questions:

- Of the actions and categories we have identified, which might make significant contributions to gender research?
- What variations are there in interpretation of the nonverbal actions?
- What is the relevant theoretical base for gender-related nonverbal interactions among parents and children working together on mathematical task?
- Does each nonverbal action have communication implications?

Manjula P. Joseph, Ohio State University

Supporting Student Learning In A Girls' Mathematics Summer Camp Classroom

This study examined pedagogy in a mathematics summer camp for girls conducted at a large mid-western university in the United States. The day-camp is for female students in the middle grades and is conducted for a period of five days with twenty teaching sessions that cover five units of middle school mathematics. Camp curriculum and video-recordings of the teaching sessions were analyzed to find correlations between curricular aspects and equity pedagogy and teaching practices that support a gender-equity agenda. Curriculum was examined to identify those practices that most support equity and activities that enhance certain equity practices.

The research questions for this study included:

- What curricular and pedagogical decisions in a middle school mathematics camp setting support girls' learning?
- How do teachers' perspectives, and practice support equitable teaching in the classroom?
- How does a teacher's ethnicity/race/gender influence classroom practice for equity?

Study participants are teachers from the summer camp. Transcriptions of video-recordings of sessions and follow-up interviews with teachers comprise qualitative data for the study. Session transcriptions were coded for those particular equitable practices that attend to gender-related issues in mathematics teaching and learning. The camp's curriculum was studied to identify connections between aspects that provide opportunities for teachers to enhance student learning and participation for girls in their classrooms. Data from the interviews with participants helped make connections between teacher perspectives and beliefs and their classroom practice.

Discussion Questions:

- What questions should be asked to identify "equitable practices" for teaching girls?
- What interview questions inform understanding teacher perspectives on girls' learning?
- Is it worthwhile to explore teacher race/ethnicity/gender as influencing classroom environment/culture in an all-girls classroom?

Katrina Piatek-Jimenez, Central Michigan University
Women's Choices of Mathematical Careers

For years, women have been earning nearly half of the mathematics baccalaureate degrees in the United States; but, they continue to make up a smaller percentage of those pursuing advanced degrees in mathematics or entering mathematics-related careers. Although these statistics are well-documented, the literature does not thoroughly address *why* many women who choose to study mathematics at the undergraduate level do not continue with careers in the field.

During the spring semesters of 2006, 2007, and 2008, I conducted individual interviews with a total of 12 undergraduate women mathematics majors at two different universities in the Midwest. The goal of the interviews was to investigate what influenced these women to choose to study mathematics at the undergraduate level and how they had determined their future career plans. I asked each of these students if they would be interested in participating in a follow-up interview three to five years after the initial interviews. During the Spring semester of 2011, I conducted follow-up interviews with the majority of these women to learn what career decisions they made after graduating and to learn what influenced these decisions.

Results suggest a variety of reasons influenced participants' choice to study mathematics at the undergraduate level. They all considered themselves to be good at mathematics and felt they had a strength in the subject. All of these women also had at least one significant person (family member or teacher) who supported and encouraged them in the field of mathematics. Many of them liked the idea of majoring in mathematics because it meant, to them, that they were breaking gender boundaries. Finally, for some of the women intending to become high school teachers, the promise of marketability also influenced their decision to major in mathematics.

The most predominant theme that influenced their career aspirations, while they were still in college, was the desire to have a career where they could help people and make a difference in the world. For those not earning degrees to become high school teachers, their lack of knowledge of mathematical careers also played a large role in their future career goals.

Discussion Questions

- How can we learn about patterns of discouragement/encouragement of women entering mathematics?
- How does perception of mathematics as a male domain interact with discouragement patterns – both sending and receiving?
- What mathematical careers can be framed as more helping?

Michael Dornoo, The Ohio State University at Newark
Addressing Gendered Needs in Mathematics Learning Through Social Networking

Mathematics educators interested in issues of gender equity have designed and implemented awareness-raising experiences for parents, counselors, and teachers as well as special programs to encourage female students in mathematics learning (Karp & Niemi, 2000). Despite these efforts, findings vary about how best to address gendered needs because female students remain less likely than male students to persist in mathematics study (Ansell & Doerr, 2000; Lubienski, McGraw, and Strutchens (2004). Leder (1992) found that gender differences in mathematics achievement between males and females are small compared to differences within gender groups. Ansell and Doerr (2000) and Lubienski et al. (2004) have identified differences between males and females in multiple areas of mathematics, including the strategies that students employ to solve problems and performance on computation tasks. In addition to differences in mathematics achievement, Ansell and Doerr (2000) documented gender differences related to affective factors, including students' attitudes, self-concepts, and self-confidence. For instance, while male students tend to have a more positive attitude and self-concept toward mathematics, females tend to lack confidence and have negative attitudes (Lubienski et al., 2004).

Damarin and Erchick's (2010) cultural/historical construction model, in the context of women and work, has gender and technology as a co-constructed foundation of the model. As technology becomes more prevalent, and advancements make working interactively under a global network more feasible, the advancements add complexity to the study of gender and mathematics and other STEM fields. How do interactive technologies that emphasize online collaboration, social collaboration and resource sharing among users free of charge support or hinder the gendered development of girls in mathematics? Web 2.0 could be an appropriate technology to build many global virtual communities among students, teachers, educators and social workers from every corner of the world, but does it help girls in terms of their relationship with mathematics? Or does it instead reinforce barriers between girls and STEM fields.

Discussion Questions

- How can a new generation of mathematics educators address gendered needs in mathematics learning through social networking?
- Will modifications in the delivery of mathematics instruction by integrating technology provide experiences that bridge gaps in gender groups or create another barrier?

Anticipated Follow-Up Activities

The following work will continue following the PME-NA meetings:

- Members will continue supporting the development and implementation of individual and collaborative projects clarified or identified in the GMWG sessions.
- Members so inclined will pursue funding opportunities in gender and mathematics research, individually or collaboratively, with grant development support as available.
- Members will expand the functionality of the PME-NA GMWG website. The website currently is used primarily as a repository for prior PME-NA GMWG proceedings papers. We expect to expand it to include a reference list of gender and mathematics scholarship, both from our members and from scholars outside of our group; a password-protected component for group discussions in between annual meetings; and a repository for PME-NA proceedings papers from our GMWG members.

Closing

In pursuing research on gender and mathematics, the 2011 PME-NA Gender and Mathematics Working Group participants continue prior work that was a part of the GMWG in its first years, and readily reconvene to again collaborate with and support each other. The most recent work on international perspectives, syntheses and new questions around gender study and gender identity, and renewed views on pedagogy inspire our work. We welcome the challenges of addressing the complexities emerging in the literature and as we commit to an interpretation of the field of gender and mathematics as complex and nonlinear. We choose, too, to do our work in support of each other, consistently respecting and welcoming the voices that emerge.

Acknowledgements

The authors thank all of the contributing scholars named in this paper, without whose collaborative efforts to abstract and represent their work here, this paper would not have been as

rich.

National reports have identified the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education. However, providing high quality mathematics education for all students goes beyond the recruitment of knowledgeable teachers. This working group is designed to offer an opportunity to examine the role that professional development and support play in the work and retention of mathematics teachers. Retention focuses on new teachers, especially those in urban areas and mathematics teachers in hard-to-hire settings. Discussions concentrate on the study of interventions through Professional Development and Support Models. Efforts to deepen our understanding of the complex and multifaceted picture of why teachers leave and why they stay, and how efforts to retain teachers impact their work in the classroom and their decisions to stay or leave, are developed through the sharing of research designs, data collection, and on-going results. This working group is appropriate for anyone who has work to share or who is thinking about supporting a retention project. Throughout, we address this very complex task in terms of both the opportunities and challenges for mathematics education researchers to provide quantitative and qualitative input on a major political issue. It is hoped that this working group will enrich the dialogue about a national crisis in mathematics education.

Brief Overview of the STIR Working Group

The Supporting Teachers to Increase Retention Working Group was launched in 2009 at PME-NA 31 in Atlanta, GA to investigate the relationship between Professional Development/Support and the retention of mathematics teachers. A second meeting in 2010 at PME-NA 32 in Columbus, OH elaborated on this initial ground work and directions identified for participants to focus on. Over the past two years, a total of 16 participants attended the working group sessions aimed at identifying the gaps in the research on mathematics teacher retention in order to move forward in tackling this complex national issue. The emerging dialogue was based on the results of research studies and ideas of the participants. Participants shared their backgrounds and interests in retention issues, and discussed potential research directions with the ultimate goal of addressing key research issues that would constitute a research agenda for the group. Participants were interested in examining the on-going preparation, support and retention of grade 7-12 mathematics teachers from a variety of angles, including: (1) Impact of Professional Development on Teacher Retention ; (2) Relationship between Content Knowledge and Retention ; (3) Obtaining Research that examines the Dimensions of Professional Development and Support that impact Retention. The overarching question of Mathematics Teacher Retention is often overlooked under the assumption that effective professional development would in essence lead to increased retention. However a closer look at what type of support helps teachers stay in their school, let alone their profession is necessary.

At PME-NA 32 in Columbus, OH, the group elaborated on the research agenda that was outlined at PME-NA 31 in Atlanta, GA. To stimulate discussions, members of the group provided summaries of on-going projects to be discussed during the group meeting sessions. These projects fall under the following categories: (1) Role of technology in support/retention; (2) Professional support community that reflect the building of networks and contacts to support work, decisions, challenges, and opportunities that arise in the teaching of mathematics, including lesson study and electronically-based communities of practice; (3) Role of leadership and/or career enhancement in retaining mathematics teachers, including the PD directed towards new teachers entering the field through alternative certifications, those coming from other careers and shifts in PD needed as new teachers move through the challenges of their first 5 years of teaching; (4) Content-based Professional development with emphases on conceptual linking and problem solving; and (5) Research issues that arise in examining teacher retention.

Issues of Psychology of Mathematics Education to be Focused on

The study of the relationship between Professional Development and Support Models on the work and retention of mathematics teachers in grades 7 – 12 merits careful examination. Several national reports have pointed to the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education and maintain the United States' economic competitiveness (National Academy of Sciences, 2007; Glenn Commission, 2000). However, providing high quality mathematics education for all students goes beyond the recruitment of mathematically knowledgeable teachers to encompass issues of teacher support, professional development, and retention. Over the past two decades, analyses of teacher employment patterns reveal that many new recruits leave their school and teaching a short time after they enter. Ingersoll, using data from the School and Staffing Survey concluded that in 1999-2000, 27% of first year teachers left their schools. Of those, 11 percent left teaching and 16 percent transferred to new schools (Smith and Ingersoll, 2003). Earlier research revealed that teachers who leave first are likely to be those with the highest qualifications (Murnane and other 1991; Schlecty and Vance 1981). This "revolving door" problem is even worse in large urban districts; for example, 25% of the teachers new to Philadelphia in 1999-2000 left after their first year and more than half left within four years (Neild and other 2003). In Chicago, an analysis of turnover rates in 64 high-poverty, high-minority schools revealed that 23.3 percent of new teachers left in 2001-2002.

Reasons for the lack of retention of new teachers and teachers in high-poverty schools are often related to "working conditions" and lack of support (Ingersoll, 2001; Smith & Ingersoll, 2004; Johnson et al., 2004), though pay also plays a role (Hanushek, Kain, & Rivkin, 2001). This support includes professional and collegial support such as working collaboratively with colleagues, coherent, job-embedded assistance, professional development, having input on key issues and progressively expanding influence and increasing opportunities (Johnson 2006). Preparation, support, and working conditions are important, because they are essential to teachers' effectiveness on the job and their ability to realize the intrinsic rewards that attract many to teaching and keep them in the profession despite the relatively low pay (Johnson & Birkeland, 2003; Liu, Johnson, & Peske, 2004).

A status report on teacher development focusing on professional development and support of teachers (Darling-Hammond et al, 2009) summarized findings and put forth recommendations for effective professional development. The basis for the paper included national surveys with self reported data, a meta-analysis of 1,300 research studies, and specific studies. The conclusion is that “well designed” professional development can influence teacher practice and student performance. The paper focuses on what is or could be regarded as well designed. One strand of the paper is that of effective support for new teachers. Although half of the states require support for new teachers (Education Week, 2008) it was found that rates of participation in teacher induction programs varied by school types with highest rates in schools with the least poverty and lowest in schools with high levels of poverty. Beyond the rates of participation and availability of support, there is the question of what is effective support. The paper cites an on-going large-scale research project currently underway, which aims to measure the impact in terms of classroom practices, student achievement and teacher mobility. Initial results seem to reflect the difficulty in identifying the impact of support.

Another study presently in its fourth year, Supporting Teachers to Increase Retention (STIR) is studying the relationship between retention and support of mathematics teachers across the state of California. This five-year study is looking through the lens of 10 sites with different support models to relate retention to content knowledge, classroom practices, professional communities of support, leadership and needed support. Initial results are complex but are showing relationships between sustained professional development and support and teacher retention. Data collected to establish a base line for retention across a five-year period 2002-2006 preceding STIR shows that yearly attrition averaged 20% across all 10 sites. For the five-year period the attrition average was 54% with sites reporting an attrition of mathematics teachers as high as 73%. In the first year the attrition dropped from 20% to 14%. Three years of data and results of intervention are now available for sharing. But, what is the relationship between the support and the retention? One of the 10 sites from this study observed that success of a retention initiative takes root in a variety of needs: the need to know your District and its teachers – a need that is often addressed by established, long-term relationships between the university and district leaders; the need to offer sustained support as opposed to punctual interventions in order to break the isolation of beginning teachers and to create a sustainable community; the need to establish relevance of the professional development activities proposed by engaging participants in deep introspection of their own knowledge gaps; the need to involve all players in the community to prevent miscommunication from annihilating attempts made towards change; the need to nurture the community created by moving its members forward into roles and responsibilities they are ready to take on; and last but not least, the need to refine even successful models to keep the momentum (Felter & Faughn, 2009). These findings align with prior research emphasizing that support must be specific in addressing the needs of teachers in their particular context (Fulton et al., 2005).

As indicated in the comments above, support comes from multiple sources. Another recent study from Peabody College, Vanderbilt University, finds that principals play a critical role in the support of new mathematics teachers (McGraner, 2009). This confirms Ingersoll’s recent analysis of Mathematics and Science teacher turnover from the past two decades indicating a steady increase in the phenomena. Since the existing pool of Mathematics and Science teachers is not as well supplied as in other non-STEM disciplines, this increase is not easily absorbed by individual schools, even though enough newly qualified teachers are produced each year to cover increases in students’ enrollment and the effects of retirement. Indeed, upon leaving their teaching position, Mathematics and Science teachers are more likely to opt for non-educational professions than teachers in other fields. According to data gathered by the National Center for Education Statistics with the School and Staffing Survey and the Teacher Follow-up Survey, the provision of useful Professional Development is one of the organizational factors influencing choices of Mathematics teachers to leave or remain in their positions. Another factor is the degree of individual classroom autonomy (Ingersoll & May, 2010). But how do we successfully involve principals in supporting professional development that increases retention?

Finally, an additional aspect of the issue at stake is the retention of mathematics teachers entering the profession through alternative certification as brought up by one working group participant. In a presentation to the group at PME-NA 2009, Brian Evans emphasized retention issues within the New York City Teaching Fellows program and provided us with the following literature review: “Teachers leave teaching in New York City for three reasons (Stein, 2002): retirement, leaving the profession, and transferring to a school outside New York City. [...] A concern with alternative certification is lack of retention, especially in large urban areas such as New York City (Darling-Hammond, Holtzman, Gatlin, & Heilig, 2005). Sipe and D’Angelo (2006) found when surveying Fellows that about 70% of them intended to stay in education. NYCTF reports that 89 percent of Fellows begin a second year of teaching after the completion of their first year (NYCTF, 2008). Boyd, Grossman, Lankford, Michelli, Loeb, and Wyckoff (2006) reported that about 46% of Teaching Fellows stay in teaching after four years as compared to 55% to 63% of traditionally prepared teachers. Kane, Rockoff, and Staiger (2006) found that Teaching Fellows and traditionally prepared teachers have similar retention rates. Further, Tai, Liu, and Fan (2006) claim that alternative certification teachers, in general, have comparable commitment to the teaching profession as do traditionally trained teachers. In a survey of 31 Teaching Fellows, 90 percent said they were considering leaving their high needs schools for better schools in or outside of New York City, or leaving the teaching profession altogether (Stein, 2002). [...] Similar to results found in other studies (Costigan, 2004; Cruickshank, Jenkins, & Metcalf, 2006; Evans, 2009), teachers were very concerned with student behavioral problems and unsupportive administration.” (Evans, 2009) During the 2010 meeting, Evans elaborated on these findings by incorporating information about the Teach of America Program: “Darling-Hammond, Holtzman, Gatlin, and Heilig (2005) cautioned that, upon becoming certified, many TFA teachers leave teaching. This is in contrast to Teach for America’s own report of retention of TFA teachers on their website. TFA claimed that about two-thirds of TFA teachers stay in the field of education upon completing their time in the program, and half of those remain in teaching. This means about one-third of all TFA alumni stayed in the classroom upon fulfilling their commitment, and another one-third maintained non-teaching roles in education, such as in administration or advocacy (TFA, 2008). As of 2010, there were 17,000 TFA alumni (TFA, 2010). According to TFA, over 5600 TFA members remained teaching in the classroom after their commitment ended (TFA, 2009).” (Evans, 2010)

This working group is designed to offer a comprehensive, multifaceted examination of the ongoing preparation, support and retention of 7-12 grade mathematics teachers based on the results of research studies and ideas of the participants. It is hoped that this working group will enrich the dialogue relating the “support gap” and the work and retention of teachers of mathematics. It is also expected that this working group will propose areas ripe for further research. In light of national efforts to close “poor performing schools” this work to identify ways to improve retention of mathematics teachers becomes especially critical.

Year 1 & 2 of the Working Group: Summary

A Summary Report from the first two years of the working group is included below. This year's proposal builds upon the proposal from last year by integrating participants' research interests and focusing the discussions around four major themes relating to teacher retention. A reference list produced by combining the references from the proposal and work of the first two years is found at the end of this proposal.

Summary Report: Activities of Working Group PME-NA meetings 2009 & 2010

<u>**Participants:**</u> *Douglas Owens (Ohio State University, OH); Drew Polly (UNC Charlotte, NC); Candice Ridlon (UMES, MD); Brian Evans (Pace University, NYC); Christine D. Thomas (Georgia State University, GA); Ellen Clay (Drexel University, PA); Allyson Hallman (UGA, GA) ; Michael Meagher (CUNY, NYC); Barbara Pence (SJSU, CA); Axelle Faughn (WCU, NC); Nancy Schoolcraft (IN); Terran Felter (CSUB, CA); Molly Fisher (University of KY); Jacqueline Leonard (UC Denver, CO); Sharilyn Owens (ASU, NC).*

Participants were asked to consider the question "Can support impact teacher retention?", and more specifically "What are the different aspects of support? How is impact measured? What are opportunities and challenges encountered when researching teacher retention?" The major task for our first session consisted of coming up with directions to work and identifying missing foci in literature. Participants organized the questions and interests into four main categories that emerged from the initial brainstorming: Impact of Professional Development on Teacher Retention; Content Knowledge and Retention; Research issues and Retention; Equity and Retention. A detailed list of questions arranged by interests under the four major themes can be found in the 2009 Working Group Summary (Faughn, Pence, Thomas, 2010).

Further discussions underlined that PD must be sustained, long-term, and involve a community of learners: Mentoring necessitates careful pairing, could be done through videotapes and reflections; Decreasing the number of preps for beginning teachers could provide more time for planning and reflecting; We need to connect retention to student learning: Is seeing students succeed part of teacher perceived success that could help with retention? i.e., would evidence of increased students' performance help build confidence & a sense of competence? Finally, advantages of "whole school" reforms and developing leadership skills of individuals to bring PD back to their site were emphasized to increase onsite presence through lesson study, lesson planning, online community, coaching, and/or videotapes.

In addition to identifying interest and gaps from the literature, participants shared the following models of support:

∑ Brian Evans – NYCTF literature review
∑ Drew Polly – UNC Charlotte - Researcher-beginning teacher onsite mentorship
∑ Candice Ridlon – PD through reform curricula in Utah
∑ Axelle Faughn – Addressing content knowledge through higher education courses
∑ Barbara Pence – CMP STIR 10 sites, 10 models
∑ Christine Thomas – Developing an online community of support

The core question of the relationship between Professional Development/Support and retention was significant and central to all discussions but due to lack of directly related research, formed the springboard for lists of questions. The 2010 working group built a more focused and active research based on active engagement of participants in productive reflection on the issues across projects. After a review of previous work for new participants, two main breakout groups aimed at lay the foundations of publishable collaborative work. Returning participants were asked to inform the group of any progress they made in their respective projects. Ideas were then shared on further work and dissemination in order to better define the direction of our efforts. In response to the question "Where do we want to go from here?", several options were put forward, including developing research and papers, participation in future conferences (New Teacher Center; AERA; 2012 Symposium on Mathematics Teacher Retention), establishment of a website/webbase on teacher retention, draft of a monograph on teacher retention, write up of a joint paper for an editorial journal (NCTM/AMTE), and ultimately publication of a book on Professional Development (Math content, Technology, Communities of Practice, Leadership) aimed at teacher educators who focus on bridging research and practice. This brainstorming was followed by a detailed overview of breakout groups by group leaders.

Description and Summary of 2010 Breakout Sessions Listed by Category

(1) Category A: Role of technology in support/retention (Axelle Faughn).

We discussed issues pertaining to the role of technology in empowering teachers both in the classroom and the larger mathematics education community. Questions to address include: (1) What model of PD has been provided that engaged participants in technology use? (2) What trends are you noticing in technology use by teachers? (3) Are you able to relate technology to Retention or Leadership? (4) What constitutes technology in the work of mathematics teachers? (5) What are issues related to equity when working with instructional technologies?

Background: Teachers constantly ask for engagement strategies, including games, technology, etc. Students live in a technology-embedded world; how does this affect their learning schemes? How can teaching take this into consideration? Teachers are often less technology-savvy than their students. How do we support teachers in increasing confidence and competence on learning the instrumentation, shifting from learning to use technology to using it for teaching math, staying up-to-date with new technology (at T^3 last year many teachers were looking for TI-84 talks, but most presentations focused on the TI-NSpire)

Questions/Issue:

- How can we best support teachers to acquire TPACK?
- Can technology help with student engagement/collaborative learning, student learning for understanding, teacher leadership, teacher retention, and access to higher cognitive demand tasks?
- What different types of technology are involved in the work of mathematics teachers and how do they support teaching: Technology for presentation purpose and/or planning; Technology for conceptual learning; Technology for Community Building (Teachers, students)
- How do we collect evidence of support through technology? (Use TPACK qualitative framework and TPACK stages of development)
- What type of technology do teachers tend to embrace first?

Work was shared about teachers using the TI-Navigator, looking at discourse through case studies (CCMS).

- Other issues raised in the discussion: How do we bring communities of practice into an online environment? What is the promotion step beyond being a Master Teacher except for leaving the classroom? (Coach, Higher Ed.)

Work in Progress: AERA paper to be presented in April 2011 in New Orleans, LA, on four CMP-STIR sites.

(2) Category B: Professional support community that reflect the building of networks and contacts to support work, decisions, challenges, and opportunities that arise in the teaching of mathematics, including lesson study and electronically-based communities of practice (Christine D. Thomas).

We share our evaluation and synthesis of the literature on Second Life, professional development within a PLC, and distance learning used in our participatory action research study of this Second Life project. The Second Life project that spans August 2009-May 2011 aims at: (1) sustaining mathematics teachers who are attempting to improve their teaching and students' learning and (2) conducting research for the dissemination of knowledge on retention of secondary mathematics teachers in these schools. We use this as an opportunity to share our understandings, interpretations, and analysis of the literature on the topic as it relates to the goals, and needs of the urban community and the mathematics teachers we serve. In addition, we share our beginning analysis, and initial findings of the study based on the baseline data collected.

Background: Description of work with an Online Professional Community of Teachers in Second Life in Atlanta, GA, allowing for more convenience and flexibility in the offering of PD, and enhancing opportunities for teacher leadership.

Themes: Online learning, social theories of learning (situated learning), Peer leadership, Adult learners.

Questions/Issues:

- Finding a framework for looking at the dimensions of teacher retention through online professional learning communities, especially for teachers in high need schools – Suggestion was made to investigate Collective Efficacy within Communities of Practice
- How do we protect users through modeling and training on the ethical use of technology?
- How do teacher leaders reinforce retention? How can teachers become more integral parts of the school leadership?
- Other issues raised: What type of mathematics is discussed among teachers? Is generating a professional community of mathematics teachers online different from other such communities in other disciplines, in other words, how do you provide math PD online?

Work in Progress: One paper in press and one paper to be presented at AERA 2011.

(3) Category C: Content based Professional development with emphases on conceptual linking and problem solving and establishing collaboration with mathematicians (Imre Tuba)

Background: Professional Development and Mathematical Understandings

- Mathematical Knowledge (Kathy Heid) –Mathematical Thinking – Problem Solving
- Mathematical Knowledge for Teaching – D. Ball
- Integrated Pedagogy and Math Content

Questions:

- Does content *driven* PD result in improved mathematical understanding?
- Can the PD content be linked to classroom practices?
- How does this effect retention?

Data:

- Pretest/Posttest on Content
- Beliefs about content understanding relative to content to be taught (Confidence, Competence)
- Classroom practice (Self reports, Classroom Observations

Work in Progress: Specific to Imperial Valley site

- Content tests linked with self reported changes in classroom practices
  - Overview of PD
  - Pre/Post results (Full test, Scales)
- Classroom observations and self reported reflections relative to the PD
  - Confidence and Competence

Plans for the Third Year of the Working Group

In advance of the conference, last year's participants will be surveyed to identify any questions or shifts in foci that occurred this year. Additional people will also be contacted. The Supporting Teachers to Increase Retention 2011 working group comes in conjunction with the working group organizers' endeavors to promote discussion and raise national awareness of the issue of Mathematics Teacher Retention through a Mathematics Teacher Retention Symposium to be held March 22-24, 2012 in Los Angeles. In preparation for this symposium, several documents have been drafted that will support the work of this working group, namely a clear statement of the current problem in Mathematics Teacher Retention, a list of guiding principles in attempting to address this national issue, and a list of guiding questions aimed at advancing research-based knowledge. All these will be shared with working group participants ahead of time, and will inform the directions and foci for the 2011 meeting.

Additionally, recent work by Ingersoll and May (2010) on the current national trends in mathematics teacher retention will guide some of the discussions and questions for the group to ponder in light of their own on-going projects. In particular Ingersoll and May investigated mathematics and science teachers' turnover using data from the Teacher Follow Up Survey through the lenses of **Magnitude, Destinations,** and **Determinants.** In preparation for this Working group, participants will be asked to read and report on these findings.

Regarding Professional Development and Support, we will continue to explore the themes of Technology, Online Professional Communities, and Content Knowledge. Additionally, models of Communities of Practice through Lesson Study, and establishment of leadership roles for teachers to support retention will specifically be addressed. Participants interested in examining the Lesson Study theme will address implementation strategies and techniques for implementing lesson study. Questions to be discussed include: (1) What is the timeline for planning, teaching and re-teaching? (2) How do teachers define/identify misconceptions by students? (3) How and what do teachers decide in changing their lesson? (4) Who is involved in the Lesson Study planning and implementation? We also plan on exploring the role of early-career leadership and/or career enhancement in retaining mathematics teachers, including the shifts in PD needed as new teachers move through the challenges of their first five years of teaching.

The general outline of the three days of the working group will include:

Day 1 • Introductions and Review of past years' work and update on work by those who are attending, including review of new literature
- Overview of MTRS and reflection/focus on work by Ingersoll and May in small groups

Day 2 • Introductions of new attendees
- Breakout groups around new and old themes chosen by participants
- Brief discussion of issues addressed in each group
- Small group work focused on challenges and knowledge base

Day 3 • Breakout group reports and future directions

The productivity of the working group will be a function of the advanced organization. But at this point, we anticipate that the breakout groups will either continue to address the questions generated from the previous years' discussions, or attempt to tackle new directions in light of recent research findings.

Anticipated Results of the Working Group

To continue addressing the particular issues of retention and technology, retention and community, retention and leadership, and/or retention and content-based professional development, each participant will share a description of the work to date in their project, the stage of development the project is in, research design and instrumentation, and a summary of current findings. Joint collaboration was already successful through the efforts of this Working Group to disseminate findings at the 2011 meeting of AERA. As noted earlier, the organizers of the working group plan to solicit more papers emerging from this collaborative work, and possibly the development of a monograph synthesizing our work on mathematics teacher retention and support.

The network will also be included in the development of a Mathematics Teacher Retention Symposium (MTRS), sponsored by the CMP-STIR group, to take place in spring 2012.

As the title suggests, this Working Group has a dual focus on issues of mathematics teaching and learning and issues of equity and diversity. This includes topics discussed at the Working Group in 2009 and 2010, namely: pre-service mathematics teacher education for social justice, culturally relevant and responsive mathematics education, supporting mathematical discourse in the linguistically diverse classroom, creating observation protocols around instructional practice, and examining student experiences. This work attempts to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships, including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Brief History

This Working Group builds on and extends the work of the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME is a group of emerging scholars (new faculty and graduate students) who graduated from, or in some cases are still studying at, three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA). The Center was dedicated to creating a community of scholars poised to address some critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).

The DiME Group (as well as subsets of that group) has already engaged in important scholarly activities. After two years of a cross-campus collaboration dedicated to studying issues framed by the question of why particular groups of students (i.e. poor students, students of color, English learners) fail in school mathematics in comparison to their white (and sometimes Asian) peers, we presented a symposium at AERA 2005 (DiME Group, 2005). This was followed by the writing of a chapter in the recently published *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007). Further, in an effort to bring together and expand the community of scholars interested in this work, DiME, at AERA in 2008, sponsored a one-day Professional Development session examining equity and diversity issues in Mathematics Education. In addition, DiME members have joined with other scholars in joint presentations and conferences. A book on research of professional development that attends to both equity and mathematics issues has recently been published (Foote, 2010). Many DiME members as well as other scholars contributed to this volume.

Moreover, the Center has historically held DiME conferences each summer. These conferences provide a place for fellows and faculty to discuss their current work as well as to hear from leaders in the emerging field of equity and diversity issues in mathematics education. Since the summer of 2008, the DiME Conference opened to non-DiME graduate students with similar research interests from other CLTs such as the Center for the Mathematics Education of Latinos/as (CEMELA), as well as graduate students not affiliated with an NSF CLT. This was initially an attempt to bring together a larger group of emerging scholars whose research focuses on issues of equity and diversity in mathematics education. In addition, DiME graduates, as they have moved to other universities, have begun to work with scholars and graduate students including those with connections to other NSF CLTs such as MetroMath and the Urban Case Studies Project in MAC-MTL whose projects also incorporate issues of equity and diversity in mathematics education.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Theoretically we have been building on the work of such scholars as Marta Civil (Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Megan Franke (Franke, Kazemi, & Battey, 2007), Eric Gutstein (Gutstein, 2006), Danny Martin (Martin, 2000), Judit Moschkovitch (Moschkovich, 2002), and Na'ilah Nasir (Nasir, 2002). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and again Megan Franke (Kazemi & Franke, 2004), as well as many others outside of the field of mathematics education.

A significant strand of the work of the DiME Center for Learning and Teaching included implementing professional development programs grounded in teachers' practice and focusing on equity at each site. The research and professional development efforts of DiME scholars are deeply intertwined, and much of the research thus far produced by members of the DiME Group addresses issues of equity within Professional Development. Additionally, since the majority of the DiME graduates, as new professors, along with a number of current Fellows, are engaged in teaching Mathematics Methods courses, the integration of issues of equity with issues of mathematics teaching and learning in Math Methods has become a site of interest for research. We have learned through experience that collaboration is a critical component to our work.

We were pleased for the opportunity offered by the first two years of being a Working Group at PME 2009 and PME 2010 to continue working together as well as to expand the group to include other interested scholars with similar research interests. In 2009 an ambitious number of sub-groups were formed. Some of these sub-groups worked together throughout 2009-20 10; others had less success in accomplishing goals set out at PME 2009. During PME 2010, several of the sub-groups were collapsed so that a smaller number of sub-groups evolved out of the 2010 Working Group Meeting. These groups have set agendas for collaboration during 2010-2011 and work is in progress. We were encouraged that our efforts were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group in 2009 and an equal number did so in 2010.

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, professional development, pre-service teacher education (primarily in mathematics methods classes), student learning (including the learning of particular sub-groups of students such as African American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools;

and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics.

Existing research tends either to focus on professional development in mathematics (e.g., Barnett, 1998; Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Kazemi & Franke, 2004; Lewis, 2000; Saxe, Gearhart, & Nasir, 2001; Schifter, 1998; Schifter & Fosnot, 1993; Sherin & vanEs, 2003), or professional development for equity (e.g., Sleeter, 1992, 1997; Lawrence & Tatum, 1997a). Little research exists, however, which examines professional development or mathematics methods courses that integrate both. The effects of these separate bodies of work, one based on mathematics and one based on equity, limits the impact that teachers can have in actual classrooms. The former can help us uncover the complexities of children's mathematical thinking as well as the ways in which curriculum can support mathematical understanding in a number of domains. The latter has produced a body of literature that has helped to reveal educational inequities as well as demonstrated ways in which inequities in the educational enterprise could be overcome.

To bridge these separate bodies of work, the Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes, and how these culturally bound distinctions afford and constrain opportunities for students of color to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions that the Working Group will consider are:

Teachers and Teaching

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving and equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?
- What are dominant discourses of mathematics teachers?
- What ways do we have (or can we develop) of measuring equitable mathematics instruction?

Students and learning

- What is the role of student academic and mathematics identity in achievement?

- How do students' out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?
- *Policy*
- How does an environment of high-stakes standardized testing affect whether and how teachers teach mathematics for understanding? How does this play out across a variety of local contexts? How can we support teachers to teach mathematics for understanding in that environment?
- How do we address issues of tracking/ability grouping and in particular the grouping of students by test designation?

Plan for Working Group

The overarching goal of the group continues to be to facilitate collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education. The PME Working Group provides an important forum for these scholars to come together with other interested researchers who identify their work as attending to equity and diversity issues within mathematics education in order to develop plans for future research. Our main goal for this year, then, is to continue a sustained collaboration around key issues (theoretical and methodological) related to research design and analysis in studies attending to issues of equity and diversity in mathematics education.

In order to support this collaborative research, smaller research groups were formed from participants in the large Working Group. The plans and goals for these sub-groups are detailed in the final section: Previous Work of the Group and Anticipated Follow-up Activities.

Much of our work is qualitative in nature and we recognize that one way to increase the number of participants is to conduct research across several sites. In order to do this, we need to use the same protocols for data gathering. One of our sub-groups has taken as its charge to develop an observation protocol. Another sub-group is collecting vignettes of practice. We intend that, during what we hope to be the long life of this Working Group, research protocols and other materials that can support researchers, teacher educators, and teachers may be developed and used across a variety of research and professional development (including preservice teacher education) projects.

More specifically, for PME 2011 we will proceed as follows.

SESSION 1:

- Review and discussion of goals of Working Group.
- Introduction of participants.
- Reports of the work of sub-groups during 2010-2011
- Initial brief meeting of sub-groups

SESSION 2:

- Sub-group meetings to discuss and delineate further plans to address and expand research questions initially developed at PME 2009, and refined at PME 2010.

SESSION 3:

- Sharing and discussion of work from Session 2.
- Planning for further collaboration.
- Developing a tentative agenda for future Working Group meetings.

Previous Work of the Group and Anticipated Follow-up Activities

The Working Group met for three productive sessions at both PME 2009 and PME 2010. In 2009, we identified areas of interest to the participants within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. In 2010, sub-groups were reorganized to streamline the work, as it became apparent during 2009-20 10 that participants could not participate in more than one subgroup during the year. During 2010, participants met in an identified sub-group of their choice. Within these sub-groups, rich conversations ensued regarding theoretical and practical considerations of the topics. Plans and goals for the 2010-2011 academic year were developed. What follows are the plans and goals of the sub-groups following the 2010 PME meeting. The activities stated in these plans are currently in progress.

Pre-service Teacher Education that Frames Mathematics Education as a Social and Political Activity

This sub-group is interested in teacher education that frames mathematics as a social and political activity, including multicultural education, teaching math for social justice, funds of knowledge, ethnomathematics, issues of equity and diversity in mathematics, and so forth. Our goal is to share resources to improve our own work as teacher educators and to support each other in our research. Our long term goals include developing an annotated list of articles, developing an annotated collection of resources (lessons, activities, syllabi, etc.), writing a paper about our differing meanings and approaches to teacher education that frames mathematics as a social and political activity, and conducting research about doing this work across contexts.

This sub-group acknowledges tensions in our work focusing on equity and social justice in relationship to reform mathematics. Frameworks are needed to understand these issues. These can build on work in culturally relevant pedagogy (Ladson-Billings, 1995), teaching for social justice (Gutstein, 2003), funds-of-knowledge (González et al., 2001) as well as more general issues of equity, diversity, social analysis, and critical pedagogy. We need to begin by defining what we mean by these terms (e.g. reform mathematics, social activity, political activity); and how we recognize them in the classroom.

Goal for 2010-2011. Each month (or so) one person will be responsible for engaging this sub-group in some fashion that that person will determine, and then recruiting someone to take over for the next month. This could be as simple as uploading a few materials and letting people know about them or it could involve asking others to read and respond to an article, task, and so forth.

Culturally Relevant and Responsive Mathematics Education (CRRME)

The title reflects our view that mathematics education needs to be both culturally responsive and culturally relevant and a primary goal of this group is develop a comprehensive collection of the scholarship we draw on to define these terms. We are interested in language, discourse, ethnicity, ways of interacting, family, community, experiences, generational issues, expectations (not high and low, but individual or community's expectations). We want to examine what we mean by social justice. Issues can be examined, such as teaching (a) about social justice (the context), (b) with social justice (status and participation), and (c) for social justice (power and question). Various aspects of CRRME include (a) local contexts, (b) local associations, (c) using cultural referents, (d) ethnomathematics, (e) critical pedagogy, and (f) teaching "classical" math. We are concerned as well with how literature on culturally relevant pedagogy is grounded in existing theory and research on culture and social constructivism.

Goal for 2010-2011. Two key goals of this group are to (a) develop a comprehensive collection of the scholarship we draw on, and (b) develop a collective definition of what Culturally Relevant and Responsive Mathematics Education means. The second goal requires an examination of what social scientists say about culture and how we view the relationship of culture to research in mathematics education.

Creating Observation Protocols around Instructional Practices

This group is developing a protocol that can measure instructional practice AND be a tool to help teachers improve their instructional practice. Our focus is on the importance of improving instruction for students of color; this is our goal. We recognize that protocols have limits. For example, protocols do not necessarily look at microgenesis, teacher change, structural issues, dispositions. At the past PME-NA we reviewed various protocols to examine discuss existing protocols posted on google groups to stimulate rich discussions around questions such as: What do we like? What are they missing? How might we revise, combine, and extend them? Since group members were using various measures and it was not viable to have everyone use the same one, we began to develop a dimension that could be added on to the different protocols. To focus the work we decided to develop a dimension on expanding notions of competence in the classroom.

Goal for 2010-2011. The observation protocol group has two goals for the year. First, we plan to develop the dimension on expanding notions of competence in the classroom. Second, we want to begin field testing this dimension and compare results across various school sites including variation in terms of geography, class, race etc. Our longer-term goal is to develop multiple dimensions that are theoretical grounded in order to produce an observation tool that does not ignore issues of race, class, and so forth. We also hope to develop a paper or report focused on the validity, reliability, and utility of this tool.

Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms

This sub-group is interested in examining language diversity in the mathematics classroom. They think about this broadly and want to be inclusive of the perspectives of teachers, students, and parents.

Goal for 2010-2011. The language and discourse group has identified two tasks for 2010-11. One is to identify vignettes embedded in academic articles or book chapters on (a) teachers' experiences with language during mathematics instruction, (b) involvement of parents who are native speakers of a language other than English, and (c) experiences of students who are native speakers of a language other than English or are bilingual speakers of English and another language. We will explore the possibility of categorizing these vignettes in such categories as (a) social benefits of bilingualism, (b) cognitive benefits of bilingualism, (c) language ideologies, and (d) policy initiatives. The second task is to network in order to identify others (teachers, researchers, students) who would be willing to write-up their experiences/journeys as they relate to the use of language in mathematics activities in and outside of the classroom.

A Critical Examination of Student Experiences

This sub-group is interested in examining the intersectionality of students' experiences as learners of mathematics and in mathematics classrooms. This involves considering students' mathematics identity in relationship to one or more of their racial, social, cultural, and gender identities. This also includes understanding how structural inequalities shape students' mathematics experience, particularly students from non-dominant groups.

*Goal for 2010-2011.*The primary goal of the student experiences group for this year is to develop our capacity for collaboration. First, we will reach out to researchers in mathematics education interested in issues at the intersection of student identity/identities and mathematics learning experiences and establish a network to facilitate the sharing of our empirical work, data collection and analysis resources (e.g., interview and observation protocols), and theoretical resources. Based on the connections that develop, we will then consider potential joint products for next year—e.g., literature review, conference symposia, edited volume.

DEVELOPING INVESTIGATIONS OF LIVED AND LIVING MATHEMATICAL EXPERIENCES: THE DIME WORKING GROUP

Larry L. Hatfield
University of Wyoming
lhatfiel@uwyo.edu

Michelle T. Chamberlin
University of Wyoming
mchambe5@uwyo.edu

The "Developing Investigations of Mathematical Experience" (DIME) working group is focused on building a research-based understanding of the interiorized experiential world of idiosyncratic mathematics. Goals of this research are to characterize individual experiences in ways that acknowledge a person's active and reflective thinking efforts within mathematical contexts linked to emotive dimensions of their lived and living mathematical experiences, in order to inform mathematics teaching practices. To probe these largely unexplored complex domains, we are using both and phenomenological and constructivist theories and methods. We seek to identify and relate expressed indicators of intended and actual mathematical experiences, as they appear to occur in the complex relationships of participants involved in mathematics teaching and learning. Because today's goals and strategies for a sound mathematical education embody a major emphasis upon stimulating, nurturing, and demonstrating high quality thinking arising from particular kinds of intended experiences, we must now seek to understand more clearly the nature of what students and teachers are actually experiencing in their "math lives." These working group sessions will build upon the DIME Research Team meetings conducted during the initial planning conference of the Wyoming Institute for the Study and Development of Mathematics Education (WISDOM^e) held September 2010 at UW. The primary goal of the PME-NA Working Group will be to involve additional interested scholars in the ongoing work of the team, through further conceptual analyses related to the phenomena of lived and living mathematical experiences, to extend our epistemological and psychological perspectives for characterizing critical elements, and to identify and address methodological issues inherent in investigating interiorized mathematical experiential phenomena.

Brief History of the Group

A core membership for this new PME-NA Working Group was established through the initial invitational "Planning Conference for WISDOM^e" conducted September 8-10, 2010 at the University of Wyoming. The background context for that conference is the establishment of three collaborative, interdisciplinary Research Teams connected to four new Ph.D. program research identities: quantitative reasoning, mathematical modeling, technology tools and applications, and lived/living mathematical experience. Each of the teams consists of UW mathematics education, mathematics, and educational cognate faculty, mathematics education doctoral students, and four-to-five young, active Mathematics Education researchers from a variety of national and international universities. Following four invited plenary papers prepared and presented at the conference by key active senior researchers, each team met to frame an initial program of collaborative work. The DIME (Developing Investigations of Mathematical Experience) Team currently includes six UW faculty members, six UW Mathematics Education Ph.D. students, and five faculty members from as many other universities.

Through the opportunity to conduct Working Group sessions at PME-NA, we seek an important venue to continue and expand discussions of the background perspectives and issues related to investigations of lived and living mathematical experience, to share information, issues, and problems related to ongoing research, to promote interest and potential participation in furthering these and other disciplined inquiries into these phenomena, and to provide continuing support to the team members to collaborate within and across ongoing and future research.

Perspectives on *Lived and Living Mathematical Experience*

Today, there is surely an implicit and implied emphasis globally upon high quality mathematical experiences within the goals and expectations for a sound mathematical education. Yet, within our literatures and advocacies for curriculum, for teaching, for learning and development, and for research knowledge there seems to be very little explicit attention to the phenomenal data of an individual's lived/living mathematical experiences. This may be partially explained by the nature of what most mathematicians and mathematics educators seem to focus upon within mathematically productive activity: cognition, thinking, sense making, reasoning, solving, explaining, etc. Research to build models of such focal emphases should surely be a fundamental cornerstone of mathematical education research. But, to further our knowledge of actual lived/living mathematical experience set against such mathematically productive activity frames an important goal DIME research efforts.

Some fundamental questions that we are seeking to investigate include the following:

- What is the nature of lived and living mathematical experiences?
- What are the particular qualities (essences) of human experience that make it a "mathematical experience?"
- Are these experiential qualities that are unique to mathematics, or are they also found more broadly in other human experiences?
- How do identifiable qualities of lived/living mathematical experiences relate to learning mathematics and to psychological models to describe mathematical thinking and feeling?
- In what ways do lived/living mathematical experiences vary or differ among humans, and why?
- What factors related to the individual or the experiential context might frame or affect the actual phenomenon of a high quality "living mathematical experience?"
- In what ways do the experiences of individuals vary within mathematical contexts, such as classroom situations that are intended to engender the "same" kinds of experiences for all participants?
- How do lived mathematical experiences accumulate within differing individuals, and with what more general intellective and emotive consequences?
- In what ways do thinking and feeling aspects of mathematical experience interact within a living experiential context, and with what kinds of impacts or outcomes?
- In what ways might a mathematics educator use what can be learned about lived/living mathematical experiences of students, parents, teacher educators, mathematicians, or others in society to improve educational practices?

These are some of the questions that serve as "starting points" for DIME research. In addition, we are confronting many research methodological questions that are challenging much of our initial struggles to conceptualize viable approaches to such phenomena.

If we want educational outcomes that mirror the empowerment that a deep knowledge and proficiency of mathematics can afford, we must now seek to move beyond our current perspectives and approaches that still seem to produce (for too many of our students) much less than we seek. If we are to understand deeply why so many of our students still achieve very poor understandings of the mathematical ideas and processes after experience with our reformed curricula and our improved teaching methods, materials, and tools, we must begin to penetrate beyond more superficial indicators, such as test scores or written work, or even observed classroom behaviors into the interior world of the student's actual lived/living mathematical experiences where we may be able to identify deeper explanatory aspects of the individual's progressive growth (or deficits) toward greater mathematical knowledge and proficiency.

There is one other rationale that seems increasingly important. Too many of our citizens bear negative feelings toward their own past mathematical education (Hersch & John-Steiner, 2011), but for us educators to help our current students avoid such debilitating beliefs, feelings and attitudes we must begin to understand the nature of their experienced emotions that occur and develop within the mathematical contexts we offer. That is, not only must we understand the intellective dimensions of a person's constructions and reconstructions of their mathematical knowledge and proficiency, but we must also understand the origins and dynamics of emotional dimensions of their experiences, and how the interplay of thinking and reasoning actually functions within their live experiential feelings, emotions and affective schemas in relation to engaged, productive mathematical thinking. It is time to seek to understand the "whole mathematical life" of our students.

The goal of such new understandings is the assumed potential that from such knowledge we mathematics educators will all be helped to engage in improved forms of mathematical education in which enhanced qualities of lived/living mathematical experiences occur for all persons. We seek a pedagogy that understands and honors the experiences of the other (surely a primary intention of humanist philosophy and constructivist epistemology).

Further perspectives on mathematical experience can be found in the limited literature on this subject. One of the notable senior scholars of mathematics education, Hans Freudenthal (1983) claimed an early phenomenological perspective. In his review of Freudenthal's book, Usiskin (1985) identified a general view of mathematics as an abstraction of reality, where mathematical ideas come from commonalities inherent in a wide variety of situations. Through his "didactical phenomenology," Freudenthal sought to return the mathematically minded to the world from which it was abstracted. In greatly detailed ways that form an analytical compendium of most school mathematics concepts, Freudenthal discussed analytical connections between an idealized conceptual world and the complex world, which relates to it. It is these connections, Usiskin explained, that form Freudenthal's personal "phenomenology" of the mathematical structure, and it is the implications for the instruction of students that forms his "didactical phenomenology."

Brown (1996) described the mathematics classroom from the perspective of social phenomenology where it is seen as an environment of signs, comprising things and people, which impinge on the reality of the child. His framework sees mathematical ideas as contained and shaped by the child's personal phenomenology, which evolves through time. He introduces the notion of "personal space" as a model for describing how children proceed through a classroom environment of phenomenal experiences toward their idiosyncratic "sense making." The report provides interesting data from children solving symmetry tasks, and demonstrates how Brown uses his framework to interpret the child's functioning in experiential terms.

Roth (2001) critically questioned some of these views and approaches in his review of Brown's (1997) book, an extensive attempt to relate many important aspects of mathematics learning and teacher education to phenomenology, hermeneutics, post-structuralism, and semiotics. In particular, Roth's central concern is whether all mathematical activity and experience can be reduced to text, based upon Brown's unequivocal assertion that "There is no experience outside the text" (p. 226).

One interesting study, reported by Francisco (2005), involved the elicited reflections of five high school students in their 12th year of a longitudinal study in which their school mathematics from grade one had been developed in ways claimed to be consistent with a constructivist approach (called "Rutgers Math"). Maher (1987) had described these learning conditions to include: collaborating in work, exploring patterns, conjecturing, testing their own hypotheses, reflecting on extensions and applications of the concepts, and explaining and justifying their reasoning. Steffero's (2010) study of one female student's beliefs and mathematical activities that occurred over a seventeen-year period in "Rutgers Math" and beyond constitutes an enormous record of her mathematical experiences from grade four through graduate school. Handa (2006, 2011) examined ways of knowing and doing mathematics using phenomenological reflections to construct views of experiential relationships with the subject matter of mathematics.

Perhaps there are good reasons why so little explicit focal attention is given to "mathematical experience." Thompson (1991) observed that while the authors of papers in an ICME conference are concerned with the epistemological foundations of mathematical experience, they offer no information about "what is a mathematical experience." Indeed, in DIME we fully acknowledge a serious lack of clarity of constructs in this domain, but through systematic efforts to study lived/living mathematical experience, we will seek to build new, grounded clarities of meanings.

It is the goal of the DIME research program to begin to study intentionally the phenomena of lived/living mathematical experiences. Why bother? Are not the traditional views emphasized in intended curriculum, instruction, learning, assessment, evaluation, and research on learning and teaching adequate? Indeed, it is exactly because the goals and strategies of a sound mathematical education today embody a major emphasis upon stimulating, nurturing, and demonstrating high quality thinking arising from particular kinds of intended experiences that we must now seek to understand more clearly the nature of what students and teachers are actually experiencing in the "flow of their math lives" (Csikszentmihalyi, 1990).

Issues in a Psychology of Mathematical Experience

We each know the centrality of our own lived experiences. Even modest personal reflection can lead an individual to a sense of realization that it is specific experiences that shape "who they are, what we know, how we think" in powerful and fundamental ways. This includes what is experienced "outside," in the so-called "real world" that involves our interactions within our proximal environment (our sensory-based physical experiences) and within our interactions and relationships with other minds (our socially-based logical and emotional experiences). But, this also includes interior experiences that occur in our mind within our "interiorized" constructed world, where our thinking and our feeling "being" (person) is shaped and functions in thought (mind).

In DIME, we acknowledge the significance of the typical "mathematical" environment that includes students, teachers, parents, discourse, textbooks, technology tools, classrooms in schools, tasks and tests, the structured contexts of lessons, local, state and national curriculum frameworks, professional preparation and development, mathematicians, societies and cultures, governance, politics---all of the usual cultural and social elements in and around a person's mathematical education today. In doing so, we also accept that the meaning structures for any or all of these elements is a totally idiosyncratic construction for any of the multitudes of persons attending to matters of mathematical education. Now, we seek to "look into" the interior phenomenal world of lived experiences where each individual dynamically encounters and processes their idiosyncratic "mathematical experiences that lead to "who they are and become," mathematically. As educators, perhaps a most important aspect of this involves the dynamics of lived/living experiences that might characterize how experience might possibly bring about change (transformations) in an individual's thought and feeling with respect to mathematics.

Phenomenology begins in the lived world, and seeks to bring to reflective awareness the nature of the events of lived experience (Hegel, 1977; Husserl, 1970, 1982). The principle of intentionality acknowledges an inseparable connection to the world (in our focus, the world of mathematical education) wherein "…we question the world's very secrets and intimacies which are constitutive of the world, and which bring the world as world into being for us and in us" (van Manen, 1990, p. 5). In DIME, we are choosing to study thematic meanings, adopting themes and conducting thematic analyses within our particular orientation to the phenomenon of mathematical experience as "people of mathematics:" all being teachers, teacher educators, students of learning and teaching, mathematically educated, and interested is pedagogic theories. We are trying to be explicit about our individual and shared intentions and orientations as a preparatory anchoring step in our research process.

As such, phenomenology accepts the curriculum of being and becoming (paideia), pursuing understanding of the personal, the individual, set against the background of an understanding of the other, the whole, the communal, or the social. It seeks to explicate phenomena as they present themselves to consciousness---the only access humans have to the world. But, consciousness cannot be described directly (the fallacy of idealism); the world cannot be described directly either (the fallacy of realism); real things in the world are only meaningfully constituted by conscious human beings, and these constructed meanings can only be revealed by the constructing human as inferences.

In our formative research approaches we presume the nature of lived/living experience to be fundamentally an internal construction/re-construction that emphasizes a consciousness of "sense-making," attempted within the unique idiosyncratic mental operations, schemas and constructive mechanisms as they exist and function in the mind of the individual within that lived/living experience. To emphasize Piaget's (Piaget & Inhelder, 1969) theoretical conclusions that both intellective and affective aspects are involved within experience leading to development, we seek to study both as a seamless whole, even as we reject many other dichotomies as false (such as "thinking versus feeling") typical of a strictly modernist structuralism.

Among the constructivist focal constructs we want to consider in our study of lived/living mathematical experience are representation and re-presentation, reflection and reflective analysis and abstraction, intuition and intuitive reasoning, and perturbation and equilibration, and particularly to search for where and how they may be found to function in, impact upon, and in turn be affected by particular experiential contexts. For example, in today's curricular frameworks one sees a major attention given to "representations" and representational activities; students are expected to learn to understand, use, and make various canonical mathematical representations. Yet, what from a study of lived/living mathematical experiences can we find about a student's actual conceptions and views of representations, and especially how they experientially use such images in problem contexts to re-present the conceptual ideas they are presumed to represent? Moreover, von Glasersfeld's (1991) view of cognitive functioning sees representation, re-presentation, and reflective abstraction as inseparable aspects; can we find this exhibited in lived/living mathematical experience?

Against these theoretical lenses, we have identified a variety of issues to confront as we attempt to study lived/living mathematical experiences. Some of these are identified below, and these will be addressed in the activities of the Working Group described next.

1. In what ways is it possible to study the lived/living mathematical experiences of anyone: one self? The "other?" We have found helpful literature that addresses important theoretical perspectives and methodological strategies for this question [e.g., Dewey, 1938; Hegel, 1977; Hurlburt & Akhter, 2006; McLeod, 1964; Moustakas (1994); Petitmengin, (2006); van Manen (1990)]. We have identified these guiding principles:

A. A research methodology for studying lived/living experience includes the theoretical precepts behind the methods---the values and assumptions of phenomenology and constructivism as briefly discussed above. Within a focus on actual experience, we are willing to yield upon procedures or techniques that certain methods, even in qualitative research, attempt to objectify or make more standardized.

B. Our overall framework is adapted from van Manen's (1990) structure "…seen as a dynamic interplay among six research activities:

(1) Turning to a phenomenon which seriously interests us and commits us to the world;
(2) Investigating experience as we live it rather than as we conceptualize it;
(3) Reflecting on the essential themes that characterize the phenomenon;
(4) Describing the phenomenon through the art of writing and rewriting;
(5) Maintaining a strong and oriented pedagogical relation to the phenomenon;
(6) Balancing the research context by considering parts and whole." (p. 30-31)

C. Some views of phenomenology aim at being "presuppositionless," warding off a tendency to construct or enact a predetermined set of fixed procedures or techniques that would rule-govern the research. We will engage our observations and analysis with general acceptance of this view, while also making efforts to stipulate and articulate, a priori, as many of our individual values, assumptions, beliefs, and attitudes about the phenomenon of "mathematical experience as we can and seems relevant. One view (van Manen) ---*our problem is not that we know too little about it, but that we know too much!* (p.46). As such, we are predisposed to interpret the nature of the phenomenon before we have even come to grips with the phenomenological questions.

D. In those research contexts where our aim will be to stimulate new experiences within real-time, unfolding events, we adopt the dynamics of constructivist orientations but set aside "teaching or learning" aims, per se (e.g., where questions from the researcher-teacher would seek to provoke particular kinds of mathematical thinking or productions). Rather, within an initial problematic situation posed to provoke or engender lived mathematical experiences, we honor the paths as determined and taken by the person.

E. We seek to address the phenomenon of mathematical experience in a variety of ways. In doing so, we will seek attentively to orient to the phenomenon as we strive to deepen our formulation of the phenomenological questions.

F. We are building a team approach with a purposeful aim of including a variety of perspectives and voices, and this brings opportunities beyond research conducted by one, or even two collaborating scholars. As such, we have adopted views and tactics to mirror what we perceive as formative, developmental research, and to be alert to elements of our inquiry that includes aspects of team building, per se.

2. Whose experiences should be studied, and why? Who are to be the subjects of the research? How are they chosen? Because mathematics as a human endeavor in society and globally is so pervasive and seemingly universal, we foresee a full range of research participants who experience mathematics in a wide array of situations and for a diverse set of reasons. Of course, one orientation we bring to this is the "enterprise" of mathematical education, and this will greatly influence our choices for whose experiences we will try to investigate, and also determine how we frame the contexts and the templates of analysis and interpretation. We want to include at least these in our sampling of lived/living mathematical experiences---ourselves, mathematicians, mathematics teacher educators, mathematics education researchers, pre-service and in-service mathematics teachers across levels of school mathematics, mathematics students across levels of school mathematics, and parents of the students. Different types of participants will allow us to address a variety of aims; specific individuals will be chosen in terms of particular aims and purposes.

3. What are sources or forms of "data of lived/living experience?" How can these be generated in ways that yield penetration into phenomena? Be seen to be accurate (true to the phenomena)? Valid? Reliable? Viable (Steffe, 2010)? We accept the following views about the nature of "data of lived/living experience." The world of lived/living mathematical experience is for us both the source and the object of our research. We each bring strong (yet varying) orientations to it. But, we share a fundamental assumption: *experiential accounts are never identical to lived/living experience itself.*

We already see that the sources and forms of our "data of lived experience can be rich and varied. Yet, we will pursue in each the step of generating written descriptions, and these may be of two kinds: (a) an immediate description of the "*life-world as lived*," or (b) an intermediate (or a mediated) description of the "*life-world as expressed in symbolic form*." While we accept that in this step there occurs interpretation, among team members we will share in an analysis of the description as produced, and engage in intentional interpretation (hermeneutic) to produce a "second-generation description" that purposefully seeks to identify and describe "essences as deeper meanings of the lived mathematical experience."

Subsequently, through team interactions, we will question the accuracy of these descriptions and interpretations to assess if they seem "true to the phenomena" (as such, are they valid?). We will try to address some sense of reliability, at least in terms of a quality of internal consistency among individuals in the team. To deepen or extend the possible derived meanings arising from group work, we will try to view the expressed perspectives of individuals in the team compared to their initial written description of "a priori conceptions about mathematical experience noted earlier [a way of possibly using "bracketed" aspects to clarify meanings]. Husserl (1970) acknowledged that "common sense" pre-understandings, suppositions, assumptions, and existing bodies of knowledge can lead one to premature influences in one's effort to interpret, to "make sense." How can we best suspend such influences? Husserl (who was at first a mathematician) used the notion of "bracketing" to describe how one must try to place outside of the present phenomenon one's prior or extant or presumed knowledge about the phenomenon.

4. In what ways can research subjects be directly engaged in experiential mathematical situations while informing the researcher about what they are experiencing? It is one of the basic assumptions of phenomenology that experience will be changed within an attempt to introspect---to "rise above" and give attention to the experience while it is occurring, and that the distinctions between what is introspection and retrospection are blurred (thus our use of "lived/living"). While we accept this assumption in theory, we also want to explore this phenomenon. Petitmengin (2006) used an interview method aimed at helping a person to become aware of her subjective experience and to describe it with great precision. Hurlburt and Akhter (2006) used a “descriptive experience sampling” method to explore inner experience. Their subjects were prompted by an electronic beeper which they carried as they moved in their natural environments. When the beep sounded, they were trained to “capture their inner experience and jot notes about it; they discussed it during a later expositional interview.

As researcher-observers interactively engaged in mathematical situations we’ve posed for the purposes of engendering active involvement by, say, a student, we intend *to become a part of the student’s experiences*, per se---to get into “the flow” of what the student is experiencing (Csikszentmihalyi, 1990). “Being there” can mean (to the student) that, as a part of their unfolding experience, we ask questions. While these questions will primarily focus upon their activity and their “thinking aloud” verbalizations related to it, at times we will ask a question pointing more directly to their conscious reflection upon their experiences, per se. In some sense, we anticipate that such a question can result in a kind of interruption of the flow of experiences related to the posed mathematical situation; we intend to ask the student later about the effects of such questions upon their perceptions of the flow of their experience. We anticipate there will be variable impacts reported by different persons, but we also expect that across time and successive observational interviews, individuals will develop a greater capacity for minimizing (or perception of) the disruptive effects of such questions.

5. When or how might a research intervention or analysis or interpretation influence or alter or “contaminate” an experiential context under study? How can this be avoided? This concern admits that there may be ways in which our research methods could negatively impact upon what is being experienced, both in immediate or longer-term ways. Indeed, one characterization of instruction are the intentional impacts that alter otherwise natural experiences of students. As such, these would not be avoided.

Here is one nexus of conflict within the aims and processes of phenomenological research and mathematics education. We accept this tension, and seek to probe and penetrate into the lived mathematical experiences while realizing the potential invasive violations we may induce into what “the other” is experiencing. We believe our resolution of this conflict resides in the distinctions to be found in “natural, every-day” experiences and “intended” experiences of mathematics education, though we realize that as effective teachers we strive for there to be a quality of “natural” in what and how a student might experience and build-up their mathematical knowledge. Here again, as explorers we will remain open, yet exercise surveillance to this concern.

6. How do we, as researchers, conduct analysis and interpretation of data to build accurate portrayals of lived/living mathematical experience? Key to phenomenological or constructivist research is analysis and interpretation as an observer, or teacher-researcher. Critical to either are the struggles to maintain, as much as possible, open thinking in which one consciously acknowledges potential biases and avoids “projecting” one’s own experiences onto the situation. Intentional “bracketing” is attempted; members of our team are trying to describe, *a priori* to individual or shared acts of analysis and interpretation, our individual perspectives on what we each may “see” in the phenomena of lived mathematical experience---we will refer to these as our “initial construct views” (ICV). We will share these written ICV descriptions, and try to use these when we are subsequently engaged in analyses and interpretations of our observations and descriptions. We are unsure about exactly how we will use these, but one could be when we disagree about what we “see” in a particular protocol or description; we may be able to find reasons for a researcher's interpretations in the anchoring viewpoints they expressed in their ICV.

We believe that through a team approach in which multiple descriptions can be generated independently and then discussed and debated, we will likely achieve more sensitively accurate interpretations of the phenomena---"negotiated meanings." Across experiential episodes we will look for consistencies as well as variation, thus being attuned to elements of cross-validation of the qualities to be found in a person's lived mathematical experiences. Also, in these we will look for how the nature of experiences for each subject may change; again, as educators we seek and expect change--growth and development as a consequence of something we call "mathematical experience."

In our studies, we will focus not only on indicators of change in relation to mathematical knowledge, but also on the emotional elements within experience and how these occur within the dynamics of various qualities of lived experience. Further, we will be alert to how the person's capacities to reflectively abstract in relation to their lived experiences might change, and what impacts that may have upon their future awareness of themselves within, and after, lived mathematical experiences. In some studies, we will explore how the subject might be given our description of their experiences, and asked to provide critical review, reaction and feedback about it; this may lead to new insights into the "essences" of it, and result in another form of "negotiated meanings."

7. In what ways can we "make sense of" our study of the observed lived/living mathematical experience in relation to its implications and potential applications? This question speaks to the important intent that our research results lead beyond information about the interior "mathematical life," although such research-based information is generally lacking today. Our goals include the possible implications for such new insights and understandings about lived mathematical experience to impact upon future mathematical experiences. We foresee possible benefits to the ways that mathematics teachers seek to stimulate and engage their students to engender certain qualities of experiences they might have. Information about what is occurring in the lived mathematical experiences of students may prompt changes in curricular topics, placements, or treatments. Deeper understandings from studies of experience may raise implications for testing and assessment strategies related to mathematics learning.

Specific Plans for DIME Sessions at PME-NA 2011

Overall, the sessions will be conducted in "workshop" format, structured by an overview presentation (20 minutes) followed by four brief (10-12 minutes each) plenary "highlighting" presentations to pose research issues and problems, guiding written resources distributed to all participants, "breakout" sessions for four working sub-groups, guided sub-group task-oriented discussions, and closing plenary summarizing presentations and discussions. Feedback and input from all discussions will be collected; post-conference written summaries for each sub-group will be prepared at UW and distributed to all WG participants, and posted to the public Institute website.

The four sub-groups will focus upon one of the following domains of discussion (while respecting that these are not a partitioning, so overlaps and interactions among the issues and questions of the focal domains will likely occur):

A. Framing 'problems and questions' for research on lived/living mathematical experience---what to study?

B. Addressing 'issues and concerns' for research methodologies to be used---how it is to be studied?
C. Discussing techniques for using and transforming data to describe, analyze, and interpret in ways that illuminate and inform---how is data to be evidentially used?
D. Discussing approaches to reporting what is found and to applying to inform improved educational practices---how results are to be reported and used?

Discussion document for the Working Group "Representations of Mathematics Teaching"

(a) Brief History of the Working Group

This is the second meeting at PMENA of this RMT working group. The idea of this working group emerged during a series of three-day conferences on representations of mathematics teaching held in Ann Arbor, Michigan in 2009 and 2010,(and earlier workshops in 2007 and 2008) organized by ThEMaT (Thought Experiments in Mathematics Teaching), an NSF-funded research and development project directed by Herbst and Chazan. ThEMaT originally created animated representations of teaching using cartoon characters to be used for research, specifically to prompt experienced teachers to relay the rationality they draw upon to justify or indict actions in teaching. The original workshops were conceived to begin disseminating those animations to be used in teacher development . The (Representations of Mathematics Teaching) RMT conferences in 2009 and 2010 gathered developers and users of all kinds of representations of teaching to present their work and discuss issues that might be common to them. These conferences included users of video, written cases, dialogues, photographs, comic strips, and animations. An outcome of the 2009 RMT conference was a special issue (Volume 43, issue 1, 2011) of the journal *ZDM—The International Journal of Mathematics Education,* guest edited by Herbst and Chazan Outcomes of the 2010 Conference included two sessions at the 2011 NCTM Research Presession. The 2011 Conference (June 13-15) will also work toward the goal of creating events related to the use of representations of mathematics teaching in other conferences. In proposing a continuation of the working group for PMENA 2011 we are interested in continuing the discussion and work we had in Columbus during PMENA 2010 around the elaboration and investigation of a pedagogical framework for teacher development that makes use of representations of teaching and work toward an edited book on the subject.

(b) Issues in the Psychology of Mathematics Education that Will Be the Focus of the Work

Review of Existing Work Relating the Theme of the Working Group to the Field

The use of representations of mathematics teaching, particularly those that are maintained in a digital form, calls for specialized pedagogical practices from teacher developers. They also open new areas for investigation of how future professionals learn to practice and the role that various technologies play in scaffolding that learning. In the 2010 PMENA discussion paper, Herbst, Bieda, Chazan, and Gonz‡lez (2010) briefly reviewed the literature on the use of video records and written cases in teacher education. We also noted that classroom scenarios sketched as cartoon animations have begun to be utilized for those purposes and argued that they have affordances that are distinct from those of video and written cases (see also Herbst, Chazan, Chen, Chieu, & Weiss, 2011) . We also noted existing literature on the use of written and video cases in teacher education and cited examples that concern mostly face-to-face facilitation. We argued that the increased capabilities of information technologies for creating, manipulating, and collaborating over multimedia point to a promising future for teacher development assisted by representations of practice. In the special issue of ZDM referenced above , several new articles have added to this literature. In particular Ghousseini and Sleep (2011) and Nachlieli (2011) describe the facilitation of face -to-face discussions around representations of practice and provide two views on what makes these effective for studying practice. Yet the features of novel media and their use with digital technologies may require other pedagogical strategies for teacher education that have not been sufficiently identified and explored.

In this document we complement the previous year's review by briefly accounting for three areas of emergi ng scholarship: (1) information technologies that support teachers' learning from representations of practice; (2) the particular challenge of helping prospective teachers understand students' thinking; and (3) research and theory about what is important or possible to achieve in having prospective teachers look at or work with representations of teaching.

Information Technology and Teacher Education

The field of teacher education is becoming more adept at using technology in teacher education classes. Communication technology is connecting teacher education students, university faculty, and mentor teachers through shared access to classroom videos (Price & Chen, 2003; Whipp, 2003), as well as providing another (sometimes more effective) mode of communication between teacher education students and university faculty (Derry, Seigel & Stampen, 2002; Reasons, Valadares & Slavkin, 2005). Teacher education is also leveraging communication technology to support the development of teacher communities (Farooq et al, 2007; Gomez et al, 2008). These communities increase teacher candidates' access to resources and interaction with peers.

Digital video technology allows for prospective teachers to interact with practice in more meaningful ways than in the past. In addition to watching videos, teacher education students can now annotate and edit video quickly and easily (Chieu, Herbst, & Weiss, 2011; Pea, Mills, Rosen & Dauber, 2004; Rich & Hannafin, 2008, 2009). These technologies allow for faster communication as well as discussions that focus on specific moments of an instructional episode and therefore on the particulars of teaching practice. Video and animations have also been used effectively to illustrate to prospective teachers how the theoretical principles that they learn in university courses can be put into practice in the classroom (Moreno & Ortegano-Layne, 2008).

The availability of new technologies to represent teaching for its use in teacher education offers an interesting challenge for research on the pedagogy of teacher preparation and teacher candidates' learning to teach: These issues are of importance to the PMENA community. Scholars have noted, for example, that in addition to the functionalities afforded by various technologies, it is paramount to consider the tasks that teacher candidates engage with, and the support that teacher education students receive from the course instructor (Lockhorst, Admiraal & Pilot, 2002). Other scholars have looked more in depth at technology-enabled instructional interventions and expanded upon features that could be situated into Lockhorst et al's list of important features. Chieu, et al. (2011) looked at the use of online forums containing embedded animations of classroom episodes and argued that this access allows for richer conversations among teacher candidates. Llinares & Valls (2009, 2010) focus on the tasks posed to teacher candidates and the effect of these tasks on learning These studies all highlight the role of pedagogy in the use of new technologies in teacher education. As technology develops, teacher educators need to continue to develop their pedagogies to make the best use of the technology.

The Challenge to Help Teacher Candidates Understand Students' Thinking

There continues to be a need for improving the connection between research on students' thinking and learning and the work of teacher development. What kind of cognitive research on students is useful for teaching and teacher education ? How might teachers come to learn it and use it? How can new media assist in this work? Researchers have addressed those questions by 1) using multimedia to show examples of actual student responses to research-based tasks (e.g. Franke et al., 1998); 2) drawing upon research to develop representations of student thinking (e.g. Balacheff, 1988); and 3) using such research to analyze pedagogical moves in classroom dialogues created by teacher candidates (Crespo, Oslund, & Park s, 2011).

Professional development connected to the research on Cognitively Guided Instruction (CGI) pioneered the use of records of student work to engage teachers with research on students' thinking (Carpenter, Fennema & Franke, 1996). By showing teachers video of students solving mathematical problems, as well as providing students' written responses for further analysis, the CGI project aimed to build upon teachers' existing knowledge of student thinking by systematizing and enriching this knowledge. The responses from participants of that program highlighted the value of having teachers analyze student work as a way to build knowledge that they could draw upon to make instructional decisions.

Beyond records of students' work, research on students' thinking has also been produced other representations of students' work, though less is known about the effects of their use in teacher education. Balacheff (1988) provides an early example, using a comic strip to represent responses provided by two students as they worked on the prompt: "provide a means of calculating the number of diagonals of a polygon when you know the number of vertices it has" (p. 220). This representation, included in a book for teachers, suggested a new way to acquaint teachers with student thinking in story form. Students' work has also been represented in narrative cases embedded within cases of teaching episodes (e.g. Stein et al., 2000). It is important to continue to look for ways of making students thinking accessible to teacher candidates and to find out what teacher candidates learn from these different representations of students thinking.

What is Possible to Achieve with Representations in Teacher Education

The combination of the use of representations of teaching and new technologies has facilitated the goals of teacher education in several areas. In particular, teacher educators have more diverse access to several types of representations of teaching (Grossman et al, 2009) and are able to use these in more flexible ways to support the learning of teaching "in, from, and for practice" (Lampert, 2010). Two important goals of teacher education are to increase teachers ' ability to notice aspects and events in the instructional environ ment (Rosaen et al, 2008; Sherin & Han, 2004; Sherin & van Es, 2009) and to afford teachers the skills and opportunities to reflect on their practice (Santagata & Angelici, 2010; Stockero, 2008). Two related goals are to enable teachers to learn from their own practice (Borko et al, 2011; Santagata & Guarino, 2011) and to alter or improve their teaching practices (Lampert et al, 2010; Polly & Hannafin, 2010, 2011; Van Zoest & Stockero, 2008).

A goal still ahead is to improve the connection between theories and conceptualizations of mathematics teaching and specifications of the curriculum of mathematics teacher education: Can we expect theories of teaching to determine the curriculum of teacher education? For example, in the context of the Teacher Education Initiative at the University of Michigan an innovative program for elementary teacher preparation has been emerging with a practice-centered curriculum. This curriculum prescribes teacher candidates' learning of specific practices of teaching that are deemed high leverage—these include "leading whole-class discussions of content" and "recognizing and identifying common patterns of student thinking in a content domain" (Curriculum Group, 2009). This curriculum gathers those practices in domains such as "assessing students" and "enacting instruction" (Curriculum Group, 2008). While it is possible to tie each of these practices and domains to the existing literature, it is not evident how one could argue that they constitute all the domains and practices that teacher candidates need to learn. A theory of practice would be useful to systematically generate all the domains and practices, to provide an underlying coherence to these domains and practices, and eventually to limit or at least modularize expansions of the curriculum.

An example of a theory of teaching that could provide such systematization is our theory of instructional exchanges in which we conceptualize the work of teaching as centered on the problem of exchanging students ' mathematical work for claims on their knowledge of the mathematics at stake within classroom environments that respond to four obligations (to the discipline, the individual students, the groups of students, and the school institution; see Herbst, 2010). But while this theory provides a conceptual basis for subject-specific descriptive models of the regulations of the work of teaching (with constructs such as situations, norms, and dispositions) it has no t yet operationalized the work of teaching in ways that support professional education or development. There is a pervasive need in the field to articulate prescriptive theories of teacher education with descriptive theories of teaching—the latter can give completeness and validity to the former while the former can operationalize the latter.

Toward a Pedagogy for Teacher Development Assisted by Representations of Practice

Building on the proposal from last year , the working group's purpose is somewhat ambitious: to design a pedagogy for teacher development that meets the goal of helping teacher candidates learn teaching in, from, and for practice by taking advantage of representations of practice and new technologies. This development includes conceptual developments, for example in articulating connections between descriptive theories of teaching and the prescription of a curriculum for teacher education. Our work will include asking questions such as, is it possible to further develop the descriptive norms (e.g. when a teacher expects students to do a proof she will provide them with 'givens' and the 'prove') into an operational specification of what a teacher candidate needs to learn to do, say, not only to be able to proficiently comply with such norms but also to negotiate tasks that depart from the norm? The working group will discuss the articulation between theories of teaching practice and practices of teacher education.

The convenors of this working group are also particularly interested in exploring how cartoon-based representations of practice facilitate teacher learning. Our thinking of how to make such representations usable for teacher education has been influenced by Lampert 's (2010) notion of learning teaching in, for, and from practice and by Grossman et al. (2009) account of professional education 's use of representations, decompositions, and approximations of practice. We surmise that cartoon-representations of teaching are sufficiently malleable to create not only representations of practice (that prospective professionals can view and annotate) but also to create decompositions of practice that prospective professionals can study from as well as approximations of practice in which prospective professionals can practice their skills. In this sense, cartoons can fashion virtual settings for teacher learning in, for, and from practice before the teacher candidates are ready to learn in real settings.

The LessonSketch environment (www.lessonsketch.org) is one example of a set of tools and resources that can exemplify what such a virtual setting for teacher development could be like. We are interested in having the RMT working group use LessonSketch to engage concretely in applying the elements of a pedagogical framework for teacher education assisted by representations. We expect that such work will help improve the framework and further develop specifications for technologies that respond to the needs of the field. With that purpose in mind, this document sketches current and envisioned features of LessonSketch as it lays out an updated version of a pedagogical framework for teacher education assisted by representations of teaching (building on last year's working group document; see Herbst et al.,2010).

This revised pedagogical framework considers the need for a larger library of representations of practice. While in the past we had only included representations of lessons in which teaching and learning mathematics were integrated in scenarios of classroom instruction, the notion of decomposition of practice proposed by Grossman et al. (2009) suggests the need for two more sets of representations. One of those sets of representations consists of representations of students' work: Depictions of how students solve problems, indexed in a database that permits searches by problems, operators, representation systems, and controls (Balacheff & Gaudin, 2010). The other new set of representations consists of representations of practices, strategies, tactics, and techniques in teaching, depicted through commented scenarios of instruction and also indexed in a database. We surmise that the cartoon medium can be useful for researchers on students' cognition in the PME-NA community to reach teachers with representations of how students think about specific conceptions; likewise the cartoon medium can be useful to support the learning of teaching skills by prospective teachers.

The remaining elements of the framework expand on what we offered last year, taking advantage of the materials we brought to the meetings of the working group and the feedback received from participants. Last year we proposed that a pedagogy of teacher preparation assisted by representations of practice needed at least four categories of elements: open ended expressions, activity types, problem types, and technology tools or screens.

The first element of the framework we call *open-ended expressions*. These are terms and expressions that can be used in transactions between teacher developers and their clients without needing to be completely defined; tokens that teacher developers and their clients may be able to take as shared so as to negotiate activities, problems, and representations. One such expression is "mathematical action" which we have observed being used in a geometry class for future teachers and in the context of having the students watch an animation of geometry instruction. Other open-ended expressions that can serve comparable purposes are "student thinking," "teaching move," "instructional goal," "resources," etc. We surmise that these boundary objects may be useful to mobilize the work with representations-- enabling explorations of practice that may lead to shaping more precise meanings.

A second element of the framework proposed in last year's document is a taxonomy of activity structures or activity types for mathematics teacher education—behavioral configurations that describe the formal division of labor between instructor and students. Some of these activity types could be the same as those found in K-12 classrooms, such as mini-lecture, homework review, etc. (see Lemke, 1990). But there are activity types that are particular to the work of mathematics teacher education assisted by representations of teaching. A quite common activity type could be described as “working on the math:” Quite often, mathematics teacher developers who intend to show a video that displays students working on a mathematical task will first have their clients work on the mathematics problem that will be featured in the video. Another activity type we have used in teacher education is a form of review of homework in which clients enact scripts of action that they conceive outside of class in response to practical problems of teaching such as how to explain a step in a procedure. Usually those enactments give some clients practice enacting teaching moves they had planned; other clients give feedback, and the event supports raising more general questions about the task of teaching being learned. In general different activity structures involve clients in interactions with (manipulate, annotate, etc.) the representations being used and for that reason they become quite important in the design of technological tools and interfaces. A partial list of activity types, which we brought to the meeting of the working group last year, is shown in Figure 1.

Annotating a representation with free written comments	Creating a mix or mash of existing representations
Discussing a representation with peers in class, chat, or forum	Searching for a representation that meets some conditions
Responding individually or in groups to a question about a representation	Scripting an event or lesson
Using a rubric to comment on a representation	Enacting scenarios or scripts of action publicly
Providing a verbal rejoinder to a representation	Rehearsing a practice, strategy, tactic, or technique given a script and a rubric
Viewing (or reading) a representation	Enacting scenarios or scripts in a chat room
Comparing two or more representations	Enacting a response to students at a specific moment
Introducing or framing a representation	Creating examples of actions that illustrate a practice, strategy, tactic, or technique given a rubric
Creating a new representation given an existing representation one (transcript, video)	Tagging a representation with elements of a rubric or coding scheme
	Adding to a representation events that might come before, after, or in between

Figure 1. Activity types

A third element of the framework consists of *problem types*. By this we mean specific intellectual work that participants do within an activity type involving representations—problem types specify the perspective or the goal with which clients confront a representation of practice. Different problem types may engage different kinds of thinking and doing on the part of clients and as a result different problem types might need to be chosen and articulated to promote different kinds of learning. A *noticing* problem might lead to developing the capacity to spot opportunities to probe student thinking, and a *norm ativity* problem might be used to engage the client in designing how to do so. Specific problem types are described in Figure 2.

What else could [the teacher/a student] do at this moment? (Alternativity)
What would you call that [teaching move/mathematical action/etc.]? (Generality)
What should be done (what should the teacher/student do) in these circumstances? (Normativity)
Which alternative is more appropriate? (Normativity)
How would you have felt (what would you have done) if those were your students? (Projectiveness)
What do you think about this episode? (Reflectiveness)
How would you interpret this episode/action?(Reflectiveness)
At what moment would you say [such thing] happened? (Temporality)
What do you predict came before/after/in between? (Probability)
Which alternative would be more typical/probable? (Usuality/Probability)
Which alternative is more desirable according to [some standards]? (Desirability)
What did you see students/teacher doing? (Noticing)

Figure 2. Problem types

The final element of this emerging framework addresses the technological affordances needed to realize this pedagogy of mathematics teacher education. Clearly one could do many of these activities having only a video projector and playing media off a single computer. But there are important pedagogical considerations associated with more technology-intensive environments. Chieu, et al. (2011) show evidence that clients' comments in forum or chat benefitted from having an embedded screen for the animation being discussed, which they could access at the same time as they interacted with peers in a forum or chat. This media-enabled-forum is one of several functionalities available in LessonSketch. We expect the working group will be able to explore these functionalities, and the potential combinations that could be made with them; we also expect the working group to have suggestions of new functionalities to add. Figure 3 includes the tools and resources that we considered in last year's meeting.

Show media	Enable the viewing and commenting of others' attached media
Show commented media	Enable the viewing and editing of others' attached media
Show media and enable comments	Show media and enable pinning moments
Pose an open ended question	Enable the attachment of media to answers to questions
Pose a multiple choice question	Show media and enable marking intervals
Enable exporting comments, pins or intervals to forums or documents	Request a decision between representation based alternatives which direct users to different paths
Enable the revision of answers	Request the sketching of a scenario with Depict
Request an entry in a forum	Enable the creation of a multimedia document
Request a diagram or picture	Request an entry in a discussion thread with embedded media
Invite to a chat room	Enable the attachment of media to forum posting
Offer a text to read	Respond to an individual user's comment or answer

Figure 3. Technology tools and functionalities

We envision that instructional actions in a pedagogy of teacher education will integrate the elements of those categories in experiences in which clients use technology tools to work on problems (that resemble one problem type) involving boundary objects and in the context of an activity type supported by a particular representation of practice. These experiences are geared to help them learn about or learn to do a particular practice of teaching.

(c) Plan for active engagement of participants in producti ve reflection on the issues

The plan includes starting with a brief exposition by the authors of the structure and contents of the present framework. We'll engage the audience in creating sketches on paper of sessions they'd like to engage their clients in. The idea is to use the collective planning of these sessions to enrich the framework by adding more items to the lists considered, and possibly also adding new categories of elements. The first meeting of the working group will involve a discussion of this document and the demonstration of the current framework. Participants will then form groups and spend the second half of the first session and the first half of the second session creating exemplars. Then the second half of the second session and the closing session will be dedicated to sharing these exemplars and improving the framework.

(d) Anticipated follow -up activities

By the time this working group meets we will have had the third conference on Representations of Mathematics Teaching in Ann Arbor (June 13-15, 2011). We will be proposing a session slot at the AMTE Annual Meeting in 2012 to continue this work. We plan to use that slot to mirror the work done at the PMENA meeting and to engage in further work on (1) improving the exemplars and (2) using the exemplars to improve the taxonomies. We hope we will be able to use those products to continue this working group at next year's PMENA.

Endnote

1. Some of the work of reported here has been done with the support of NSF grants ESI-0353285 and DRL- 0918425 to Patricio Herbst and Daniel Chazan. All opinions are those of the authors and do not necessarily represent the views of the Foundation.

The proposed working group will review some basic definitions on the features and affordances of Dynamic and Interactive Mathematics Learning Environments (DIMLE) and explorative learning. First, we suggest setting a stage to explore, identify, and conceptualize the features and affordances of DIMLE. Then, we aim to conceptualize explorative learning, dynamic learning, visual learning, and multiple-linked representations in the context of DIMLE. It is our goal to organize this discussion so that it will deepen our understanding of the explorative activities in learning mathematics and develop possible strategies for increased implementations of and our expectations from existing and prospective DIMLE. It is also our intention to establish a working group to continue exploring the topic after the conference and to contribute to the academic studies with a new publication.

Introduction

The innovations in technology have accelerated the evolution of mathematics education and mathematics itself, and this evolution is well-documented in the literature (e.g., Moreno-Armella, Hegedus, & Kaput, 2008). Not surprisingly, mathematicians, mathematics educators, and cognitive scientists have been interested in exploring, discussing, and improving their understanding and possible implementations of technology use in mathematics education at various national and international conferences such as ICME, ICMI, PME, and PME-NA (Arcavi, 1999; Duval, 1999; Galbraith, 2006; Hitt, 1999; Hoyles, 2008; Kaput, 1999). Moreover, some specific working groups, i.e., ICMI 17 Study Group and the Working Groups at PME-NA, have been established to take these discussions even further (Hoyles &Lagrange, 2010; Karadag & McDougall, 2009; Radakovic, Karadag, McDougall, & Stoilescu, 2010).

In addition to the growing interest in this topic in scholarly community, many well-argued articles and reports on the descriptions and needs of learning habits of N-Gen'ers (Attewell, 2001; Caron & Caronia, 2007; Freiman & Lirette-Pitre, 2009; Martinovic, Freiman, & Karadag, 2011; Ministry of Children and Youth Services, 2007; Newman, 2008) have motivated us to propose a working group for PME-NA201 1. The focus of this proposed working group will be on Dynamic and Interactive Mathematics Learning Environments (DIMLE), a term coined by Martinovic and Karadag (2010), and explorative learning, which are at the heart of technology use in mathematics education.

The following sections will briefly address the theoretical framework, which is also closely related to the literature that we plan to share with the audience at the conference, the rationale and the goals of the working group, the format of the proposed meeting, and a future proposal to publish an international book in the area of discussion.

Theoretical Framework

The contemporary technological tools provide DIMLE for learners to explore, learn, and model mathematics. These environments provide many intuitive affordances such as multiple-linked representations to engage learners in explorative learning. By explorative learning, we also mean experimentation, inductive reasoning, and visual learning. Of course, explorative learning in DIMLE may also include deductive learning with a proper guidance. The following themes are intended to spark the discussants' interest and initiate a collaborative effort to explore and discuss DIMLE and explorative learning more deeply.

Explorative Learning

A literature review searching for the definition and possible implementations of explorative learning usually results in either discovery learning or computer science applications (e.g., simulations) while some people use discovery learning and explorative learning interchangeably. For example, Njoo and de Jong (1993) argue that "exploratory or discovery learning" (p. 821) is based on free exploration in an open learning environment, where learners can interact with learning objects to uncover the relationships among them and to track the processes to create and/or employ them. Then, they claim that explorative learning triggers learners' inductive reasoning through exploration. Similarly, Bass (2011) puts exploration and experimentation together by claiming that: "we explore and experiment with the context" (p. 4). He, then, argues that "mathematics is not merely a descriptive science" (p. 5) because learners need to explore the concept or the process to be able to develop an insight for the mathematics behind them. For other scholars, this development of insight as a process and as an outcome is the abstraction itself (Gray & Tall, 2002; Hershkowitz, Schwarz, & Dreyfus, 2001).

Presently, we have enough evidence that the emergence of contemporary digital tools affects learning habits of 21st century youth and that this youth, also called N-Gen'ers, prefer explorative approaches to learn about the world around them. Therefore, the shift in the learning habits of youth motivates curriculum developers and policy makers to seek new approaches (Martinovic, Freiman, & Karadag, 2011; Ministry of Children and Youth Services, 2007; Newman, 2008). Kondratieva (2011) speculates on the results on these attempts by saying that: "Modern curriculum is moving from a formal approach towards more exploration based and inquiry-based study of mathematics." (p. 376)

Multiple-linked representations. Multiple-linked representations usually refer to different representations that are accessible through a computer and that are linked by the software (Kaput, 1992). For example, learners can easily access algebraic, graphical, and numeric representations in GeoGebra (see Figure 1) and similar DIMLE, and navigate from one representation to another (Martinovic, Freiman, & Karadag, 2010).

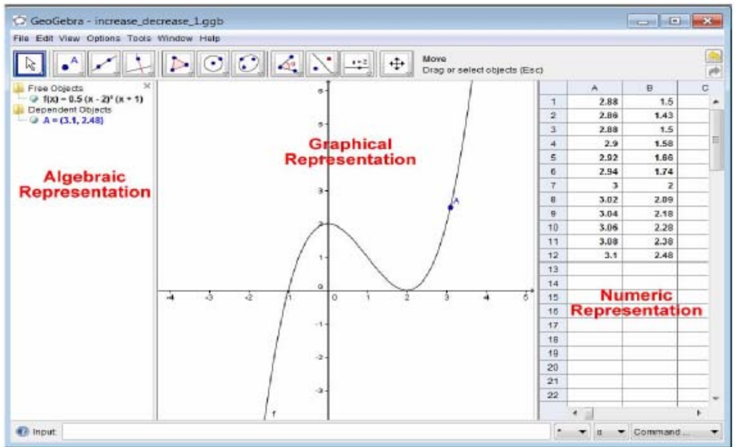

Figure 1. A snapshot of algebraic, graphical, and numeric representations in GeoGebra

In such a context, learners have the opportunity not only to explore one specific representation, but also to compare, contrast, and analyze different representations (e.g., algebraic, graphical, and numeric representations as illustrated in Figure 1), and conjecture on how each is related to another. Furthermore, once a conjecture is created, they can test it through experimentation and see if it holds in all cases.

Experimentation. The process of experimentation in mathematics education refers to the student interaction with mathematical objects such as exploring, comparing, and contrasting to create and test conjectures (e.g. Bass, 2011). The ultimate goal of experimentation is to help students identify patterns, to generate rules based on their observations, and to build upon their existing knowledge or further their own understanding.

Computer technology is specifically conducive to experimentation, because users can work on open-ended problems and easily re-do them by changing parameters and navigating among different representations. Borba and Zullatto (2006) mention that different technologies provide for different levels of experimentation intensity. What additions, if any, would make DIMLE the highly intensive experimentation spaces?

Inductive reasoning. Inductive reasoning refers to "examining particular cases, identifying relationships among those cases, and generalizing those relationships" (Greenes & Findell, 1999, p. 128). Students studying mathematics in DIMLE have the opportunity to benefit from multiple representations and to generate conjectures or test conjectures.

Visual learning. Visualization, visual learning, and visual thinking have different meanings depending on the discipline: "Visualization is multifaceted: rooted in mathematics, the field has important historical, philosophical, psychological, pedagogical and technological aspects" (Zimmermann & Cunningham, 1991, p. 7). Its potentiality 'urges the student to decide on the representations to be displayed in his/her interface so as to best support his/her investigation' (Buteau & Muller, 2007, p. 1117).

As many others, Zimmermann and Cunningham (1991) consider that visual representation is equivalent to graphical representation and is valuable if linked to algebraic and numeric representations. In a more recent publication, Sinclair and Yurita (2005) argue that "dynamic features of *Sketchpad* promoted a shift in the nature of questions and actions along the way, placing the visual in a central role in the process of exploration" (p. 5). In contrast to considering visual representation and visual thinking as a complete dichotomy, Giaquinto (2007) suggests taking them as a spectrum. Is it so? We may speculate on the existence of multiple visual representations within the same representation means (see Figure 2) to explore the boundaries between various representations.

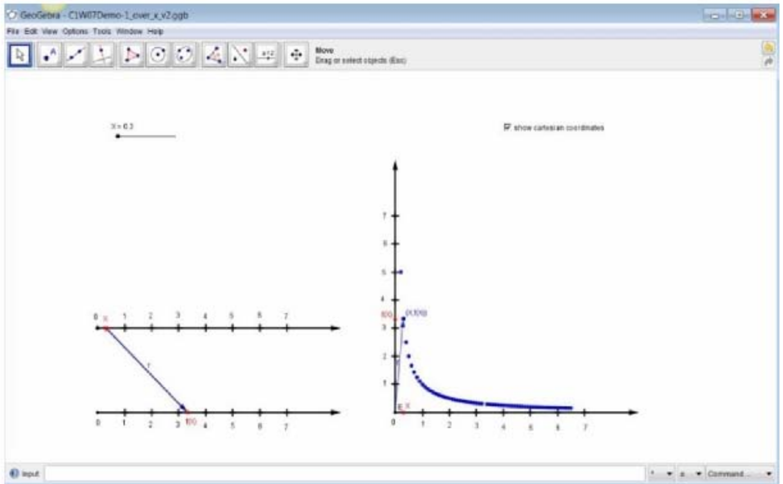

Figure 2. Two different graphical representations of the function f(x)=1/x created in GeoGebra

As seen in the figure 2, it is also possible to integrate other representational systems (algebraic representation in this example although numeric representation is also possible). The perception in this context could be more complex than one may assume. For example, what does f(x) on the second axis of dynagraphs represent? A number or a distance from zero?

Dynamic and Interactive Mathematics Learning Environments (DIMLE)

Having these questions in mind, we aim to conceptualize the features and affordances provided by DIMLE. Dynamism and interactivity seem to be most striking affordances of DIMLE and will be briefly discussed below.

Dynamism. New technologies may help Net Gen'ers in handling mathematical problems in new contexts and in new ways. Without these technological means, at the school level, many sophisticated mathematical results and procedures could not be explained, applied, and efficiently obtained. Dynamism used in software packages is not a pure dynamism in the sense we understand in science, rather it is a quick transition among discrete states of the mathematics system; states that depend on the user action (i.e., input), to present transition from one image to another as a continuous and dynamic process. As emphasized by Laborde (2007), "the meaning constructed by the individual is not only affected by the features of the representations available but also by the possible ways to use them. Mathematical activity requires manipulations of and operations on these representations" (p. 71).

Moreover, this perception of continual change in mathematical objects may affect the users' understanding of mathematics concepts and lead them to develop a new type of learning, what we call *dynamic learning.* Does dynamic learning and dynamic perception provide opportunities to learn mathematics in a natural way? According to those who write about "hyperproof" (Barwise & Etchemendy, 1991) and "visual proof" (Gravina, 2008), it is possible. Therefore, we suggest exploring dynamic learning as a theme in the working group meeting.

Interactivity. In the context of computer software, interactivity provides a kinaesthetic experience to the user and is often seen as some kind of a feedback to the user's action. The interaction mechanism is actually an action-reaction-new action iterative process, because when users perform action (i.e., virtual manipulation), they get reaction from the software (in terms of changing representation), and consequently perform another action (self-regulated action).

According to Buteau and Muller (2007), "the potentiality of interactivity encourages the student to make explicit the parameters that could play a role in the investigation of his/her conjecture or real-world situation in such a way that they are accessible from the interface" (p. 1117). In this way, through use of learning objects and simulations, students apply inductive reasoning and conjecturing; interactivity of the software may enhance students' inductive reasoning by providing opportunities to build their own mathematical understandings through experimentation.

The Rationale and Goals of Working Group

The goals of this proposed working group are to explore and discuss the features and affordances of DIMLEs and explorative learning and their dimensions. Furthermore, we shall suggest discussing the consequences of a possible shift in designing mathematics learning environments and formal mathematics learning in the context of college and university mathematics. We shall invite invite participants to explore the relevancy of explorative learning for N-Gen'ers.

Objectives

- To perform a comprehensive review of concepts regarding DIMLE and explorative learning
- To explore and conceptualize the features and affordances of DIMLE
- To explore and conceptualize the dimensions of explorative learning
- To identify possible effects of explorative learning in formal mathematics education.

Questions to frame our discussion

- What are characteristics of DIMLE?
- Which representations are more compatible with the nature of N-Gen'ers' learning?
- How can DIMLE alleviate algebra being a barrier to progressing through school mathematics?
- How can we observe or track the effects of visual versus symbolic representations in learning mathematics and their effects on concept development?
- How could the DIMLE be effective in explorative learning of concepts and processes?

Format for the Discussion Group Meeting

Day 1: Identifying the features and affordances of DIMLE

We propose to begin the discussion with a brief introduction of the topic, and then, ask the participants to reflect on these definitions in small groups and share their reflections with the whole group. The second hour of the discussion will be devoted to generating a workingdefinition for DIMLE and engaging the participants to brainstorm on the features of DIMLE by demonstrating examples from GeoGebra, Geometer's SketchPad, and Cabri.

- Introducing group members
- Introducing discussion group topics and goals
- Reviewing related literature on definitions and engaging participants in reflecting on these definitions
- Brainstorming on the features and affordances of DIMLEs
- Brainstorming on the various forms of representations used in DIMLEs
- Re-assessing the features of DIMLE suitable for addressing the needs of N-Gen'ers
- Conceptualizing the features and affordances of DIMLE.

Day 2: Discussing explorative learning and its components

We will start the meeting by briefing previous day's discussion and by outlining themes emerging from the discussion. Then, we will set the stage for the use of DIMLE in mathematics education, that is, explorative learning and its dimensions. We will demonstrate a couple of dynamic worksheets created in GeoGebra and ask participants to develop scenarios in their small groups on how to use these dynamic worksheets in learning mathematics and to share their scenarios with the whole group. During the last half hour, we will encourage the participants to discuss the connection of explorative learning to formal mathematics curriculum.

- Summarizing previous discussions
- Revisiting the concept of DIMLE
- Exploring the dimensions of explorative learning
- Brainstorming on the various forms of representation ideas in the same mode of representation such as dynagraphs and Cartesian coordinate systems in graphical representation
- Exploring the relation between explorative learning and the learning habits of N-Gen'ers.

Day 3: Summarizing the discussions and setting goals for the future collaboration opportunities

- Summarizing previous discussions
- Forming an international working group on the topic
- Setting an agenda for the future.

Possible Future Agenda Items

- Set up an international collaboration on DIMLE and explorative learning
- Create possible research questions to explore in the field
- Discuss opportunities to disseminate the outcome of the discussions, likely a book publication.

In this Working Group, we will continue to reflect on a Models and Modeling Perspective (MMP) to understand how students, teachers, and researchers learn and reason about real-life situations. During the Conference, we will continue ongoing discussions of the role of Model-Eliciting Activities (MEAs) and model-centric Design Experiments in our work in Student Development, Teacher Development, Assessment, Curriculum Development, Problem Solving, and Research Design. We will also dedicate special attention to two emerging themes: the application of MEAs in Elementary Grades, and the exploration of a Mathematics of Collections/Collectives, bridging the perspectives offered by Statistical and Complex Systems approaches to modeling phenomena.

Introduction

The *Models & Modeling* Working Group of PME-NA has been a significant presence at the Conference since its inauguration in 1978. Over that time it has been successful in supporting the pursuit of high-quality research projects and programs, and it has acted as a means of convening a diverse set researchers to work collaboratively on larger projects and research problems. The purpose of the Group is to discuss and extend the ways in which models are used both to learn mathematics and applied science and to study those very learning processes in action.

In this context, models are considered as conceptual systems that are expressed using external representational media or notation systems, and that are used to construct, describe, or explain the behaviors of other systems. Models are thus conceptual and representational tools that have the additional advantage of providing illumination into how students, teachers, researchers, and other educators learn, develop, and apply relevant mathematical concepts (Lesh & Doerr, 2003; Lesh, Doerr, Carmona, & Hjalmarson, 2003).

The study of model development is a robust area of research: it appears in a variety of settings and is generally a complex, dynamic, and iterative process. In the classroom, the tradition of Model-Eliciting Activities (MEAs) has grown over the years, reaching an ever-broadening range of learning settings. Such MEAs generate rich information and *thought-revealing artifacts* that can both extend our understanding student thinking and learning and provide the basis for various nuanced forms of assessment. At other units of analysis for educational research, model development has also yielded fruit as a framework for inquiry. In particular, Design Experiments of various kinds have enabled researchers in the Models and Modeling Perspectives (MMP) tradition to study the types of models that students, teachers, and researchers develop (explicitly) to construct, describe, or explain mathematically significant systems that they encounter in their everyday experiences (Lesh, Hoover, Hole, Kelly, & Post, 2000).

We would like to invite participants to this Working Group to foster the continued development of a community of researchers and practitioners to enrich the field of research on the ways in which models are used in Problem Solving, Curriculum Development, Student

Development, Teacher Development, Assessment, and Research Design. In addition, this year we intend to give special emphasis to two emerging themes, described briefly below.

Emerging Theme One: Model-Eliciting Activities in the Elementary Grades.

The first theme concerns the application of Models, Modeling, and Model-Eliciting Activities (MEAs) in elementary grades. For example, Data Modeling with learners of this age group has been an area of particular focus for Lehrer and Schauble at Vanderbilt (see, e.g., Lehrer & Kim, 2009; Lehrer & Schauble, 2010). Also, during the past year, other leaders among the *Models & Modeling* Working Group have been using videoconferencing seminars to work with more than forty faculty members and graduate students in countries ranging from Turkey, Cyprus, and Israel, to Australia and Mexico – as well as the United States. The use of modeling activities with primary-grade children has been one of several key foci for this group. For primary-grade children and pre-schoolers, working group members' research shows that the use of children's *stories* often sets the context for productive inquiry–similar to the way "real life" contexts have functioned for older students. At PME-NA, we hope to share detailed results from this work and encourage expanded participation and collaboration across these discussions and research efforts.

Emerging Theme Two: A Unified Mathematics of Collections/Collectives.

Our second theme would bring together researchers in both statistics and complex systems/dynamic systems education, in order to explore common issues and themes concerning the "mathematics of collections/collectives" – that is, mathematics that concern the measures, models, data, and trends that describe collective or systemic phenomena. The consideration of complex systems is certainly not new to the Models and Modeling Working Group (see, for example, the proceedings of the Group at PME-NA XXIV and XXVIII for themes that engaged complexity as a subject area and as a fruitful perspective on educational systems, respectively); and a focus on statistical thinking has been strong in the Group from its beginnings. This year, however, we propose to explore ways in which *bridging* these two areas might be generative for both pedagogical and research purposes.

Examples may include work exploring student or teacher understanding of the emergence of exponential growth from probabilistic and multiplicative roots (Confrey, Maloney, Nguyen, Mojica, & Myers, 2009; Confrey & Smith, 1995; Doerr, 2000); of the encapsulation and quantification of behaviors enacted at multiple levels (Wilkerson-Jerde & Wilensky, 2010); of inference from measures of sampled populations (Abrahamson & Cendak, 2006; Garfield, 2002; "Developing Reasoning about Informal Statistical Inference" [Special Issue], 2011); and of nonlinear behavior stemming from collective feedback, limiting behaviors, and other characteristics of complex systems ("Dominance of Linearity in Mathematical Thinking" [Special Issue], 2010).

The rationale for bringing together an interdisciplinary group to discuss the mathematics of collectives has both pragmatic and theoretical dimensions. At a pragmatic level, literate and effective citizens require increasingly sophisticated skills in reasoning about the behavior of collectives. While these skills are not currently well represented in the curriculum, our experience is that many of them can be introduced to students at quite a young age. Thus, it would be opportune for the community to propose and study options for integrating these subjects, for consideration and research. At a theoretical level, while there is a great deal of research on student learning within each of the individual components of the mathematics of collectives, many exciting avenues for inquiry might emerge in addressing the challenge to design and implement curricula and learning environments that address these components.

Continued focus on the historically-successful themes of the Group.

In addition to the two Emerging Themes described above, the Working Group will foster the ongoing discussion of the cross-cutting strands of inquiry— Problem Solving, Curriculum Development, Student Development, Teacher Development, Assessment, and Research Design—that have provided a framework for numerous collaborations among Group members over the years.

Advisory Group

Beyond the principal organizers, we propose to draw upon an Advisory Group to engage interested researchers, advocate participation, and support the Working Group's activity both during and after the conference sessions. This Advisory Group will include the following members (listed alphabetically):

- Lyn English, Queensland University of Technology
- Stephen Hegedus, University of Massachusetts, Dartmouth.
- Joan Garfield, University of Minnesota
- Beste Gucler, University of Massachusetts, Dartmouth
- Richard Lehrer, Vanderbilt University
- Bharath Sriraman, University of Montana
- Uri Wilensky, Northwestern University

During the course of the summer leading up to the conference, we will confer with members of this group, as well as with other leading researchers who have participated frequently in the Working Group's meetings, to ensure that the subgroups around each of our themes are well-supported and positioned for effective work both during the Conference and afterwards.

Goals for the Working Group at PME-NA Reno and Beyond

The Working Group will convene for three sessions during the Conference. In the first session, an overview of each of the theme-based subgroups will be provided, and members will select the subgroup in which they wish to participate. Subgroup leaders will facilitate initial planning discussions and identify objectives for the three-day discussion sessions. At the end of the first day, the subgroup leaders will gather to share objectives statements and identify points of common interest that may merit connections between the subgroups during the following two days. On the second day and third days' sessions of the Conference, the subgroups will work independently toward the objectives they have set for themselves, with subgroup leaders maintaining communications.

The Working Group will reconvene as a whole for the final two hours of the third day's session, to share findings and opportunities for collaboration following the Conference. In addition, mailing lists and subgroup Wikis will be put in place by the organizers during the Conference. These tools will be employed during the work sessions and will also be explicitly demonstrated in the final session, to ensure that all members are familiar enough with them to employ them as supports for the work that will continue after the Conference.

Accomplishments of the *Models & Modeling* Working Group

The Models & Modeling Working Group has been one of PME-NA's most active working groups—beginning with the very first PME-NA at Northwestern University in 1978. The Group has a long history of encouraging research collaborations among group members — and of including junior colleagues in a variety of research and development activities. Consequently, since the founding of both PME and PME-NA, models and modeling perspectives (MMP) have provided useful frameworks for a large number of books, journal publications, funded projects, and conference presentations which featured collaborations among multiple working group members.

During the past year, leaders in the Models and Modeling Working Group have been using videoconferencing seminars to work with more than forty faculty members and graduate students in countries ranging from Turkey, Cyprus, and Israel, to Australia and Mexico – as well as the United States. The focus of this work has been on four on areas: (a) modeling activities for primary grade children, (b) modeling activities focusing on integrated approaches to mathematics for high school students, (c) modeling-based activities for teacher development, and (d) modeling-focused design research methodologies. We intend for such fruitful and cross-cutting collaborations to continue into the future, and to continue to feed into the Working Group community's annual discussions.

WISDOM[e]: QUANTITATIVE REASONING AND MATHEMATICAL MODELING WORKING GROUP

Robert Mayes
University of Wyoming
rmayes2@uwyo.edu

The Quantitative Reasoning and Mathematical Modeling (QRaMM) working group is one of three research strands initiated by the Wyoming Institute for the Study and Development of Mathematical Education (WISDOM[e]). QRaMM brings together researchers from multiple universities across the country to share ideas and conduct research on quantitative reasoning and modeling within an interdisciplinary context. As part of the work of QRaMM and in collaboration with the National Science Foundation MSP Pathways in Environmental Literacy Project, a national virtual seminar QRaMM in Science was initiated in Spring 2011. The seminar engaged 15 speakers from across the country in the online video conference, including experts in quantitative reasoning and modeling from the fields of science, computational science, mathematics, science education, and mathematics education. The context for the discussion of quantitative reasoning and modeling was environmental literacy. The issues in psychology of mathematics education for the seminar included students' development of quantitative reasoning and mathematical modeling from 6th to 12th grade, creation of parallel QRaMM learning progressions for those being created by the MSP Pathways project for environmental literacy, and study of the impact and interplay of QR and modeling on students' development of environmental literacy. The national experts informed a QRaMM Science research team consisting of faculty and graduate students who developed Environmental Science QR interview protocols based on MSP Pathways learning progressions. Data from these protocols will lead to the creation of Environmental Science QR assessments and research-based professional development that supports learning environments that lead to environmentally literate citizens capable of making informed decisions about the grand challenges facing the next generation. Participants in the QRaMM working group will join members of the QRaMM research team in critiquing environmental science QRaMM learning progressions, interpret data on QR in the sciences, vet QRaMM assessment items, and debate the QRaMM theoretical framework.

History of WISDOM[e]

A core membership for this new PME-NA Working Group was established through the initial invitational **Planning Conference for WISDOM[e]** conducted September 8-10, 2010 at the University of Wyoming. The background context for that conference is the establishment of three collaborative, interdisciplinary Research Teams connected to four new Ph.D. program research identities: quantitative reasoning, mathematical modeling, technology tools and applications, and lived/living mathematical experience. Each of the teams consists of UW mathematics education, mathematics, and educational cognate faculty, mathematics education doctoral students, and four-to-five young, active Mathematics Education researchers from a variety of national and international universities. Following four invited plenary papers prepared and presented at the conference by key active senior researchers, each team met to frame an initial program of collaborative work. The QRaMM (Quantitative Reasoning and Mathematical

Modeling) Team currently includes faculty from multiple universities and a cadre of mathematics education graduate students at the University of Wyoming.

The QRaMM research team is working in collaboration with the National Science Foundation Pathways in Environmental Literacy Project. The Pathways Project is focused on creating learning progressions for three content strands that are fundamental to the development of environmentally literate citizens from sixth to twelfth grades: carbon cycle, water cycle, and biodiversity. The Pathways QR Theme team is exploring the impact of quantitative reasoning on the development of environmental literacy. These two teams have come together through an online virtual seminar, where researchers from mathematics, mathematics education, science, and science education discuss QR and mathematical modeling from their respective points of view. The research papers and presentations are informing the development of QR and mathematical modeling learning progressions, as well as assessment items for clinical interviews and the creation of written assessments of QR abilities in the context of environmental science.

Through the opportunity to conduct Working Group sessions at PME-NA, we seek an important venue to continue and expand discussions of the background perspectives and issues related to investigations of quantitative reasoning and modeling, to share information, issues, and problems related to ongoing research, to promote interest and potential participation in furthering these and other disciplined inquiries into these phenomena, and to provide continuing support to the team members to collaborate within and across ongoing and future research.

Issues in Psychology of Mathematics Education

The primary research question for the Pathways project is: What are the characteristics of a 6th to 12th grade learning progression aimed at developing environmentally literate citizens? The purpose of the QR Theme is to determine the quantitative reasoning aspects of the learning progression leading to the primary QR research question: What are the essential quantitative reasoning abilities that are required for the development of environmental literacy? Specific research questions include the following.

- How does quantitative reasoning integrate and interact with environmental literacy?
- What is the relationship between learning progressions for quantitative reasoning and environmental literacy – should they be integrated or is a separate learning progression for quantitative reasoning required?
- What is the current state of quantitative reasoning supporting environmental literacy at the 6th grade level (defined as the lower anchor for the learning progression)? What is the required level of quantitative reasoning for an environmentally literate citizen at the 12th grade level (defined as the upper anchor)?
- How does the learning progression inform professional development supporting the development of environmental literacy?

The Pathways project is based on the theoretical framework of learning progressions. The Consortium for Policy Research in Education defines learning progressions as follows:

> Learning progressions are hypothesized descriptions of the successively more sophisticated ways student thinking about an important domain of knowledge or practice develops as children learn about and investigate that domain over an appropriate span of time (Corcoran, Mosher, & Rogat, 2009, pg 37).

The panel identified essential elements of learning progressions to be:

- Upper Anchor: target performance or leaning goals which are the end points of learning progression and are defined by societal expectations, analysis of the discipline, and requirements for entry into the next level of education.
- Progress Variables: dimensions of understanding, application, and practice that are being developed and tracked over time.
- Levels of Achievement: intermediate steps in the developmental pathway(s) traced by a learning progression.
- Learning performances: tasks students at a particular level of achievement would be capable of performing.
- Assessments: specific measures used to track student development along the hypothesized progression.

The Pathways learning progressions for environmental literacy are based on research in science education and cognitive psychology, foundational and generative disciplinary knowledge and practices, and strive for internal conceptual coherence. The QR in environmental literacy frameworks build on these characteristics, incorporating mathematical and statistical frameworks.

The Pathways learning progressions have a lower anchor which is the typical accounts of environmental issues given by students at the upper elementary and middle school level (Anderson, 2009). These accounts are empirically tested through a cyclic research process of clinical interviews informing the learning progression and leading to the development of written assessments given on a large scale. The Pathways learning progressions upper anchor is based on experts views of what a scientifically literate citizen should know and be able to do by the 12th grade. The upper anchor is much like a NSTA or NCTM standard, but learning progressions differ from standards in that the lower anchor and intermediate achievement levels are research-based, reflecting the actual trajectory of student learning. A limited number of achievement levels (4 or 5) are identified as plateaus in students' development of more sophisticated ways of thinking about enduring understandings, concepts, and processes. The progress variables for the Pathways project at the meta-level are the carbon cycle, water cycle, and biodiversity, which are considered areas in which students must develop conceptual understanding if they are to become environmentally literate citizens. Within each of these areas progress variables are identified. For example, in the carbon strand the progress variables are generation-photosynthesis, transformation-food chain/web/biosynthesis, oxidation-cellular respiration, and oxidation-combustion. Learning performances are exemplars drawn from the clinical interviews and written assessments which demonstrate student responses at different achievement levels. Learning progression matrices are created by cross tabulating achievement levels (rows in matrix) with progress variables (columns in matrix). A number of learning progressions in science are currently under development including: tracing carbon in ecological systems (Mohan, Chen, & Anderson, 2009), particle model of matter (Merrit, Krajcik, & Swartz, 2008), modeling in science (Schwarz, Reiser, et. al., 2009), genetics (Duncan, Rogat, & Yarden, 2009), chemical reactions (Roseman, et. al., 2006), data modeling and evolution (Lehrer & Schauble, 2002), explanations and ecology (Songer, Kelcey, & Gotwals, 2009), buoyancy (Kennedy & Wilson, 2006), atomic molecular theory (Smith, Wisner, Anderson, & Krajcik, 2006), and evolution (Cately, Lehrer, & Reiser, 2005). Examples of three of these learning progressions are provided in (Corcoran, Mosher, & Rogat, 2009).

The QR Theme of the Pathways project is using the learning progressions theoretical framework to research the impact of QR on students' development of environmental literacy.

The overarching goal is to study the capacity of students to understand and participate in evidence-based discussions of socio-ecological systems. Three overarching progress variables are hypothesized: quantitative literacy which consists of arithmetic understandings supporting science, quantitative interpretation which is the process of interpreting scientific models to determine trends and make predictions, and quantitative modeling which is the creation of models by the student. Within each of these areas four progress variables are identified that are hypothesized to be critical QR for science (Table 1).

Table 1. QR Progress Variables

The development of learning progressions is an iterative process typical of design-based research. The Pathways environmental literacy learning progressions began with hypothetical frameworks based on theories about reasoning about processes in socio-economic systems, including discourse, practices, and knowledge, as well as linking processes between lower and upper anchors. Challenges for the QR Theme researchers are to determine which of these theories carry over to QR aspects of environmental literacy and to discover potential theories that are more QR-centric. For example, students achieving the upper anchor in the environmental literacy learning progression should function as informed decision makers within the socio-economic system at three levels: discourse, practices, and knowledge. "Knowledge is embedded in practices, which in turn are embedded in discourses" (Anderson, 2009). We all participate in multiple discourses that associate us with communities of practice (Gee & Green, 1998) and as we gain understanding of a phenomena as our discourse around it matures. The lower anchor discourse for the environmental literacy progression is force dynamic, relying on students' theory of the world with a focus on actors, enablers, actor's purposes, conflicts between actors, and settings for the actions (Pinker, 2007; Talmy, 2003). At the upper anchor scientific discourse is essential, with students moving away from actors in settings to laws that govern the work of systems. Certainly there is a parallel development of mathematical and statistical discourse that is essential for quantitative reasoning. There are four practices that are essential for environmentally responsible citizenship: inquiry (What is the problem and who do I trust?), accounts-explaining (What is happening in the system?), accounts-predicting (What are the consequences of my course of action?), and deciding (What will I do?). At the lower anchor explaining and predicting practices are expressed in force dynamic discourse, while at the upper anchor they are expressed using the language and theory of scientific discourse. These practices reflect the public roles (voter, advocate, volunteer) and private (consumer, owner, worker, learner) roles in which decisions are made. Informed explaining and predicting practices often require QR, which allows for connecting observations to patterns and models, as well as analyzing data from a scientific perspective. Finally knowledge is embedded within discourses and practice. At the lower anchor students focus on knowing facts, while at the upper anchor scientific knowledge is applied to create coherent systems of observations, patterns, and models which serve as the basis for scientific inquiry and accounts. QR parallels this trajectory from knowing mathematical or statistical algorithms to an understanding of enduring concepts that allow one to analyze problems quantitatively.

A framework for the Pathways learning progression consists of progress variables (matrix columns), levels of achievement (matrix rows), learning performances (content of matrix cells), and linking processes which are common processes that are recognized by students at all levels of achievement (Anderson, 2009). The carbon framework in Figure 2 provides an example of linking processes within the carbon strand. What are the linking processes for QR? How do they interact with the environmental literacy linking processes? Another aspect of the Pathways learning progressions which is highly quantitative in nature is scaling. Students at the lower anchor often function at a macroscopic or "individual" scale in which they view the world from their sensory purview. Hence, their accounts of environmental issues are based within their daily perceptions at this scale. Moving students to the upper anchor requires that they scale up to a global view, as well as scale down to a microscopic view and even an atomic view. Regardless of the scale, moving up or down the scale becomes intensively quantitative.

Figure 2: Carbon Linking Processes

Carbon-transforming processes	Generating organic carbon	Transforming organic carbon			Oxidizing organic carbon		
Scientific accounts	Photosynthesis	Biosynthesis	Digestion	Biosynthesis	Cellular respiration		Combus-tion
Linking processes	Plant growth		Animal growth		Breathing, exercise	Decay	Burning
Informal accounts	Plants and animals as actors, accomplishing their purposes in life, using their abilities, if their needs (food, water, sunlight, and/or air) are met					Natural process in dead things	Flame as actor consuming fuel

QRaMM Reflection Tasks

The three QRaMM working group sessions will actively engage the participants in discussion of the research questions stated above. Each session will begin with a 15 minute plenary presentation by a member of the QRaMM research team to pose research issues and problems for discussion. Seminal readings related to the presentation will be provided to all participants in the first session, serving as support materials for discussions in later sessions. Breakout sessions for four working sub-groups will be organized around task-oriented discussions. The last session will provide plenary summarizing presentations and report out discussions by the working groups.

The four sub-groups will focus on the following domains of discussion:

1. Framing problems and questions for research on quantitative reasoning and modeling related to learning progressions and assessment.
2. Addressing issues and concerns for research methodologies to be used.
3. Discussing techniques for using and transforming data to describe, analyze, and interpret in ways that will illuminate and inform.
4. Discussion approaches to reporting what is found and to applying to inform improved educational practice related to interdisciplinary aspects of quantitative reasoning and mathematical modeling.

QRaMM Follow-up Activities

We are proposing a follow-up national seminar on QRaMM with virtual presentations by the participants of this working group. With the assistance of the WISDOM^e research group we are proposing a monograph on QRaMM learning progressions and interdisciplinary teaching issues. The monograph would solicit articles from the participants of the working group as well as the WISDOM^e and Pathways research teams.

Number Talks are an innovative pedagogical approach that has great potential in shifting mathematics teaching and learning practices to support students' conceptual reasoning. The proposed discussion group will examine the features of Number Talks, how students and teachers learn through this approach, and the variations of its use in classrooms, as well as in pre-service and in-service teacher education settings. The goal of the discussion group is to provide mathematics educators and mathematics teacher educators a context for sharing their work with Number Talks and deepen their understanding of this pedagogical approach.

In 2000, the Mathematics RAND committee proposed that mathematical practices, such as reasoning, generalizing, and making connections, should be at the center of instruction (RAND, 2002), and these practices are now enshrined in the Common Core State Standards (2010). However, engaging students in mathematical practices places a new demand on U.S. teachers. Despite research evidence outlining the need to engage students in activities that also develop conceptual understanding (Fosnot & Dolk, 2001; Fuson, 1992; NCTM 2003), computation in elementary and middle school classrooms has traditionally been taught through memorization of number facts and repeated practice of procedures. One of the reasons that teachers continue to focus on memorization of number facts is that they have not received sustained opportunities for learning how to engage students differently (Ball & Cohen, 1999). Thus, teachers may feel at a loss when trying to teach mental computation and numerical reasoning in a more conceptual manner.

One of the innovative pedagogical approaches for conceptual numerical reasoning is called 'Number Talks', a method that has been used in a small number of cases but with extremely impressive results (Parish, 2010, Boaler, 1998). This method begins with teachers presenting a simple, context free number problem to their class of students. The number problems can target many different levels. For example second grade students may feel challenged by a problem such as 38 + 55; whereas, 8th grade students might initially struggle with problems such as 48 x 27 or 12% of 80. After teachers present a problem to students, they ask students to work out the answer in their heads or on paper but with no discussion. They then elicit different student solution strategies. The problems generally produce multiple solution methods in any class of students. Teachers continue by facilitating student discussion; for example, they may ask students to discuss the ways the methods are similar and different or explain how they could represent the methods visually. Additionally, the teachers may show student methods using numerals or drawings (e.g., number lines or geometric representations) to highlight common mathematical ideas across the methods and ask students to share connections they notice among the different mathematical ways of thinking. In the process, the core mathematical concepts are highlighted and discussed, while students become agents of numerical reasoning. As students work to find answers mentally and then discuss the connections between different methods, they develop both computational fluency and numerical reasoning. For teachers, the discussions offer important opportunities to hear their students' thinking (Schifter, 1998) and to extend their students' understanding to the next conceptual level, working at and with the students' 'zone of proximal development' (Vygotsky, 1978). As teacher educators and mathematics educators, we are interested in understanding the features of this pedagogical approach that advance and enrich students' conceptual pathways (Fosnot & Uittenbogaard, 2007; Huffered-Ackles, Fuson, & Sherin, 2004).

Goals and Activities of the Discussion Group

In this proposed discussion group, we will examine and explore the features of Number Talks, unpack their benefits and challenges, and discuss their potential for mathematics teaching and learning. Different video cases will be presented, and varied Number Talk formats (e.g., Number Strings, Math Talk) will be compared and analyzed. The organizers of this discussion group will present examples of using Number Talks both in pre-service teacher education courses as well as in in-service professional development programs. The goal of the discussion group is for mathematics educators and mathematics teacher educators to have the context to share their work with Number Talks, to deepen their understanding of this pedagogical approach, and to plan for future research on the topic.

The guiding questions for the discussion group are as follows:

1. What are the features of Number Talks that support students' numerical reasoning?
2. How do teachers learn to focus on students' mathematical thinking through Number Talks?
3. What are the different formats of Number Talks, and how do they support students' numerical reasoning differently?
4. What are the challenges of using Number Talks in classrooms?
5. 5. How are Number Talks used to support pre-service and in-service teachers' learning?

Work and Research with Number Talks

Number Talks have been successfully taught to teachers, as well as to teacher education students, with clear evidence of increased student learning and engagement. The method was also used in a research project aimed at re-engaging failing middle school students (Boaler et al., *in press).* Researchers in the middle school study found that students who learned through 'Number Talks' changed their views of mathematics, reporting that they had never before realized that mathematics problems could be solved with more than one method. The students also increased their achievement significantly and improved their subsequent grades in algebra courses (Boaler et al., *in press).* 'Number Talks' represent what Grossman & MacDonald (2008) have called a 'high leverage practice' as they are linked to increased student understanding, but they also have the considerable advantage of being easy to learn (as opposed to many other high leverage teaching practices). They can be added to any curriculum scheme, as they take about 15 minutes of class time.

The current research on Number Talks is limited (Parish, 2010, Boaler, 1998), but there is a wide body of research related to the goals and practices encompassed by Number Talks. We know that students who have learned to reason with numbers in a variety of ways demonstrate a deepened understanding of place value (Fosnot & Dolk, 2001; Kamii, 2000), that students with differing backgrounds are supported by learning communities where talking mathematics is the norm (Spillane, 2000; Hufferd-Ackles, Fuson, & Sherin, 2004), and that equitable outcomes are promoted when students engage in communication and reasoning (Ladson-Billings, 1997; Martin, 2009).

Number Talks have the potential to help teachers shift their teaching to focus more on student thinking and on mathematical connections, while helping students learn foundational mathematics with greater understanding.
